DATE: April 10, 1989

SUBJ: 313 EMISSION DATA PUBLIC REACTION

For your information, attached are two articles regarding the recent Congressional Report released on March 22. Also attached are two reports:

- 1) The National Toxic Release Inventory (released on March 22)
- 2) Danger Downwind - A National Wildlife Federation Report on the same data.

As we suspected, the public and governmental reaction to the 313 database was slow to start but is gaining momentum.

This report reemphasizes the need to include "federal" governmental representatives, such as your local congressmen and representatives in your 313 communication efforts. Please consider this action as you develop your programs for this year.

REPORT ON TOXIC EMISSIONS: AN OPENING SALVO ON CLEAN AIR

The first comprehensive look at the amount of toxic chemicals U.S. industry emits into the air has produced outcries from some environmentalists and calls for tougher legislative controls. The report, issued March 22, indicates 2.4 billion pounds of toxic chemicals are released annually, an estimated 886 million lbs/year of which comes from the chemical industry—the single largest source of the air pollutants.

"The magnitude of this problem far exceeds our worst fears," declared Rep. Henry A. Waxman (D., CA), chairman of the health and environment subcommittee of the Energy and Commerce Committee, as he released the report. The emissions statistics based on 1987 data collected by the EPA under Section 313 of the Superfund Amendments and Reauthorization Act (SARA), appear to be an opening volley in the upcoming debate over reauthorization of the Clean Air Act. Indeed, Waxman indicated he plans to use the emission information to build support for a stringent control bill he will introduce shortly after Congress reconvenes from its Easter recess on April 3.

Total chemical-plant emissions are far greater than suggested by Waxman's informal 1985 survey of chemical executives, which concluded some 80 million pounds of toxics were released annually. "That figure was sharply criticized as inflated by industry spokesmen. Now we see that chemical industry releases are fully ten times as high," said Waxman. Moreover, he said, total emissions are probably even greater, because the current data does not include emissions from motor vehicles and small sources, such as dry cleaners and gas stations.

"Such high levels of toxic releases are sure to be accompanied by comparably high levels of human suffering," said Waxman. While it is difficult to demonstrate scientifically the health impacts of air emissions, he argued, "we do know that millions of pounds of carcinogens, mutagens, and neurotoxins are getting into our air supply. We do know that there are numerous studies showing higher cancer rates among those who live near to chemical plants.

We have EPA estimates of thousands of additional deaths each year as a result of air toxics."

Don R. Clay, EPA's acting assistant administrator for air and radiation, says the level of toxics in the air "is a public health problem, but it's not a crisis."

And many in the chemical industry

Waxman: 'releases ten times as high.'

challenge Waxman's interpretation of the emission data, cautioning against the drawing of connections between numbers and possible health impacts. "Anyone who says you can make a link between these numbers and health effects is misleading you," says Jeffery Van, a spokesman for the Chemical Manufacturers Association. He says the raw data contains none of the information about concentration or duration of exposure necessary to reach such conclusions.

Van adds that since the emissions numbers are in many cases estimates rather than data based on monitoring, they cannot be relied upon as exact emission figures. And he suggests chemical emissions are lower today than when the reports were filed because of increased company commitments to reduce emissions.

"Clearly there needs to be reduc-

tions in the emissions, but the concern that there is a public health crisis is not warranted," says Ronald Lang, president of the Synthetic Organic Chemical Manufacturers Association. "We don't believe there are any significant concentrations that would affect public health." While Lang acknowledges that the emission volumes reported by Waxman "are higher than most predictions," he points out that in most areas exposure levels will still be orders of magnitude less than levels determined to be safe for workers.

While the compiled numbers "can serve as a reasonable benchmark for relative performance and as an excellent inventory of what chemicals are being emitted," says David W. Graham, Dow Chemicals' environmental issues manager, any health impacts associated with the data remain unknown. The emission numbers appear relatively large, he says, but "we can't take the next step" and try to convey the health impact of a particular number without significant additional information about individual sources.

But whatever the health implications of the emission numbers, Waxman's report seems sure to focus attention on regulating air toxics as part of the reauthorization of the Clean Air Act. Only seven of the 320 substances industries are required to report on are regulated by EPA. Waxman noted that, by contrast, the Occupational Safety and Health Administration has set nearly 400 workplace standards for toxic chemicals. "If OSHA can regulate these pollutants, so can EPA," he says.

The bill Waxman intends to introduce would no longer leave regulation of dangerous chemicals to EPA discretion. Instead, he explains, it would list hazardous air pollutants and mandate that sources of these pollutants use "all the technology available to reduce their release and protect public health."

According to Waxman, the current system, relying largely on self regulation, discourages responsible companies from spending money to control pollutants. "If they take such steps and their competitors do not, they are put at a competitive disadvantage. The result

is a least-common-denominator approach to air-toxics control."

In addition to curbing routine releases, Waxman said his bill will also contain measures to prevent accidental releases. He cited a 1986 EPA report that documented 6,900 accidental releases leading to 135 deaths over a five-year period. He said facilities in Houston have had more than one chemical accident daily over the past year.

EPA's Clay readily admits that Section 112 of the Clean Air Act is "broken

and needs to be fixed." The law stipulates a cumbersome chemical-by-chemical analysis requiring the development of risk assessments for each substance. Clay thinks "a technological approach would be a reasonable way to go," requiring facilities to install equipment for maximum achievable controls. The Bush administration has promised to address the air-toxics issue in legislation it is preparing but has not yet taken an official position, he says.

Indeed, some change in air-toxics

legislation seems all but inevitable. The recently released emission numbers, says Thomas Helscher, director of congressional affairs at Monsanto, focused attention on the debate. "The difficult step for Congress," he notes, "is to determine what are appropriate reductions and how to achieve them." And, he adds, "it is still very early in the legislative process."

CHINA FINDS AN OPEN DOOR IN U.S. PLASTICS

In a bid to blow the polypropylene market wide open, Himont and a group of consumers in the People's Republic of China have set up a joint venture that will own and operate PP plants in the U.S. and help develop promising downstream applications in the huge Chinese market.

The new group, to be called International Multi Petrochemical Enterprises Ltd. (IMPEL), teams Himont with a "consortium of several prominent coastal region and Special Economic Zone companies" in mainland China. In an exclusive interview with *Chemical Week*, Zhang Wanxin, vice-director general at the Beijing-based Research Center of Economic, Technological and Social Development, and Alexander F. Giacco, chairman and CEO of Himont, talked about the venture's origins and promise.

IMPEL will acquire a 50% interest in a 340-million lb/year slurry process PP plant at Lake Charles, LA and a 20% interest in an existing 375 million-lb/year Spheripol process PP unit there. Later, it will build a worldscale Spheripol plant in the U.S. Resins from those plants will flow to Chinese and Hong Kong markets. Under the deal, Himont gets the option to participate in downstream facilities in

China, making such products as film, fiber, and molded articles. Those products will be consumed domestically—particularly in the case of fibers—while others will go to world markets.

Zhang and Giacco both stress the mutual benefits of the deal. Currently, 50% of plastics resins used in China are sourced outside the country. The IMPEL deal gives added security of supply. But more important, for the Chinese players, IMPEL will support "a 'shadow market' of regional production facilities that aren't fully utilized," says Zhang. He emphasizes that IMPEL will cooperate, not compete, with Sinochem and Sinopec.

For Himont, the potentially vast Chinese market represents a "huge test market" for its latest technologies based on Spheripol catalysis.

Himont has been arguing in recent months that PP is a plastic of immense

promise for the engineering materials field (*CW*, March 29, p. 17). "We want to do advanced polymers in China," Giacco insists. "We can get massive volume expansion there to test the rest of the world. I'm a marketing man, and it's a marketing man's dream." What China also represents to Himont is a *tabula rasa*: "It's a huge market, somewhat exclusive and with no prejudices."

In other world markets, those prejudices—about substitution of PP for other plastics, or retooling to meet PP's growing product sophistication—are something Himont is determined to break down. Later this month, it will announce new process developments that relate to products with better extrusion and flow properties. "We want markets where we can change things," says Giacco. Hence China.

To the Chinese participants, IMPEL doesn't exist "just to fulfill short-term PP demand in China," says Zhang. "It's the value added to the resin that matters. The shareholders are downstream people. There'll be more value added by use of cheap local labor in conjunction with high technology. Our ability

to balance foreign exchange will be strengthened." Downstream processing operations are "twenty times" more labor-intensive than resin production, making it sensible to make resins in the U.S. but fabricate products in China—a method both sides agree on.

Neither party is saying much about the financial structure of IMPEL or its source of funds, though Zhang concedes that foreign and domestic sources will be tapped.

THE NEW YORK TIMES MAR. 23, 1989

U.S. Calls Poisoning of Air Far Worse Than Expected and Threat to Public

By PHILIP SHABECOFF
Special to The New York Times

WASHINGTON, March 22 — The first national survey of toxic chemicals released into the air by industry shows they are being emitted at rates that threaten public health, members of Congress and Federal officials said today.

The survey, based on data the Environmental Protection Agency collected from industry last year, was made public today by the House Energy and Commerce Committee's Subcommittee on Health and the Environment. It covered more than 320 chemicals, only seven of which are currently regulated by the E.P.A. The agency said 60 of the

A survey traces chemicals from industry and everyday use.

chemicals were listed by the Government as causing cancer.

The 320 chemicals covered by the survey include such substances as carbon tetrachloride, butadiene, acrylonitrile, and cadmium, all widely used in various manufacturing processes. Other chemicals listed are known to cause neurological disease or birth defects.

The agency said the survey found 2.4 billion pounds of the chemicals were emitted in 1987. But E.P.A. officials said the situation could actually be far worse because the survey did not include pollution from automobiles, releases from toxic waste dumps and pollution from companies that produce less than 75,000 pounds of the toxic substances annually.

"The magnitude of this problem far exceeds our worst fears," said Representative Henry A. Waxman, a Califor-

nia Democrat who is subcommittee chairman.

Agency officials said, that while data on the health effects of most of the toxic chemicals were limited, the Administration would support changes in the Clean Air Act to deal with the problem, possibly requiring industry to redesign plants and equipment to reduce emission, for example.

Jeffrey C. Van, a spokesman for the Chemical Manufacturers Association, said, however, that "to suggest a national health problem based on the raw numbers in the survey is very misleading and troubling."

But he added, "It is becoming apparent that the current approach to air toxics isn't doing the job." He said the chemical industry would support new legislation to deal with the problem.

Sources Are Many

The chemical industry is the largest single source of airborne toxic substances reported in the survey. The industry released about 686 million pounds in 1987.

Other emissions come from plants that produce metals, paper, rubber and plastics, electric equipment, petroleum and coal products, furniture and a wide variety of other manufactured products.

No specific maximum levels were established for the 320 chemicals by the Clean Air Act of 1970. The agency was instead charged with assessing the risks of these chemicals and then drafting rules for controlling each one.

But the act did set maximum levels for other pollutants: lead, sulfur dioxide, nitrogen oxides, carbon monoxide, ozone and particulate matter such as dirt, dust and soot.

Progress and Setbacks

In a separate report, the E.P.A. said today that these pollutants had abated from 1978 to 1987, but that levels of ozone and particulate matter had increased between 1986 and 1987 and that improvements in controlling nitrogen

oxide emissions had leveled off.

E.P.A. officials said that the provisions of the Clean Air Act governing airborne toxics were so cumbersome and expensive to carry out, and so vulnerable to legal challenge, that they have not been able to issue more than the seven regulations in the 19 years since the law was enacted.

Mr. Waxman and three other Democrats, Representatives Mickey Leland of Texas, James J. Florio of New Jersey and Gerry Sikorski of Minnesota, said they planned to introduce legislation in the near future that would amend the Clean Air Act to require that industry make sharp reductions in its emissions of toxic substances.

Information on toxic air pollution is now available because of 1986 amendments to the 1980 toxic waste law requiring industry to report all releases of toxic substances into the air, water and land to the E.P.A. as well as to state and local authorities.

'Public Health Problem'

Data on concentrations of airborne air pollution at the local and regional level should now be obtainable from these authorities, Mr. Florio said today.

Don R. Clay, the E.P.A.'s acting Assistant Administrator for Air and Radiation, said that, while little was known about the health effects of most of the chemicals surveyed, "the data suggests there is a public health problem."

Mr. Clay said that some progress had been made in reducing toxic substances in the air, but that emissions continue to constitute a serious problem that requires new legislation. He said he expected the Bush Administration to support such changes.

Mr. Van of the Chemical Manufacturers Association, a leading industry trade group, said that the survey figures based on 1987 data are already out of date because many chemical companies are substantially reducing their emissions of the toxic air pollutants.

He said that companies had begun to reduce their emissions even before the

Poisoning the Air: State by State

Millions of pounds of toxic industrial pollutants released into the air in each state. Number in parentheses is state's ranking in terms of pounds per square mile.

Source: Environmental Protection Agency

The New York Times/March 23, 1989

public-disclosure amendments to the toxic waste law were passed because the accident at Bhopal, India, where more than 3,000 people were killed by an release of methyl isocyanate, had "shocked the industry down to our toes."

Caution Against Panic

He said that the high numbers in the survey do not mean there is a national health problem and added, "If the data is misused, people will be needlessly frightened."

The E.P.A. had previously estimated that toxic air pollution accounts for some 2,000 cases of cancer a year. But that estimate was based on an analysis of only 20 chemicals. Nor did the agency's study consider the combined effects of the chemicals.

The National Wildlife Federation, the nation's biggest conservation organization, issued its own study on toxic air pollution, which was also based on the information submitted to the E.P.A. and had results similar to those re-

ported by the House Health and Environment Subcommittee. Dr. Jerry Poje, a toxicologist for the group, that the reports present, "for the first time, a snapshot of toxic pollution" across the country, and that the results "speak to a nation at risk."

The federation called for passage of national air toxic legislation that would reduce routine emissions of dangerous chemicals, control such pollution from smaller sources and require stringent action to prevent chemical accidents that could produce acute poisoning episodes. It also called on industry to set goals for reducing its toxic emissions and pointed as an example to the Monsanto Chemical Company, which has pledged to reduce such emissions by 90 percent by 1992.

Other environmental groups joined today in demanding new legislation to reduce toxic air pollution.

"You can stop eating apples and grapes, but Congress has to stop toxic air pollution because, you can't stop breathing," said Daniel Becker of Environmental Action, a Washington-based group.

EMBARGO:

DO NOT RELEASE UNTIL 11:00 A.M., MARCH 22, 1989

**THE NATIONAL
TOXIC RELEASE INVENTORY**

PRELIMINARY AIR TOXIC DATA

March 22, 1989

Subcommittee on Health and the Environment
Committee on Energy and Commerce
U.S. House of Representatives

Henry A. Waxman, Chairman

VVV 000010294

THE TOXIC RELEASE INVENTORY: SUMMARY AND BACKGROUND

Attached are preliminary Environmental Protection Agency (EPA) data on the amount of toxic substances released into America's air supply each year. Made public here for the first time, the preliminary data offer the most comprehensive look ever at the magnitude of the air toxics problem in the United States. They show that some 2.4 billion pounds of toxic air pollutants are released annually into America's air supply.

This data was collected as part of the Toxic Release Inventory mandated under section 313 of the Superfund Amendments and Reauthorization Act (SARA) of 1986. The inventory includes estimates for releases of more than 320 chemicals included within the Superfund Section 313 definition of a toxic release.

A Quick Look at the Data

The largest single source of air toxics, by more than four-fold, is the chemical industry, which reported releases of some 886.5 million pounds of toxics into the air supply. The contribution of 19 other industries are provided in table III.

The state with the largest quantity of air toxic releases is Texas. Nearly, 230 million pounds of toxic air pollutants are estimated to be released into that state's air supply annually. Seven additional states -- Louisiana, Tennessee, Virginia, Ohio, Michigan, Indiana, and Illinois -- reported air toxic releases of more than 100 million pounds annually. Only one state, Hawaii, reported less than one million pounds in annual air toxic releases. Tables I and II provide the aggregate levels of toxic chemicals released into the air by each state. Table IX lists the levels of each of the more than 320 air toxics emitted in each state.

The inventory includes some surprises aside from simply the cumulative magnitude of air toxic releases. For example, the state of Kansas is site of the release of some 69,000 pounds annually of phosgene, a potent neurotoxin which killed thousands when used as a nerve gas in World War I. Well over three quarters of the national emissions of this compound originate in Kansas.

The inventory is based on industry estimates of their own emissions, and not on actual monitoring. Hence, there is some reason for concern that the data may underestimate releases. In addition, the inventory only includes toxics released directly into the air supply. Millions of pounds of toxic substances released into surface waters or soil, which then evaporate into the air supply, are not reflected in the data. The inventory does not include releases from small sources, such as dry

cleaners and gas stations.

The inventory data are only preliminary. EPA explains that they are currently working to "upgrade the quality and usability of the database before it is released to the public." EPA cautions that the final data, which they plan to release later this year, "may vary somewhat" from the data supplied to the Subcommittee.

Chemicals Included in the Inventory

More than 320 chemicals are included in the Toxic Release Inventory. Substances included are those listed in the Superfund law as falling within the definition of a toxic chemical. Included on the list are carcinogens, mutagens, neurotoxins, and other substances associated with serious human health effects.

Sixty of the substances in the inventory are listed as carcinogens by the National Toxicology Program of the U.S. Public Health Service. Some examples of listed carcinogens include: dichloromethane (methylene chloride) (112.2 million pounds), benzene (24.8 million pounds), chloroform (23.7 million pounds), formaldehyde (15 million pounds), butadiene (9.9 million pounds) and carbon tetrachloride (4.3 million pounds). Table V provides a list of carcinogens included in the inventory. Releases of listed carcinogens total 235 million pounds nationally.

Neurotoxins on the list include some of the most prevalent chemicals in the inventory. Examples include: xylenes (120 million pounds), toluene (235.6 million pounds), methyl ethyl ketone (124.6 million pounds), and trichloroethylene (TCE) (47.5 million pounds).

Table IV lists the 100 most prevalent chemicals in the inventory. Ten chemicals are reported to be released in quantities in excess of 100 million pounds annually. Among the most prevalent are toluene (235 million pounds), ammonia (233 million pounds), and acetone (186 million pounds).

The section 313 list was drawn from toxic release reporting programs in New Jersey and Maryland. EPA is authorized to remove from the list chemicals not associated with serious health effects. Three chemicals been removed by EPA in the years since the reporting requirement was put in place.

Health Impacts

While each of the chemicals on the list present serious health risks, it is extremely difficult to establish the precise

VVV 000010296

health impacts of the reported releases into the air. One reason is that we do not have the information needed to estimate just how much of which toxics individuals are actually breathing. In addition, many of the chemicals are poorly studied, and their health impacts are not thoroughly understood. This is particularly true when the combined impacts of simultaneous exposure to numerous air toxics are taken into account.

Nevertheless, it is clear that the release of 2.4 billion pounds of toxic pollutants into the nation's air supply is a serious public health problem. For example, studies by a Tulane University researcher report cancer rates at more than four times the national average for residents living within a mile of chemical production facilities. Similarly, the West Virginia Department of Health reports cancer rates at twice the national average in neighborhoods near chemical plants in Charleston, W. Va.

The Federal EPA concluded in a 1986 study that air toxics cause more than 2000 cancer cases annually. That study examined effects of only 20 chemicals, only about six percent of the inventory, and did not consider combined effects.

Other EPA studies have associated chemical plant emissions with extremely high cancer risks for nearby communities. According to EPA, individuals near chemical plants in many areas of the country face lifetime risks of cancer from chemical exposure of greater than 1 in 1000. EPA has estimated cancer risks from releases into the air of the chemical butadiene at one especially dangerous chemical plant in West Virginia as 1 in 3 for nearby residents. EPA commonly takes regulatory action in other areas, such as hazardous waste clean-up, to prevent far smaller cancer risks on the order of one in one million.

A 1985 EPA study evaluated the cancer risks posed by breathing air in five cities, Baltimore, Los Angeles, Houston, Philadelphia, and northern New Jersey. The study assessed the levels of 15 air toxics in the ambient air in the cities. It concluded that even in neighborhoods not located near major factories, urban dwellers commonly experience cancer risks as high as 1 in 1,000.

EPA's 1987 study, Unfinished Business: A Comparative Assessment of Environmental Problems, ranks air toxics highly as one of the most severe environmental health risks that we face.

The Regulation of Air Toxics

In the 19 years since the Clean Air Act was enacted, EPA has regulated seven substances as hazardous air pollutants.

These substances are listed in Table VI.

Clean Air Act section 112 calls for prompt regulation of substances that pose risks of serious illness, such as cancer, reproductive disorders, or neurological effects. The Agency has been able to avoid the Clean Air Act mandate for regulation of air toxics by declining to formally designate clearly dangerous substances as toxic.

Examples of substances that EPA has been unwilling to list as hazardous include: formaldehyde, chloroform, PCBs, carbon tetrachloride, and acrylonitrile. All of these compounds have been formally listed as carcinogens by the National Toxicology Program of the U. S. Public Health Service. (See table V for a more complete list of carcinogens.) Other prominent examples include phosgene, a nerve gas used in World War I, and methyl isocyanate (MIC), a toxic gas which killed thousands in Bhopal, India in 1984.

By contrast, the Occupational Safety and Health Administration (OSHA) has set standards for nearly 400 substances released into the air, including all of those listed above, and the vast majority of the 320 substances included in the Toxic Release Inventory. Workers are therefore protected from workplace exposures to these substances. Air toxics regulated by OSHA are listed in Table VI.

Unfortunately those who live in nearby communities enjoy no such protection. Except in instances where states have stepped forward to fill the vacuum, releases into community air supplies of the more than 300 substances in the inventory not covered by one of EPA's seven standards are entirely unregulated. The level of releases into the air of such substances are determined entirely by the sources, usually on the basis of economic considerations.

LIST OF TABLES

- Table I: Releases of Toxic Chemicals to the Air by State in order of rank.
- Table II: Releases of Toxic Chemicals to the Air by State in alphabetical order.
- Table III: Releases of Toxic Chemicals to the Air by Industry in ranking order.
- Table IV: 100 Toxic Chemicals with Highest Total Reported Releases to the Air in order of rank.

402 SW 15th
Wagoner, OK 74477

Dear Mr. Bates:

On March 20th, Paula Hubbard notified me that you had indicated three of your employees had experienced unusual "rashes" after handling a Vista PVC dryblend. Based on what was described to Paula, It appears the symptoms experienced are of an unusual nature and extent and unexpected as a result of contact with dryblend.

Vista is investigating shipment samples to determine if there are differences in the batch the plant was handling during the period your employees experienced the rash. In addition to this, we are under regulatory obligation to establish and maintain records of allegations of health effects resulting from our products. This is required by Section 8(c) of the Toxic Substances Control Act.

To meet this obligation we are asking you to complete the attached form with details regarding the health effects experienced and what employees were effected. The form should be returned to me in Houston.

Please contact me at 713-531-3445 if you have questions regarding completion of the form. We will inform you of any significant results from our internal investigation.

Sincerely,

Thomas G. Grumbles, C.I.H.
Environmental Quality Manager

**Report of a Possible Adverse
Effect To Health or the
Environment**

If you think a chemical substance or mixture has caused an adverse human effect, identify that substance and describe how affected. If you think the environment (for example, the air, water, soil, animals, or plants) has been adversely affected by one of the facility's chemical substances or mixtures, identify the substance (if known) and the affected plant and/or animal or contaminated area of the environment.

If you cannot identify the suspected chemical substance or mixture, identify the product, material, or item believed to be the cause of the adverse effect or describe the process or operation or the effluent, emission, or discharge from the facility that you think has caused the adverse effect.

Insert-Type Hearing Protector Stability as a Function of Controlled Jaw Movement*

GORDON L. CLUFF

Department of Speech and Hearing Science, Arizona State University, Tempe, AZ 85287-0102

Samples of five insert-type hearing protectors (three viscose foam, one poly-flanged, and one glass fiber) were evaluated for change in attenuation as a result of 30 min of controlled jaw movement. Protected-ear, narrow-band noise thresholds were obtained at octave intervals (between 0.25 and 4.0 kHz) before and after the jaw-movement activity. Frequency and interaction effects were not significant. Protector effects were significant beyond the 0.01 level of probability that chance caused the observed differences. As a group, the viscose foam protectors were more stable than the others. The most stable protector was E.A.R., and the least stable was Bilsom Soft.)

Introduction

Personal hearing protection currently is accepted as a primary means of preventing hearing loss from noise exposure.⁽¹⁾ Recent studies indicate that the amount of protection obtained from protective devices used on the job is significantly less than is obtained under laboratory conditions.⁽²⁻¹¹⁾ Three causes are hypothesized: (1) the person using the devices may not insert them in the ear canal correctly⁽⁴⁾; (2) ear canal variations may prevent proper insertion or seal therein; and (3) movements of the jaw and head over time degrade the fit of the protector in the canal.⁽¹²⁻¹⁴⁾

Problem

During personal interviews with over 1000 noise-exposed employees, the author encountered comments to the effect that insert-type protectors, after having been fitted within the ear canal, tend to work loose. Accordingly, it is hypothesized that one reason for poor performance of these devices in the field is that they do not maintain a proper fit after having been inserted. A secondary hypothesis is that there are differences among insert-type protectors in their ability to maintain a proper fit.

The two hypotheses above form the basis for this investigation. First, to what degree does controlled jaw movement over time contribute to change in attenuation provided by selected insert-type hearing protectors? Second, are there differences among the selected protectors in their ability to provide stable attenuation under these conditions?

Experimental Materials and Methods

Data were collected from 23 young adults drawn from the largely-female, undergraduate student population enrolled in speech and hearing science classes at Arizona State University. All had normal hearing, which was defined as (1) a Type A tympanogram with maximum compliance within a

range of ± 50 mmH₂O, (2) pure tone thresholds not exceeding 20 dB HL between 0.25 and 4.0 kHz, and (3) no visible structural abnormalities in the ear canal. Five different hearing protectors were used that sampled the insert-type devices commercially available (except for custom molded devices.) The following five devices were used:

- Bilsom Soft (Bilsom International, Inc., Reston, Va.)—plastic encased glass fiber with a foam core;
- Com-fit (North Health Care, Division of Siebe North, Inc., Rockford, Ill.)†—triple flanged, solid core;
- 3M-6300 (3M Company, St. Paul, Minn.)—conical, self-expanding viscose foam with a relatively smooth, even-textured surface;
- Pura-Foam (Moldex/Metric, Inc., Culver City, Calif.)—cylindrical, self-expanding viscose foam with a relatively coarse uneven-textured surface;
- E.A.R. (E.A.R., Division of Cabot Corp., Indianapolis, Ind.)**—cylindrical, self-expanding viscose foam with a relatively coarse, even-textured surface.

Time and other constraints did not allow a broader sampling of insert-type protectors, though there are numerous other brands available.

The subjects were tested by a technician, within a sound-treated test room, at a distance of approximately 1 m (39 in.) from, and in front of, a loud speaker. The subject's head was held in position during testing by having him/her maintain light contact between the tip of the nose and a small but heavy cylinder suspended by a nylon cord from a fixed point on the ceiling of the test room. This method of maintaining head

†Com-fit devices are manufactured in three sizes (small, medium and large). The large size was not included within this study because there were no subjects wherein a large size was indicated, based on the judgment for proper fit made by the technician.

**Note: It has been reported to the author that Decidamp viscose foam protectors (North Health Care) are structurally identical to the E.A.R. protectors evaluated herein.

*This project was supported in part by Biomedical Research Support Grant S07 RR07112, awarded to Arizona State University by the Biomedical Research Support Grant Program, Division of Research Resources, National Institutes of Health.

position during testing is suggested by the American National Standards Institute (ANSI).⁽¹⁵⁾ The point of nose contact on the cylinder for each subject was constant for that subject across all threshold measures.

The test stimulus was a speaker-delivered, narrow band of gaussian noise generated by a GSI-10 audiometer, the center frequency of which varied in one-octave intervals between 0.25 and 4.0 kHz. Fixed-frequency Bekesy tracings were obtained using a 1-min test time at each center frequency and an attenuator slew rate of 2.5 dB/sec. The noise was pulsed using a 400-msec duty cycle.

The order of testing across the various noise bands was constant from the lowest to the highest center frequency for all 115 test sessions. The order of protectors was selected randomly for each subject. Each subject-testing session was conducted in the following order. (1) Written instructions, approved by the author, pertaining to the method of insertion of the hearing protector to be used and the threshold procedures to be followed were read to the subject by the technician. (2) An open-ear, prechewing reference threshold was obtained at 1.0 kHz. (3) The subject inserted the hearing protectors, and then proper fit was determined by the judgment of the subject that the protectors felt tight and the technician's observation that they were fully inserted into the ear canal. The plastic insertion cylinders provided by Com-fit were not used for those protectors. (4) Occluded-ear thresholds were obtained at 0.25, 0.5, 1.0, 2.0, and 4.0 kHz. (5) The subject chewed gum at a constant rate of one jaw stroke per second for 30 min, during which time he/she was not allowed to adjust the fit of the protectors. (6) At the end of the 30 min of chewing, a second set of occluded-ear thresholds was obtained for the same test frequencies as given in Step 4. (7) The protectors were removed, and a postchewing reference threshold was obtained at 1.0 kHz.

The prechewing and postchewing open-ear reference thresholds at 1.0 kHz were obtained to establish the test-retest reliability of postchewing, occluded-ear thresholds compared to similar prechewing thresholds. The reasoning was that if the postchewing, open-ear thresholds were essentially the same as their prechewing counterparts, a strong argument for test-condition stability (and hence, test-results reliability) could be made.

Though the noise level at a typical subject's ear location (the subject not present), with the reference output of the audiometer set at 70dB HL, was measured periodically throughout the study using a precision sound level meter (and maintained within a narrow range); absolute sound levels were of incidental interest. The primary value of concern was change in the measured occluded-ear thresholds between the prechewing and postchewing activity. As long as the reference sound level was constant at these two points in time with respect to each test session, adequate instrumental accuracy was considered to have been maintained. The fact of this condition will be discussed later within the context of test-retest reliability.

Each subject was tested five different times, each time with a different hearing protector. The order of testing the protec-

tors among the 23 subjects was varied so that sequence and practice effects were distributed randomly across the 115 test sessions. The resulting Bekesy self-recording audiometer tracings were converted to numeric threshold values using a rigid transparent plastic overlay scale with lines precisely etched in 1-dB increments. The decibel value (estimated to the nearest 0.5 dB) was recorded for six adjacent low and six adjacent high reversal points at each test frequency. The arithmetic average of these 12 values constituted the threshold. The postchewing thresholds (T_{po}) for each test frequency (obtained from a given test session) were subtracted from the prechewing thresholds (T_{pr}) from that session. The resulting difference values (T_d) then were multiplied by -1 to achieve a proper direction-of-change relationship between each pair of thresholds, and these values became the data units used in subsequent analysis ($T_d = -1[T_{pr} - T_{po}]$).

For convenience hereafter, stability will be used to differentiate among the protectors as a function of the magnitude of the occluded-ear T_d values. Protectors that achieve the largest negative T_d values will be considered the least stable. Protectors at the other end of the continuum will be viewed as the most stable.

Results

The average difference between the prechewing and postchewing, open-ear reference thresholds at 1.0 kHz over the 115 test sessions was 0.66 dB. A t-test analysis of the prechewing and postchewing threshold means indicated that they were significantly different ($P = .01$), suggesting that there was a consistent tendency for the postchewing thresholds to be slightly worse than the prechewing thresholds. Since the magnitude of the tendency was less than 1 dB, and since the generally accepted margin for error in sound level measures is 1 dB or greater, its practical significance is minimal. It is assumed, therefore, that postchewing test conditions were the same as prechewing conditions, except for the chewing-dependent changes in protector attenuation.

The 575 T_d units were evaluated using a two-factor analysis of variance (ANOVA) based on general linear modeling (SAS), with the main effects being (1) the five test frequencies and (2) the five protector types. Differences caused by the main effect of test frequency were not significant (F-ratio [F] of 0.85 and a chance probability [P] of 0.49). Differences caused by the main effect of protector type were very significant ($F = 44.87$ and $P = 0.0001$). Differences caused by the interaction of test frequency with protector type were not significant ($F = 0.41$ and $P = 0.99$). The differences among the five protectors are illustrated in Figure 1.

The results of a Scheffe test to identify differences between pairs of protectors are summarized in Table 1. These data, and those presented in Figure 1, indicate that the self-expanding viscose foam devices were the most stable (average $T_d = -0.3$ dB). The remaining two protectors produced a mean T_d of -6.1 dB. The differences between the mean T_d for the E.A.R. protectors and those for the 3M-6300, Com-fit, and Bilsom Soft protectors were significant, indicating that the E.A.R. devices were more stable than all of the others

Figure 1—Average change in protected-ear thresholds following 30 min of chewing, re: similar thresholds measured prior to chewing (0.25, 0.5, 1.0, 2.0, and 4.0 kHz).

except Pura-Foam. The differences between the mean T_d for the Bilsom Soft protectors and those for the Com-fit, 3M-6300, Pura-Foam, and E.A.R. protectors were significant, indicating that the Bilsom Soft devices were less stable than all of the others. Able and Rokas⁽¹²⁾ obtained similar results in this respect. During subject testing, a Bilsom Soft protector fell out of the ear canal on three occasions.

Discussion

The two questions for which this study sought answers were (1) to what degree does repeated jaw movement contribute to change in attenuation provided by selected insert-type hearing protectors and (2) are there differences among these protectors in this regard? Repeated jaw movement did result in a significant overall mean T_d for the five protectors tested, and there were significant differences among the five in terms of the magnitude and direction of change that occurred.

Three factors may have contributed to the above differences: (1) resistance between the plug and the ear canal wall,

(2) force resulting from opposition to compression of the plug, and (3) force resulting from canal wall movement. Considering the first, resistance between the plug and the canal wall would be influenced by (a) force that is exerted perpendicular to the canal wall, (b) area of contact between the plug and the canal wall, (c) texture of the plug exterior, (d) surface texture of the canal wall, and (e) the presence of any lubricating substance such as cerumen or moisture. Where resistance to movement of the plug within the ear canal is large, positional stability should be enhanced.

Total opposition to compression of the plug within the ear canal may result from the complex sum of force effects delivered along two planes, perpendicular and parallel. Force exerted perpendicular to the canal wall should increase resistance to drift and contribute to positional stability. Force exerted parallel to the wall should decrease resistance to drift and result in reduced positional stability. Plug taper and flanges (if flanges are present) should contribute to the parallel force vector and, hence, should decrease positional stability. Absence of flanges, along with a cylindrical shape, should minimize the parallel force vector and increase positional stability.

Force vectors generated by the movement of the ear canal wall may vary depending on the design of the protector. A tapered plug, or one with flanges, should translate more of this force into the parallel component than would a cylindrical plug. The result would be a natural decrease in positional stability.

Based on the above reasoning, flangeless plugs of cylindrical shape, capable of generating substantial expansion force, with a coarse surface texture, and a large area of contact with the canal wall should be very stable. Physical examination of the five types of plugs used herein reveals that the E.A.R. and Pura-Foam plugs conform well to all five requirements and were the most stable.

The 3M-6300 plugs differ from the E.A.R. and Pura-Foam plugs primarily in that they are conical in shape (rather than cylindrical) and have a smoother surface texture. It is reasonable to assume that their relative loss of stability resulted from both factors.

The Com-fit plugs have multiple flanges, are basically conical in shape, have a relatively smooth surface texture and may (because of the flanges) have achieved less contact area with the ear canal than did the three viscose foam plugs. When dry, their surface texture is slightly tacky to the touch, but when lubricated in any way, this effect is reduced. The expansion force generated by compressing the Com-fit plugs within the ear canal (compared to that generated by the viscose foam plugs) appeared to be less, but this was only crudely measured. The combination of flanged design, conical shape, smooth surface texture, and, possibly, less expansion force likely contributed to their instability compared to the three viscose foam plugs.

The Bilsom Soft plugs were the least stable of the five. Three features may have contributed to this result. First, they have a very smooth surface texture. Second, the expan-

sion force generated when they are compressed within the ear canal appeared to be less than that generated by the foam plugs and possibly less than that generated by the multiple-flange devices. Finally, they appear to have a slight taper.

Placed in perspective, the data reported and observations made herein do not indicate that one protector is "better" than another. Other factors also must be taken into account, such as NRR value, cost, durability, comfort, convenience, preference, and hygiene. The data do indicate that those who use the less stable protectors will need to readjust the fit on a more frequent basis in order to maintain optimum attenuation. If users are not adequately informed of this need, they may obtain less overall benefit. Because there are differences in stability among the five, the education and training sessions associated with each may require differing content.

For the E.A.R. and -Pura-Foam protectors, the need for readjusting the fit once the devices are properly inserted within the ear canals appears to be minimal. For the 3M-6300 protectors, it may be necessary to remove them periodically, roll them again into a tight cylinder, and reinsert them. It is questionable that they can be refitted by attempting to push them deeper into the ear canal without first removing and rerolling them. For the other two, the need for refitting likely will be frequent, and this probably can be done by pushing them back deeper into the canal.

TABLE I
Paired-Comparison Differences in
Attenuation Stability among Five
Insert-Type Protectors Following
30 Minutes of Controlled
Jaw Movement

Protector	Compared to	Mean Difference In Decibels
E.A.R.	Pura-Foam	0.8
	3M-6300	3.0 ^A
	Com-fit	4.9 ^A
	Bilsom Soft	9.0 ^A
Pura-Foam	E.A.R.	-0.8
	3M-6300	2.2
	Com-fit	4.1 ^A
	Bilsom Soft	8.2 ^A
3M-6300	E.A.R.	-3.0 ^A
	Pura-Foam	-2.2 ^A
	Com-fit	1.9
	Bilsom Soft	6.0 ^A
Com-fit	E.A.R.	-4.9 ^A
	Pura-Foam	-4.1 ^A
	3M-6300	-1.9
	Bilsom Soft	4.1 ^A
Bilsom Soft	E.A.R.	-9.0 ^A
	Pura-Foam	-8.2 ^A
	3M-6300	-6.0 ^A
	Com-fit	-4.1 ^A

^AChance probability is not greater than 0.05

Before a user will refit a hearing protector, he or she must first recognize that the attenuation has decreased to the point that such action is needed. If change in performance is abrupt, it seems reasonable to assume the user will detect it readily. On the other hand, if the change is gradual, it is equally probable that the user might not detect it until the reduction in attenuation results in a potentially dangerous noise level at the tympanic membrane.

With respect to the above, there are two questions that need to be answered. First, when the attenuation provided by an insert-type hearing protector changes as a result of head and jaw movement, does it typically change in abrupt steps or does it change gradually over time? Second, how much change in attenuation must occur for the typical user to detect it while engaged in normal work activities? The type of instruction and training needed to achieve proper use of insert-type devices may be dependent upon the answers to both questions. Therefore, these questions should be pursued via subsequent research, perhaps using *in situ* measures to continuously track changes in attenuation.

Conclusions

(1) The attenuation provided by self-expanding, viscose foam protectors appears to be less affected by jaw movements than is the case for multiple-flanged or glass-fiber devices. At the same time, there are significant differences among self-expanding viscose foam protectors in this regard. The E.A.R. protectors were not significantly more stable than the Pura-Foam devices, but they were more stable than the 3M-6300 units.

(2) Users need to be instructed and trained in the need for, and the proper means to achieve, refitting of insert-type hearing protectors, depending upon the type of protectors being used.

(3) The typical manner in which insert-type hearing protectors change attenuation as a result of head and jaw movements needs to be identified.

(4) The minimum detectable change in attenuation provided by insert-type hearing protectors used on the job needs to be identified.

A final point may be in order. Industry may wish to restrict activities that generate significant jaw movement, such as gum and tobacco chewing, when insert-type hearing protectors are required to be worn.

International Labour Office Book on Major Hazard Control

The International Labour Office, within its safety and health program, has published guidance on how to set up systems for the control of major hazards.

Fires, explosions, and the release of toxic gases can cause deaths and injuries to workers and the public and adversely affect the environment. Disasters such as those at Basel, Bhopal, Fixborough, Mexico City, and Seveso have given rise to the term *major hazards*. The prevention and control of such hazards have become a subject of public discussion in all parts of the world. This comprehensive, practical manual is a response to that pressing issue.

With the increasing production, storage, and use of dangerous substances, there is a need for a well-designed and systematic approach if disasters are to be avoided. The manual deals with the safety aspects of siting, design, construction, and operation of plants, explains how to identify major hazard installations, and describes all the components of a major hazard control system. Extensive information is provided on planning for emergencies both on site and in the community.

This book is aimed at all countries considering major hazard control for the first time and at those where certain aspects of a system already are in operation. Factory inspectorates and managers of major hazard installations and trade unions, and local authorities and emergency services will find it indispensable.

The ILO manual on major hazard control can be ordered at the cost of 45SFR from ILO Publications, International Labour Office, CH1211 Geneva 21, Switzerland.
