Ohio State University Dairy Cattle Test

The OSU Ag Research Facility was visited by Monsanto staff, including the DMEH Quality Assurance Audit Team, to review progress on the dairy cattle feeding study.

Production data indicate no adverse effects of ingested PCBs up to 1000 mg/cow/day on milk production.

The contract for Phase II of the OSU study, which will include reproductive effects, was signed and the study is in progress. All control animals and 3 of 4 dosed cows have been diagnosed pregnant. First calves are expected in November.

- Ohio Stats University (OSU) Dairy Cattle Research

  The OSU dairy cattle research project has begun Phase II which includes study of reproductive effects of PCB fed animals.

  The research protocol and grant have been reviewed and approved.

  Report #3 from Dr. Willett covering work in the second quarter of this year has been received. The results indicate that milk production was adequate for all animals and that high doses (1000 mg/day) of PCB did not have significant effects on milk productivity.
