SUBJECT: Asbestos Fiber Count Data - April 1, 1976

Asbestos fiber count data for February and March is shown on the attached chart and graphs. The three points for each month represent the high, low, and average counts reported for each month. The small figures within the average circle are the total counts included in the average. The solid horizontal line at the 10 fiber level represents the maximum allowable ceiling concentration and the broken line at the 5 fiber and 2 fiber levels indicate the permissible airborne concentration for an 8 hour time-weighted average.

The February and March readings have followed the typical pattern. We are still maintaining counts below five but the average is still over two and the high range still close to a four count.

The end of March saw more readings closer to the three count than in February. We are now actually running more production with less utility people to do the cleaning.

We will have to do more special cleaning in order not to expose our employees to a creeping higher count. More monitoring will be done in the following weeks to assure as low a dust concentration level as possible until we completely shut down.

Counts in the Finishing department were from 0 to .14, which is very good. Unless something unusual develops we will concentrate in the other areas and not monitor the Finishing area.
