As a first step, all points of potential Aroclor air emission were identified. These are summarized in the attached list. Observations made at the time of inspection are included.

The plant pollution group has received equipment which should enable us to quantify this amount of Aroclor being lost to the atmosphere from all points where a flow is occurring. Sources like Therminol vent lines that are only breathing will be sampled, but data will be more qualitative than quantitative. Sampling will also be done at various plant locations to determine whether or not there is a detectable amount outside using or producing areas. Sampling will begin in August. Level of air losses will be determined and a reduction program laid out by the end of the month. Obvious problem areas such as the Therminol furnaces in Departments 239, 245, 248 and 255 will receive immediate attention.
