

PROCEEDINGS
of the
National Safety Council

*EIGHTH ANNUAL
SAFETY CONGRESS*

Held at the
HOTEL STATLER
Cleveland, Ohio
October 1-4, 1919

INTRODUCTION

"The 1919 Congress was the greatest Congress ever held in the history of the National Safety Council." This was the unanimous verdict of the 3,000 representatives who attended the Congress in Cleveland, September 29 to October 4. Previous congresses have been characterized by great enthusiasm, splendid programs of speakers and round-table discussions, but there was a new spirit manifested at this Congress resulting doubtless from the war experience, a spirit of the faith in the cause of Safety, a vision of the future, a conviction of certainty of the future development of the Council and the Safety movement, and a spirit of determination to grip the accident problem and to solve it just as we gripped and solved the difficult problems during the war.

This volume of 1460 pages will bring to the members who were at the Congress something of the spirit which animated that great gathering and will place in their hands the valuable experience which was contributed by the various speakers and in the round-table discussions. The proceedings represent the best piece of literature on Safety which will be published this year—the most valuable compendium of experience for any individual or concern to use in developing Safety work in industry.

This volume constitutes one of the important items of service which the Council, as the clearing house of information, is able to furnish to its members.

INDEX

The Proceedings of the 1918 Congress included a cumulative index covering the Proceedings of all the Congresses held up to that time—1912 to 1918 inclusive. As a measure of economy, this cumulative index is not included in the present volume. By referring to the index at the end of this volume, covering the 1919 Congress only, and referring also to the cumulative index at the end of the 1918 Proceedings, covering the other Congresses, you will readily find a great variety of information on almost every phase of accident prevention and allied subjects.

National Safety Council

Annual Meeting of Members

Cleveland, Ohio

October, 1, 1919

PRESIDENT DAVID VAN SCHAACK, Presiding Officer

WEDNESDAY MORNING SESSION

THE meeting convened at 10:15 A. M., Mr. David Van Schaack, President of the National Safety Council, presiding.

PRESIDENT VAN SCHAACK: The Eighth Annual Meeting of the National Safety Council will please come to order.

Our deliberations will be opened by prayer by the Rev. Dr. Blanchard.

INVOCATION

REV. DR. BLANCHARD (President, Federated Churches of Cleveland): Almighty God, Our Father, Thou the source of all life and power and love, by Thy wisdom do we come to acknowledge that by Thy life do we see light. We thank Thee that Thou hast led the children of men through all the years into a wider understanding of the value of life, and we thank Thee that Thou dost guide us in this day and generation by Thy spirit of compassion to care for others, and we pray that Thy blessing may rest upon this great convention as it seeks to make life richer and fuller and more safe and that Thou wilt guide all the deliberations and all the plans that are formed that there may come throughout this nation, through industry and through education and through all the ways of life in which men move, a deeper sense of personal responsibility and a wider and greater understanding of Thy value upon life. And so by the spirit that hast led and art ever leading men to understand Thy will, may that spirit keep all these, Thy servants, and may it be granted unto us all to hear without fear and without shame the words that shall be

spoken, "Inasmuch as Ye have done it unto one of the least of these my brethren, Ye have done it unto me." We ask it in the name of Jesus, Amen.

PRESIDENT VAN SCHIAACK: It gives me pleasure to introduce Director Waite of the Department of Parks and Buildings of the city of Cleveland who, in the unavoidable absence of Mayor Davis, will welcome us to the city of Cleveland. Mr. Waite.

ADDRESS OF WELCOME

MR. FLOYD WAITE: Mr. Chairman and Delegates to this great convention: It is not only a pleasure from the standpoint of hospitality, but it is also a great privilege to welcome you to this city. Cleveland has endeavored throughout the years to place herself as one of the leading municipalities of these United States. We have endeavored always to look forward, to strive to attain the best in municipal government and in the things of life. We feel that you are going to bring to us rich blessings for being here. We know that you are going to inspire the people of this city to better things in the way of human life.

I wish that I could express to you the feelings of the people of this great city. I wish that I might be able to let you know the hospitality that is within their hearts, but I do feel that as you go about this city and as you meet our people, you will really understand that we are not only glad to greet you, but that we want to do everything in our power to make your stay here a happy one and a profitable prosperous one.

I have the great honor to be associated with you in this great movement for safety. The Mayor has seen fit to appoint me as Chairman of the Public Safety Committee, and I feel that in doing this he has extended to me one of the greatest honors that has ever come to me in my life, and I want to say that we are going to carry this great work forward—the work that you are going to leave here with us.

The Committee that is being appointed is a committee of men who have the reputation of doing things, and when you come here again for one of your meetings you will find that Cleveland is not only one of the cities in the forefront in this great work, but I am going to prophesy to you that it is going to be the first city in this great work of safety.

We have learned a great many things during the last few years. We have learned a lesson that we thought we knew, that of coöperation. We believe here in this country that we understood what it meant to stand together, and yet we never realized for one moment the great possibilities of this great Republic until we were called together to face the enemy, and then we began to see what it all meant. We never dreamed of the great preparation that could be made by American business until the hour came that we were compelled to prepare through bloodshed and war, and then we learned the lesson of what we actually could do, and it seems to me that as we go forward in these days of peace we should understand our powers and our resources. If we work together, and if a great body like this, united throughout this country,

will only continue with enthusiasm to do the work they have started and to get others interested in it, the time will come when people will look back on the days when men and women and children were maimed and killed as days of barbarism comparable only to the days of witchcraft of old New England.

Everything moves toward the rising sun. It is the organization and the man with a vision, who look forward and see the things that lie beyond, who succeed. It is that spirit that has made this young Republic the greatest power in all the world. It is that spirit that has carried us forward through every contest victorious, and it is going to be the same spirit that makes these United States the leading nation in the accomplishment of all good things for humanity and for civilization.

We ought to be proud and happy that we are permitted to undertake a great work of this kind. We ought to be happy that we have such an organization as this in our country; but we should never be satisfied until we have interested in this great movement every man, woman, and child in these United States. That work can be done; it is being done. It is marvelous the work that is being done right here in Cleveland today. Every school child you talk with has but one subject of conversation, and that is safety. Every policeman you meet talks about the same thing, and it has gone into every home until today the great subject in Cleveland is SAFETY. We don't want to allow this thing to become a great message just for one week, or for one day, but we want the message to endure; we want to keep on and on in this great work until it becomes a part of a man's religion, a part of his life to be careful, and to be careful of the lives and the rights of others.

We are learning through this great Safety Council a lesson here in Cleveland. It is going to teach us how we can work together for the common good. It is going to teach the various municipalities how they can work together for the public safety, and it is going to leave behind it a great record of achievement.

I welcome you on behalf of the Mayor of Cleveland. I welcome you on behalf of the people of this great municipality; I welcome you for the lives of the men, women, and children that you will save in this city through your deliberations. I say to you that you are bringing a rich benediction to our community and I wish you every success in your great endeavors. I thank you.

RESPONSE BY PRESIDENT

PRESIDENT VAN SCHAAK: I cannot tell you, Mr. Waite, how much we appreciate the hearty welcome you have given us, just the kind of welcome which, I may say, we felt sure we would receive. Cleveland has long and deservedly been noted for unfailing and warm hospitality to her guests, upon whatever errand they may come.

Any organization may well be glad to hold its meeting here, but especially such a one as the National Safety Council, for both Cleveland and the Council stand for the initiation and furtherance of progressive ideas. The inventive genius and organizing ability of Cleveland men

have done much to revolutionize business and industry in many lines and thus to advance our country to the commanding position which it now occupies, and in civics and in sound philanthropy your city is second to none. So, too, is the National Safety Council a pioneer and leader. With a mission which is both humanitarian and economic, it seeks, through practical methods only, to conserve life and limb and health, to diminish suffering, to reduce privation, to promote efficiency, to further a better industrial understanding between those whose interests are essentially common, to make a real and a large contribution to the well-being of both industry and society.

There is another striking point of similarity between Cleveland and the Council. Both are firm believers in the principle of coöperation as the best means of advancing a purpose. Your churches were the first of any city to federate. Your activities for promoting the public health are coördinated. Your welfare work is carried on through a Federation of Charity and Philanthropy. The achievements of your Chamber of Commerce are a notable example of what can be accomplished when the leading men of a community pull together. Every branch of the National Safety Council's varied work, whether industrial, public, or educational, is based likewise upon coöperative effort, and whatever measure of success that work has attained has been due primarily to the whole-hearted concert of thought and action of the Council's membership.

I feel, Mr. Waite, that acknowledgment of your kind welcome would be incomplete if I did not take this opportunity of expressing our deep gratification at that other welcome which Cleveland is giving us, in conducting an active "Safety Week" campaign while our Congress is here, a campaign which I am sure will be followed by continuous organized effort along the same lines.

Permit me to offer to you, Mr. Waite, and to the City and people whom you represent, our sincere and appreciative thanks.

The next item of business is the roll call of members. The Secretary and the Registration Committee, having advised the Chairman that a quorum of members entitled to vote are present in person or by proxy, The Chair will be glad to entertain a motion to dispense with the calling of the roll. Do I hear such a motion?

(A motion was made that the calling of the roll be dispensed with. The motion was duly seconded and carried.)

The Chair would suggest that the members present who have filed proxies may withdraw them if they so desire to avoid duplication in voting. All proxies not withdrawn before the first vote is taken will be considered as in effect.

The Executive Committee having appointed three Inspectors of Election at its meeting yesterday, The Chair will appoint those men also Tellers of Election, which will take place today. The gentlemen are Mr. Davidson, Chairman, Mr. Stanion, and Mr. Case.

The next order of business is the annual address of the President. I am sorry I am not a ready public speaker, but I must ask you to bear with me with a manuscript.

PRESIDENT'S ADDRESS

DAVID VAN SCHAAK, PRESIDENT NATIONAL SAFETY COUNCIL, DIRECTOR.
BUREAU OF INSPECTION AND ACCIDENT PREVENTION, AETNA LIFE
INSURANCE AND AETNA CASUALTY COMPANY, HARTFORD, CONN.

Ladies and Gentlemen: It gives me profound pleasure to have again the privilege of welcoming you to an Annual Meeting and Congress of the National Safety Council and of reporting to you, on behalf of your Directors, Executive Committeemen, and Officers, upon the manner in which they have cared for your affairs, and upon the progress of your organization, during the past year.

As I note the large number present, I am once more deeply impressed with a keen sense of the constantly increasing interest taken in the cause which you are all endeavoring to serve, and of your clear understanding that, only through general personal participation in the conduct of your Council, and through cordial coöperation of all its members, can that cause be advanced as it should be and can the Council take its proper and important part in that advancement. Without such participation and such coöperation, the best efforts of those to whom you have entrusted the active management of your affairs could not have achieved anything like the measure of success with which the Council has met, and the safety cause would not be what it is today, a national movement of already wide range and with practically unlimited possibilities.

Time does not permit my reviewing the really marvelous progress of the Council since its formation only a few years ago, or my describing in detail the work of the past year, but those twelve months have been so marked by both accomplishment and unfolding of opportunity that I must call your attention at least to the broad lines of development.

THE HEADQUARTERS

As you know, the growth of the Council and the expansion of its activities have necessitated the removal of its Headquarters to larger offices which, I am happy to say, involve no greater rental than that paid for the offices which had become insufficient. You know, too, of the changes in our official staff made necessary by the resignation of the General Managership by Mr. Cameron, that far-seeing enthusiast whose works justified his faith and to whom both the Council and the safety cause are greatly indebted. We were fortunate in having available as his successor Mr. Price, another man of vision and faith, whose administration of his new office has proved, even in a few months, that we made no mistake in advancing him to a field of wider opportunity. We were fortunate, too, in being able to associate with Mr. Price in the administration of the Council's affairs a Secretary and Chief Engineer of the fine technical training and sound judgment of Mr. Williams, and a Treasurer and Business Manager of the capacity of Mr. Pardee, who, to our great regret, has recently found it necessary to resign his office.

Our headquarters' staff has been further reorganized and expanded by appointments of a new assistant secretary, an additional safety engineer,

a new librarian, with more assistance, a director of publicity, two regional field secretaries, and a public safety field secretary, the last three being W. R. Rasmussen, Frank E. Morris and Carl L. Smith, men favorably known to you all through good work they had already done for the Council.

These additions to our headquarters' staff, together with a further increase in membership and an improvement of the sound financial condition which was developed during the previous year, have done much to enable the Council to carry out its plans for improving its service and extending its activities and influence. We have not been able to do all that we would have liked to do, but I believe that we have done about everything possible within the scope of the funds available. It is both unfortunate and encouraging that the Council never has enough money to avail itself of all its opportunities—unfortunate because good work must be left undone, encouraging because the field in which the Council is operating always presents new possibilities of good work to be done.

A YEAR OF PROGRESS

Though we may wish that more could have been accomplished, we can look back upon a year of real progress, and in many respects. Our direct service has been notably improved. General bulletins have been of better quality and wider range, large-size ones have been issued more frequently, sectional bulletins show improvement in both nature and appearance, and a useful catalogue of bulletins has been prepared. A Safe Practices pamphlet has been issued every month, as against eight in all the previous year, and two sectional pamphlets have been published. The supply of films, slides, and phonographic records has been enlarged and a catalogue of slides has been issued. Our information bureau and library have increased largely in quantity and value of material, especially on industrial relations, and extensive progress has been made in proper cataloging.

In making use of its industrial relations material, the Council has followed, and very properly, a conservative policy. It has not attempted to give expert advice, but it has endeavored to bring together all that is really known upon this subject and to place it at the disposal of its members. This latter object has been accomplished in two ways; hundreds of inquiries have been answered by sending the inquirer printed matter relating to his question, as, for instance, on various employees' representation plans now in effect, and the Council has issued sixteen executive series bulletins, designed principally to stimulate the interest of its members in industrial relations subjects.

All of this improvement in direct service has been made possible largely by the continuance of that cordial coöperative effort on the part of the entire membership which has always been a distinguishing characteristic of the Council, and the value of which I wish to emphasize once more, and more strongly than ever. I think it no exaggeration to say that there has never been a finer illustration of close and hearty coöperation than that given by the membership of the National Safety Council from

its organization to the present day. As I said to you a year ago, you yourselves have made the Council what it is, and only you yourselves will make it whatever it is to be. You have always given to the Council freely, or more so, than you have taken from it. You have viewed the opportunity to give as an obligation to a worthy cause.

Your concert of effort is reflected in every phase of the Council's activities, in each feature of its service, whether headquarters or field, as well as in the formulation of its policies and the furtherance of its propaganda, and I cannot adequately express the deep gratitude which your Executive Committeemen and Officers feel for the warm support and invaluable aid which so many of you have given, as committeemen, in Local Council and sectional work, and as Directors, and which literally all of you have given in counsel and contribution, both voluntarily and upon request.

EXTENSION OF LOCAL COUNCIL ORGANIZATION

In three essential directions other than the service already mentioned the Council's work has developed rapidly and most satisfactorily during the year—in the extension of permanent Local Council organization, in the promotion of public safety, and in the advancement of safety education. Just as the Chicago headquarters are the heart of organized safety effort, so the Local Councils are the arteries and veins which carry life-giving blood throughout the entire body of the national safety movement. They bring the Council into direct and intimate touch with its membership, permeate communities with a real safety atmosphere, and spread far and wide the gospel of care for humanity. A year ago we noted with appreciative interest the earnest of success for the Local Council permanent secretary plan given by the progress of the experiments being conducted at Pittsburgh and St. Louis. Today we can feel, with more than reasonable assurance, that the promise afforded by these experiments has been fulfilled, that the permanent secretary idea is thoroughly practical and of far-reaching value. The Local Councils at Pittsburgh, St. Louis, and Rochester are now well established on this basis and doing excellent work. The plan has been put into effect also at Cleveland, covering Northeastern Ohio, at Cincinnati, at Kansas City, and at Portland, Oregon. Movements are actively in progress, and some of them nearing completion, for permanent secretaries in Chicago, San Francisco, Detroit, and Springfield, Mass. The Council has also assisted in organizing the Border Cities Local Council in the Canadian towns opposite Detroit and in coaching its new permanent secretary.

Not only are these developments highly encouraging in a general way, and demonstrative of the Council's wisdom in initiating the permanent secretary plan, but there is a feature quite common to them which is particularly significant. This is the manner in which it is undertaken to supply the funds necessary to support a permanent organization during the first year. The achievements of the first Local Councils to adopt the plan have made such an impression upon the more progressive men in industry in other communities that they are not waiting until

their Locals become of such size as naturally to demand permanent secretaries, but, under the leadership of one or more of them, are grouping themselves in small syndicates to underwrite the first year's expense and thus enable the permanent organization not only to start earlier, but to be fully equipped from the very beginning both to render service and to increase membership. With this financial backing the officers of the Local Council are able to make such a demonstration of the value of the work as will win the confidence of the business men generally and thus assure continuous support. There could be no better proof that the permanent secretary plan is sound and fills a real need, and no more convincing indication of a rapid increase in the Council's membership and, therefore, a correspondingly larger opportunity to render the service to industry and to humanity which I believe it has shown that it is qualified to give.

Local Council activities have by no means been confined, however, to this development of the permanent secretary plan. The many Locals which necessarily are without such secretaries have shown a lively interest both in their immediate work and in extending their influence, and several new ones have been established.

SCHOOLS FOR SAFETY SUPERVISORS

One of the most striking features of Local Council work has been the schools for safety supervisors, four of which have been conducted during the year, at St. Louis, Pittsburgh, Rochester, and Cleveland. In these schools a course of fifteen lessons has been given and 464 men have been graduated. Not only have these schools been of much direct benefit to those attending them, but they have had a notable influence upon other branches of the Council's work. A most gratifying development, for instance, has been the coöperation of the students in stimulating attendance at foremen's meetings. Taking St. Louis as an illustration, the average attendance for such a meeting in 1918 was about 150. After the opening of the safety supervisors' school, the attendance at foremen's meetings ranged from 1,200 to 2,000. It is believed that the graduates of these schools will also be of much assistance in securing large attendance at the similar schools for foremen which are one of the Council's new plans for the coming year.

PUBLIC SAFETY WORK

Closely connected with the development of the permanent secretary plan for Local Councils, in fact dependent upon it so far, has been the expansion of the Council's public safety work, which promises to become a real factor in many communities. The experiment conducted in Rochester early in 1918, now a permanent enterprise, pointed the way to work along generally similar lines in St. Louis which, ever since its memorable Safety Week at the time of the 1918 Congress, has conducted an active public safety campaign, and has led to the recent inauguration of such a campaign in Pittsburgh. The impulse given by the present Safety

Week here will doubtless result in Cleveland likewise undertaking to establish systematic public safety work.

The Council's public safety plan is based upon right principles. While the Local Council undertakes to stimulate public safety interest in a community, and while its permanent secretary takes an active part in the resultant campaign, the fundamental basis of the plan is to bring together in a comprehensive safety organization representatives of those departments of the municipal government which would properly be concerned, and representatives of the leading organizations naturally interested in the welfare of their city and its people, and to give this organization the benefit of definite knowledge of what has been done elsewhere and how it has worked out. Your Council is thus attempting, and I believe successfully, to fill a need which has hitherto remained unsatisfied, and I say this with all due deference to previous public safety efforts. It encourages a genuine and wide appreciation of, and demand for, public safety, aids in the creation of an organization which will be fully representative of the community, and then lays before this organization a carefully thought-out plan of action based upon all the experience available.

This method is exactly in line with that so successfully followed in industrial safety work and is in full keeping with the Council's general policy. There is no attempt by an outside agency to impose its individual theory or to arrogate to itself the practical application of such a theory. Coöperation by all interested, and by all who should be interested marks the Council's public safety work just as distinctively as it does its industrial safety efforts. In each field representative committees decide upon the plan and carry out its details, and there is the same endeavor in both to arouse that deep and general interest which can come only from every one feeling that he has his own particular bit of work to do, and that the success of the plan as a whole depends upon his doing it.

The efficacy of this method is evident from the results, of which, in order to avoid burdening you with details, I shall give only a couple of illustrations. In St. Louis the Coroner's report for the first eight months of 1919 showed 90 less inquests than in the corresponding months of 1918. Deaths from automobile accidents were $11\frac{1}{2}$ per cent less, notwithstanding a 25 per cent increase in the number of automobiles in use. In Rochester the accidental deaths during the first six months of 1919 showed a reduction of $13\frac{1}{2}$ per cent from the figures for the same months of the previous year.

SAFETY EDUCATION

In many respects perhaps the greatest advance made by the Council during the year has been in the matter of safety education, though not so much in the way of what has actually been done as in that of building a solid foundation for future accomplishment. No branch of the Council's progress is, in my opinion, more deserving of our keen interest. Promoting safety education in the schools and colleges is reaching to the

fundamentals of the safety problem and is in the natural line of development of the Council's work. What has been our chief task during our six years of active existence? Has it not been education? Admitting the great value of the Council as a bureau of exchange, as a collator and distributor of the best experience in safeguarding and in safety organization, has not the Council's chief mission been to carry the message to Garcia, to educate both employer and employee?

We have been trying, and with ever-increasing success, to educate the employer to a sense of appreciation of the need for accident prevention on both humanitarian and economic grounds, and of the value of the safeguards and organized methods which experience has shown to be the most effective. We have been endeavoring, and I believe with equal success, to educate the workman to an understanding of what accidents mean to him and to his, and of the fact that if they are to be reduced to the minimum, he must personally cooperate in the work of prevention. We have had to do this because unfortunately safety has so far been largely an afterthought, because it has been in no sense a factor in the ordinary education of either employer or workman, and because, in the absence of an instinctive tendency to think for safety, we could only try to get them to think against danger.

We soon came to appreciate that, necessary as this education was and for a long time will be, it was at best but a stop-gap, and that the safety movement must go deeper. Our experience was the same in this respect as it had been in the matter of safeguarding. While our first effort naturally was to see that existing buildings, machinery, and other physical equipment lacking elements of safety were safeguarded as well as possible, it quickly became apparent that the ultimate solution of this problem would be to make them right from the start, designed, constructed, and installed with due regard for every safety consideration. It is the same with safety education, and I am happy to report that the Council has made real progress during the year in approaching a solution of this problem.

A handbook on "The Principles and Practice of Safety," prepared by the Council for use in technical schools and universities, will be applied in many such institutions during the coming year. Mr. Keefer, of our Safety Engineering staff, has made a successful trip to eighteen Eastern and mid-Western colleges, and special lectures have been given by members and employees of the Council at several engineering schools.

The most distinguishing feature of our safety educational effort, however, has been the working out in St. Louis, by Dr. E. George Payne and his associates, of a definite plan for safety education in the common schools of the country, and the publication, at the request and with the endorsement of the Council, of a book describing and illustrating this plan, which has been brought to the attention of the National Education Association and which it is to be hoped will soon have wide circulation. In this plan the problem has been approached with full appreciation that it is psychological, that the object is to get people to think in terms of safety, and that if this object is to be attained, if regard for safety is to

have a controlling influence upon the lives of men and women, it must be developed in their minds while they are children, throughout the formative period of their school education, so that it will permanently affect their way of thinking.

As it has been so ably put by Mr. Whitney in his illuminating address before the National Education Association, from which I am taking the liberty of freely borrowing both thoughts and even the manner of their expression, education is the building up in the child, through the acquisition of certain processes, principles, and point of view having a direct application to life, of a mechanism for grasping the world. This cannot be done through abstractions. Materials in the child's life must be used. Principles must be developed from experience. The school should be approximately a working model of life, and both the principles and the facts of life should be got at the same time.

It is upon this theory that Dr. Payne's plan of safety education is based. Safety is not introduced into the curriculum as a new subject, but is made a part of all subjects. The child's knowledge and intuition of safety and danger figure as a part of that body of experience out of which the mechanism for right thinking is to be constructed. Safety thus becomes one of a considerable number of interests having equal importance and occupying an organic place in the body of experience which is used as a medium for teaching.

Safety has been handicapped by being misunderstood. It has been too commonly looked upon as merely a system of inhibitions, and, as we all know, a negative appeal stirs only with difficulty and incompletely either the heart or the imagination. This misunderstanding is due to the fact that safety is a bilateral idea. It has its positive as well as its negative side, but, like most people with two faces, it presents only one to the public. We are thoroughly familiar with the face "Safety from," but we have not seen clearly enough the face "Safety for." We have been too apt to ignore the fact that safety puts something in as well as takes something away, that it is not a process of deprivation but a process of substitution. I can think of no better, no larger, illustration of this than that furnished by the Great War. In the first flush of the French soldier's hot resentment against the invader, he threw himself into the fray with the utmost recklessness. His fine patriotism gloried in the sacrifice of his life. As the months and the years passed, he increasingly made use of every means of protecting that life. He had come to see that the safety of his country demanded all possible safety for himself and that he might the longer and the more effectively stand between her and the barbarians who were trying to destroy her. He sought safety, not from the enemy, but for France.

Safety gets its true meaning from the fact that life has a value. The positive side of safety lies in the thought that nothing must be allowed to interfere with full realization of this value. The St. Louis plan for safety education is based upon recognition of the need for furthering this positive side of safety. It seeks to avoid letting safety appear as a deprivation, as robbing life of the characteristic of adventure; on the

contrary, viewing life itself as the great adventure, its object is to substitute a worthy adventure for a mean one. This is a new thought in the conception of the safety movement, and I hope and believe it will go far. It lifts the safety movement from the material sphere to a spiritual one. It makes the fight for safety a fight for a real, a worth-while adventure, a fight which shall make life the measure of a purpose, and not the marred result of purposeless chance.

NATIONAL IN THE SCOPE OF ITS ACTIVITIES

It is unmistakably evident, I think, from this general review of what the Council is doing, that it is national in the scope of its activities. It is just as clear, from many events of the past year, that it is steadily becoming more and more national in reputation. Its coöperation has been more generally sought and, of course, it has always been freely given. To cite only a few instances: The State of Washington asked and obtained the Council's aid in training the staff which will put into effect the provisions of that State's new safety law. The Federal Board for Vocational Education has continued to call your organization into counsel upon certain features of its work. So, too, has the Working Conditions Service Bureau of the Department of Labor. The American Red Cross has increased its endeavor to work with the Council in every practicable way. Such organizations as the National Association of Employment Managers have felt that the Council should have a place on the programs of their conventions to explain how safety is connected with other national movements. I have just come from Pittsburgh, where, as president of an organization recognized to be national in both purpose and scope, I was invited to serve on the honorary committee in charge of the exercises incident to the dedication of the Bureau of Mines' magnificent new buildings. The Bureau of Standards has asked the Council to work with it in the formulation of certain standards. The American Engineering Standards Committee has invited the Council's representatives to advise with it regarding the whole standards situation.

These last two instances of appreciation of the Council's national character lead me to emphasize the fact, as I see it, that we must face important new problems during the coming year. We are called upon to take a responsible part in the standardization work which has been a crying need for a long time. It is natural that we should be, for we represent in larger numbers than any other organization the industrial interests upon whose application of standards their practical success must depend, and because those interests are in the best position to know the extent to which theory can be converted into practice and the degrees by which this should be done. In the fulfillment of our plain duty to our members, to industry generally, and to the cause of safety at large, we must meet this call, and fittingly. There has arisen, also, an urgent demand for engineering research in connection with safety as applied to certain industries and groups of industries, and I believe that, in some at least of our sections there must be early development along more

technical lines. Such work is in precise accord with that logical evolution of the Council's activities which has led us to the endeavor to place safety education upon a more scientific basis. It would be unbecoming for me, when about to retire from your presidency, to undertake to prescribe the manner in which these calls should be met, but I cannot refrain from expressing the feeling that meeting them is an imperative necessity and that the best means of meeting them should receive early and most careful consideration.

Speaking of my retirement from office, which will be within a day or two, I hope you will pardon my taking a moment of your time to express my appreciation of the honor you have done me in twice electing me your president, and my gratitude to my fellow members of the Executive Committee, and to you all, for the pleasant relationship, as well as the unselfish and wholehearted coöperation, which it has been my privilege to enjoy.

It is indeed an honor to be chosen to head such an organization as your Council, an organization national in the scope of its activity, national in reputation, and, from the nature of its self-evident mission and the manner in which it endeavors to forward it, destined without question to be a vital national force.

Little did any one foresee when the Council was started a few years ago by a small group of men who sought help from each other in the details of what is now but a part of our work, that from such simple and restricted beginnings there would develop a society, the several but homogeneous activities of which would influence our national life in so many ways and would have an enduring effect upon the true welfare of mankind. This development has been normally gradual, as well as astonishingly rapid, for it has come from the attempt to fill one need opening up the existence of another. Serving those already interested in safety, has pointed out the way to interesting others. As industry is but a part of community and national life and its interests are inseparably interwoven with both, the forwarding of industrial safety has been followed closely by efforts along public safety and safety educational lines.

We have unavoidably been led into fields other than our own immediate one, but we have entered them only in a coöperative way, or, as in the case of preventive and curative medicine, to enable a closer, and wider, application to industry than would otherwise be possible, to intensify in one specific direction the work of others.

Inasmuch as it is you members of the National Safety Council who really have done all that has been done, and who have built up an organization of such possibilities, there can be no tinge of self-gratulation to my inquiry as to whether you do not derive a keen satisfaction from what you have already accomplished, and do not feel an increasing enthusiasm to grasp the opportunities which lie before you.

In what more useful, what nobler effort, could you engage? In what way, or ways, could any one, or all, of you take part in a movement of more lasting benefit to humanity? Through your Council you are promoting better conditions under which men and women in industry may

work and better working conditions inevitably lead to better living conditions. By bringing employer and employee together, man to man you are furthering a better feeling between those who too often, unfortunately, have considered themselves as belonging to different classes, and are doing much to forward that new industrial day, the first rays of whose morning sun we hope we see creeping above the horizon. By saving thousands of men and women each year from accidental death and maiming, you are conserving the greatest resource of any nation, you are promoting our national efficiency, you are reducing the suffering, grief, and privation of which at best the world must have too much, and you are preserving to many of the rising generation the educational opportunity which will give them their chance in life.

I cannot imagine a better, a more soul-satisfying, work, and again I say, let us rededicate ourselves to our cause, let us strain every nerve to render the personal service, and raise the funds, necessary to take advantage of every opportunity that logically presents itself to us. Let us go further and seek for opportunity. Let us with renewed and constantly renewing vigor wage the battle until not only every individual, not only every community, but the American people as a nation shall think in terms of safety. Let us carry on with ever greater enthusiasm to the time when it can and will be universally said of the men and women who are the National Safety Council. "Well done thou good and faithful servants."

PRESIDENT VAN SCHAAK: The next item on our program is the approval with, or without, corrections of the minutes of the last Annual Meeting. As those minutes have already been printed a motion is in order to dispense with their reading and to approve them as printed. Do I hear such a motion?

(A motion was made that the reading of the minutes of the last Annual Meeting be dispensed with. The motion was duly seconded and carried.)

PRESIDENT VAN SCHAAK: We have next to hear the reports of our officers and committees. I will call first upon Mr. Price to report as General Manager.

GENERAL MANAGER PRICE: I think that in view of the fact that my report was published in our weekly letter which was circulated some ten days ago and which probably every man in this room has read, that I may well follow the custom of my honored predecessor, Mr. Cameron, and I therefore suggest that we omit the reading of the General Manager's Report.

(On motion the General Manager's Report was accepted as printed and placed on file.)

REPORT OF THE GENERAL MANAGER

In looking back over the year which has passed, the outstanding event which comes first to our minds is the resignation of our much esteemed General Manager, W. H. Cameron. We who are left to carry on the work which he organized appreciate more than anyone else what an invaluable

contribution he made to the Council and to the Safety Cause. He did more than any one man to make the Council possible and to develop its work.

But Mr. Cameron is not lost to the Council nor to the Safety Movement because he is now an active member of the Executive Committee of the Council and in his new field is doing most valuable work in Safety.

LOCAL COUNCILS

At the time of the last Congress three cities, Pittsburgh, St. Louis, and Rochester, had organized local councils with paid secretaries. During the past year Cleveland, Cincinnati, Kansas City, and Portland have been added to the list.

The paid secretary plan has solved the problem of local councils in large industrial centers. The thoroughgoing and effective work which has been done by these local councils has attracted wide attention and is encouraging the officers of local councils in other large cities to employ paid secretaries.

Local councils without paid secretaries have been organized in Delaware, with headquarters at Wilmington, and in Bellingham, Washington. Aggressive work is being done in these new councils as well as in many of the older councils in other cities.

FIELD SECRETARIES

Three new field secretaries have been added to the Council's staff during the past year, Mr. W. R. Rasmussen, Mr. Frank E. Morris, and Mr. Carl L. Smith. Mr. Smith is specializing in public safety.

The efforts of the field men have been largely centered on the large cities where they have helped to organize the work and train the new secretaries.

SCHOOLS FOR SAFETY SUPERVISORS

In Pittsburgh, St. Louis, Cleveland, and Rochester, Schools for Safety Supervisors have been conducted during the past year. Four hundred and sixty-four students have been graduated and given diplomas after finishing the course of fifteen lessons covering the fundamentals of safety. In view of the fact that the students are all picked men—men who occupy responsible positions in their respective plants—these schools have undoubtedly rendered a more direct and tangible service to the members of the Council than any other activity of the local councils.

PUBLIC SAFETY

The demonstration of public safety which was made in Rochester last year has borne good fruit. The Safety Week in St. Louis last September, which was made possible by the Rochester experience, has resulted in a most successful campaign in public safety during the past year. Strong public safety organizations are now being developed in all of the cities mentioned above where paid secretaries are employed and steps have been taken to encourage the smaller local councils to emphasize

public safety. The thought is rapidly gaining ground among all people interested in safety that Safety must be incorporated into the life of the community. When safety is systematically taught in the schools and in the homes, and when the public officials, the police force, the churches, the commercial clubs, and other organizations coöperate in promoting safety, then not only will the appalling increase in public accidents be checked, but the industries will be directly reached because of the widespread awakened thought on safety.

SCHOOL SAFETY

The most significant feature of the public safety work in St. Louis has been the development in the public schools of a plan for the systematic teaching of safety. This plan was developed by Dr. E. George Payne, Principal of the Harris Teachers College. The demonstrations of this plan which have been witnessed by the officers of the National Safety Council have been so convincing that the Executive Committee has decided to do everything in its power to secure the adoption of this plan in all the public schools in the United States. Some four hundred copies of the syllabus, which Dr. Payne has published, will be distributed to a selected list of members. A bulletin outlining the plan will be sent to all of the members of the Council and, through the efforts of our publicity department and other methods, it is hoped that within the next twelve months the schools of every city of any considerable size will be induced to add safety instruction to their curriculum. The response of all of the cities which have been approached thus far has been most cordial.

INDUSTRIAL RELATIONS

The enlargement of the service of the Council along the lines of Industrial Relations has been a most significant and encouraging development. The widespread interest in employees' representation and kindred subjects has brought to the Council hundreds of requests for information and help. The Council has not sought to give expert advice, but rather to stimulate interest and furnish information.

THE LIBRARY

The Library and Bureau of information at our headquarters has grown steadily with the growth of the Council. During the past year valuable additions have been made covering industrial relations subjects. Our efficient Librarian, Miss Mary B. Day, has visited the best libraries in the East and has gathered much valuable data along new lines.

Through the weekly news-letters and other means the Council's members are being constantly encouraged to avail themselves of the services of the Library.

PUBLICITY

From the inception of the Council the officers have looked with longing eyes on the great field of publicity and have keenly appreciated the pos-

sibilities of promoting safety through publicity but, owing to lack of funds, only limited efforts in this field were possible.

On August 1, a publicity director, Mr. Louis Resnick, was added to the staff of the Council. Through weekly letters to hundreds of newspapers and periodicals, and other methods, a nation-wide publicity campaign is now being launched. Thus far the response of the press has been most encouraging, which promises much for the development of this work in the future.

SERVICE TO MEMBERS

The bulletins for workmen have been improved in quality and the sectional bulletins are now being printed in two colors. Large size bulletins have been issued every two weeks.

A catalogue of bulletins has been prepared, including some 1100 miniature cuts of bulletins which have been issued. This catalogue will be valuable to members in ordering back numbers of bulletins covering hazards which may arise in their plants from time to time.

The weekly letter has been enlarged to a four-page publication and includes not only the current news items covering the Council's work and the development of the safety movement, but also the news-letters of the sections which heretofore have been sent out in separate forms to members only of the respective sections. The enlargement of our engineering staff and increased efficiency have made possible the issuing of twelve "Safe Practices" pamphlets as compared with eight during the previous year. Two sectional "Safe Practices" pamphlets have been issued. The Executive Series bulletins have included industrial relations subjects. The bulletin on employees' representation recently published brought many letters of appreciation from our members.

SAFETY INSTRUCTION IN TECHNICAL SCHOOLS AND UNIVERSITIES

A handbook has been published entitled "The Principles and Practice of Safety," for use in technical schools and universities. This handbook includes suggestions covering equipment and safe practices in college shops and outlines of lectures which are to be delivered by the members of the faculty in their regular courses on machine design and labor relations.

In June, Mr. W. D. Keefer of our engineering staff visited all of the larger colleges between Chicago and the Atlantic Coast and had conferences with the faculties of the engineering departments. He met with most cordial response. Forty-four colleges have indicated their intentions to include at least a part of the safety instruction outlined in the handbook.

SAFETY CALENDAR

One hundred and sixty thousand copies of the 1919 calendar were printed and distributed. The 1920 calendar is now in preparation.

THE STAFF

In addition to the appointment of the three field secretaries and the

director of publicity previously named in my report, the following changes have been made in the Council's staff:

Mr. Sidney J. Williams, Chief Engineer, has been given the added title of Secretary and his duties have been increased to include the supervision of the Library and the Publicity Department.

On January 11, Mr. F. W. Pardee was appointed business manager and later was elected treasurer. I regret to report that during the past two weeks he has severed his connection with the Council to take the position of secretary of a newly formed national trade organization, including steel foundries. Mr. Pardee's ability and experience as a business man has enabled him to render a valuable service to the Council in organizing and systematizing the work at our headquarters and in guiding the financial policies of the Council. His work in conducting membership campaigns and in organizing the Congress Safety Exhibit, and his helpful coöperation with the local councils' officers are examples of his service to the Council which deserve special mention.

Mr. R. T. Solensten has been appointed assistant secretary to succeed Mr. Lamont. Mr. Solensten has made a special study of industrial relations and kindred subjects and will devote a large part of his time to the development of the service along these lines.

Mr. W. D. Keefer has been added to the engineering staff. His experience in practical safety work along industrial lines has equipped him to share in the work of drafting "Safe Practices" pamphlets and bulletins.

Miss Mary B. Day has succeeded Miss White as librarian. Miss Day was formerly the librarian of the Portland Cement Association and has had unusual experience in industrial library work.

Mr. J. W. Bready has recently been appointed director of printing to succeed Mr. Seaman. Mr. Bready has had a number of years experience in handling printing and advertising in several of the large concerns of Chicago.

NEW OFFICES

On May first the Council's Headquarters were moved to 163 North Michigan Avenue, Chicago. The new offices occupy practically double the space of the old—but at a saving in rent and insurance of over \$300 per year. This increased space was absolutely necessary to carry on the increased work of the Council.

MEMBERSHIPS

The present membership is 3,761, including 16,700 representatives and 6,275,000 employees; gain in membership for the fiscal year ending July 31, 1919, one hundred sixty-one.

Income \$153,000; surplus \$45,000; no debts.

C. W. PRICE, General Manager.

STATEMENT OF RECEIPTS AND DISBURSEMENTS

JULY 31, 1919

RECEIPTS

Membership Dues—		
Active	\$134,898.56	
Associate	1,390.47	
	<u>\$136,289.03</u>	
Less: Refund of dues.....	154.55	
		<u>\$136,134.48</u>
Sales of Pamphlets, Bulletins, Calendars and Miscellaneous Receipts		14,796.62
Revenue, account 1919 Annual Congress Exhibit to date		2,045.00
Sale of Louisville Gas and Electric Company Bonds—		
Cost	\$ 4,923.33	
Gain	89.17	
		<u>5,012.50</u>
Refund of Advances to Field Secretary.....		308.60
Cash Balance, August 1, 1918—		
On Hand	\$ 200.00	
In Bank	6,755.13	
		<u>6,955.13</u>
		<u>\$165,252.33</u>

DISBURSEMENTS

Salaries of General Manager, Assistants and Office Staff	\$ 50,532.38
Office Printing and Supplies	2,893.99
Additions to Office Furniture and Equipment....	5,152.34
Postage	2,369.75
Rent of General Offices	6,202.50
Traveling Expenses	3,725.33
Telephone and Telegraph	1,001.07
General Office Expense	2,605.35
Library Expense	436.25
Membership Solicitation Expense	1,165.30
National Committee Expense	647.63
Shipping Room Expense	192.66
Service Account, Reprints of Bulletins, Slides, Films, etc.	2,705.55
Expenses of various Local Councils	10,640.11
"Safe Practices" Pamphlets ..	1,592.18
Annual Congress Expense	11,229.42

Eighth Safety Congress

Expense to date of 1919 Annual Congress	
Exhibit	841.09
Expense to date of 1920 Calendar	.94
Weekly Bulletin Service	20,875.52
Sectional Activity Expense (Including Printing	
Bulletins)	3,895.44
Public Safety Account	855.30
Moving Expense	1,367.51
Rochester Public Safety Campaign	134.60

INVESTMENTS

U. S. Certificates of Indebtedness	\$ 10,000.00
U. S. Victory Bonds	10,000.00
	20,000.00
Loans to Local Safety Councils.....	2,857.90
Advances to Local Councils for Petty Expenses,	
Net	866.74
Advances to Field Secretaries	1,401.48
Cash Balance, July 31, 1919—	
Cash on Hand	\$ 500.00
Cash in Bank	8,564.00
	9,064.00
	\$165,252.33

We have examined the above Statement of Receipts and Disbursements of the National Safety Council, have compared it with the books and vouchers and have found it correct.

ARTHUR YOUNG & Co.,
Certified Public Accountants.

Chicago, September 5, 1919.

PRESIDENT VAN SCHAAK: Will Mr. C. P. Tolman report as the Chairman of the Committee on Business and Administration?

MR. C. P. TOLMAN: The General Manager sets a very fine example. The address of the President, together with the General Manager's Report and the report of the Treasurer thoroughly cover the field of business and administration. Possibly one thing that I would like to add is that I have had occasion to visit the Chicago Office of the Council a great many times in the course of the last few months and I know you would all be immensely gratified at the enthusiasm and efficiency displayed in the execution of your work in that office. I know of no business office maintaining as high a standard as you will find there.

PRESIDENT VAN SCHAAK: What is the pleasure of the Congress in connection with this lengthy report which we have just heard?

(On motion the report was adopted.)

PRESIDENT VAN SCHAAK: I will call upon Mr. H. H. Robertson to report as Chairman of the Committee on Internal Development.

REPORT OF THE COMMITTEE ON INTERNAL DEVELOPMENT

MR. H. H. ROBERTSON: Your committee on Internal Development begs to report as follows:

The details of the work of this committee as outlined upon the Committee's appointment last year, contemplated a close and intensive study of the council's service and its plans for further activities in the following departments:

The increasing of *membership*.

The establishment, financing, and control of additional *Local Councils*.

The activities and future needs of the various *Sections*.

The development of the council's efforts in the field of *Industrial Relations* and kindred problems.

The inauguration of a more active *Health Service* program.

It was not contemplated that this Committee would be called upon to do any of the actual work of carrying out its recommendations resulting from the study of these various branches of the Council's work, but rather that the Committee should act as a planning board which would by intensive study of each individual problem place itself in a position of being able to offer constructive suggestions to the Executive Committee, and through the Executive, the headquarter's staff of the Council, in order that greater service might be rendered to the membership at large.

Meetings of the Committee have been held from time to time, and specific recommendations have been made upon the various activities referred to. Those of value and practical application have resulted in departmental activities already covered in the reports of the President and of the General Manager. Frequent conferences with the various members of the headquarters staff have been held from time to time.

While your Committee feels that its accomplishments during the year are less than had been hoped for, it realizes the fruitful possibilities of the sub-committee method of planned and "thought out" suggestion. It recommends that greater activities of this character be arranged for during the coming year.

B. F. TILSON

MARCUS A. DOW

W. E. WORTH

C. R. HOOK

C. A. LAUFFER, M. D.

H. H. ROBERTSON, Chairman

(On motion the report was adopted.)

PRESIDENT VAN SCHIAACK: The next item is a report from the Committee on Public Coöperation. Inasmuch as Dr. Frederick L. Hoffman, the Chairman of this committee is in Europe, I will ask Mr. C. M. Talbert, ranking member of that committee to report for the committee.

MR. C. M. TALBERT: I think, Mr. Chairman, I can well follow the precedent that has been set and make it very, very short. I would like

to say for the benefit of the membership at large that the President's very able address has covered almost completely the activities of the Public Coöperation Committee. It has been the policy of the Council in every manner possible to coöperate and coördinate with public authorities and with those particular municipalities in furthering the work of the Council, and as to the different items that have been taken up, as to the manner of carrying out that policy, as I said before, the President's Address has much more fully covered it than I could in any short statement. We have endeavored to formulate that in municipalities, in the schools, in conjunction with engineering societies, with the Bureau of Standards, with the Bureau of Mines, and with two or three others along that same line. As to whether or not those general policies have been successful the address of Mr. Waite as to the conditions in Cleveland can best be its own answer. We believe that we have secured that coöperation and that we are going still further to secure it. We will, in the various sections, take up the manner of doing that much more in detail and hope to be able to present at the end of this Congress the outline mentioned by the President that will cover this system of coöperation in municipalities and those other educational features. Those will develop as the Congress proceeds and will be brought out in the next annual report and will be laid before you then much more in detail and in a manner that we hope will prove beneficial to those who are interested in it.

I merely want to say that the report of the Committee itself will be embodied in those various proceedings as they are brought out during the sessions of the Congress and to say that Dr. Hoffman has done a great deal of work on that during the past year, and I am very sorry that he cannot be here to tell what has been done along that line. We hope the proceedings will answer that question when they are published.

(On motion the report was adopted.)

PRESIDENT VAN SCHLACK: The next item is a report from the Committee on Service to Members. I will ask the Chairman of that Committee, Mr. Sinn, to report on that.

REPORT OF THE COMMITTEE ON SERVICE TO MEMBERS

MR. F. P. SINN: Your Committee on Service to Members has the privilege of presenting to you the following report which has been made possible through the active coöperation and the continued effort and initiative of the headquarters staff.

Safe Practices Pamphlets: Twelve of these have been issued in the general series—one each month. A similar schedule will be maintained during the coming year. It is believed that the pamphlets have been considerably improved in their scope and thoroughness. Their value is largely due to the continued good work of the Safe Practices Conference Committee, under the able Chairmanship of Mr. R. J. Young, of the Illinois Steel Company. Too much credit cannot be given Mr. Young and his co-workers for the time and detailed effort put into this work. In addition to these, a Sectional Safe Practices pamphlet was

published last winter on "Cleaning and Finishing Rooms in Foundries." Two other Sectional pamphlets are now in preparation, one for the Mining Section on "Underground Cars and Haulage" and one for the Metals Section on "Blast Furnaces." In each case the Sectional pamphlets are reviewed before publication by the officers and committees of the Section. During the coming year, we hope to issue at least an equal number of Sectional pamphlets, turning now to those Sections which have not previously had any of this service.

Bulletins: During the year we have distributed 177 bulletins in the general series and 312 Sectional Bulletins. In accordance with the wishes of a considerable majority of the membership, as shown in a referendum vote, we have continued to distribute our large-sized bulletin (17 inches by 22 inches) every alternate week. We have continued to include occasional bulletins on health topics. A start has been made in issuing Executive Bulletins on Industrial Relations subjects other than safety. These and the Executive Bulletins dealing specifically with accident prevention have been distributed on alternate weeks. Great care has been taken to keep these Industrial Relations bulletins on a conservative basis. Sectional bulletins have been produced and distributed varying in frequency, according to the size of the section and the amount of material contributed by members. If any section is not getting a sufficient number of Sectional bulletins, it can get more by furnishing the headquarters with a greater quantity of material.

Bulletin Catalogue: There has been prepared a Bulletin Catalogue which contains miniature reproductions of about two thirds of all the bulletins ever issued, including all those which are of practical value as at present. These have been arranged according to the subject, with a classified index, which will enable any member to select from the catalogue, the bulletins on almost any subject desired. It is believed that this will be of the greatest value to our members in securing bulletins applicable to particular situations, especially new members who are not familiar with bulletins previously issued and which are available upon request.

Weekly Letter: This letter made its first appearance in printed form last winter, and has now increased to four pages, placing the Executive Series Bulletin on the last page and using the inside pages for Sectional and Local Council news, for the monthly Safety Engineer's round table letter, and for miscellaneous announcements and information. This change has been widely commended.

Films and Lantern Slide Service: This service has been continued, the collection of lantern slides largely increased, and a catalogue thereof issued. Slides are furnished to members without charge except for transportation. Members are urged to take advantage of this opportunity to secure a fine set of lantern slides on almost any phase of accident prevention. The phonograph records of safety talks which were demonstrated at the St. Louis Congress have also been furnished to members desiring them.

Library and Information Bureau: The work and service of this divi-

sion has been considerably developed during the year, especially during recent months, under the supervision of Miss Mary B. Day, our new Librarian. In particular, this division has accumulated a very valuable collection of data on industrial relations subjects, including employees' representation, and has answered many inquiries relating thereto, in addition to continuing to supply information on specific accident prevention problems, to the extent of some 3,000 inquiries. Members who have made use of this part of our service are, in many cases, most enthusiastic about the results obtained and those members who have not tried it are urged to write to the Council headquarters the next time they are confronted with some particular problem.

In closing, I wish, on behalf of this Committee, to commend to you in the highest terms the work of Mr. Sidney J. Williams, the Secretary and Chief Engineer of the Council, that of Messrs. F. M. Rosseland, R. H. Guerrant, and W. D. Keefer, Safety Engineers of the Council, and that of Mr. R. T. Solensten, the Assistant Secretary, all of whom have given their best thought and effort to this branch of the Council's activities.

Further, I wish to emphasize strongly, the self-evident fact that all of the work being carried on under the supervision of this Committee, is for the benefit of the Council's members and it is only through the continued coöperation and help of the individual members, that the Committee and headquarters staff can furnish the kind of service desired by the membership at large.

PRESIDENT VAN SCHAAK: Will Mr. A. W. Whitney report as Chairman of the Committee on Education?

REPORT OF COMMITTEE ON EDUCATION

MR. A. W. WHITNEY: The Educational Committee can report material progress during the year and the promise of still greater results during the coming year. Our two main attacks have been upon the engineering schools and the public schools. You will remember that last year we got out a pamphlet for the use of universities which gave a preliminary view of the field to be cultivated. This formed the basis for a pamphlet of some 200 pages which was gotten out this year, entitled, "The Principles and Practice of Safety." The additional matter included first a brief outline of the work of making university shops safe. Second a syllabi of five lecture courses as follows: First, a few lectures and an inspirational course for freshmen on the general field and problems of engineering, which is being given by many technical schools. Second, several lectures in a junior or senior course in industrial management. Third, fourth, and fifth, matter to be included in courses on machine design, building design, and construction and electrical design. Later pamphlets will include similar material for such courses as chemistry, mining, transportation, home economics, etc.

The National Safety Council is also prepared to give as part of its university service, first, assistance in securing experts to aid in the work of getting university shops in good condition, and second, outside speakers who can address the students in the various schools on particu-

lar aspects of the safety problem. During the year visits have been made by members of the staff to more than twenty of the leading universities and technical schools and correspondence has been had with 224 persons on the faculties of 82 educational institutions, as well as a considerable correspondence with people interested in education but not directly connected with institutions. Thirty-four universities and technical schools have signified their intention of using the pamphlet on "Principles and Practice of Safety" in their university work, thereby definitely incorporating safety instruction into their curricula. In some universities this work is being developed very extensively. For instance the University of Cincinnati has appointed an experienced safety man to take care of the work, who is also acting as Secretary of the Local Council in immediate connection with this work. This university is establishing a department of industrial medicine.

I will not report on the most remarkable educational work for shop foreman and safety supervisors which has been carried on this year by several of the local Councils, as this has not been under the direct charge of the Committee on Education.

This opportunity should be taken to note the most admirable work that the Federal Board for Vocational Education is preparing to do along the lines of safety and hygiene in the vocational schools. The work will be made compulsory in all such schools. The Board has recently issued its bulletin No. 31 which is practically a textbook on safety in the building trades. Other similar bulletins for other trades will follow. The Federal Board is represented on our Educational Committee and is coöperating with the National Safety Council in every possible way.

The greatest advance during the year in the educational field has been made in the work in the public schools. I will do no more than briefly to summarize this as it is to have a whole afternoon for itself—Saturday afternoon. While we were talking in the National Safety Council about how to teach children safety, St. Louis "up and did it" and did it so successfully that our efforts have been directed toward getting this most excellent plan before the country. For this purpose we have appeared before the National Educational Association at its general meeting in Milwaukee and have formed a section on Safety Education in connection with the Mid-winter Meeting of the National Education Association—that is the National Association of School Superintendents, the next meeting of which, by the way, will occur here in this city.

There is also to be formed at a luncheon on Friday of this week, to which all interested parties are invited, an educational section of the National Safety Council. The most important step has, however, been the publishing by Dr. Payne of the Harris Teachers' College, St. Louis, and under the auspices of the National Safety Council, of a book on, "The Theory and Technique of the St. Louis Plan." Copies of this book are to be had at this convention. The plan is now therefore available for introduction into any school in the country.

The next problem is to get this book into the hands of the teachers in every school and to push the movement hard. Neither the Committee nor the officers of the National Safety Council can accomplish this result

alone. The help is needed of every member. Every member should see that this book and this work is introduced in their own home schools.

(On motion the report was adopted.)

PRESIDENT VAN SCHAAK: I would like to ask Mr. C. P. Tolman, as Chairman of the Resolutions Committee to report any resolutions which in the judgment of that committee should be entertained by this Conference.

MR. C. P. TOLMAN: Mr. President, to do proper justice to part of the field covered by the Resolutions Committee I have asked a far more eloquent speaker to cover that portion of it, Mr. Arthur Morey, after which I will cover certain other phases of the work.

REPORT OF COMMITTEE ON RESOLUTIONS

MR. ARTHUR MOREY: Mr. Chairman, we know that where there is a great accomplishment there must have been great thought and great effort. The appearance on all sides here in Cleveland, the experiences that we have already had, and from the program's indications the experiences yet to come, should cause us to offer some form of appreciative resolution. Therefore, Mr. Chairman, the Resolutions Committee would like to offer the following, and having made inquiry as to some of the chief conspirators for our comfort, convenience, and safety and who have thus expedited the important work of our Congress:

RESOLVED that we express the extreme gratification of the National Safety Council in Annual Congress assembled to the city of Cleveland and to its citizens, particularly to the Mayor, the Hon. Harry L. Davis, and to all City Departments that have generously coöperated for the success of Safety Week. In like manner also to Hon. W. M. Pattison, Mayor of East Cleveland and to the late B. M. Cook, Mayor of Lakewood. We understand that Mayor Cook could not be gainsaid doing all he could, and that he raised up on his deathbed to sign the safety proclamation, and we offer to the citizens of Lakewood and to his bereaved family our loving sympathy and condolences. We thank the Chamber of Commerce, the Convention Bureau, the industries of Cleveland and its environs, the Cleveland Advertising Club with its especially cordial cooperation, Col. E. E. Fuller of the U. S. Army, the splendid and complete efforts of the Public School Authorities and the Parochial Schools, the Federated Women's Clubs, the Boy Scouts, the splendid help the Police and Fire Departments have given, the Church Federation, the Automobile Club, the very fine support of all the Cleveland Newspapers and the officers and employees of the Statler Hotel. And last, but not least, to S. W. Tener, President, and Adam H. Lintz, Secretary of the Northeastern Ohio Division. Oscar McNab, Chairman of the Arrangements Committee, B. W. Nutt, Chairman of the Reception Committee and their associates, and the members of the splendid Northeastern Ohio Division of the National Safety Council and the many other organizations and citizens too numerous to mention specifically, and it is expressed as our trust and our hope that Cleveland and its citizens thus aroused to welcome

the Safety idea, as represented by this Congress, may be permanently blessed by the spirit of the Safety Movement which, as it enters the hearts of men and brings them into coöperative agreement, touches and inspires them with that fundamental truth that is the precursor of Peace on Earth, Good Will Toward Men, and be it further

RESOLVED that the grateful appreciation of this Congress be offered to its President, Mr. David Van Schaack, for the constructive guidance and inspired leadership and able executive direction he has brought to bear upon the activities of the National Safety Council which, during the past year, has registered such spiritual and material growth, and made such substantial progress toward the goal for which it was organized, and be it further

RESOLVED that the hearty thanks of this Congress be unanimously extended to our former General Manager, W. H. Cameron, our General Manager, C. W. Price, and to all of the Headquarters Staff of the National Safety Council for the faithful devotion and painstaking efforts with which they have fulfilled the various offices and duties committed to them during the past year.

(On motion, the resolution was adopted.)

MR. TOLMAN: I will continue the report of the committee. Section 5 of Article VIII was amended sometime ago to make the fiscal year of the Council end on July 31. Other sections relating to the treasurer's report and to the reports of local councils should be changed to conform to the section first mentioned and for that purpose the following motions should be offered:

"(1) That the last paragraph of Section 7 of Article VII of the By-Laws be amended by striking out 'thirtieth day of June' and inserting 'thirty-first day of July'; and that the same section be amended by striking out the word 'sixty' and inserting the word 'thirty' (the latter refers to the number of days prior to Annual Meeting, when Treasurer's Report is to be mailed to members).

"(2) That Section 16 of Article III be amended by striking out the word 'sixty' and inserting the word 'thirty' for the same reason as above.

"(3) That Section 5 of Article XI be amended by striking out the word 'July' and inserting the word 'August'; and by striking out the words 'Thirtieth day of June' and inserting the words 'thirty-first day of July'. (This refers to the reports of local councils.)

Section 10 of Article V was amended sometime ago to add the General Manager to the list of officers to be elected by the Executive Committee each year. For the sake of uniformity, the third sentence should be amended in like manner, by the following motion:

"(4) That the third sentence of Section 10 of Article V be amended by inserting the words 'General Manager' before the word 'Secretary.'"

The next change is in order to permit the General Manager to sign checks:

"(5) That Section 2 of Article VIII be amended by inserting the words 'General Manager or' before the words 'Assistant Treasurer' in line 3, and likewise in line 5."

(On motion the resolution was adopted.)

PRESIDENT VAN SCHLAACK: The next item is the report of the Nominating Committee. Will Mr. Geo. E. Morgan report as Chairman of the Nominating Committee?

REPORT OF THE NOMINATING COMMITTEE

MR. GEORGE E. MORGAN: The undersigned Nominating Committee of the National Safety Council, appointed by the President and approved by the Executive Committee as provided by the By-Laws, reports the following nominations for election, at the annual meeting, as Directors of the National Safety Council, to succeed the Directors whose terms of office expire at the said annual meeting, and to hold office for three years:

David S. Beyer, Vice-President, Liberty Mutual Insurance Company, Boston, Mass.

L. H. Burnett, Assistant to the President, Carnegie Steel Company, Pittsburgh, Pa.

W. H. Cameron, Manager, Industrial Relations, Eastman Kodak Company, Rochester, N. Y.

C. L. Close, Manager, Bureau of Safety, Sanitation, and Welfare, United States Steel Corporation, New York City.

Robert F. Coleman, Director of Personnel, Pierce Arrow Motor Car Company, Buffalo, N. Y.

J. B. Douglas, Manager, Claim Department, United Gas Improvement Company, Philadelphia, Pa.

A. F. Duffy, Chief of Safety Section, United States Railroad Administration, Washington, D. C.

Dr. Otto P. Geier, Manager, Employees' Service Department, Cincinnati Milling Machine Company, Cincinnati, Ohio.

Isaiah Hale, Safety Superintendent, Atchison, Topeka & Santa Fe Railroad, Topeka, Kans.

Julien H. Harvey, The Bracken Company, Kansas City, Mo.

Dr. F. L. Hoffman, Statistician, Prudential Insurance Company of America, Newark, N. J.

Arthur T. Morey, General Manager, Commonwealth Steel Company, Granite City, Ill.

B. W. Nutt, Strong, Kennard, and Nutt Company, Cleveland, Ohio.

Lew R. Palmer, Director, Safety and Personnel, The Equitable Life Assurance Company New York City.

R. C. Richards, Chairman, Central Safety Committee, Chicago & North Western Railroad, Chicago, Ill.

H. H. Robertson, President, H. H. Robertson Company, Pittsburgh, Pa.

Francis P. Sinn, Assistant to Vice-President, The New Jersey Zinc Company, New York City.

Philip Stremmel, National Enameling and Stamping Company, Granite City, Ill.

Stephen W. Tener, Manager, Accident and Pension Department, American Steel and Wire Company, Cleveland, Ohio.

E. G. Trimble, Manager, Employers' Indemnity Exchange, Kansas City, Mo.

James E. West, Chief Scout Executive, Boy Scouts of America, New York City.

Arthur Williams, President, Safety Institute of America, New York City.

H. M. Wilson, The Associated Companies, Pittsburgh, Pa.

Mrs. Joseph R. Wilson, Albuquerque, N. M.

J. M. Woltz, Safety Director, Youngstown Sheet and Tube Company, Youngstown, Ohio.

George E. Morgan, Otis Elevator Company, Buffalo

H. G. Ellerd, Armour and Company, Chicago

R. S. Sperry, Scoville Manufacturing Company, Waterbury

John R. Brownell, Equitable Life Assurance Society, San Francisco

R. W. Campbell, Illinois Steel Company, Chicago (Chairman)

(On motion the report of the Nominating Committee was adopted.)

PRESIDENT VAN SCHAAK: No members' ticket having been nominated, under the provision of our Constitution and By-Laws a motion to close the nominations is now in order.

(A motion was made that the nominations be closed. The motion was seconded and carried.)

PRESIDENT VAN SCHAAK: As there have been legally nominated just enough men to take the place of those directors whose terms expire and to fill other vacancies, The Chair suggests, in order to facilitate the transaction of our business, that the Secretary be directed to cast one ballot for the candidates named for the terms for which they have been nominated.

(The suggestion of the President was put in the form of a motion and adopted.)

PRESIDENT VAN SCHAAK: The Secretary has cast the ballot. The inspectors of election who are serving as tellers will report the result of the vote.

SECRETARY WILLIAMS: Mr. Davidson has handed me the report of the Inspectors of Election and Tellers showing that there are 1,973 votes cast in favor of the nominees as read, and no votes against.

PRESIDENT VAN SCHAAK: The report of the tellers shows that 1,973 votes have been cast for the nominees and none against. It therefore gives me pleasure to announce that these gentlemen have been unanimously elected directors of the National Safety Council for the terms for which they have been nominated.

I would like to take this opportunity of asking all the directors to attend a meeting of the Board of Directors to be held at five o'clock this afternoon in Private Dining Room No. 3 on the mezzanine floor.

Is there any unfinished business to come before this meeting?

MR. LITTLE: There is the report of Special Committee on the Formation of an Engineering Section in the National Safety Council.

REPORT OF THE SPECIAL COMMITTEE ON THE FORMATION OF
AN ENGINEERING SECTION IN THE NATIONAL
SAFETY COUNCIL

In accordance with a resolution adopted by the Executive Committee, President Van Schaack appointed Messrs. Little (Chairman), Tolman, DeBlois, Talbert, and Sinn as a special committee to report on the advisability of forming an Engineering Section in the National Safety Council. This committee, together with Mr. C. C. Rausch, Assistant Director of the Safety Institute of America, and Mr. Sidney J. Williams, Secretary and Chief Engineer, National Safety Council, met and discussed the subject at considerable length.

The Safety Movement has, in our opinion, now reached a point where definite technical information must be developed and accumulated just as rapidly as possible in order to secure maximum results from the splendid educational propaganda which the Council has carried on with such notable success.

Furthermore, the work on Safety Standards, to which the Council is now definitely committed, can be carried on much more satisfactorily if there is established within the Council a Section which will be recognized without question as equal in professional attainments and dignity to the great national engineering societies.

An Engineering Section will give an opportunity for men of recognized standing in the profession to meet frequently for the exchange of ideas and information upon strictly engineering problems related to Safety, for a larger recognition of their professional status, and the service which they can render the Safety Movement.

For these reasons your committee recommends the formation of an Engineering Section, on substantially the following general basis:

Membership

The membership of the Engineering Section shall be composed entirely of individuals who are members of the Council or who are employed by or affiliated with members of the Council, and who in addition have the following qualifications: Either (1) they must be members of the American Society of Civil Engineers, The American Society of Mechanical Engineers, The American Institute of Electrical Engineers, The American Institute of Mining and Metallurgical Engineers, or the American Society of Chemical Engineers; or (2) they shall have had at least ten years' experience in engineering work and shall have been for at least five years in responsible charge of such work—a degree from a recognized college of engineering being accepted as equivalent to two years' experience. Persons who are members of the Council, or employed by or affiliated with members of the Council, may become associate members of the Engineering Section if they are either (1) associate members of the American Society of Civil Engineers or the other engineering societies above mentioned or (2) if they have had five years of practical experience in engineering work—a college degree being given the same credit as above. Such associate members shall have all the rights and privileges of members except the right to vote or hold office in the Section.

Organization

The Section shall have a Chairman, a Vice-Chairman, and a Secretary, the Secretary being a member of the engineering staff of the National Safety Council; and an Executive Committee of not more than twenty-five, including the officers; and including at least one member representing each of the industrial sections of the Council. Among the sub-committees of the Executive Committee there shall be a committee on Membership, with five members, which shall pass upon all applications for membership in the Section. Your Committee recommends that Messrs. D. S. Beyer, J. R. Brownell, A. P. Costigane, L. A. DeBlois, G. T. Fonda, H. W. Forster, E. B. Morgan, L. R. Palmer, C. E. Pettibone, C. C. Rausch, H. A. Schultz, F. P. Sinn, Thos. Stanion, C. M. Talbert, R. F. Tillson, C. P. Tolman, E. B. Tolsted, and S. J. Williams be constituted a temporary Executive Committee to perfect the organization of the Section.

Functions

The functions of the Engineering Section shall be:

(1) To help to meet the technical demands of the various industrial sections and furnish them technical information as desired:

(2) To perform technical service for the Council, on request of the Executive Committee of the Council, such as the development of Standards or participation therein; the solution, by inquiry or through research, of special engineering problems arising in safety work; and helpful coöperation with the casualty department of Underwriters' Laboratories, with the National Engineering societies, etc.

(3) To conduct one or more meetings as a part of the Annual Congress, at which engineering problems shall be discussed, being grouped with respect to the engineering operations involved rather than with respect to the industry—as, for example, a discussion on the collection of injurious dust, the guarding of transmission, etc.

(4) To conduct, if considered desirable, one or more additional sectional meetings throughout the year, or in different localities.

(5) To carry on such other activities as will, in the opinion of the Executive Committee of the National Safety Council, promote the Safety Movement and the best interests of the Council

Upon motion the report of the Committee was approved in principle and the engineers named in the report appointed to perfect the plan for the Engineering Section and report to the Executive Committee of the National Safety Council for final ratification.

PRESIDENT VAN SCHAAK: Is there any other new business to come before this meeting?

If there is no other new business, it is the privilege of The Chair to call your attention to a fact with which you may not all be familiar. You of course all know that the National Safety Council is constantly seeking members. Perhaps you do not all know of one way in which we have endeavored to secure a larger membership. Some few months ago it occurred to your Headquarters Office that the personal efforts of the men directly engaged in safety work in connection with the membership of this Council might be productive of a considerable increase in our membership, and they therefore offered prizes to such safety men

as would by their direct efforts secure new members for the National Safety Council. I may say that the result has been so encouraging that we look forward to much greater results next year.

**LIST OF MEN RECEIVING MEDALS FOR SECURING MEMBERS
DURING MEMBERSHIP CAMPAIGN**

Mr. H. P. Heyne, United Alloy Steel Corporation, Canton, Ohio.

Mr. G. E. Clarkson, Secretary, Western Pennsylvania Safety Council, Pittsburgh, Pa.

Mr. A. H. Lintz, Secretary, Northeastern Ohio Council, Cleveland, Ohio.

Mr. M. L. Fellmer, Secretary, Central Mississippi Division, N. S. C., St. Louis, Mo.

Mr. L. A. DeBlois, E. I. du Pont de Nemours and Company, Wilmington, Del.

Mr. R. T. Read, E. I. du Pont de Nemours and Company, Wilmington, Del.

Mr. Clarence Parker, Safety Engineer, Everett, Wash.

Mr. R. C. Paul, State Workmen's Insurance Fund, Harrisburg, Pa.

Mr. T. H. Boyd, Safety Engineer, Seattle, Wash.

Mr. Julien H. Harvey, The Bracken Company, Kansas City, Mo.

Mr. H. W. Donald, American Mutual Liability Insurance Company, Boston, Mass.

Mr. W. L. Myers, Tebo Yacht Basin Company, Brooklyn, N. Y.

Mr. R. A. Shaw, Ford Motor Company, Detroit, Mich.

Mr. A. B. Sherlock, American Mutual Liability Insurance Company, Portland, Maine.

If any of these gentlemen are here and will kindly come forward it will give me pleasure to present the medals. Those who are not here can procure their medals from Mr. Williams who will have them in his possession.

We are beginning to attract the interest of other cities which would like to have the Congress meet with them. I wish to advise this meeting that I hold in my hand a very cordial invitation from the Governor of the state of Indiana, from the Mayor of the city of Indianapolis and the Chamber of Commerce, inviting the National Safety Council to hold its Congress in 1920 in the city of Indianapolis.

It is in order at this Annual Meeting that reports should be presented from the several Local Councils. Those reports have all been received and inasmuch as they will be included in the Proceedings of this Congress in connection with the Meeting of Officers of Local Councils, The Chair takes the liberty to facilitate the proceedings by not calling upon the representatives of those Councils to read their reports at this meeting.

The business of this meeting having now been transacted it is in order to adjourn, but before entertaining a motion to adjourn. The Chair would like to ask all those present to remain and join in singing America.

The audience arose and sang two verses of America, after which the meeting adjourned.

General Session: Employees' Representation

October 1, 1919

ARTHUR H. YOUNG, Chairman

Manager, Industrial Relations, International Harvester Company, Chicago

CHAIRMAN YOUNG: The interest in this meeting and the subject to be discussed this afternoon is manifest by the assemblage here. It is eminently fitting that employee representation—that particular phase of industrial relations—should be discussed in the Annual Congress of the National Safety Council, for after all the Safety Movement and the Safety Committees are the parentage of the employee representation plan. It was through the non-controversial medium of safety that employers and employees found they could group themselves to mutual advantage around a Council Table, and in the discussion of safety which, in every aspect, is non-controversial, they came to know that they were of the same common clay and that their ideals, aims, and purposes were after all the same.

The splendid success obtained through employee representation in safety made it an easy and natural step to go further and include other possible controversial points such as wages and hours and working conditions generally for discussion and for determination in conference—in family conference. The movement of employee representation may be termed a movement of such recent origin that those who have been indulging in experience with it for only a few months are almost termed pioneers. Probably the great war had a very substantial effect in hastening the rapidity with which employee representation has been taken up so generally both directly and indirectly, indirectly because it was only natural and logical that after four years of concentration of thought by all of the civilized people of the world for the destruction of autocracy and for the establishment of democracy, that the culmination of that effort and the return to industry of the millions upon millions of men who had fought and suffered and worked together for a common cause should bring about a new change in industry. It is probable that there had been such autocracy in industry prior to the war as existed in Prussia, and therefore the democratization of industry was necessary to follow upon the return of these men to industry.

There was also a further direct effect. Abroad the formation of the Whitley Council and its reports lead definitely to the information of Inter-works Councils and Industrial Councils. Here in this country the

National War Labor Board's pronouncement and their adoption of the policy of employee representation had a very specific effect. It is true, however, that the voluntary assumption of employee representation in industry has been much greater than that forced through the War Labor Board.

The program this afternoon will give us a discussion of the subject from several different angles. The first two numbers on the program are by men who are interested in production, the production managers in large industrial establishments, and then we have a slant at the problem from an engineer, from a representative of organized labor, and then from the standpoint of the labor manager. It would be unfair for the Chairman to take up further time in a general discussion of the subject when it will be so ably presented by the speakers.

In introducing the first speaker, if I were to indulge in personalities, which are hardly within the province of The Chair, I feel that I could preach a real sermon because of my close relationship with Mr. McCormick in the Harvester organization. To those of you who know the Harvester organization and to those of you who do not, I can sum it all up in the simple phrase that Mr. McCormick is "a Harvester man," and I take pleasure in introducing to you Mr. Cyrus McCormick, Junior, Works Manager of the International Harvester Company.

COOPERATION AND INDUSTRIAL PROGRESS

CYRUS MCCORMICK, JR., WORKS MANAGER, INTERNATIONAL HARVESTER
COMPANY, CHICAGO

What I shall say here today is not propaganda; it is explanation, and for those of you who care to listen, the facts, purely from the standpoint of a man engaged in production and not in the social economics of industry, are as I am going to give them to you.

Some people blame the present industrial unrest as due to the war; some the cost of living; some this and some that; and some say it is merely a revolt due to conditions which they frequently hesitate to describe, a revolt against the older order of things.

Through every opinion there is, in one form or another, clear evidence of a realization that the war has brought home to us all the final chapter of the long lesson that individual workmen must be regarded as human beings. This new element has claimed for itself a permanent place in industrial thought and practice. We are now realizing what we saw before but perhaps not so clearly, that this human question is paramount. Industry is becoming humanized and the workmen are conscious of that fact. The man, as opposed to the machine, has the power to think and is endowed with a soul. He is at last seeking recognition of that fact.

This trend toward humanization in industry is expressing itself in the expressed desire of labor to share in the management of a business. The desire has taken various forms in various parts of the world. In Russia we have Bolshevism, Bolshevism being a practical application of the

theories put forward several years ago in this country by the I. W. W. and translated into a very fiery, but essentially—as they see it—practical form. Bolshevism seeks to establish the superiority of the workman upon a class basis, upon a basis from which everything else except actual manual labor is excluded. They tell us now that they are employing entrepreneurs to help them out of the difficulties under which they first labored, but at any rate the theory remains the same. I am told by people who ought to know that 65 per cent of the strikes which have swept over central Europe—and I am going farther west now, I am no longer referring to Russia—over France, over Germany, over Italy, have been of Syndicalist origin. That is to say, not merely with the demands for wages or hours or this or that, but with a political purpose in view.

In England the unrest first showed a definite reaction in the Whitley Report. That report was an answer to a very definite unrest, and since it was published last April, we have had many manifestations, (and now see one in progress) in which the plea for nationalization is put forward as the only solution of the unrest. Behind it all, as I have said, is this desire for self-expression, and one more thing, a demand for a realization of the fact which we must now admit, that the relations of employer and employee can no longer be based solely on a cash foundation. That is to say, the transaction is not complete when wages have been paid. Again, there is a man, endowed with a soul, who is asking for recognition.

COLLECTIVE BARGAINING

In answer to this, management in this country is beginning seriously and has in many large companies and many small ones, begun to take the men into its confidence. This, of course, applied through the terms of employee representation, involves a recognition of the principle of collective bargaining. Properly speaking, collective bargaining involves bargaining with groups rather than individuals; but the form the group may take is not restricted. Collective bargaining is a spirit rather than a form. Every company which has employee representation in any one of its forms is an advocate of collective bargaining. Now that theory of collective bargaining is condemned by many of the older economists. They fear it is going to get us into trouble. I feel that it is going to let us out of trouble. We are not defying economic laws when we set up a system of collective bargaining, but we are permitting other laws to operate which, through the weakness of the individual, to adopt a well-known phrase, cannot operate unless that individual is enabled to re-enforce himself collectively. Collective bargaining is with us now, and we might as well recognize it. It is the one great change that an old-style employer has to face when he adopts employee representation.

REASONS FOR EMPLOYEE REPRESENTATION

There are various reasons why employers are turning to employee representation. In the first place, there may be a fear of syndicalism, a fear

that if legitimate interests of employees are not recognized in this or some other way, or that because of repression they are unable to get things which they believe are legitimately theirs, they will have resort to revolution in order to secure a new state of things in which they shall be on top.

Secondly, I might compare the growth of employee representation to the growth of democracy, and call to your mind the history of the eighteenth century when Frederick the Great ruled over Germany. Frederick was a despot because he held the only reins of power. He was responsible to nobody. He did what he pleased, how he pleased; but he was a benevolent despot because he chose to be a despot in a good way. He built fine schools, colleges, roads, public works, and had a pretty decent system of taxation as it was understood in those times. Of course it was all for his own ends. It was despotism veiled sufficiently by fair deeds to be called benevolent. Now up to a very few years ago our industrial system was also benevolent despotism. It was benevolent because large corporations tried to do the best they could to start safety campaigns, to start scientific employment, to start welfare work, give recreation, and the like; but because all this came from the top and had no reference to the opinion of the governed, in other words amelioration without consent of the governed, that benevolence was still tinged with despotism.

There is another point, another reason why this is being considered, with which some practical men may quarrel, and that is what might be called the ethical side of the question. Are you willing to do something on a new and different basis simply because you no longer desire to operate in the materialism that is part and parcel of the lives of so many of us? Are you trying to accomplish something simply because it is right? You will find many men take that view of industrial democracy. They believe they see in employee representation an answer to the materialistic domination of industry, whether that domination is by the management or by the men. They wish to substitute principle for that domination which has for its end the mere accumulation of dollars.

A fourth and final reason is that employee representation is good business for the company and for the man. Scientific industry has just one more step to take. We have done about everything we could in progressive machinery and assembly. We have secured such experts as we could find to study the technique of our operations, including many things that were never thought of fifty years ago—safety work, for example. We must now endow scientific management with soul. When this is done, industry can claim to be for the benefit of management and men alike and the community as well. When this is done, when industry is endowed with soul, it can at last claim to be fully and finally scientific.

WHAT REPRESENTATION MEANS

Now what is employee representation? Rather than attempt to define it, I will try to describe the conditions that must obtain in order to secure it. Of course, mechanically, employee representation is

the institution of one or another kind of shop committee or legislature or council in which representatives of the management and men sit together and discuss problems of mutual interest. Well now, how may that be made effective? In the first place there must be full representation in all questions affecting wages, hours, and on through the whole list of industrial activities; don't leave out one. If the men do not have a share in the control of wages, the plan has no vitality. If you start with wages you might as well include hours, and if you continue with hours you might as well put them all in—they are all there. Every question that affects the relations of man and management must be susceptible of discussion between the representatives of the employees and of the management.

That does not imply, in my mind, any demand for executive control; that does not necessitate the bringing into your Board of Directors of representatives of the employees. It simply means that in questions which affect the men directly, that is where you want to put committeemen—call them what you will—who will represent the men and give the management the innermost feeling of the men in every decision affecting important questions.

Secondly, there must be joint conference. If your committees meet separately you lose the personal contact of man and management. The object is to get together, seated around a common table, not on each side of a common table but all together *around* a common table, and then face the subject in hand and debate it. See what you can find out about it. Go down to the vitals of the idea, lay every card on the table, see what the innermost feelings of the men and of the management are, and then as a result of that debate get together and understand each other.

There is something very refreshing, something very different in a point of view that the men have of the management and that the management have of the men after a discussion which has lasted hours. I have sat through these discussions which have gone on for hours, and after it is over you say, "Well, before I didn't quite understand his point of view." In the average case both sides can say as much if they will go to the limit, get right down to fundamentals, and explore the vitals of the subject. When they get through the debate, then let the agreement come by itself, because in each or both of two reasonable beings (and I assure you, Gentlemen and Ladies, that the average American workman and the average American manager is more or less of a reasonable human being), there is something which can be appealed to by one side or the other, if you only go at it hard enough and long enough. Ultimately you will find it, and the agreement—after all the debate and understanding that must arise from frank debate—will come by itself.

There must be easy, secret elections. You can well understand that a real representation is more indicative of the real feeling of the employees than representation where thoughts may have been influenced. There must be secret election in order that the unfettered opinions of the men can be brought to light. There must be no red tape. Red tape will tie up any plan and cause it to fail. The simplest plan is the best. Any

plan which can secure the results for which I am asking—and just these few points: any plan that secures those through an absence of red tape that will permit quick, instant operation, that is a satisfactory plan no matter what may be its details.

There must be absolutely no discrimination at any time on the part of the employer as against any one or any number of the employees for any such thing as race, sex, religious affiliation, and as it is stated in our plan "political or other organizations."—in other words there is nothing in our plan that would permit us if we so desire (when we obviously do not) to discharge a man or to refuse to listen to him simply because he happens to be a member of some labor union. When we take a man into our employ, and if we are willing to take him into our employ, that ends the matter. He is then one of the family and he is able to come up, after he has qualified by the brief period of residence that is needed, and to sit in council with us if he is elected. Take care in the beginning, because after a man is in, under a plan of this kind, you have no right to consider for a minute what he is or what he believes—he is one of the family and you had better treat him as such.

The last important point is that there must be executive supervision of such a plan. Just as we have experts in heat treating or progressive assembly or any of our thousand and one mechanical tasks, employment work, or safety work, so must we have experts in industrial relations. It may be difficult in these days of the birth of this new science to find these men, but they must be found. The best man in the country (indicating the Chairman, Mr. Young—Applause) is none too good to guide such a plan as this.

The management must understand the men and the men must understand the management. As soon as any such plan is in smooth operation it is going to operate both ways. It is not simply a question, as I have heard some employers say, "How can we get the men to understand our point of view?" The converse is just as true and the management, through this plan, must be able to understand the point of view of the men.

Contact between management and men used to be very close. Now, sorry to say, things are changed; yet we cannot ask or want to go back to the time when the owner of a business knew every man in his factory. Society demands large units because it needs large production, so we cannot go back to the small shop. Society is looking to employee representation to re-establish the contact between men and management. The man in charge of production of any great corporation cannot know every one of his employees, but through employee representation, if it is fairly and freely operated, he can feel the pulse of his employees and they can feel his pulse.

OBJECTIONS TO REPRESENTATION

There are certain objections that have from time to time been made to employee representation and I would hardly be frank if I failed to mention them. It is said, for example, that employee representation is merely an invitation to the men to come along and boost the wage scale.

Some people believe that. Some people say to us, "You have increased your wages since you instituted employee representation. Look, we told you so!" But as I have sat in these discussions I have found, frequently as not, a demand not so much for higher wages as for shorter hours; frequently, as many times as not, a demand for shorter hours even at the expense of higher wages. I can show you many decisions reached by our Works' Council in which hours have been shortened and wages decreased because that was the way the men wanted it.

A great many workmen, and perhaps they are the majority, think that they will get something while the getting is good, as it seems to be at the present time; but others—and many believe them to represent the thinking majority—aren't so much interested in mere wages as they are in the philosophical side of industry. They want decent living conditions. They want real life. They want something else besides hours of toil and high pay from sunrise to sunset.

In the second place, many people say to me, "Well, how do you prevent your men from electing poor representatives? How do you keep a bunch of radicals out of these councils? How do you know what you are going to get?" To all those questions I would answer, "We do not." We do not endeavor to keep radicals out of our conference. We do not endeavor to insist upon our men electing good representatives. We do not put up to them a strong propaganda to keep the best only on the councils. We do not need to because they take care of that themselves.

Among our employee representatives, for those who may doubt, the average age is 37 years, a pretty good average and not indicating in any way a bunch of young radicals as some people say, or a bunch of old pensioners as other people say. Three-quarters of them are married. There again is an indication of desirable stability. The average employment is over seven years. In other words, although they were not in any way restricted in their election of representatives except by the requirement for employment of more than one year, they have chosen to select men who have been with the company long enough to understand some of its ideals, and to feel that its ideals are not positively detrimental to their own interests. The majority own either stock in the company or their own homes.

As an example of the responsibility of the men of the kind that I have just described to you, the very first demands that came in were for increased wages. The workmen thought "Well, we have here a toy that will give us whatever we want." The representatives put up these demands. We examined them. We showed them our books, told them we regretted very much that our business could not stand an increase in wages, in the first place, and in the second place that the cost of living as it was at that time was lower than at the time of the armistice.

So with that explanation before them the men considered the case. They went back to their constituents and in every case the demand for higher wages was withdrawn. Again later on in the summer when the cost of living went kiting upwards again, they returned with other demands for higher wages, and at that time the management representatives were convinced of the sincerity and the reasonability of the re-

quests and demands put forward by the men, so they were granted. There you have the thing operating both ways.

We were also enabled to discover some things which, while we probably would have known of their existence if it had occurred to us to look up the records, had never really been driven home in our minds. We found that we had some men working for us seven days a week, twelve hours per day. Somebody kicked. He had a legitimate channel through which a complaint could come. Those particular men who were then relieved of that long work were, in order to find relief, willing to accept shorter hours combined with lower wages.

In other cases we have had piece work rates raised because the existing rate in one place wasn't right. In other cases we have had piece work rates lowered because they realized that that man was getting more than this one on a similar task and that this rate was the correct rate. That may seem unbelievable—workmen agreeing and telling you that they expect and agree to a reduction in wages—but they are the facts.

It is also said that employee representation, inasmuch as it is a committee system, ruins discipline. The average person who says so will quote the experience of the Russian army during the time of Kerensky, when through the institution of committees the discipline of the Russian army was shot to pieces. There is no reason why discipline should be in any way affected by employee representation or any shop committee system, if the effort is sincere and fair on both sides. Discipline is intelligent obedience, not skill in executing the goose-step. If a foreman is absolutely fair and square and acts on principle and not on personality, if he disciplines a man or discharges him because he has done wrong, then employee representation has nothing whatsoever to say against him. If, on the other hand, he discharges a man because he doesn't like him or because of some petty spite or because of something he doesn't understand, the man has a recourse. Several years ago the average employer in big factories took away from the individual foremen the right of hiring and firing and gave it to the employment manager. At that time it was said that that would ruin the foreman's ability to discipline his men. It didn't, and no more does employee representation, provided (and it is a big proviso) that the effort is sincere on both sides. I know a factory where the discipline is ruined because the foremen, every one of them, are afraid of the representatives and the representatives, every one of them, think that they have something on the foremen because of this new way of doing things. They don't realize that neither knows anything at all about what they are talking. They don't realize that they don't understand the scheme. They don't realize that the people they are hurting most are themselves.

ATTITUDE OF ORGANIZED LABOR

At the Atlantic City convention in June of this year the American Federation of Labor took considerable exception to shop committees in general. They said, for example, in the resolutions which were there passed, that the elections as a rule were unfair, that democratic organ-

ization was not permitted, that committeemen were intimidated by the management, and that the employee in pleading his case before the shop committee was not allowed such expert aid as he received through the person of the business agent.

I take it that experience means something. I have sat through meeting after meeting, not in one factory but in a half dozen, and I have talked with representatives of other factories and other companies besides ours, employee representatives as well as management representatives, and yet I have never seen a single reason why any one of those charges should be made or can be upheld. I do not know whether the American Federation of Labor would have that same view today as it did last June. A lot of water has gone over the dam since then and people are more skilled on this thing now than they were, but the facts are that committeemen are not intimidated, that the elections are not unfair, that democratic organization is permitted, and as for the employee representatives needing advice—let me tell you that the average employee representative, after he has had a little experience, can put up problems that it sometimes takes a lawyer to unravel. I know. I have sat up all night trying to match the intelligence of some weighty question, and I have gone the limit in trying to give the best possible answer. They are clever; they are brainy, and they are that because they are good Americans.

The object of organized labor, I take it, is to improve the conditions of men through the institution of a system of collective bargaining. Employee representation gives the same results more quickly and more intimately. I have no battle of any kind to fight with organized labor; neither do I think that organized labor has any legitimate cause for an attack upon the shop committees. They are different things; they are both seeking good results. If there are two ways of doing things it does no harm to go at it in both ways. I do not pretend for a moment that employee representation is a panacea for every ill. You can't institute a plan of employee representation and then throw up your hands and say, "All our troubles are over," because it is not any plan that counts, it is not the particular system that you happen to choose, it is the way you work whatever plan you choose—that is what counts.

You can't expect to get results too quickly. You can't expect to put something in and get dividends right away. You can't expect that the momentum of mutual education, the training of men by management and the training of management by men to produce results all at once. We have been doing things in the other way ever since the eighteenth century when the Industrial Revolution made big business possible. Now we are changing. You can't expect that transition to take place in a minute. Give it time; give it a sincere chance to work out.

THE HARVESTER STRIKE IN CHICAGO

Possibly it might be of interest if I said a few words on the so-called International Harvester strike in Chicago and its relation to employee representation. You all know that in July we had 10,000 men out on the streets. It happened in this way. We have committees in nineteen

of our twenty plants. In the one plant where there is no committee 400 men started to strike. What the strike was about, I don't think anybody to this day knows. Some demands were presented fifteen days after they went out. They were made up fourteen days after they went out, and as I say, I doubt very much if any of the 400 men who started the trouble knew why they stirred things up so that 10,000 men were soon out of work. In a few hours the 400 had the whole of this plant out on the street. Then a gang of excited men, joined by some strikers from a neighboring plant, marched over to our next plant. Nothing happened, except that about twenty or thirty men were pretty badly beaten up.

Next morning this other plant started to work. Every man, with four exceptions, reported for work, every man out of 1,800. So there can hardly be said to have been any quarrel with the company. The disorder outside was such and so many were slugged that the Works' Council recommended cessation of work. The company agreed because we did not propose to have any violence if we could help it. We told the men there was going to be partnership in wages and hours, so we thought they might as well help us settle the strike. In another works, three days later, the same thing happened. An augmented crowd of about five thousand clamored around in the streets and pretty soon a few of them went out and more men were beaten up. The Works' Council recommended cessation. But notice there was no strike except in the first plant which had no Council. Then, unfortunately for us, the street car strike and the race riots in Chicago intervened and it was about three weeks before we operated again, but we operated again at the end of three weeks because the Works' Councils in the various places asked the company to operate. We promised them we would not operate until they agreed it was safe to do so. We opened at their request and inside of one week were running normal again. That I call a tribute to the employee representation way of handling industrial disputes.

I was asked yesterday what I thought of employee representation in view of the fact that our steel mill in Chicago was just as much closed as any of the rest. The obvious answer is that there also the Works' Council invited us to close, and remember that the Works' Council is composed not only of representatives of the employees but of the management as well. That was forty-eight hours after the strike had begun, and I venture to say that if every other steel mill in South Chicago had been equipped with a Works' Council there would have been no strike because the morning the steel strike was called we had just exactly ninety per cent of men in our mills working. If every steel mill in Chicago had had ninety per cent of satisfied men working there wouldn't have been any strike.

THE WHITLEY COUNCILS

I don't pretend that our plan of employee representation is the only plan. There is the Leitch plan, organized as a kind of legislature. There are other plans beside that. All of you have heard of the Whitley plan in England. Many people say, "Why not adopt the Whitley plan and go

the same way England is going?" Personally I wouldn't want to go the way England is going, but that may be immaterial. The Whitley plan presupposes complete organization on the part of industry and complete organization on the part of labor.

I do not know how many laborers there are in this country. I do not know how many are members of one or another of the organizations which constitute organized labor, but it is safe to say that there is a minority of the men in this country who are organized. In England it is about 90 per cent, so I am told. In England it is lawful for corporations to organize for mutual benefit. Here it is said to be dangerous. We in this country are not organized either in industry or on the part of labor.

In the second place the English plan presupposes a large share of participation on the part of the government. For generations the British government has been skilled in participating in the handling and arbitration of labor disputes. Here we are just beginning. Our government is not yet skilled enough to participate in, and adjudicate, the differences between capital and labor or men and management. They are much better acquainted with each other, and if one can find some basis of contact where they can meet and work out their own difficulties, they will be far more satisfied than to submit to any intervention on the part of an unskilled government.

Thirdly, we have instituted vertical divisions for horizontal divisions which characterize the Whitley Plan. We have taken—and when I say "we" I mean the whole trend in this country that is giving birth to employee representation—our industrial society and divided it vertically. Here is a company from manager down to workman with all its interests identical. The old idea that capital and labor are deadly enemies has gone by the board completely. We have divided industrial society vertically and we have made it a family affair. There is no place in this country for anything resembling class division. There is no place in this country for class warfare of any kind or class prejudice.

• IMPORTANCE OF REPRESENTATION •

One final word: I believe that employee representation is a more important subject today than is profit sharing or any other of the many things that are considered in any industrial program. I believe it is important because it is the gateway through which every other consideration will be approached in the future. If you want a plan of profit sharing you had better wait until you have employee representation first and then the men can understand (which they do not now) the economic aspects of profit sharing. If you want them on the Board of Directors wait until they have gained through employee representation the experience you have acquired from years of endeavor and years of practice. If you want the men to participate heartily in a safety campaign let them help run it. In other words, employee representation is a basis for every future relationship between capital and labor, between men and management. Employee representation is a sincere endeavor to find a point of contact and to work upon that point of contact until the two are drawn so

close together that they are no longer two but one, striving together for the mutual interests of each and of both. I thank you.

CHAIRMAN YOUNG: Just an ordinary Harvester talk by an ordinary Harvester man.

We were to be favored with an address by Mr. Feuerbach of the Demuth Company giving an outline and a recital of experience under the so-called Leitch Plan of employee representation. We are sorry to say that Mr. Feuerbach has wired that he is unable to attend because of illness and his paper has been presented to The Chair.

EXPERIENCES OF WM. DEMUTH & CO. IN INDUSTRIAL DEMOCRACY

F. L. FEUERBACH, FACTORY MANAGER, WM. DEMUTH & Co.,
RICHMOND HILL, N. Y.

No doubt the most important topic in the mind and on the tongue of every business man today, not only in this great country of ours, but all over practically the entire world, is the existing unrest and unfortunate strife between Capital and Labor. Many of our best thinkers are deeply interested in the solution of this serious problem, feeling that this tide of discontent in its mad rush toward Bolshevism must be stemmed before it reaches the point where it will do a good deal more harm to all mankind than the bloody world-conflict just ended. The various systems under consideration, some old and some new, such as Shop Committees Plan, Employees' Representation Plan, Industrial Relationship and Industrial Democracy, may differ slightly or essentially in their application to practical business, but they all aim toward a better understanding toward representation in industry, which is the problem of the hour with business owners and executives, as well as the workers.

The plan of representation Wm. Demuth & Co. adopted at their factory in Richmond Hill, Long Island, in April, 1917, is that known as Industrial Democracy, introduced by John Leitch, whom most of you probably know as the author of the very interesting book, "Man to Man," which deals with this very important subject, and gives a very detailed and comprehensive description of industrial democracy.

As practically every man who talked to me about this system, in this country as well as in England and France, which I visited recently, seems to have a different conception of, and definition for, Industrial Democracy, it may be well at this time to give our version of it.

INDUSTRIAL DEMOCRACY DEFINED

To have Industrial Democracy is to have some internal plan of government in each industrial plant, whereby the employees may have a direct voice in the formulating of such policies as directly affect their physical, moral, social, and economic welfare, as well as that of their families. This means length of hours, character of work, physical surroundings under which they work, the moral influences that surround them, the freedom of self expression, and the question of wages or some form of profit and loss sharing. All of these things vitally affect the employee

and his family. Therefore, he must have a voice in their control, if we are to have Industrial Democracy.

Ethically it means a square deal in wages and working conditions. What a square deal in wages means, no living man can definitely describe. Some people consider the living wage as such—if we suppose that this expression can be defined, but under present conditions, and perhaps all future conditions, it appears a certainty that labor will not consider that minimum as a fair wage, nor is there in my mind any justifiable economic or ethical theory which makes it so.

Labor will continue to demand with even greater solidarity and persistence, collective bargaining with regard to wages, hours, working conditions, and all those matters which mutually affect employers and employees, and upon which selfish interests are bound to conflict from time to time. Whatever may be decided, and temporarily accepted as a fair wage and just working conditions will not stay decided, or really be decided, unless worked out in joint man to man conference between representatives of the two sides. This, in short, is the essence of Industrial Democracy, an organization and a spirit in which all concerned shall have effective voice in matters which concern all.

I do not advance this idea of democratic representation and personal contact in industry as a final solution of the so-called labor problem. This problem is too vast, too complex and is enmeshed too deeply in human passions to be settled off-hand by any method or system, however admirable in itself. I am afraid that no one really understands the whole labor problem, but I am convinced that Industrial Democracy is a wonderfully efficient teacher for both the employer and the employee.

The labor problem is much more than a class issue. It has steadily risen to the consciousness of mankind from economics to politics, from politics to ethics, and from ethics to a world issue involving the very safety and sanctity of governments and societies.

Better relations between employers and employees can best be arrived at by granting to the latter a greater share in the consideration of matters with which they are concerned and about which their entire life and existence center to a great extent.

Labor and Capital are meant to be partners, not enemies. Their interests are common interests, not opposed, and neither can attain the fullest measure of success and prosperity at the expense of the other, but only in company and by coöperation with the other. In an accomplishment of this sort the proper relationship of the money-supplying and money-receiving forces would naturally involve industrial peace, which cannot be secured by any conciliation or arbitration scheme thus far practiced or tried out.

Such schemes settle disputes, or at least try to settle them, only after they have arisen. Industrial Democracy means to settle disputes before they arise and by aiming to reduce to a minimum the development and intensity of hostile attitudes and putting in their place mutual understanding and the effective good-will to coöperate. The full benefits of coöperation cannot be realized unless there exists a spirit of friendliness among those who have come together to work for the common good of

all. Not much can be accomplished with a man who persists in believing himself always right, for to him it is the whole human race that's wrong. Cooperation means that individually-cherished ideas must at times be shattered and give way to the will of the majority.

In the past, the employer, generally speaking, regarded the laboring man simply as a necessary means to the productive process, whom he would buy as cheaply as possible, just as he would make his purchases for materials, endeavoring to make as much profit as possible out of both. Fortunately this attitude is undergoing a decided modification, but on the part of a certain type of employer it is still altogether too prevalent. Two influences are bringing about this rapid change in attitude.

In the first place, employers are discerning more clearly the meaning of loyalty, and now can see that this spirit cannot be obtained through the old autocratic attitude. They are beginning to realize that the growth of their business depends upon the growth of the people in their organization, and that loyalty, like electricity, works only when there is a return circuit.

The big man today realizes that up to the present time hands only have been employed, and regrets that he did not see years ago that all the humans in his place had not only hands, but also heads containing brains, capable of adding intelligence to their work, which means a larger quantity and better quality of merchandise. He realizes that he cannot get the activity and cooperation of these brains unless he first assures these people of a square deal, and, therefore, takes a new attitude that cooperation is far better than competition between employer and employee, and that fair dealing is the fundamental and basic principle on which relations between employers and employees should rest.

In these days of efficiency and economy, we all recognize—or will do so before very long—that the greatest waste in the world is the waste of our human resources, and it is quite natural that we start the big work of economy in our own organization.

Secondly, there is more general recognition of the fact that political democracy without a measure of Industrial Democracy or self-government is somewhat hollow.

The fact that American workingmen have been fighting in Europe to make the world safe for Democracy helps to suggest the ideal of a better, more thorough and truer Democracy at home, and it is generally conceded that the social and economic destinies of our country in the next few years depend largely upon the attitude of the employers toward Industrial Democracy within their respective establishments.

The workingman desires—yes, demands most emphatically in some cases—to be considered a human being, to have proper physical conditions surrounding his labor, to secure a sufficient return to give his family the right kind of a home and education.

Realizing the need of a better understanding between our employees and ourselves to stimulate an interest in their work and clear from our industrial pathway some of the difficulties which you all have faced from time to time, we installed, about two and a half years ago, a system of organiza-

tion government, generally termed and known as Industrial Democracy.

PLAN MODELED AFTER UNITED STATES GOVERNMENT

We took as example the United States Government, which having been successfully established and carried on for more than 140 years, seemed a pretty fair guide. We have a Cabinet, Senate, and House of Representatives. The Cabinet consists of the executive officers of the company, with Mr. Demuth as President of the Company, acting as its Chairman. This body is not elective, its personnel existing by virtue of position in the organization. It is primarily an executive body, and while it has the power to veto, the same has never been used, there being no occasion for it. It also has the power to initiate legislation, by making suggestions in a message to the Senate or House of Representatives, which, of course, may or may not be accepted.

The Cabinet meetings have before them the bills which have been passed by the Senate and the House, and also the minutes of all meetings and discussions, which give a very clear conception of what is in the minds of our people. The Cabinet deals with the larger and more intimate problems of management, which would naturally come before a meeting of executives. Any desired change affecting employees in the least manner is not framed as an order, but put in the form of a suggestion, stating the reason for same very frankly and clearly, and is sent to the Senate or House. No matter what its fate may be, it is sure of a full and complete discussion from every possible angle, and if the measure be rejected, the executives may rest assured that they have been prevented from issuing an erroneous order and saved from the results thereof.

The Senate also is not an elective body. It is made up of about thirty foremen and heads of departments, who are in positions of authority over the workers themselves. It elects a president, vice-president, secretary, and sergeant-at-arms, and standing committees, and special committees as the occasion may demand. Its power and practices are identical with those of the House of Representatives.

The House is the popular body of government, being elected by secret ballot by the whole body of workers. Each department has representation—thirty workers electing one representative, either man or girl. The representatives are supposed to act as counsellors within their departments, receive all complaints and suggestions from their fellow workers, and in turn acquaint them with the doings of the legislative bodies.

The Speaker of the House is elected, and he appoints committees, through whom business is transacted to a considerable degree. Each measure is generally referred to a committee to investigate and report, so that when the time comes for open discussion, all available facts will be at hand.

The meetings of the Senate and House are weekly and always in the company's time, which we consider very necessary for the success of the undertaking. A set of by-laws has been devised for the use of both bodies by a joint committee, and all their business is transacted in accordance with same. Any question affecting working conditions, safety, sanitation, wages, piece-work rates, etc., is brought up before either of the three

government bodies, and any recommendation decided upon after a careful discussion and deliberation is brought to the next body for their action. No change becomes a law until it has been approved by all three bodies. In that way we believe we have found a much better way of feeling the pulse of our people, in learning what they desire, and in avoiding difficulties rather than curing them, which is usually the case in the ordinary shop committee plan. We do not wait for the trouble to culminate, for the sickness to develop. The men hear the report and progress of their respective departments, learn about the troubles of another department, and are helping their fellow workers in getting over any difficulties that they may experience.

We can clearly see the actual formation of a threatening cloud. The open discussion of any dispute has never failed to avoid accumulation of such clouds and outbreak of storm.

Permitting the men to have a say in adjusting their wages removes this perplexing question as a field of dispute. The fairness with which the members of the House have always considered and handled all questions of this sort has been most remarkable, and has come to us as a complete surprise. Our experience has shown us very plainly that people learn to be responsible by exercising responsibility; learn to participate in decisions by participating in discussions—even though the experience may at times seem costly to all concerned.

I will give one little example that will show very clearly how industrial Democracy and the wage question work together.

Last fall twenty-five men of one of our departments were somewhat influenced by an outsider who had formerly worked for us and was then working for a competitor. He advised them that this would be an opportune time to strike for more money. The matter was brought to my attention. I called the boys together and said to them: "If there is anything that is not satisfactory, bring it up in your House, through your representatives. That is the place to air all your troubles and bring your difficulties. The next day, I am glad to say, the representatives of that particular shop came to the House and presented their case. A committee was appointed to investigate the matter and report at the next meeting. The committee came back with quite a detailed report, after having gone to the office to obtain figures as to the rate of pay a year ago, six months ago, and three months ago, and having convinced themselves of the true facts, reported back to the House of Representatives:

"We do not favor any change of piece-work rates for this department, because we find that the men are absolutely unfair in their demands."

The House voted to accept this report, and the twenty-five men went back to work.

Any man or woman is eligible for the position of representative, provided they have the following qualifications:

FIRST: They must be absolutely on the square, in order that their fellow employees may have undoubted confidence in their fairness and honesty, so that they may be entrusted with any and every mission which should be carried to the House.

SECOND: They must be able to speak and understand English, so that they may fully understand what is going on at the meetings and be able to report to their co-workers.

THIRD: They must have been in the employ of the company for at least one year. This gives us the assurance that the man knows enough about the institution itself and about the work so that he is fairly well qualified to take part in all discussions, by having some fundamental knowledge of the business as well as of his co-workers. This also excludes the possibility of having a labor agitator come into the place for a short time to have himself elected as representative.

We have a large sign hung up in our meeting room reading: "We come here not to convince or convict, but to understand," and while this served as a gentle reminder during the early stages of the game, it has become such a definite habit that this sign today is more ornamental than necessary.

PLAN INTRODUCED BY MR. JOHN LEITCH

No doubt you will be interested to learn how Industrial Democracy was first introduced into our organization by its father, Mr. John Leitch. His fundamental and most serious problem, of course, was to get all workers interested in their jobs, to make them one with the company, to introduce a spirit of coöperation which would reflect higher and happier pay for the men and a better product for the company. Recognizing Justice to be the basic principle of all relations to which every human being willingly responds, it was necessary to lay our foundation on that principle. If we wanted Justice we should have to "show them." All of our people, numbering close to 900, were brought together in the large shipping department of our warehouse, and Mr. Leitch explained the principle of Justice. He then described a dividend system showing just how we intended to work together—that we should not only govern ourselves, but that of all the savings made in the cost of production, one-half would go to the company and the other half to them. They warmed up a bit to the idea of getting some extra money, but otherwise they remained fairly cold. We held meetings once a week through five weeks, to adopt what was to be the business policy of the whole company—from President to the Office Boy—and which was to guide all our actions. The policy rests on the four cornerstones of Justice, Coöperation, Economy, and Energy, supporting the capstone of Service, and reads as follows:

JUSTICE

The fullest meaning of this word shall be the basis of all our business and personal dealings—between ourselves as individuals, between our Company and those of whom we buy, and between our Company and those to whom we sell.

Justice shall be the first cornerstone upon which we agree and determine to construct broader character as individuals and broader commerce as an institution.

We recognize that JUSTICE to ourselves necessitates taking advantage of every opportunity to do the best that is in us, and each day improve upon that growing ability.

We realize that merit must be recognized, whether in ability or merchandise. With this certainty, we cheerfully, hopefully, and courageously press forward to certain and unqualified success.

COÖPERATION

To accomplish the greatest possible results as individuals, and as an institution, we find COÖPERATION a necessity.

We recognize that business without COÖPERATION is like sound without harmony. Therefore, we determine and agree to pull together, and to freely offer and work with the *spirit* of that principle—COÖPERATION.

So shall we grow in character and ability and develop individual and commercial supremacy.

Differences of opinion shall be freely and fearlessly expressed, but we shall at all times stand ready to COÖPERATE with and heartily support the final judgment in all matters.

ECONOMY

As each moment is a full unit in each hour, and each hour a full unit in each day, so each well spent unit of thought and well spent unit of action makes for each victory and the final success.

When the hour, the day, the year, or the life, is filled with well spent ability—and an institution is composed of individuals who recognize the value of and so use their time, then success is controlled and governed and is no longer that vague uncertainty of a blind and unreasoning hope.

Recognizing that ECONOMY is time, material and energy well spent we determine to make the best use of them and so shall time, material, and energy become our servants while we become the masters of our destiny.

ENERGY

As energy is the power back of action, and action is necessary to produce results, we determine to ENERGIZE our minds and hands, concentrating all our powers upon the most important work before us.

Thus intensifying our mental and physical activity, we shall "make two grow where one was," well knowing that our Individual and Commercial crop of results will yield in just proportion to our productive and persistent activity. This power of ENERGY directed exclusively toward sound and vigorous construction leaves no room for destruction and reduces all forms of resistance. Having set in our business policy the four cornerstones of Justice, Coöperation, Economy, and Energy, we are convinced that the capstone of the superstructure must be

SERVICE

We believe that the only sound and sure construction of success as an individual or an institution depends upon the quality and quantity of service rendered.

We neither anticipate nor hope to be unusually favored by fortune, but we are thoroughly persuaded that fortune favors the performer of worthy

deeds and of unusual service. We, therefore, determine that our days and our years be occupied with such performances.

Quality shall always be the first element of our service, and quantity shall ever be the second consideration. Thus shall we establish not only the reputation, ~~but~~ the character of serving best and serving most.

Therefore, by serving admirably, we shall deserve and receive proportionately.

After accepting this business policy as a future guide for our work and actions, we then started to govern ourselves under this new dispensation, with the understanding that all rules and regulations affecting the employees were to be in the hands of the Legislature, subject to the confirmation of the Cabinet.

No limits to the self-governing zone were set, and subsequent events proved that no limits needed to be set. Employees given responsibility will honestly discharge it.

HOW THE PLAN WORKED

At the outset the representative system did not work smoothly. A few of the elected representatives did not attend meetings—some because they did not grasp the idea, others because they were afraid they might be called on to speak, and thus expose their curious English. But other members did catch the theory of representative government from the start. Some of course, at first believed that the whole idea was a fake, but they were willing to be convinced; and once they had the conviction of our sincerity, they went to any length to make the experiment a success. They knew and were in touch with the mass, and they learned and appreciated the mass psychology thoroughly in a very short time.

It is true that their initial interest was purely financial. These people had no practical conceptions of democracy, and democracy in business was something entirely unknown and foreign to them—almost as much as it was to ourselves. Representative government meant nothing to them at the start. They had heard vaguely of various assemblies, but they never had discovered that the form of government made much difference to the individual. They simply came to work to make a living and to get as much money out of their job as could possibly be extracted. A mighty few of them, like most laboring men, realized their responsibility in returning as much as possible for the money which they took out of the business. Each man worked for himself, showing very little concern about his neighbor in his own or the next department.

Coöperation to them seemed entirely superfluous and had to be taught in a practical manner, as preaching with the labor class usually does not go very far. They have heard too much of that in the past and received too many promises which were subsequently not kept, and a lack of response and confidence in preaching or ethical lessons is not their fault so much as the fault of those who are responsible for their disappointment.

The practical way we found to be our dividend system, and this is how it taught coöperation:

A number of men desired to celebrate an Italian holiday, and stayed away from work. At the next meeting of the House of Representatives it was announced that the dividend for the past two-week period would be only 12 per cent, but that it would have been higher had not the men taken the holiday. That is, a man who earned \$20 per week, or \$40 for the two-week period, received a dividend of \$4.80 instead of \$6, thereby losing \$1.20 because some other fellows did not work. It is one thing to stay away from work knowing that possibly the company and only yourself will lose money by your act, but it is quite a different proposition to realize that you are guilty of a loss of money to your fellow-workers. Dividends are due to mass action and coöperation is a mass force. The mass can bring in and create coöperation as quickly as it can cause disorder.

Our plan for paying dividends on top of wages as an incentive for better work and a pride in the man's or woman's job, and in the product which he or she manufactures is as follows:

At the expiration of a two-week period the efficiency of the entire shop is determined by the relative value of its output to its cost of production. Standards of production and cost have been established in each department and the savings occasioned by increased production and quality of work, as well as decreased cost and overhead are shared on the 50-50 basis with our employees.

Our first dividend amounted to 6½ per cent of the salary of each employee and has gone as high as 17½ per cent. These dividends are paid bi-weekly in a separate envelope marked "employees' dividend," and represent their share of profits derived by interest and better work—a bonus upon service.

To stimulate their efforts for higher dividends by the element of competition, we have arranged to award a prize—a large American flag—to that department which shows the greatest saving for the two-week period, in other words, the leader in the struggle for higher dividends; and they certainly fight hard for the privilege of displaying the Stars and Stripes in their respective departments for two weeks. The department which succeeds in securing the banner three times during a certain period is honored in some special manner. The last reward was a dinner given to all workers in the prize-winning department.

I recall going through the plant one day during the first month we had our dividend system and noticed, on entering the sandpaper shop, that one of the boys tried to attract the attention of his fellow worker who, however, would not be disturbed. Jack insistently called to Jim until the latter finally turned around quite indignantly and said: "Now, here, Jack, cut it out: you are stealing my dividends." This and many similar instances showed very plainly that the folks were getting interested, and time and again we could see very plainly that the dividend envelope was quite an incentive to them and that in return meant a good deal to us as far as quality and workmanship were concerned.

After the dividend was established for about three or four months, the House of Representatives came to a conclusion that some of the folks did not do as much to earn these dividends as others. For instance, some

would stay out on Mondays and take it easy, have a good time while those in the shop were working hard and earning dividends for them. They subsequently suggested in their House of Representatives that a committee be appointed to work out rules for penalty of tardy, careless, and disinterested fellow workers. The committee brought in the following recommendations which were unanimously accepted and approved by both Senate and Cabinet and have been in force ever since.

If any employee comes late or stays away without a proper excuse for one day during the two-week period he loses one-fourth of his dividends. If this happens twice he loses one-half, three times three-fourths, and if it occurs four times during the same period he loses all of his dividends.

This plan, remember, was a suggestion from the men themselves and not a penalty imposed by the employers.

In connection with this the question came up as to what should be considered legal holidays. Having a number of different nationalities it was quite natural that at one time a number of Polish people would stay away to celebrate one of their own holidays, and next week Italians would do the same thing. One of the representatives said at the House meeting: "This will never do. Every time a group of people stay away down go our dividends because it interferes with production and the idle machinery and waste of power increases our overhead." He then proposed a list of strictly American holidays, which again found whole-hearted approval of the other two governing bodies, so that any one celebrating any other holiday except those officially adopted would lose dividends.

ENGLISH CLASSES AND AMERICANIZATION

The folks realized in investigating ways and means to increase dividends that a great handicap was due to the fact that some folks did not understand English well enough, and the Ways and Means Committee suggested in the House that we introduce a rule that we do not employ any people who cannot speak English. Now, we had a good many men in the place who had been there a number of years, who couldn't speak English, so the only thing for us to do was to follow their suggestion and introduce English classes. The Board of Education established two classes for non-English speaking people, and out of every department quite a few of them flocked to the school.

There again we applied our 50-50 principle, as time spent in these classes is one-half in company time. In other words, school lasts one hour, from 4:30 to 5:30 P. M. We pay those who attend up to five o'clock, our regular closing time. In compliance with a recent request from the scholars the time has been extended to 1½ hours under the same arrangements, paying them for 4:15 to 5 P. M., or one-half of the time spent at school, the other half is their own contribution.

Besides the English language, we are teaching the first principles of Americanism, and I point with particular pride to a record of 95 applications for citizenship papers, which our Employment Manager filled out recently for some of our foreign-born employees.

WORKING HOURS CHANGED

One of the important accomplishments which was a direct result of Industrial Democracy was the change of working hours. We had been working fifty-three hours per week for a number of years, when in November, 1917, the question arose in the House of Representatives whether same could not be reduced to fifty hours. After a long and careful discussion at a joint session of House and Senate, followed by a mass meeting—usually held about once in six to eight weeks—at which the idea was fully explained to all employees, it was mutually agreed that we should try the fifty hour service for three months. Every-one pledged himself to a full honest 50 hours' service, promising to avoid tardiness and idle machinery, furthermore, that if the earning or production would be decreased, or if for any reason the change did not work satisfactorily, it was understood that everybody would be perfectly willing to return to the 53 hour schedule. Before the trial period was over the production was increased by about 8 per cent, which meant better income and saving for all concerned.

Encouraged by this success and the evident happiness of everybody around us, the Cabinet, in October 1918, suggested to both Senate and House to consider the advisability of changing to a 48 hour per week schedule. Some of our employees were somewhat reluctant as they doubted their ability to produce as much work in 48 hours as they had formerly done in 53 hours. To show our appreciation of their willingness to put forth their best efforts in making the change, we adjusted all rates, guaranteeing them from the start the same income as they had before. Consequently results showed no falling off in our production and when a few weeks ago the 44 hour question came up for consideration there was little hesitancy on anybody's part to try out this new change. At this time I am not in a position to give definite figures as to the production. However, several of our departments have made very satisfactory individual records so far.

LIFE INSURANCE

We have had a Mutual Benefit Association since 1902, which provides for free doctor service, a weekly sick benefit of \$6, and death benefit of \$100 at an expense to the members of 10 cents per week. As this field was quite well covered, the Senate turned its attention to life insurance, and within a short time after a thorough investigation by Committees of Cabinet, Senate, and House of Representatives, a plan for insurance was evolved and installed in December, 1917, whereby in case of death the beneficiary receives an amount equal to one year's wages, the maximum amount being \$3,000. The premiums for same are paid by the employees themselves by one of the percentages of the bi-weekly dividends. In other words if the dividends are found to be 15 per cent for a certain two-week period, 14 per cent is paid in cash and 1 per cent is retained for the insurance. As we have had sixteen deaths since inaugurating insurance, the few who did not believe in the wisdom of insurance at the beginning have been thoroughly and permanently convinced. By the people's vote every employee is thus covered by insurance.

LABOR TURNOVER

One of the important and most constructive functions of both Senate and House is the consideration of the labor turnover. For each meeting—the Senate convenes every Wednesday at 1:30 P. M., the House at 3:30 P. M.—a complete record of employees having left our service is given on a large blackboard, stating name, department, how long in our employ, and reason for leaving or discharge. The foreman of the respective department usually volunteers or is asked for detailed information in any doubtful case.

The men and girls, realizing that losing experienced help—and replacing same by green hands at an average expense of about \$100 in some places—means a reduction of dividends for all, do their level best to keep them at work. Many a disheartened boy or girl was induced by his or her fellow-workers to stick to the job and try it out a little longer, by offering to show them a more advantageous way of handling their work.

During the war, when we all experienced a shortage of labor, a few appeals to the mass to bring along friends to fill vacant positions in order to avoid increase in overhead and decrease in production—and consequent decrease of dividends—were quite sufficient to fill our depleted ranks, so that when most of our neighbors were constantly short of help, we actually had a waiting list of applicants.

RESULTS OF INDUSTRIAL DEMOCRACY

Since the installation of this system of shop government, each employee realizes that instead of his being a mere cog in a wheel, to be used or dispensed with at some person's convenience, he has become a useful and intelligent unit of the organization with a voice in its management, something to say about how long and under what conditions his best work can be done, and how much he shall receive for it. This has the effect of increasing his self-respect and respect for his job, together with a sense of his personal obligation to his fellow workers. It is giving him an insight into the problems that harass his employers and it creates respect for them and makes him willingly share their burdens. Above all, it awakens the sense of civic responsibility, inspires him to study our language and our customs, and in that way strikes a blow at what is perhaps the most insidious evil at the root of our republican form of government—the ignorance and indifference of the individual of and to the things that are of vital importance.

The reason for the successful operation of the industrial scheme, I believe, is due to the fact that the people are being educated to be self-reliant. With welfare work, etc., they think and feel that you are trying to do something for them, and it is looked upon by them as being too paternal.

We have been asked by business people and workers who are not very familiar with our Industrial Democracy plan, whether we shall continue with this form of government or whether it was simply a war measure used to pacify our men in these turbulent times and to be done away

with as soon as possible. I believe I can safely speak for the company, as well as for the employees, when I state most emphatically that our democracy plan is here to stay. Nothing would be more foolish than for either the employees or employers to try to do away with something which has been as beneficial to both sides as the Industrial Democracy plan.

As a sample of the splendid democratic spirit of being one family, I would like to refer to a most wonderful Christmas entertainment which was arranged by a joint committee of House and Senate, and to which the Cabinet and New York office force were invited as guests. It started at 3 o'clock with a minstrel show, followed by a few unavoidable speeches, and a splendid musical program, all carried out by the employees. Under a 10-foot Christmas tree, beautifully decorated, were about 300 presents, which Santa Claus—we had many volunteers for this job—distributed among those present. No one left the place until the conclusion of the program at about 7 o'clock and all the younger folks danced to the merry tunes of our Glee Club until 10 o'clock at night.

This new system of representation does not mean that the workers are to manage the business, any more than it means that shareholders shall manage the business. Management remains a factor by itself, the only difference being, that whereas, management had as its task the direction without personal relationship to the workers, now it directs and coöperates with these men as partners in the business. The management no longer represents only capital. It now represents labor as well. Labor no longer represents only itself, but now represents the community, and in a certain sense, both capital and management.

Frankly, we cannot say specifically whether or not Industrial Democracy has reduced the costs of production during the last two years. Our costs have risen as we expected they would, due to the same war conditions which affected everyone else. We did not in the beginning have any illusion that Industrial Democracy would keep our costs down to a pre-war basis. How much lower they have been than would have been the case if we had not had Industrial Democracy is largely a matter of speculation. We honestly feel however, that we have benefited distinctly from this point of view. We are convinced that under the old system we should have had a much more rapidly rising production cost, considerable difficulty with our employees, all of which would have increased total manufacturing costs far beyond the point to which they did rise.

In addressing the assembly of Mayors and Governors at Washington last March, President Wilson said:

"We are at last learning that the whole matter of the prosperity of peoples runs down into the great body of the men and women who do the work of the world, and that the process of guidance is not completed by the mere success of great enterprise—it is completed only by the standard of the benefit that it confers upon those who in the obscure ranks of life contribute to the success of those enterprises."

This very plainly describes our present conditions and makes clear to us the duty which lies before every business man. We must get away from our old time industrial autocracy and turn to a new mode of run-

ing our business, considering not only ourselves and our profits, but also those who work for us and help to make those profits, and have them share the benefits of their labor in the proper proportion.

CHAIRMAN YOUNG: The third number on the program is a discussion of employee representation by a man eminently fitted to do so. Mr. Tolsted has had an exceptionally fine opportunity of seeing plans at work and of seeing the plants in which these plans were not at work and through all of that experience, his keen analytical mind, the trained mind of the engineer, he has set out the high points and I think we are indeed fortunate this afternoon in having Mr. Tolsted present to us his analysis of the fundamentals of employee representation. Mr. Tolsted.

PRACTICAL ASPECTS OF EMPLOYEES' REPRESENTATION

E. B. TOLSTED, INDEPENDENCE BUREAU, PHILADELPHIA

The annals of the country are full of examples of misused power both on the part of employers individually and collectively and on the part of organized workmen. In the interest of the nation as a whole the disastrous effects of misused power must be eliminated. It must no longer be possible for employers by virtue of their financial resources and solidarity to treat workers unfairly, or for the workers through the open strike or the passive "strike on the job" to cripple industry.

To careful thinkers the solution lies definitely along the lines of a clear understanding by each side of its own attitude and of the problems of the other, and of their joint recognition of their relation to society. The result is bound to be in many instances the substitution of responsibility for irresponsibility, of coöperation for antagonism, of good will for ill will. This greatly desired result, the securing of industrial peace and efficiency, is so gigantic a problem that even the best thinkers in the economic field have as yet reached no definite practical solution. We are as yet in a state of flux.

Many workers appear not to be satisfied by good working conditions, shortened hours, and high wages; they strike even after these things have been granted them. No doubt some want a voice in the determination of these matters, although the dissatisfaction is largely due to the spirit of the times. It may be that the real desire is for first-hand information about the conditions which cause managers to come to their decisions. Probably no body of American men, for instance, would deliberately demand wages which they know would bankrupt the business which employs them.

Of the various plans for producing industrial satisfaction which have been advanced up to the present time, the one which is attracting the greatest attention is employees' representation. Some feel that this is just another short-lived fad; others think that it is here to stay. A safety man cannot help recalling the time when the safety movement was considered a fad of the moment.

Many employers, not hostile to union organization, feel that better re-

sults will be obtained through an employees' representation plan than through the customary union channels, because of the direct relation and the mutuality of interest which can be obtained. In effect, the usual employees' representation plan creates a company or household union, sometimes alongside a national union. There need be no conflict between the two.

There are at the present time about one hundred and fifty employees' representation plans in operation in the United States. The details of many of them have been published in pamphlet form or in current magazines. By personal investigation of approximately fifty of these plans, we have found that employees' representation may provide simply an orderly method for the adjustment of grievances; it may include machinery for collective bargaining with reference to wages, hours, and working conditions; it may be the means of eliciting from workers their hearty cooperation and valuable suggestions regarding processes, organization, and policies; or it may involve all of these or any combination of them. Its structural features may be very simple and the procedure altogether informal, or these may be highly elaborate. The power possessed by employees through their industrial representation may be that of "public opinion"—the authority of the representatives being merely advisory to the management—or the management may delegate to the employees final authority in regard to certain specified matters, or authority may be exercised jointly by the men and the management. I wish to emphasize the fact that in no plan which we have investigated have we found the measure of control implied by the term "Industrial Democracy."

For the purposes of this paper I shall regard as an employees' representation plan any plan which provides for committees of employees elected by their constituents to confer with the management in the consideration of matters affecting them, no matter how simple or how few. Ignoring wide variations in scope and form, then, I shall discuss in the limited time available some of the generally applicable facts established by personal investigation of plans used; and without attempting to analyze or even to state the underlying principles, I shall attempt to give some practical suggestions which may be found useful to those about to install plans or to those who contemplate doing so.

It must be noted at this point that the shortness of time during which these plans have been operating and the prejudices of their sponsors and opponents make investigation of results complicated and interpretation difficult. Having adopted a plan, the employer wants to believe it desirable; therefore, it is difficult to obtain adverse criticism from any except those who have never tried the plan or who have been forced into it. It is pertinent to mention, however, that many favorable comments have been obtained even from those who have been forced into adopting a plan. My statement of results embodies in it opinions of employees' representatives as well as of managers, and, as far as it has been possible to make it, is representative of present conditions.

In the following remarks the term "works committee" is used to refer to any kind of representation plan.

RESULTS ACCOMPLISHED BY WORKS COMMITTEES

Several years ago, Henry T. Noyes of Rochester stated that his own company, Art-in-Buttons, Inc., after over ten years of periodic departmental meetings during which the company and the employees had been working earnestly for their joint good, found that approximately 90 per cent of all complaints made by the employees were justified in whole or in part. Mr. Noyes hazarded the opinion that there must be under the usual form of management a tremendous aggregate of dissatisfaction incapable of elimination chiefly because the management knew little or nothing about it. Consequently we have not been surprised to find that the existence of a works committee not only brings complaints to light before they are too serious to handle, but that it eventually reduces the number and seriousness of complaints.

Almost invariably foremen have undertaken to reform their ways when their attitude of petty tyranny was the cause of grievances, and have endeavored to adjust complaints satisfactorily when first brought to their attention, rather than to allow their negligence to be the subject of discussion by committees, and thus also by the rank and file of employees, and eventually the object of a reprimand from the management. This means that complaints are more and more adjusted out of court, consequently the time of the works committee is reserved for more important matters.

While it is true that a majority of the matters are usually decided in favor of the complainant, it seems to be the feeling of most concerns that decisions are, in the main, altogether just. It should be pointed out, moreover, that in a large proportion of the cases it is immaterial to the management whether the decision is one way or the other, and it is obviously wiser to have the decision in such cases in accordance with the wishes of the employees. Many of the matters decided by the committees are such as have heretofore generally been left unsettled and allowed to become the cause of constant complaint and unrest.

Most of these plans are so worded that matters relating to discipline and discharge may be heard by shop or works committees, the same as other questions. In a few cases, the employees have been given unusually extensive authority in regard to such matters. The management of one company, for instance, granted to the employees permission to lay down the rules governing disciplinary measures. As a result, the conference board of the employees' association adopted rules and penalties governing all employees. The penalties imposed are somewhat lighter than is customary in most plants where the management retains absolute authority, being principally fines or suspension, rather than discharge, but they have the effectiveness due to their representing the judgment of associates rather than superiors, and this seems to result in a reduction of the number of offenses. In other cases the employees have imposed penalties more severe than the company would have done, and the company has been forced to request a modification of the penalties.

The Filene Coöperative Association, which for many years has had authority to amend or to initiate any rule affecting the discipline or working conditions of the employees of the store, has reduced the number of

offenses through its "arbitration board," which has final authority with reference to discharges. The Filene management goes as far as to permit employees to be represented by legal counsel at hearings. Mr. Cory, Vice President and Store Director, states in his genial way that he and his associates have been subject to some remarkable excoriations at these hearings. That this broad-gauged attitude has paid in an industrial relations sense is beyond question. The American Rolling Mill Company reports that discipline has been greatly improved as a result of the shop committee in its sheet metal and tin shop.

Many companies report that cooperation is greatly increased as a result of their works committee. The committees of the American Multigraph Company urged the management to discharge "slackers" at a time when the entire production of the plant was essential for war purposes. The committee of the Midvale Steel and Ordnance Company recently submitted a resolution to the management recommending that in laying off men, superintendents give preference to American citizens and in general endeavor to rid the works of radicals, Bolsheviks, and other undesirables. This resolution was passed upon favorably by the general superintendent and incorporated in an order which he sent to all of the department superintendents. The Prinz-Biederman Company attributes to its works committee the fact that many better class workers who had left the company returned to its employ.

One very definite advantage of works committees which seems to be reported without exception is that representatives take back to the employees from the meetings a more adequate appreciation of the problems of the management, and that this, together with the increased comprehension by the executives of the problems, desires, and ambitions of their workers, results in a much better understanding on both sides.

One board of directors showed its faith in the educational value of a works committee by authorizing the employees of the plant to elect a "board of operatives," to take over the complete management of four hundred houses owned by the company. A sum of money was set aside to be expended by the board of operatives on the repair and upkeep of the tenements. The company reports that while the employees have made several somewhat serious blunders in the management of the properties—such as putting a new roof on a house which should have been torn down—as a whole the education of the employees in the problems of management seems to be worth all that the company is spending on it.

One company reports that during the first few months after the establishment of its works committee system, production was increased about 20 per cent and expenses advanced less than 5 per cent, while another reports an increase of 15 per cent in production without an advance in wages. Both attribute the increased efficiency largely to the better plant spirit brought about by the works committees. The White Motor Company claims that the works committee was responsible for considerable reduction in turnover and absenteeism. The American Multigraph Company ascribes to its plan of representation a great reduction in the amount of tardiness. The Leeds and Northrop Company has observed a marked decrease in the amount of time wasted by workers since the shop committee was established. The same company reports that its works com-

mittee appointed a special sub-committee on housekeeping which conducted clean-up campaigns which greatly improved conditions of the plant. The "house of representatives" of the Edmund D. David Company established a suggestion committee and awarded prizes to employees for suggestions of improvements in machinery, methods, and designs.

Several concerns report that, while at the first election a number of "radicals" were elected, the employees soon learned to distinguish between mere talkers and competent representatives. This resulted in the election the second time of conservative persons who feel the responsibility of representing the employees effectively and winning the confidence and respect of the management. Several company officials with whom we talked stated that the employees' representatives were frequently more inclined to be conservative than the management's representatives.

Without exception, where a works committee has been in operation for several months, the company reports that it has revealed capacity for leadership among employees which otherwise would have been suppressed or have found an outlet in some undesirable channel. William Demuth and Company has made it a practice to regard its employees' representatives as the natural group from which to select assistant foremen. Its attention was called to this possibility by the recommendation of the representatives that a certain assistant foreman be removed because of incompetency. The management, after investigation, complied with their request and appointed the chairman of the workers' committee to fill the vacancy. The Joseph and Feiss Company reports that their works committee "has greatly developed leadership."

It has been reported that some of the best leaders developed by industrial representation have ultimately been forced out of the company by unpopularity. These men, elected by their fellows to represent them, because of their intelligence and spirit of fairness, agreed with the management too often to suit their constituents. Do not be discouraged if the representatives of the workmen disagree with the management. The men will distrust their own representatives if they agree too much with the employer. Do not educate the representatives too far ahead of the rank and file or they will be accused of being "company men."

A classification of cases which were settled during a four months' period of employees' representatives in three plants belonging to a large company is indicative of results in many other companies. Following is the classification:

Apprentice, back pay, charity, department, discharge, docking of pay, economy, employment, equipment, health, holidays, lighting, living conditions, machine equipment, over-time, pay methods, pay time, piece price, police, practice, promotion, quitting time, relief, rules, safety, sanitation, shifts, short pay, suspension, termination, theft, working condition, working hours, time clocks, repairs. The total number of cases for this period was one hundred fifty-four for the three plants, of which one hundred thirty-two were settled in the affirmative, that is, in accordance with the request as originally presented to the committee.

Our study reveals the fact that while minor matters of complaint involving personal discrimination are likely to be the first matters brought

before the committee, it is not long before the committee is required to consider broader questions involving a discussion of shop practices, efficiency, discipline, and company policies. Industrial representation has tended, I believe, to make lighter the task of management by reducing the causes of friction between employers and employees, and by arousing in the workers a constructive interest in the progress of the industry in which they are engaged.

INSTALLATION OF REPRESENTATION PLANS

Industrial representation is in successful operation in plants varying widely as to process and products, size and complexity of organization, and as to the character of the working force. None of these factors seems to determine the success, although each of them affects it and must be taken into consideration in working out the application of any plan to particular needs. But here are a few suggestions which I think it would be well for every one to consider when contemplating a plan:

Install it under peaceful conditions. One large company inaugurated a plan as the result of a strike, and the plan ended in another strike some time later. The company is now attempting to make a new start. To propose a plan to men on the verge of a strike is also almost certain to result in failure to win over the men.

To attain its highest success, a plan should be developed gradually, each step in so far as possible resulting from suggestions or requests of employees. By all means, do not impose a ready-made plan; let the men help work it out; it will be a better plan and they will feel that it is their own. Remember the attitude of our forebears toward English-made laws applied to the colonies. And no matter how good the plan seems to be, actual use will show need for changes.

See that the plan is simple in form so that procedure under it is easy to understand and to carry out. As to the specific form, we find that the best results have been obtained with the joint-committee. But give opportunity for free discussion, that is, discussion without the presence of the management. It has been found good practice to alternate joint and separate meetings, with final action taken only in joint meetings. At a banquet held recently by the Standard Oil Company of New Jersey for the representatives of the men and the management, one of the employees' representatives suggested the establishment of separate boards for the management and the men. This action was not especially desired by the representatives, who had already taken up the subject once and voted against separate boards, but the men felt that their delegates would not speak freely before their "bosses."

In some plans the committees deal only with working conditions and welfare work, such as light, ventilation, locker rooms, etc.; in some they deal with all matters which directly concern the worker, including wages and hours. There are drawbacks to both plans. On the one hand, committees which have been restricted in their activities have grown restless and felt that they were deprived of their just rights. On the other hand, committees which have been given free sway have sometimes failed to use judgment in the determination of hours and wages. In one plant,

it is said that wages were forced up, despite the company's claim that they could not meet an increase. The reply of the men was, "Raise the price of your product." Experience would seem to show that a middle course works best. Give your committee supervision over working conditions and welfare work; educate them through the use of this function to a better understanding of the position and problems of the management; then as they show themselves capable of handling the more serious problems, extend their authority toward grievances, hours, wages, absence, cost of living, community conditions, etc. In most cases, it will be found that the desire for a wider scope of activities will go hand in hand with the growth of ability to handle the bigger subjects.

We advise that every employee, man or woman, citizen or alien, be made to feel as far as possible that he has a part in the operation of the plan. In one plant, voting was restricted to citizens, but all were, of course, allowed to present grievances. A group of foreigners did not understand this point, and struck because they thought they had no means of presenting their grievance. After the plan has been formulated be sure that every employee knows what it means and who made it. The men first consulted will advise as to the best method to be followed. Use the plant organ again and again to supplement word-of-mouth publicity. Do not hurry at this, or, indeed, at any point. Frequently the management fatuously prides itself on its excellent plan, when the men know nothing about it. In a plant which we visited several months after the installation of a representation plan, almost half the men who could not speak English either did not know of its existence or had no idea of its purpose.

It is especially important to make it plain that the plan in no way interferes with membership in unions or with existing relations of the management with labor unions.

Keep adequate records of all meetings and make them accessible to all. The main decisions should be posted on bulletin boards in each department and published in the plant organ.

Usually best results follow holding meetings during working hours. In one case, which has come to our attention, the representatives requested that the conferences be held out of hours, as they would feel less constraint in voting as they pleased. As a rule, however, committees which meet outside hours have failed to hold the interest of the representatives.

This lack of interest is one of the foes of employees' representation. Many feel that after the first enthusiasm attendant upon any new enterprise has worn off, the committee will fall into the apathy characteristic of so many committees. This has not generally been true. It should never be the case, for the matter is of vital interest to both sides. As with any other form of human activity, the success of a plan is in a large measure dependent upon the standing and capacity of the men who sponsor the plan. The best men and their best efforts are the answer.

SUCCESS OR FAILURE

The degree of success or failure of any plan of employees' representa-

which it believes well designed and best devised to solve the problems of today, to lay the foundation for a better understanding and for a more friendly, fraternal, and coöperative relation in the future, and to remove all of the iniquities and injustices still present in our body politic. The program outlined by it comprehends an orderly, intelligent, and legal procedure for the removal of those iniquities and injustices, and in a progressive manner and not by revolutionary policies and by a destructive procedure.

The American workers realize that one of the first and great principles which will require solution is that one which shall determine to what extent the government shall control industry, regulate our industrial life, and limit the rights and privileges of a free people, or whether we shall revert to voluntary individual or corporate enterprise. It is upon the final decision of this question that many of our future relations and activities must ultimately be founded.

THREE SCHOOLS OF THOUGHT

We have three distinct schools of thought striving for supremacy in the solving of this great problem. We have the socialist, who, as you well know, believes that all instruments of production and distribution should be owned and all of our industrial activities should be controlled by the Government. These good but erring persons would establish an industrial democracy through the ownership of all means of production and distribution by the Government. The American Federation of Labor, the only organization able to speak for the workers, is emphatically opposed to that school of thought. It is opposed to the Government owning all means of production and of regulating all our industrial activities. Diverting ownership from private and individual to government ownership and control does not mean the establishing of industrial democracy, but creates in its stead a bureaucratic autocracy.

THE I. W. W. MOVEMENT

Then we have another school of thought known by what is termed Syndicalism, and it is better known in our country as the I. W. W. movement. The I. W. W. in its philosophy is socialistic. It believes in the paternalistic form of government. It differs only from Socialism in that it holds that the voting power or the right and exercise of suffrage is not efficiently designed to empower the workers to throw the private ownership of industry into the hands of the Government. It believes that this can be done only through industrial and economic action, and it proposes to organize all the workers into one great big union. Having organized all of the workers into one large group of workers it proposes at a given time to call a general strike and render Capital useless, and then take over the reins of industries and place them into the hands of the Government.

Since the development of Bolshevism the philosophy of the I. W. W. has altered. It no longer teaches that industries should be owned and controlled by the government. It has come to accept the philosophy of the Soviet form of government, recognized by Bolshevism in Europe.

Like the Bolshevist of Europe, the I. W. W. now advocates that the state itself should be destroyed and that industry should be operated by the men working in these industries, and that only those manually producing should be the dominating factors in our industrial life. It is proposed by these men and this philosophy, if it may be termed a philosophy, that the future parliament shall be the factory and the workshops, and that the institutions we now recognize as the state should be forever destroyed. It needs little on my part to make clear that the American Federation of Labor is unalterably opposed to that form of industrial ownership or industrial democracy. It spells industrial tyranny of the worst kind and does untold injury to the ideals of freedom, justice, and the pursuit of happiness expressed by that world hope, democracy.

THE AMERICAN FEDERATION OF LABOR

It is the viewpoint of the American Federation of Labor that the greatest happiness and contentment will come to men where the greatest individual freedom is allowed. To the same proportionate degree that individuality is limited and restricted, autocracy is established. We hold there should be left to the individual as much freedom as is consistent with the benefit of the whole. Only where individual freedom may be jeopardized and the collective good of all may be injured should the government step in and determine the rights of all and do justice to all. Only where certain activities or principles affect all men alike or where either by nature or by virtue of arbitrary rule, special advantages are enjoyed by a certain group, there should the government step in and seek to provide for equal opportunities and privileges. It is only in such instances and under such conditions that we believe the governments should function.

The relation between employers and employees is not a matter of legislation. This is a function properly and rightfully exercised by those directly concerned and interested. Employers and employees should jointly and collectively determine the relations of employment and by conference establish the standards and requirements which ought, and of right, should prevail. We hold that those immediately engaged in a particular class of manufacture or production, because of their experience and training and by reason of their interests and direct connection, are best able to determine the relation which should prevail between employer and employee, and the standards and the requirements which should be observed in the particular industry or craft.

We believe that employers and employees of each particular group of manufacture and of each distinctive process of production should jointly and collectively determine the requirements and standards of their joint enterprise. To illustrate: I am a photo-engraver by trade, a member of the printing industry. Is it not foolish to ask me to determine, as a citizen, what particular standards of production, what essential trade requirements, shall prevail in the mining industry or in the railroad enterprise, or in the metal industry, and of which I have no practical knowledge whatsoever and with which I am not conversant? So, it would be equally absurd to ask a miner or to ask a metal trades-

man or to ask men of any occupation other than photo-engraving to legislate or to regulate the relations, standards, and requirements which shall prevail in the photo-engraving craft.

The American Trade Union movement is founded on practical lines, tested by years of experience under the most diverse circumstances. We have builded up a movement based on a policy we believe the most practicable, the most efficient method of operation, a movement which is democratic in character, permits of individual freedom of expression and judgment and brings into harmony the hopes and aspirations and desires of all wage earners for an improved life and a higher civilization.

We want to build up our industries and industrial relations on a practical and not a theoretical basis. Much as we like to see ideals prevail, we can only give our approval to plans and policies which are practicable and which can be put into successful operation. In giving approval to private initiative and enterprise and disapproving the systems and relations proposed by the Socialists, Syndicalists, Bolshevists, and I. W. W.'s, the American wage earners are insistent that the old order of industrial autocracy shall pass and that a new order of industrial democracy shall enter. It is unfair and radically wrong to permit the old order and relation of master and servant to continue. This relation must give way to the more humane and modern relation of coöperators. The employer cannot and must not be permitted to say to the workers in the future as he has in the past: "These are the standards, these are the requirements which you are to observe if you are to have employment with me. If you do not like these standards, if you do not meet these requirements, then go on; I shall have nothing to do with you."

INDUSTRIAL DEMOCRACY

To the workers this is industrial autocracy of the same vicious form that was formerly exercised by the Kaiser when dealing with his subjects. This arbitrary and autocratic rule of employers must be destroyed and the ideal of democracy must be put in its place. The right of the workers to be consulted, the right of the workers to have an impelling voice in the management of business and in the determining of the relation, the standards, and the requirements of employment which should govern, must be permitted a full and free exercise. It is through collective action and by collective bargaining that the American wage earners intend to establish industrial democracy.

We believe the democratic control of industries can only be enjoyed wherever the workers are thoroughly organized and where they select their own representatives who with the representatives of the employers, determine the relations that should prevail and set up the standards and requirements which will be observed from time to time, and which experience and a thorough knowledge shows to be for the benefit of all concerned. The American Federation of Labor is not opposed to the organization of employers. On the contrary it favors the organization of employers. In doing so, it likewise demands for the wage earners that same right of organization, that same privilege of assisting and

helping each other, in determining the conduct of business. I do not fully understand the distinction made by some persons between industrial managers and capital. It is mainly with the industrial managers that Labor comes into a more immediate contact. Dealing with this subject in a practical way the relations and contact between employers and employees have always been in the main with industrial managers, and much to our regret, it has been the hostile attitude of many of these industrial managers, rather than the attitude of the real owners of industries, which has made for industrial dissension and conflict. It is a fact that many of these men believe they are serving their masters best by keeping down wages and denying their employees the right to be consulted in industrial affairs. It is this denial of equal rights and opportunities, this denial of representation and participation in our industrial life which is the real cause for the disturbance and conflicts in our field of industrial activities.

The right to democracy in industry is coming and is bound to become the prevailing condition in industry. He who seeks to deny that right however well he may manage the shop, however well he may pay the workers, whatever conditions of employment he may establish for them, if the workers are denied the right to organize, to express their ambitions, their aspirations, to participate in industrial affairs freely and collectively and democratically through their representatives, so long will there be industrial conflict and unrest, and so long will there be denied a proper agency and procedure for the orderly, proper, and happy adjustment of the relations between employer and employee.

SOLUTION OF OUR INDUSTRIAL PROBLEMS

If in dealing with the representatives of the workers, you find that these men and the workers do not understand your trade difficulties, you have no one but yourself to blame. It is only by inviting the workers and their organizations into your councils, by informing them of your trade difficulties, by taking them into your confidence and advising them of the trade problems which need to be solved, that you will find in them that intelligent responsibility which is essential for the harmonizing of interests and the adjustment of the difficulties and differences. Conferences between associated employers and organized workers having to do with the regulation of mutual rights are the solution of our industrial problems. They will make for industrial efficiency and bring into practical existence and application in our industrial affairs the ideal of democracy.

When workmen are given the right to help determine their destiny in life, their conditions of work, and their conditions of labor, then you will find that happiness and contentment which is so well expressed in our constitutional authority, that governments should be organized for liberty, justice among men, and the pursuit of happiness.

CHAIRMAN YOUNG: The next paper on "Labor Management and Collective Bargaining" is by Mr. William Leiserson, Billy Leiserson, as he is commonly known to us all. Mr. Leiserson has had a unique experience

and background for presenting his thoughts on this subject. He has worked in industry and now is a labor manager in industry. He has gone to college as a student and he has also been in college as a professor, expounding theory. He has been a decent, law abiding citizen for a long time and he has also been a government officer and a minister of the law. It is with great pleasure indeed that we will hear from Billy Leiserson.

MR. LEISERSON: That introduction reminds me of a story about Abraham Lincoln when he was nominated for President. Of course the man making the nominating speech said a lot of very nice things about him. When Lincoln read in the papers about it he was surprised some, and he met the man who made the speech a day or so later and said, "Say, that was a great speech you made about me the other day." "Yes."

"Don't you think you exaggerated a little?" The man replied, "Exaggerated! Why, I lied like the devil."

I have been asked by the committee which arranged your program to apologize for the absence of some of the speakers, that as far as they were concerned until this morning they thought all of them would be here. For one of them I can speak. I saw Mr. Matthew Woll in Washington yesterday and he was unavoidably detained on account of the hearing on the Steel Strike there and couldn't come, so that wasn't the fault of your committee.

When you hear me give my paper I am afraid you will think that I should have read Mr. Woll's paper, that I am presenting labor's side instead of the side of an impartial person, so because you might think that, I want to tell you in advance that I really am an impartial. I hold the position where I am paid both by the unions and by the employers, so I have to be impartial. I warn you in advance because you may not notice it in the paper.

LABOR MANAGEMENT AND COLLECTIVE BARGAINING

WILLIAM M. LEISERSON, CHAIRMAN, LABOR ADJUSTMENT BOARD, CLOTHING INDUSTRY, ROCHESTER, N. Y.

Labor management and collective bargaining are two phases of the general problem of industrial relations, and when we discuss them together the exact nature of the difficulties and complexities in the industrial situation today can be easily discovered. Labor management means control, discipline, and a business organization held together by rules, orders, and authority reaching down from an executive head at the top. Collective bargaining implies a questioning of that authority. It is based on the principle that an individual employee cannot effectively question the authority of the management. It says there must be no rules or orders affecting the income and lives of the wage-earners without the consent of those who obey them. It joins the individual employees into a union and forms a democratic legislative body representing both employer and worker for the purpose of giving to those who have to obey the laws of industry a voice in determining what those laws shall be. Labor management implies power, authority, and law-making in the hands of the

employer. Collective bargaining means democratic representation in the process of that law-making and democratic control of the exercise of that industrial authority.

Here we have the age-long problem of reconciling authority with democracy. Law and government we must have in industry as in all other human institutions, but the day of autocratic control is gone, at least in all Western civilizations. To maintain law and government in the industries of these Western countries, there must also be democracy, the consent of the governed. Without such consent, without such democracy, our industrial governors find themselves unable to control their organizations, or to have their laws and orders obeyed. This is the essence of the industrial problem today.

But, let me warn you. When we have found the difficulty, we haven't by any means solved it. After a hundred years of trying to reconcile authority with democracy in politics we have not yet solved that problem; and in industry the administrative difficulties are much more formidable. We have gone a long way in politics, however, and we have learned to settle political differences by means of legal machinery and orderly methods. We can go a long way in accomplishing the same thing in industry, if we but understand the problem and recognize the inevitability of democracy.

To get such an understanding, however, it is first necessary to give up the idea of placing blame or praise on individuals for the bad or good that may appear in the industrial situation. Not long ago I had occasion to discuss labor conditions with a group of engineers in New York, and they belabored me with the unreasonableness of trade unions in general and the crookedness and arrogance of certain labor leaders in particular. "Suppose," I said to them, "I were to blame all employers for the things I have seen many of them do. I have known employers who made it a practice to seduce girls who worked for them. I have seen inefficient employers unable to make profits because of poor management, who were sweating profits, nevertheless, out of their employees by squeezing down wages below the living point. I have had to prosecute employers for refusing to pay employees their honest earnings, and I have known foremen to graft on their employees and take rake-offs from wages. I know employers who blacklist and employ spies in the most approved fashion of Imperial Germany. Suppose I were to say all our industrial troubles were caused by autocratic, abusive, dishonest, and immoral employers?" No, Ladies and Gentlemen. It is fruitless to blame individuals for industrial conditions. If we try to pass judgment on individuals, then employers will be found more guilty than workmen, not because they are any worse, but because they have more opportunities for perpetrating injustices.

LABOR MANAGEMENT

With the naive notion that industrial ills are caused by bad men eliminated, we may take up the first of the two phases of the industrial

problem: namely, labor management. The employer borrows capital, buys or builds a plant and machinery and hires labor. He, or his agent, uses these factors in producing marketable goods, and he has to manage and manipulate them so as to leave a profit when all costs and expenses are paid. The title to the money he borrows and to the plant and machinery he uses belongs to the employer. From this he naturally concludes that the business is his own. He knows how he worked and sweated to build it up, and he gets the idea that the labor he hires is also his own, to do with as he will. If any one does not like the way he manages, he is not compelled to work under such management; but when a person agrees to sell his labor to the employer, he must be prepared to do as the management disposes. Thus the employer learns to treat labor on the same basis as his machinery and materials. They were all bought in the market and he paid the market rates for them. This was the employer's idea of justice.

But his labor could not be separated from the human beings that did the work; and that caused trouble. They revolted, went on strike, and asked for living wages, not market wages. The employer fought. If he had a small competitive business, he lost out and had to compromise with the strikers. If he had a large or trustified business, particularly if most of the employees were unskilled, he whipped the strikers and maintained what he called an open shop. It cost him a lot of money, but he was willing to pay the price to keep his business free from interference.

Then he discovered that labor had more than one way of revolting against the principle of management which regards labor as a commodity. He might prevent them from organizing a union and striking, but they could quit, as he had told them. They left as individuals, but at the end of the year when he counted up the people hired and those who had quit, he found that it wasn't a few who left him. His whole force had left. He was hiring as many people in a year as he had working for him. This in ordinary years when there were many unemployed. Then came more opportunities for employment throughout the country, and the supply of cheap immigrant labor was restricted. How his labor did quit then! He couldn't believe it. Instead of a new force every year, he was hiring two, three, four, and even as high as six forces a year. He awoke to the fact of labor turnover, and he saw that it could go as high as 600 per cent or more a year. It was the new form of revolt against his authority, and it not only cost money, but it caused inefficiency and decreased production. Some employers still think labor turnover is due to the peckishness of labor and to its roving disposition, but most of them are about ready to concede that management has something to do with it.

Those employers who studied the causes of labor turnover, soon discovered that management had a lot to do with it. They found that treating labor as a commodity led to class wages instead of wages based on personal efficiency, and that hiring, selecting, and handling of employees on the assumption that they are commodities does not give to wage-earners any incentive to stay on the job and do their best.

This realization was the beginning of a scientific system of labor management. It came to be called Employment Management or Personnel Management and employment managers or directors of personnel were hired to look after labor relations.

This was a long step in advance, but the old system dies hard. And it is not dead yet by any means. Foremen, superintendents, and other production officials were not going to give up their traditional authority to what they considered impractical young men with new fangled notions of kindness and consideration in the treatment of labor. They had come up through the mill, they were practical, they knew how labor had to be handled, because they had learned only too well from the knocks they had received when they were laborers themselves. So, most of the employment managers had beautiful plans and theories and charts and reports; but in actual practical authority they were clerks.

SERVICE RENDERED BY THE EMPLOYMENT MANAGER

But many of them were high-minded, persevering men and they had faith in the new profession that they were creating. They worked and they talked and they overcame difficulties and they demonstrated, in spite of all the opposition, that they could reduce labor turnover, that they could make labor feel more satisfied, more loyal to the industry—and that it paid. Then was the practical business man convinced. And from a skeptic he suddenly became an unquestioning believer. Whatever it was that the employment manager established successfully, a centralized employment department, a new labor record system, a plan of profit sharing, a bonus system, or a shop committee plan—that became the great remedy, the panacea that would solve all labor troubles. But, actually, what the honest and competent employment managers were doing was attempting to deal in an intelligent and scientific way with the personal or human relations between the laborer and his managers or employers.

They didn't find this a simple problem capable of a single solution. They had to restrict the foreman's power to hire whom he pleased and to institute systems of selecting men fitted for the work in hand by means of intelligence and trade tests. Instead of letting the men they hired learn their jobs without instruction, or by means of shouts and curses from the foremen, they introduced systems of training men and fitting them for the jobs. They heard the men's grievances and tried to find redress for them when they were just. They took away the foreman's power to fire a man from the plant. Instead, the man was sent to the employment department, and, if possible, he was transferred to another department. This, and much more, is what has come to be called employment work; and while much has been done on the various phases of it, we still have far to go before we can say that all the employment problems have been solved.

Long before the employment managers had undertaken this work, the safety movement had made great headway, stimulated very largely by workmen's compensation laws. At the same time, a number of large employers had instituted so-called welfare work. The employment man-

agers saw in these activities another phase of their own work. The health, safety, education, recreation, and general welfare of employees must be looked after if they are to work and live as human beings. The employment managers called all this Service Work and they extended their own activities to include Service.

Today this employment and service work has reached its greatest development. Every plant of considerable size has its employment and service manager or corresponding official. And yet today, we are having more strikes, more industrial worries and discontent, more revolts of the worker against the employer than ever before. Why? Is it because the development of employment and service work has been wrong? Yes and no. Yes, in the cases of those employers who thought they had in these activities a cure for all their troubles, a substitute for industrial democracy. No, in the case of those far-sighted employment managers, who saw that they were dealing with only one phase of the industrial problem, the personal relations, and recognized that another phase, the economic relations—that which has to do with wages, hours, bargaining, and democratic control of industry—would need other methods, other devices, other administrative machinery to be handled properly and intelligently.

LABOR DEMANDS VOICE IN REGULATING WORKING CONDITIONS

The American employer has pretty well learned the lesson of the employment and service manager. He is ready to go the limit in providing the best physical conditions, establishing service facilities, and inaugurating scientific employment methods. But the industrial world has gone beyond that. Labor is contesting the control of industry today, denying that the business is the employer's own, questioning the employer's claim of absolute right to fix wages, hours and conditions of employment, demanding a voice in making the rules and regulations of the factory which the worker must obey, and insisting that government in industry as in the State derives just powers only from the consent of the governed.

But this American idea, first stated in our own Declaration of Independence, that every man has a right to a say in making laws and regulations which he must obey, some employers are still fighting. They are not ready to give up their absolute control over their employees, to share their power over wages, hours, and industrial law making on an equal partnership basis with their employees. Like the monarchs of old, they offer to treat every employee with equal justice and consideration and to give to all what they call a square deal. But the King's justice and the King's square deal, was not what the people wanted. They insisted that there were two sides to the justice question, and they wanted and got representation so their own idea of justice might find interpretation in the law. Just so, labor to-day insists that there are two sides to the square-deal-in-industry question. The employer wants to remain an industrial monarch, and offers to his industrial subjects a square deal as he sees it. But the wage-earners idea of

a square deal differs from that of the employer. He insists on his interpretation and demands an *equal*, not exclusive (*Bolshevist*), voice with the employer in determining what square dealing and what justice in industry shall be.

THE END OF ABSOLUTISM IN INDUSTRY

The day is not far off when we shall all be able to see that there is no more reason for permitting the employer to have absolute sway over the income and lives of his employees, even though he assures them justice as he sees it, any more than it would be to give to the employees absolute control over industry on their promise to give the employer a square deal as they see it. When wage-earners control absolutely, we have Bolshevism, the Dictatorship of the Proletariat. When employers have absolute control of industry, we also have Bolshevism, the Dictatorship of the Plutocrat! Neither is Democracy or Americanism, and the American people will not stand for anything but democracy. Democracy means no absolute control by any group. All must have a say.

You will agree with this in the abstract; but the real test of your devotion to American Democracy comes in its practical application. Apply the principle to the present steel strike.

The officials of the Steel Corporation are quoted in the New York Times of last Saturday as saying that the real issue in the steel strike is the question of control. "Is the management of the plant to decide conditions of employment in the plant?"

There is no doubt that this is the real issue. But see what this means. The steel worker sees American miners meeting with mine owners to determine jointly what conditions in the mines shall be. He sees the same in the building trades, printing trades, clothing trades, and he sees the American Government itself through Director-General Hines making an agreement with railroad workers jointly determining labor conditions. In every kind of industry he sees that labor in America is beginning to get a voice in determining conditions in plants either through a company union or a regular trade union. But the Steel Corporation says, "No! In our industry we must decide the conditions in the plant." The steel worker scratches his head. "Isn't that 'All power to the employer?'" he asks. "Isn't the Bolshevist motto the same thing, 'All power to the workers?'" He wonders then: "Is Judge Gary a Bolshevist? All power to the employer! Dictatorship of Capital!"

And what does the American public see? It beholds mining, building, transportation, and most other lines of manufacturing organized on a democratic basis, with employers and workers jointly determining wages, hours, and conditions of employment; but the steel industry remains in the absolute control of the employer. A similar situation existed in Europe before the war. All Western Europe was organized on a constitutional democratic basis. Only Russia and Germany remained behind. From these two countries where absolutism prevailed came the two big dangers to the democratic peoples of the world. They are (1) Benevolent despotism, which treats its subjects well, and (2) Bolshevism, which means dictatorship by a small group. In the steel industry,

where absolutism prevails in this country, both these doctrines are promulgated. The Corporation refuses to give a hearing to representatives of its employees and says it spends great sums of money on welfare work. It denies that any one or any group of its employees has as much right to hire Fitzpatrick and Foster as labor experts, as the Corporation has a right to hire Close as welfare manager or Gantt or McKenzie King or any one else as labor experts. It says all power over employees belongs to the employer. This is a dangerous doctrine because of the ideas it breeds among employees.

Realizing that the days of absolute control over employees are fast passing, and that concessions to the democratic movement in industry must be made, many employers have established so-called Industrial Democracy plans, known by various names—Shop Committee, Works Council or House of Representatives. Whatever the name, they are designed to head off the kind of democracy organized labor offers and to prevent unionization of the plants. This has led organized labor to oppose company unions, but the movement of employers to establish collective bargaining plans of their own is not to be condemned simply because it is designed to prevent the kind of collective bargaining that the regular unions offer.

COLLECTIVE BARGAINING THE ONLY DEMOCRATIC METHOD

The essence of democracy in industry is collective bargaining. Whether it is private or public industry, democratic control can be secured only by the employees dealing collectively with the executives of the enterprise. Organized labor has developed certain methods and a certain technique of collective bargaining which wage-earners have spent years of struggle and sacrifice to establish. Naturally, they are jealous of any rivals. But we cannot assume that there is only one brand of collective bargaining. The employers' Industrial Democracy plans must be judged on their merits, by their sincerity, and by their success in establishing genuine collective bargaining.

Many of the plans provide for shop committees which deal only with safety, employment, and service problems. They have no power over wages, hours, and discipline. This is legitimate activity, but it is not collective bargaining. When an employer offers it to his employees as industrial democracy, he is either deluding himself or trying to delude his employees. In either case, he is playing with fire; for the wage-earners will see in the attempt only insincerity and deception on the part of the employer. In the end he will pay for it in opposition and hatred from his employees.

Many other plans have the form of collective bargaining, but not the real thing. Representatives are elected to take up with the employer all questions, but in actual practice the employer's absolute control of wages and discipline is not restricted, and if there is disagreement between the men and the management, no real arbitration of disputed points is provided. Some officer of the company has final authority to decide. This is a travesty on democracy. The employer holds to his

power, yet pretends to share it with his employees. Confidence between employer and employee, which is the foundation of all good management and proper labor relations, can not be built up on such pretenses. The employer has no confidence in his employees when he establishes such a plan, and they in turn will learn to have less confidence in him.

A few of the employees' representation plans are genuine attempts to introduce collective bargaining. The organizations created by these companies are real unions, but restricted to one plant or to the plants controlled by a single company. The Brotherhood organized by the Interborough Rapid Transit Company of New York proved it was a union by going on strike, and the works councils of the International Harvester Company in Chicago and Akron proved the same thing by voting not to strike when called to do so by a national labor organization.

To the extent that these organizations practice real collective bargaining, they compete with the regular trade unions and win away members; and this is a situation which the unions must prepare to meet by more efficient methods. But organized labor has nothing to fear from works committees, by which the employer tries to camouflage the exercise of his autocratic power with democratic forms. The employer may fool himself, but he can't fool the workmen who sense soon enough whether they have a real voice and vote in fixing terms of employment or not. Sooner or later they will go to organized labor and ask help to get the real thing, or an organizer will come along and show them what the real thing is. If an agitator can come along and win away the employees from a company union to an outside union, that is pretty good evidence that the company plan did not give them real democracy, just as it is pretty good evidence, when the company union wins away employees from organized labor, that it must be offering real collective bargaining, or else the employees wouldn't be satisfied.

With all the publicity that the so-called Industrial Democracy plans have received and with all the progress of organization of works committees, it should be remembered that the typical form of collective bargaining, the vast majority of collective dealings between employers and employees, is that carried on by organized labor. The number of plants having company unions is insignificant compared with the number of shops that deal with the regular trade unions. During the last four years when the works council movement has made such great headway, more wage earners have joined the ranks of organized labor than are included in all the company plans put together. Let us not over-emphasize the importance of these company plans of collective bargaining. Even if all of them were genuine, and most of them are not, they would be far from solving the problem of industrial control. Organized labor is growing very much faster and stronger than the competing movement launched by employers. Labor management, therefore, is face to face with the problem of adjusting its methods to the demand for collective bargaining as carried on by organized labor.

DEMOCRACY IN THE CLOTHING INDUSTRY

Now let me describe an industry where an attempt has been made to put labor relations on a democratic basis, where collective bargaining

with a union prevails, and where the administrative machinery necessary to make collective bargaining work satisfactorily has been created. I refer to the clothing industry. This industry employs over 200,000 people. It has four great market centers: New York, Chicago, Rochester, and Baltimore. In all of these markets it is now almost completely organized, and only a few firms are outside the agreement between the clothing workers union and the employers' associations. Observe that both sides are organized. There can be no real collective bargaining if only the workers are organized and enforce their will on the employers, any more than when the employers enforce their will on the employees.

In each of these cities there is an agreement between the employers' association and the local branches of the union. The agreements fix minimum wages, establish a working week of forty-four hours, provide for open or preferential shops or closed shops, prohibits strikes, and restricts the employer's rights to discharge by making him give a good reason for every dismissal.

The local unions of the various trades in the industry elect delegates to a central body, known as a Joint Board. The Joint Board employs managers and deputies, whose business it is to represent the employees in negotiations and in handling their grievances.

On the employers side, there is a similar organization. Each of the large plants employs a labor manager who has charge of all bargaining and labor control, as well as employment and service functions. For the smaller plants, the employers' associations employ labor managers who perform the same duties for groups of employers.

When there is to be a general revision of wages or hours, or when a new agreement is to be made, the Board of Labor Managers and the representatives of the union meet and work it out. When there are adjustments to be made that apply only to one shop, the individual or group of employees affected takes it up with the labor manager of the plant. If a satisfactory adjustment cannot be made, one of the managers or deputies of the union is called in. In the vast majority of cases, amicable adjustments are arrived at. Where such an agreement cannot be reached, the matter is left to impartial arbitration, for which permanent machinery is created by the industry itself—in effect an industrial court.

The employer's association of each city, together with the joint board of the union, selects an impartial person to act as judge of all disputes. Technically, he is the chairman of a labor adjustment board, consisting of the labor managers and the union representatives who argue cases before him. His salary and the expenses of his office are paid half by the employers and half by the union. He hears no cases of men who have stopped work. Strikes are illegal. The employer may suspend a worker, but if on appeal to the chairman this dismissal is found unjustified, the employee is reinstated and must be paid by the employer for the time he lost.

Here we have the machinery of democracy. The institution of the impartial chairman or judge is a recognition that law, order, and government must prevail in industry, that peace must be maintained, and the interests of the public conserved.

How is it working out?

Well, it hasn't solved the whole labor problem, nor has it eliminated all labor troubles; but it has shown that you don't have to have absolutism in industry, that you can get along without Dictatorship of the Plutocrat and Dictatorship of the Proletariat. It has shown that this attempt to maintain a dictatorship by capital is what puts unions on a war basis and fosters bolshevism in the ranks of labor. The plan is beyond the experimental stage. It began five or six years ago in the Hart-Schaffner and Marx factories of Chicago, and the success of it in these factories has spread it through the entire industry. It has taught the employers to respect union leaders who they once thought were crooked agitators, and it has made unions and their leaders have confidence in their employers and cooperate with them. It has enabled unions and employers to work together on such problems as the elimination of strikes, the introduction of machinery, time studies and standardization of occupations, increasing production, and maintaining shop discipline. Disputes on all these questions have not been eliminated. They never will be; but they have been settled, in a peaceful, orderly manner according to the laws of the industry, which labor and capital alike have had a share in framing. More than all this, however, the plan has enabled the union to take on a peaceful character and to concern itself with the questions just mentioned, which are the real problems of collective bargaining, instead of emphasizing war policies.

CONCLUSION

What then shall be the conclusion of our discussion of Labor Management and Collective Bargaining? For the reasons outlined in this paper, it is my judgment that labor management must adjust itself to include within its functions methods and policies of dealing with its employees collectively through organizations and representatives of their own. Labor relations are of two kinds: personal relations and economic relations. The first does not necessarily involve the question of democracy. Personnel management dealing with employment and service problems has developed during the last few years methods and policies for handling the personal relations in industry. But the economic relations need other methods and other policies. Representation of interests must be provided; machinery for industrial law making, for democratic decisions by majorities, and for interpretation and arbitration must be created. Because democracy in industry is inevitable, labor management must include personnel management and collective bargaining. The arrangements existing in the clothing industry show how the two can be combined, how management and authority can be harmonized with democracy, and how the two can be made to serve the best interests of all concerned—employees, employers, and the public.

CHAIRMAN YOUNG: I thought, instead of accusing you of reading Mr. Woll's paper, we might accuse you of reading Mr. Fitzpatrick's paper, Billy.

One day last week there passed over my desk a few newspaper clippings. One of them read as follows: "There are persons who constantly clamor. They complain of oppression, speculation, and the pernicious influence of accumulated wealth. They cry out loudly against all banks and corporations, and all means by which small capitals become united in order to produce important and beneficial results. They carry out mad hostility against all established institutions. They would choke the fountain of industry and dry all streams. In a country of perfect, unbounded liberty, they clamor against oppression. In a country of perfect equality, they would move Heaven and earth against privilege and monopoly. In a country where property is more evenly divided than anywhere else, they rend the air shouting agrarian doctrines. In a country where the wages of labor are high beyond parallel, they would teach the laborer that he is but an oppressed slave."

This is not a current clipping but an extract from a speech of Daniel Webster in the United States Senate in 1838.

The other clipping referred to the fact that a Y. M. C. A. worker who was teaching illiterate Chinese coolies their native language, found among Confucius' characters, more than four thousand years old, very definite instructions to resort to arbitration on all disputes.

Our discussion has been more on the practice of employee representation than upon the principle. As a matter of fact, I don't think there is anything new whatsoever in the principle of employee representation. Coöperation, brotherhood, frankness, justice, fairness were all preached by Confucius, by Aristotle, by the Disciples, by the framers of the Magna Charta, and by the signers of the Declaration of Independence, and all men subscribe to them and believe in them today. We are, however, making rapid and definite progress toward a perfection of practice, if not the principle involved.

The open season for the speakers is now on. There are some very simple rules governing the slaughter. No marksman is permitted to shoot for more than three minutes without the unanimous consent of the floor and in rising he must state his name and business connection. Ladies and gentlemen, the floor is yours.

DISCUSSION

MR. PORTER (Worcester, Mass): I am requested to ask the last speaker if safety committees are a good start toward this form of organization that he speaks of?

MR. LEISERSON: I think safety committees are a very good start, provided you always remember that you are starting and not stopping.

CHAIRMAN YOUNG: A bull's-eye, gentlemen.

MR. PHILLIPS (Central Iron & Steel Co.): I would like to ask Mr. McCormick whether employee representation and efficiency experts can figure with one another?

MR. MCCORMICK: Yes, they can. The practical application of it is

dependent upon the amount of interest that the employees can take in that particular form of democracy under which they are operating. I think there is no possibility of doubt that a man who has a share in the control of his own destinies will operate more efficiently because of that reason.

MR. LEISERSON: May I suggest in that connection that union officials in the clothing industry have told scientific managers who were working in some of the plants. "We are pushing up wages; we want to go further; we know we can't go further unless there is more production, so go ahead and show those employers how they can produce more, and God bless you—for then we can get more."

MR. J. B. DOUGLAS (Philadelphia): I would like to ask Mr. Leiserson what is the attitude of the garment workers on the question of physical examination?

MR. LEISERSON: There is no absolute position taken by the employees officially on the question of physical examination. They are divided on the question. But just now what the employees tell me is this. "We are in favor of physical and mental tests, but we want the employer examined as well as us. (laughter) because he controls our lives and our destiny, and he examines us when he may not be fit for the industry at all."

MR. J. B. DOUGLAS (Philadelphia): Isn't it a fact that many large employers, in introducing physical examinations, have started at the top and gone right down the line?

MR. LEISERSON: Probably they have. If I were introducing it, that is what I should do. I don't think you will have any trouble with employees when they know about the whole machinery, when they know that the employer has been examined, and that the foreman who isn't competent will be fired for that reason.

MR. NAYLOR (Bureau of Labor, Manitoba): I want to ask Mr. Leiserson a question. I am tempted to believe that the remarkable success of the arrangement under which he is working is due in a very large measure to the charm of Mr. Leiserson's personality. I want to ask him if he knows of a similar arrangement working equally well with some one else in his capacity?

MR. LEISERSON: I can plead not guilty, because I have been on the job only one month. It is very true, Ladies and Gentlemen, that leadership and personality have a great deal to do with it. The leadership in the union and the leadership of the employers have been of a very intelligent nature. In Chicago, the clothing industry has emptied the universities to put men in as labor managers. I can name at least six men who have left colleges. One man left the dean-ship of the College of Commerce of the University of Minnesota to become labor manager of the Employers' Association of Chicago.

The stove moulders have been working on this arrangement for years and years. The mine workers have been working on a similar arrangement for many years. You hear them talking a great deal, but you don't have a real strike in the industry unless somebody is trying to destroy the union. It is easy to arbitrate demands, but you can't arbitrate the question of the union. So I say that leadership and personality have a

great deal to do with the success or failure of such a plan, but that same leadership exists in all of the other industries.

MR. HAMILTON (American Radiator Co.): Mr. Leiserson has made one statement that struck me quite a perceptible wallop. It may have affected some of the others in the same way. He says that in this clothing arrangement, organized labor is working to increase production. The opinion that prevails in most circles is that organized labor wants to decrease production and increase the wage. I would like to know whether in your opinion they are actually making the effort to increase production.

MR. LEISERSON: I know a case where pressers came along and asked for \$35 a week. They were getting \$29. The employers said, "If we give you \$35 it will break up the business." They had the facts and figures there and showed them. They talked back and forth and threatened and all that. You know, whenever you do away with real war, you take it out in imagination, in talk. They finally reached an agreement. The increase in one case would have been from eight to ten per cent. If the employer gave \$35 it would have been an increase of nearly twenty-five per cent. The employers said, "If you will increase production so that the net cost to us will be only eight or ten per cent, we will give you that." The employees said, "We will try." They have been at it now for more than a month, and they are making good. They have done the same thing now with three other occupations. This is the clothing workers' union that is not affiliated with the American Federation of Labor. There is another clothing workers' union, the United Garment Workers, which is affiliated with the American Federation of Labor. In co-operation with the United Garment Workers, Morris L. Cook, a Frederick W. Taylor man, is working in several plants putting in scientific management. The idea you get—that organized labor is for decreasing production—is the same that organized labor gets—that all these company plans are fakes. Each is about as true as the other. You don't know anything about their policies, and they don't know anything about your policies: but when you get together and have an impartial Chairman, you find out because you have to talk to one another.

MR. ROSE (Goodyear Tire & Rubber Co.): I would like to ask Mr. Leiserson how production is going to be increased when the hours of labor are reduced to forty-four hours a week?

MR. LEISERSON: The employers have told me invariably that the reduction from forty-eight to forty-four hours a week has not decreased production one iota.

MR. GREENWOOD (Carnegie Steel Co.): If I understood you correctly, industrial democracy has been established in the coal mining industry. Why are the coal miners threatening a strike, if there is perfect harmony between them and the employers?

MR. LEISERSON: There are two answers to that question. When I said industrial democracy has been established in the mining industry, I said it was established just about as thoroughly as political democracy has been established in this country. Why, if political democracy has

been established in this country, do we have race riots, and why don't the negroes vote in the South? Because we have not established complete political democracy. It takes years and years to work that out. The mining industry has made a long step in advance toward industrial democracy, but it isn't anywhere nearly so far advanced as our political democracy; and our political democracy is not yet complete democracy.

Threatening a strike and actually striking are two very different things. What happens when you want to sell steel? You quote the price as so-and-so. The man says, "No, I can't take it; you ought to take so much for it." You bargain back and forth. The man tells you, "I won't buy and if you need his trade, you will be a little bit scared, and you will try to deal with him." Now all these threats of strike are just bargaining, manipulation, the bargaining method. Note this, that when you buy coal, the company quotes a price to you; when you buy steel, the steel corporation quotes a price to you. Why shouldn't labor quote its price to the employer? The beginning of industrial democracy is when Labor is permitted to quote prices. The mine workers are now quoting prices. The companies say these prices are too high, and they are bargaining.

I would like to bring this very important point out in connection with this matter. The coal companies issued a statement that what the men want (a 36-hour week) is very unreasonable, that it will cut down production, and it will cost the people of the country a billion dollars. The employees came back with the statement, "The only reason we ask this is because we don't want to lie idle three days in the week and make up forty-eight hours on the other three days," or, "We don't want to lie idle for five and six months in the year and then make it all up the other months." The company put up the proposition that continuous employment is not possible because there are no facilities for storage.

Now, if you don't have this industrial democracy machinery by which the employers and employees can talk these things over, you do not see that back of the demand of the mine workers is the request that this unemployment be not put entirely on their backs. You can't store coal at the mine. That is the burden that the public and the employer, as well as the wage earner, should bear; but the employers refuse or find it impossible to store coal, and the public refuses to buy in the summer for winter use. The employees now have to bear the whole burden, but because they have the democratic power to state their case they say, "If you want us to bear this burden, we will work only thirty-six hours a week, and it will cost you so much," or, "you will order coal in the summer and you will provide storage facilities." In other words, they have the means of bringing up their problem which they would not have without this democratic arrangement.

MR. FRENCH (California Industrial Accident Commission): I should like to ask Mr. McCormick this question: Imagine, Mr. McCormick, that three other plants were in close competition with your corporation, that the shop committee system existed in each, and that it was agreed in each shop that the wages and hours should be based on such and such a standard, and that they varied in each of the four corporations; how

would you stabilize the industry in those very important particulars?

MR. McCORMICK: The three plants all members of one corporation?

MR. FRENCH: Different organizations in close competition with you.

MR. McCORMICK: Would it not be likely that in all those plants there would be a certain market value of labor which would in itself economically tend to stabilize those wages without resort to any artificial means?

MR. FRENCH: I should say that it might not work out that way, and that there might be a difference in the wage rate which would be very important. The Central Trade Union idea is to have a minimum standard, and I wondered how you might arrange for that under the shop committee plan?

MR. McCORMICK: If the standard of living, or the standard of skill required were different in one plant from the other, I should think that the employers would have a reasonable answer for keeping that wage scale different. When all conditions are similar, and the plants are adjacent to each other, I see no reason why, economically, there should be a different wage scale. I think the point you are getting at is this: many employers object to a flat wage scale all over the country, because of different conditions in different parts of the country and in different shops. I do not know of any objection to a similar wage scale in adjacent shops where conditions are identical.

MRS. HOKE (Printz-Biederman Co., Cleveland): I wish to say, on account of the question that was asked about the decrease in production when the change is made to forty-four hours, that our production has increased because the people really have more efficiency when they don't work as many hours. The forty-four hour plan has been very satisfactory all the way through in our plant.

MR. DEBLOIS: I would like to ask Mr. Leiserson a double-barreled question. Mr. Leiserson, you have instanced the fact that political democracy after a great many years of effort has not been attained. That is perhaps the largest scale of effort that we could imagine. The shop union is the small union. The clothing union is the large industrial union. Why do you expect, as I think you do, better attainments from the large idea than from the small idea when political democracy, which is the wholesale scheme, has not worked out very well. That is one barrel.

MR. LEISELSON: Suppose we take them one at a time.

While it is true to a certain extent that Switzerland, a small country, is a purer democracy than ours, I think the reason it is a purer democracy is because it hasn't the problems that we have. The great problems of democracy have been worked out in this country, which is as big as all Europe put together. We have, in my judgment, more democracy in this country than there is in any other country, and we have it for one reason: because we have worked it out on a large scale; we have a lot of difficulties and we may not entirely perfect it for two hundred years, perhaps longer, because our problems are bigger. It isn't quite a question as to whether we have the perfection. The real question is as to whether we have the purpose to allow everybody democracy; and when we see a place where it isn't working out, we ought to fix it

up right away. The benefit of democracy may not be in efficiency. It is in the development of character, when everybody has a say. For the same reason you will let your boy of fifteen make a fool of himself and go away and not stick to your apron strings, because it would not be advisable for you in every case to tell him how not to make mistakes. You want to let him be free. You act on the democratic principle because you know it will develop his character. For that same reason I favor the inevitability of democracy; and the more problems the boy has to face, the better character he will be; the more problems a country has to face, the more democratic it will be, the more character among the citizen. The larger the country, the more climates, the more nationalities, the more problems it has to face, the more democratic it will be. That is why I think America is the most democratic country.

But you get correctly, I think, that it is my opinion that the organized labor kind of democracy is better today than the company union kind of democracy. I judge that, by the experience up to date. I am perfectly willing that there be real competition to show which is better. I have myself talked to union people, and I have showed them that there are some things in the company plans that they ought to get quickly or the company unions will get them.

Democracy will be worked out not by any one scheme. We want everybody to be experimenting with it, and while today I favor the national union because I see no way of establishing equal conditions of labor except through a national organization, if one can work it out through the company and do it more efficiently and get more democracy—the real thing—then I should be for that.

Now your next question.

MR. DeBLOIS: This is the second barrel. Let us take an imaginary industry that has not been unionized, that has no tendency toward it, in which the employers have not adopted any shop scheme of industrial democracy. Which would you consider the best way to attack the problem, by the union idea, organize your employees into a union, or start in the single factories and introduce the shop principle?

MR. LEISERSON: My usual way of answering a question like that in my industrial court is to say, "A judge never answers hypothetical questions." But I don't want to take advantage of my privileges. But there really is something in that, that a judge never wants to answer hypothetical questions, because every one of these things depends upon the circumstances in the case. When I was with the Department of Labor doing consulting work on these things, and I came into a plant and they wanted my advice about organizing shop committee plans. I said, "I don't know whether you ought to have one or not: maybe you ought to have a union, but I want to look through your plant first and see what the relationship between you and your employees is." Now if the union has never attempted to organize and the employer has never fired people because they did try to join the union—you see all the hypotheses we have to bring in—if there is the very best relationship between the employers and the employees (which is a very big hypothesis), it might do

very well. One of the men connected with our Division of the Department of Labor has actually told an employer, "It would be fine if you put in a shop committee plan, because you can do it better than the union could in this particular plant. Your relations are fine, but you are telling these employees always, 'Stick to your job, no absenteeism.' But when the armistice was signed, and you didn't know where you were coming out, you laid a bunch off, and as soon as you lack material in a certain department you lay them off. In other words you are making them irregular. Now if you will issue a statement to your employees saying 'Fellow workmen, or whatever you want to call them—we, the firm, acknowledge that in the past we have been making mistakes: we have in the past told you not to be irregular, but when our production methods were such that we couldn't keep you regularly, we laid you off and made you bear the burden. Hereafter we won't do that. If our production methods are such that we can't keep you working regularly, we will pay you for the time.'" He said, "If you will do that, then you can run a company union all right, and your men will be satisfied. The employer did it, and he has that arrangement now, and it is working well. But for an employer who is not willing to go the limit on a thing like that, I would say, the best way to introduce democracy is to have it come from the outside, forced on him, because he can't learn the lesson himself and somebody has to teach it to him.

MR. GREENWOOD (Carnegie Steel Co.): When this ideal condition of democracy is arrived at between the employer and the employee, have we any guarantee that they, with their combination, will not increase the high cost of living? Have they the power to take advantage of the consumer if they see fit to do it?

MR. LEISERSON: A very serious and important question. You introduced it by saying, "This ideal arrangement, etc." We are all standing for ideals. We are all working for Heaven on earth. If we are not, there is something the matter with us; but we are going in different ways toward it, and we are a long way from it, but the fact that we are a long way from it is no reason for stopping right here.

Now there is real danger that employers and employees will get together and hold up the public—very real danger. But before you come to that danger, you have a very much greater danger: that the employer himself will hold up the employee first and the public afterwards. Now that is the first arrangement. When the employer can dictate to his employees and dictate to the public, you have a very bad situation.

Then the union comes along—it is the next step toward this Heaven—and says, "Here you have got to divide this dictation business fifty-fifty." That is a step in advance, and I am for it. It is a start, like the safety business, and remember I am for it. The mine workers and the printing trades and the building trades usually don't have impartial chairmen and they are not as far ahead as this clothing industry. To bring in an impartial chairman is bringing in an outsider. The clothing industry is taking men from public institutions, your teachers and your professors, who are trained as public employees. That is another step in

advance. When I make a decision about wages, I always have in mind that if I have to pay \$60 for a suit of clothes—not on your life! And I think the people will think of that. They will frown on such collusion; they will destroy the whole arrangement and take the public point of view into consideration. It is another step in advance.

In connection with taking these men from colleges to act as chairmen, the union in its official weekly paper said, "The clothing workers have not only improved the conditions of the working people in the clothing industry, but the conditions of the professors in the universities as well." And they need it.

Now the day will come when the public will be on to its job. The public today is not considered by these industries because the public does not consider the industries and the people in them. It took a strike, a revolt, a revolution of the order-keeping authorities in the person of the police, to show the people of this country that they ought to pay policemen decent wages. It was bad, unjustified in my estimation, to have a strike of the law-keeping authorities, but you can't get away from the fact that every city in the country today will pay its policemen decently, because they have heard what happened in Boston—and they didn't do it until something happened. Something is needed to wake up the public. Some day the public will wake up about its teachers, about its professors, about its policemen, its firemen, and about the salaried employees in your industries—and Lord knows they need it. When the salaried employees strike, the employers will say, "Those people are on confidential relations with the employers; they know the secrets of their business and they ought not to join a union." Well, if they are on confidential relations, why don't you pay them for it? You pay the common laborer because he forces you; you pay the mechanic because he has a union that forces you. You don't pay the salaried employee because he doesn't organize and because he takes your advice. If he puts wages up, why, then the cost of living goes up; so he doesn't put wages up, and he is waiting for cost of living to come down. Some day the public will appoint these judges to take care of the public interests.

MR. R. M. LITTLE: I would like to ask Mr. Leiserson to give us a brief definition of democracy.

MR. LEISERSON: My judgment of democracy is that no one must have absolute control, that every one must have a say. We have worked it out in the church and in politics; we haven't worked it out in industry. That is all that I can define. Every one, no matter how low he is in your estimation, if he is an adult, normal human being, must have a say: and if he isn't educated, you have got to give him a say because otherwise you will never educate him. In this country we didn't have the public schools when we started. We didn't have the vote for every wage earner in this country until down to about 1850. Did you know that? In spite of the Constitution and the Declaration of Independence, a man had to have property to vote. Remember what Ben Franklin said about the mule? A man owned a mule. It was property. It was worth a certain amount of money. When the mule was alive the man had a

vote, but the mule died and he lost his vote, and he wanted to know whether he or the mule voted. The common people fought and by the end of the first quarter of the nineteenth century they got the right of manhood suffrage in this country. New York State didn't give it to them until the Constitution was made somewhere in the fifties. Then when they got the vote, everybody said, "Oh, what have we done? We have given all these ignorant people the vote; we will have to educate them," and that is why we have the finest public school system in the world.

-And so with this democracy—every one must have a say, whether he is ignorant or not, because you will never educate him unless you can see the dangers of his ignorance.

MR. R. M. LITTLE: I would like to present this thought: government by the consent of the governed. It comes then to a matter of degree—every man a say—does every man have an equal say of authority?

MR. LEISERSON: Every man has a vote, but that does not mean that every one has an equal say. It means—if what I am saying is making any impression on you people and you think I speak the truth and with authority—I will have more to say in anything you do than any one of you individually, because I will influence maybe a dozen of you to vote my way.

In a democracy every man has a vote. In the old country they used to start with the idea that all people are not equally intelligent. "How shall we find out if they are? Well, if they have a business, why they must be more intelligent." That is an assumption that I won't agree with. "If they have land they must be more intelligent." So they gave the landholders three votes and business people two votes and the rest of them one. In this country we say, "Every man is created equal." I don't believe we are created equal. I believe every man is created with equal opportunities, and he ought to have them. Every one of you ought to have equal opportunity to stand up here and argue the way I am. That is all, and by that freedom (of having each individual get one vote), the men who can influence the others by leadership, knowledge and other qualifications, will have more influence, more votes, so to speak but it will work out naturally. Also, there will be danger that men who are ignorant or passionate might lead other people away. True, but we must never be afraid, because a thing will be abused, that, therefore, we must not use it. No matter how efficient anything is for good, the more efficient it becomes, the more dangerous it becomes if it is abused. The sharper your knife, the better it is when you cut meat with it; but the worse it is when you cut throats with it. But we don't say, "Let's have dull knives because somebody might cut throats with them." We want our knives as sharp as possible, and then we want to make people intelligent so they will use them properly. We want as much democracy as possible. Give all citizens the vote, and they will be responsible to the public if we educate them and make them as intelligent as possible.

MR. E. W. CASE (New Departure Mfg. Co., Bristol, Conn.): I would like to ask Mr. McCormick whether he has in mind, or can give us, the percentage of labor turnover he has under his working conditions?

MR. McCORMICK: No, sir, it is small in actual figures. It is smaller than it was before we put in the plan. That may be due to the plan, or it may be due to a resumption of somewhat normal conditions following the close of the war. We have only been operating since about April 1, and I doubt very much if we can get any real indication of the answer to that question until the end of a suitable period, say a year. My impression is, as in the case of efficiency (having to do with the question which some one asked a moment ago) that questions relating to labor turnover will be answered satisfactorily by those who believe in employee representation.

CHAIRMAN YOUNG: There has been a very definite reduction of the labor turnover but, as Mr. McCormick said, it is not directly attributable to our plan of employee representation.

MR. LEISERSON: Let me tell you what the union does in regard to that. It makes an agreement with the employers that, "The following shall be the scale of wages for this season." The employers are awfully anxious to get out their stuff and they go swiping labor from one another. It upsets the wage scales, and the union has, in a case that I know of, issued an order that men who have gone to other places for \$5 a week more, did that in violation of the agreement. "You must go back to the other place because we have got to keep our word or we can't make this thing work." That is reducing the turnover in spite of the employers.

MR. MACLACHLAN: In connection with the Whitley scheme as carried out in England at the present time: it might be of interest to you to know that among the forty-three industries in the Whitley Councils, there has not been a strike. In the Whitley Council the representatives of labor have not had the privilege of speaking except at the request of the chairman or members in the Council.

It has been said a number of times, especially in the United States, that the Whitley scheme necessitated or presupposed complete organization on both sides. If you will change that word "complete" to "reasonable," I think you will get closer to the facts. There are operating in Canada at the present time Councils under the Whitley plan in which complete organization is not the fact. Reasonable organization is all that is necessary.

MR. McCORMICK: If you will read the pamphlets on the Whitley Plan, you will find that while the word "complete" may not be one hundred per cent correct, it indicates a strong desire. I do not remember the words, but there are various stages of industry described in the Whitley reports in which the industry can be catalogued until such a time as the organization is complete enough for it to operate under the Whitley Plan. The intent and the direction of the intent is organization.

MR. PALMER: Some little while ago a gentleman asked if there had been other plants operating under joint control, the success of which could not be attributed to the charming personality of Mr. Leiserson. I would like to know if Mr. Leiserson is familiar with the electrical contractors' industry. Some time ago I listened to Mr. Sullivan Jones

describe their Conference Club and their industrial citizenship, the definition of which he gave as, "The right of the employee to self-regulation and self-direction." Are you familiar with their plan in New York?

MR. LEISERSON: I am not familiar with the electrical workers' plan alone, but the building trades of New York City have for many years had a plan very similar to ours. They had a board of business agents of the union and a board appointed by the employers, which tried to settle all difficulties, and if they couldn't agree they had an umpire. That thing in my judgment was a mistake. They called a person in who was not familiar with the industry, and he usually split the difference, satisfying neither one side nor the other, and so, when the next case came along, they didn't want the same umpire, and that always caused difficulties which they never have gotten over. I think that when they have a permanent chairman who will be on the job and know the industry completely, then they will be able to take their plan very much further than they have gone so far. I think they have done a great deal in stabilizing conditions in the building industry in New York, and that has been going on for quite a number of years.

MR. C. P. TOLMAN: I would like to ask Mr. Leiserson: Are you familiar with the practice of conducting balloting in the locals of the unions?

MR. LEISERSON: Yes, sir.

MR. C. P. TOLMAN: Having in mind your definition of democracy, do you consider the unions as democratic as the McCormick organization is?

MR. LEISERSON: I am not able to say, because I don't know the McCormick organization, but I will say that I do know Mr. Young pretty well, and anything that he has to oversee will be thoroughly democratic. I will say that balloting in the union organization on the whole is just about as honest as the balloting for political offices in the United States. Not a bit better and not a bit worse.

MR. R. M. LITTLE: The tap root of democracy is the consent of the governed to the will of those in control. That means leadership. We American people are trained to recognition of the majority vote when one vote counts just as much as another. When you come to apply the principles of democracy to industry and you make it by majority vote, is it going to work?

MR. LEISERSON: I will say it will work in industry just about as well as it worked in politics, because I know of no other scheme, or kind of voting, that is half as good as this. This isn't perfect, by any means, but any other scheme—and many schemes have been tried from Grecian times down—any other scheme by which you give one man power is bound to fail.

CHAIRMAN YOUNG: The keynote of this afternoon's meeting is that after all it is the spirit of the plans that counts and not the word; it is the manner in which they are executed and not the mere phraseology of their structure that counts. Please bear that with you.

General Session: Americanization

October, 2, 1919

RICHARD A. FEISS Chairman

Joseph and Feiss Company, Cleveland Ohio

CHAIRMAN FEISS: While it is most unfortunate for me, it is fortunate for you, I believe, that I am forced to leave you very shortly, having been suddenly called out of town, and Mr. Price has secured Mr. Morey for my place.

I wish to add my little welcome to all of you who have come here to take part in this great meeting. I have indeed a great privilege and pleasure, although it is going to be curtailed, in being the presiding officer of record at this afternoon's meeting, because I think there is nothing more important than the Americanization movement in connection with the safety work that is the real work of this organization. It is not only the hand saw, the blade for the cutting machine, that has to be guarded, but there are a lot of things that affect citizenships and the individual. And so, it is mentally as well as physically that we should safeguard and I believe alongside the slogan "Safety First", "America First" would be a very good second slogan.

I feel sure that the thing you are going to hear today is going to be of that real kind of Americanization not tinged with any race fear or race prejudice, but the kind of Americanization the American needs as well as the foreigner. And I know of no one who better could introduce the subject than Mr. Allen T. Burns who we know so personally headed up the famous Pittsburgh and Cleveland campaign. I take great pleasure in introducing Mr. Burns, Director State of Workings of Americanization, formerly of Cleveland and now of New York and the United States.

PRINCIPLES AND METHODS OF THE AMERICANIZATION MOVEMENT

ALLEN T. BURNS, Director State of Workings of Americanization,
New York City

An Americanization worthy of America sums up the principles and methods of Americanization that are most effective. An Americanization as broad, as human, as ennobling as America itself, nothing else.

will compass the task that we think of and should think of under this much used and much abused term of Americanization.

To be sure, during the war we inevitably view the situation in a narrow, prejudiced, and biased way. We cannot take the general, broad, and inclusive view of America's tasks when we need to concentrate on a single great objective, as under the circumstances of the recent war. Doubtless, on that account, with the hysteria and fears growing out of the war, we felt that any difference, any variation, any non-conformity, was a danger to the welfare of our country, and for that reason we have been carrying on definite Americanization and think of it as a means of securing exact similarity or conformity, identity with some particular type of external form or set of performances.

But, if we think at all of America, we will know that America from the time of its earliest settlement was no such uniform, homogeneous group of people. America has given its great contribution to the world just because it drew from the riches and treasures and labors of all the past and has turned them to the good use of humanity.

It is such an idea of America that is adequate and only such that is adequate in fulfilling this task in which all of us are now so interested.

So, this afternoon let us turn away from some of the narrower views, some of those we have been driven to by war and its necessities and emergencies, and let us examine some of those great principles and practices of America which must be followed in an Americanization that is worthy of our country.

JUSTICE FOR THE FOREIGN-BORN

Nothing is more fundamental to America than justice. No abstract, obsolete justice is referred to but in this connection an even-handedness and fair play as between native-born and foreign-born. That is what the immigrant expects when he dreams of coming to the land of liberty, and it is with that standard that he judges America after his arrival.

So, whether America becomes the promised land to him or not depends very largely on the justice he finds, and today we are in grave danger on this score. Among the injustices practiced upon him, none are greater than that which is now to the forefront of trying to lay our industrial troubles at his door, attributing to the men who were good enough Americans to fight for us, to subscribe to the Liberty Loans for us, the underlying cause of our great industrial unrest.

We should all be thankful that Mr. Gary in his appearance before the United States Senate did his part in laying this bogey to rest, for he said, as you will remember if you read the testimony: "Throughout the war our workmen were loyal. While it is true that there is a radical element of foreigners at the present time, it is only doing justice to say that in my opinion the majority of foreigners were good citizens."

"Do you mean by foreigners," he was asked, "those not naturalized?"

"I include all foreign-born."

And yet in connection with this regrettable struggle in the steel industry, the cosmopolitan press is laying the trouble entirely or almost

entirely at the door of the foreign-born. A little thought such as Mr. Gary evidently had taken should remove that mistaken idea from our minds.

Will you just stop and think it was only a month ago we were raising a hue and cry about the demands of the railway organization made up of over ninety per cent native-born.

In this city last week or week before the miners were meeting, almost as foreign a group of working men as the steel workers themselves and they formulated a demand which is the subject of considerable anxiety and more than that, they formed a very close working alliance with these same foremost, from the native-born point of view, railroad brotherhoods. So that in the very near future it is going to be hard for us to pick between the native and foreign-born American, if we think we can explain our industrial unrest in any such easy way.

If you take the various steel towns affected by the steel strike, you will find that there is no consistency as to the foreign or native-born group in the towns that are closed or operating. To be sure Gary closed down and it is a little more foreign than Homestead which was open. Duquesne stayed open with sixty-seven per cent foreign-born and Sharon closed with only forty-two per cent foreign-born. So, I could go down the list showing the line did not run between the foreign-born and native-born communities in the success of the strikers pulling out or stopping complete operation in any mill.

In the same way, you will find the variations run in the proportions of the foreign-born in the various communities who have become naturalized. The mill town that shows the largest proportion of foreign-born adults seeking Americanization is the same great steel town of Gary, which only a week ago when I went down through there with a steel engineer showed no chimney showing smoke and in the steel engineer's opinion that would indicate it was entirely closed down.

STRIKING POLICEMEN ALMOST ALL NATIVE-BORN AMERICANS

Not only the question of any particular strike but all the general industrial, economic, and political unrest is thus unjustly attributed to the immigrant; and yet when you remember that most un-American police strike in Boston less than a month ago was made up almost entirely of native-born Americans and three hundred who had fought in our armies across the seas, you will see that there is something that underlies the situation deeper than native and foreign-born. So again the newspaper reports from Omaha indicated exactly the same situation there.

Take the most radical movements in this country like the I. W. W. and it has practically never been called to the public attention that every delegate attending the annual convention in Chicago was a native-born American. If you have studied the split between the Left Wing and the Conservative Group in this country, you will find in the Radical Group names like Reed, Young, Eastman, and in the Conservative Group such names as Hilquit, Meyer, London and Berger.

So again whichever way you turn, the Americans if they stop to think would realize that if they are trying to get rid of industrial unrest merely by attributing it to the foreign-born, it is like trying to clean the dirt in your room by sweeping it into the closet. It is as ungrateful and unfair as to put an unwelcome new-born babe on the doorstep of your neighbor to get rid of him.

Industrial unrest is a much greater problem than native and foreign-born. We are only further protecting the art of alienating the alien in making such accusations. We should be grateful to Mr. Gary for defining the issue as one of unionism and not of alienism.

But, there are constructive forms of justice in industry and elsewhere which it is necessary for us to practice and as we do practice them we most thoroughly and effectively unite the immigrant with us.

SAFEGUARDING THE IMMIGRANT

Americanization has been talked of almost altogether too much as we used to talk of religion, something that is a separate department of life, something you could shut off and use on Sunday and not use on the other days. Americanization is no more that thing. Americanization cannot be confined to any department of industrial, political, or educational life. Nor do I know of a better form of Americanization than the work that you men and those you represent are doing, the providing for the safety of the immigrant as well as for the native. That is the kind of even-handed, fair play that makes him a part of us, unites him solidly with us.

You men might well, it seems to me, have a section conference where the rest of us could be learners, where you would tell about the methods that are most effective in safeguarding the limbs and bodies of the immigrants because with his lack of knowledge of our language, his more direct coming into industry from the peasant life of the old country, you know how additional problems for you are produced by him.

Now the kind of Americanization for which we must plead is that which goes just as far in providing for him, not doing exactly the same thing you do for the American but making just as cock-sure that he is safe as that the native-born is safe. I am sure that is the kind of Americanization in which you believe because it is American justice.

Again, I suppose there is nothing in which you are more interested after your work of safety than our accident compensation law. You know that in some states there is a great difference made in the compensation paid according to whether the man is an alien, and according to where his family lives. Now, hunger and cold and all kinds of deprivation are no respecters of nationality. I have always found that the foreign-born family would suffer from cold and hunger as well as the native-born.

I plead with you because of your intense interests not only in American justice but in our accident compensation law to see to it that our alien feels that his interests are as adequately protected by American

laws as our own sons. There again is the kind of even-handedness which means general Americanization.

THE MCKEES ROCK STRIKE

Do some of you remember the McKees Rock strike, that bloody struggle of ten years ago? That and its settlement again showed the necessity not only of absolute justice but of giving the immigrant as fair a show as is given the native-born.

All of you are more or less near the employment service of the firms you are connected with. You are another one of the human elements of service. How far with our rapidly advancing science of employment have we considered that it might be relatively as profitable and human to give the particular personal attention to the immigrant employee as to the native employee? More and more you are studying personalities and capacities. But, how easy it is to do that with the native-born and to treat the foreign-born all as herds of cattle or as mere cogs in the industrial machines!

Some of our foremost plants, we find, are being careful to introduce as assistants into their employment service men who can speak to these men, coming into close understanding with their problems and possibilities and what they have to offer to the industry. This McKees Rock strike was brought about by a failure to do that, and its settlement by doing that for which I am pleading.

The pool method of production and wage payment according to what the gang turned out and not according to what each man turned out, was put into effect without any effort being made to explain to the working force, so that when they came to pay day and their envelopes differed from what they had been receiving and expected to receive, they struck: and the settlement was made largely upon the basis of the company agreeing to establish such assistants in their employment office as to make it possible for the immigrant workers to understand and confer with the company about their grievances and problems.

If we are to give the impression that America is a land of justice, of equal treatment and opportunity for all, in the development of our employment service we must be as careful as that to see that the impression and treatment given the immigrant is even-handed.

Just as much can be said about the need of justice and fair play to the labor union as to the employer, for one of the reasons that the immigrant is suspected of all this radicalism is that he has been like a flock without a shepherd, left in an unorganized state. He has been more easily the victim of those who would exploit his ignorance or his lack of familiarity with American conditions and because from the great American labor movement he has felt excluded. He has felt neglected and ignored by them as much as he could possibly feel in the case of the employer, so that it is a general plea for justice as a fundamental feature of Americanism, justice in our relation to the immigrant, which is so fundamental to his well-being and which is equal to what we Americans expect of America—what the immigrant himself has hoped of us.

PUBLIC EDUCATION

Another great principle of Americanization is public education. And here again the industry has been most progressive in helping public education and our school systems to find the way to educate the immigrant. The danger now is that many a plant here and there, having found successful teachers for the immigrant, shall be convinced that the whole problem of instruction of the immigrant can be handled under private auspices and at private expense. In this way there are springing up all kinds of royal roads to learning of English and citizenship.

There are classes in which foremen can be trained in four lessons to teach foreigners English adequately. There is perhaps no greater specialty than the teaching of a foreign tongue, and with all the good work that has been done in the industry, we can be quite sure that in the long run our great American school system is going to be the only adequate agency for meeting this problem. That does not mean in any sense that industry is to give up its part. Very often the easiest places for the classes are in the shops where they can be held immediately after the men are through their toil, where they do not have to go home and change their clothes and wash up and where they can feel perfectly at home. The practice has become wider and wider in cities like New York, Chicago, and Cleveland which have made the greatest progress in this work, of the industry helping to organize the class and looking upon the public schools as the means of furnishing the teacher, the standard of work and the general supervision. The Y. M. C. A., which is one of the pioneers in this field of work, has come more and more to this practice and is coöperating with the Americanization Committees in organizing classes, only to turn them over to public school systems.

The resources, the technique, the general right of the public and duty of the public to provide such education, I am persuaded America will not overturn when it comes to those who perhaps need more urgently than any others of our people the services of the public schools.

But, let me add one other reason why it is going to be increasingly more effective to use the public school system and let it be known that the classes are under its auspices. Industry has enough troubles, as has already been indicated, growing out of many suspicions, some true and some false, many of them false, to be embarrassed by any unnecessary suspicions among the working men. There is spreading the idea that there is some kind of industrial education—largely untrue but yet suspected—that the employer is going to put over on his employee, and that fear you can “pooh-pooh” at until you stop to realize that the best administration that New York City ever had was overthrown very largely because it was suspected that a very large employing interest had control of the public schools for the purpose of doing just that sort of thing.

So that in the matter of the educating of the immigrant, America can do nothing better than to reaffirm its practice and to preserve the responsibility of public education for the needs of the immigrant.

FREE COMMUNICATION

Very closely connected with public education in an adequate idea of Americanization is that of free communication, including free speech, one of those Americanisms which were inevitably restricted and interfered with by the war. But as we come back from that swing of the pendulum, we need to be sure that war necessities are not made peace practices.

There seems to be considerable danger that in the field of Americanization, our fear of differences of languages, identified with differences of loyalties in our minds, unnecessarily and unjustly will prevail under peace conditions. The result has been that many states have tried to enforce laws that would suppress the use of foreign languages in public assemblies. There has been a great deal of talk about the suppression of the foreign language press. Of course, that is all said without a thought about the century-old attempts that Europe has been making to suppress languages, because it was just that sort of policy that lay back of German imperialism and that policy that has broken the Central Powers. The attempts to suppress the languages of the subject people, their minorities, has resulted in breaking the Austro-Hungarian Empire into small fragments, for it is true, the more you attempt to suppress and coerce the use of a language, the more it strives and flourishes. All the world history points in that direction, so that there is danger that America shall disregard and fall into the errors of the European autocrats in this respect, for think what it means, not only in the way of creating opposition and resentment but in the direction of cutting off freedom. It means practically striking deaf, dumb, and blind most adult immigrants.

We all more or less have tried to learn a foreign tongue, and what facility, after we become adults, have we for reading, for instance, in another language? So that in all we say about schooling for the immigrants, don't think that the majority of the immigrants' information is going to come to him in the English tongue. That is contrary to human nature and practice. So whether as a fundamental of democracy the immigrant American keeps in touch with all that is going on in this country depends largely on whether he can be addressed in his own language and whether he can receive a newspaper in his own tongue.

VALUE OF FOREIGN LANGUAGE PRESS

There were some very startling indications of the usefulness of the foreign language tongue in the war. The much-discussed Committee of Public Information established a precedent for giving to the foreign-born in their own languages everything that the Government wanted any of us to see. In a letter the provost marshal has stated that whereas the provost marshal's office had expected the greatest difficulty in the registering of the foreign-born, he wanted to testify that the enrollment had been as nearly one hundred per cent and as easy among the foreign-born as among the native-born because the army had had the facilities of the foreign language press.

The same thing can be said of the Liberty Loan Division of the Treasury and so on through the Employment Service, through the War Savings Stamps, and through every one of the Government agencies that needed to mobilize resources and men for the great purposes of the war. The foreign-born responded so nearly a hundred per cent because we did not cut them off from free communication with us. In fact, there came to our notice many illustrations of how foreign languages through their newspapers and their addresses had shown us the way into this war.

For instance, there was a foreign language newspaper in Chicago, a German paper, that had gone just as unnoticed as another one that had been advocating kaiserism and German autocracy ever since its foundation. But this first paper, of which we had been just as ignorant as of the second, had been, since its foundation around the time of the '48 revolution in Germany, trying to tell German-Americans, and would have told the American-Americans if they had listened, that they must overthrow this outpost of autocracy in the world, proving it understood America's task in the world much earlier than America did.

One day there came to our desk in New York a letter from a Division Commander in France expressing much concern because the French were so misunderstanding of our purposes, and he proposed that we establish in France a French newspaper that would explain to the French what the Americans had gone into the war for. That same day there came in this report from one of our staff in the northwest, that up in a Swedish community where all the papers were now being printed in the English language, was one continued in Swedish. Upon inquiry for the reason for that, it was given that this paper had a large circulation back home and it was now at work explaining to the Swedes the American purposes in the war. That was just at the time when we were wondering whether Sweden might go over to the cause of the Central Powers. The thing that this General saw as a piece of military strategy in France, an obscure paper in the Northwest was doing for us in Sweden. Thus, if the great idea of American freedom of communication is not maintained, not only will we cause the utmost resentment and provoke a revolution, perhaps, more quickly than anything else can do, but also cut off the most valuable means of our Government's and our localities' getting and keeping in touch with the immigrant groups.

There is now a national organization, the sequel or successor of this foreign language division of the Public Information Committee, doing this work for the Government and every Americanization committee in local communities could do nothing better than form alliances with the foreign language papers so that when we announce special exhibits at our art museums, etc., the foreign-born would know about them as well as the native-born, or whenever there is a safety parade, he would know of it.

Whatever is of interest to the native-born is perhaps of greater interest to the foreign-born for we are as curious to him as he is to us, and he reads it with as great avidity as the American as the experiment of the Government shows that every attempt to enter into free, general communication with him was met eagerly.

SELF-DIRECTION AND SELF-ASSERTION

But, there is one other great practice and principle of Americanization, the greatest of all, that is also in my mind most effective in Americanization. It is all summed up in that phrase "self-determination". Whatever else the American is, we pride ourselves on being self-reliant and self-assertive more than any other people on the face of the globe. We are freer from traditional restraint and control and habit. We are more willing to sail uncharted seas. In industry, we are most familiar with its effect on production. We are constantly boasting that the reason American factories can turn out so much more merchandise is because the American is more resourceful, has more initiative.

We take pride that our army was as effective as it was because the ordinary private showed that same self-assertion and resourcefulness.

Now, that most peculiar characteristic of the native American is just as much a characteristic of the immigrant American for immigration is a great process of natural selection, whether we are talking about immigration in 1919 or 1619. It takes the same kind of people to break with their past, to pull up their own roots from where they have grown, and transplant themselves into a foreign soil! We scarcely realize, perhaps, how much the immigrant is exactly like ourselves in this most fundamental characteristic! That which brought our forefathers here brings these new Americans and it is because of this great insistence upon individual initiative and freedom that America is the kind of land and government it has come to be.

That being true, there is no more precious characteristic of this new America, no more tenacious characteristic, than this right of self-direction and self-assertion, and you may be sure that this fundamental ingredient of American democracy is going to be as much safeguarded by the new as by the old America. So, if there is any attempt to coerce to a conformity that is artificial, that is inhuman, our efforts are going to fail utterly.

AMERICANIZATION THROUGH GROUP ORGANIZATION

The most effective things that are being done for Americanization today are the things that could be well-defined as self-Americanization. If it were possible for us to take away this initiative, this self-reliance and self-assertion of the new America, we would never have an American left. He would become some kind of a puppet, but never that individual that makes up the great democracies.

Now, with that understanding, you will understand what your next speaker is going to tell you about why the Liberty Loans succeeded so well among the immigrant groups. It is because the immigrant groups themselves were called in by the Treasury Department to do that piece of work. In every single other task that we want immigrants to do the work, the immigrants themselves are often running far ahead of that which we are planning for them, and if it is planned by us as a program to be put over upon them, the failures are so numerous that it is no wonder we give up in despair as often as we do.

We will take a safety program or a health program, which is so popular now in American communities, and we devise them and we promulgate them and we promote them and we wonder why under heaven, for instance, the children's year took so little with the foreign group.

Mr. Rieg is going to tell his experiences in the Liberty Loans. On the fourth of July we were together at a great Italian picnic in Chicago where one hundred and twenty-five Italian societies that were founded primarily because of sickness and death were represented. That certainly was of health interest in Chicago. They were gathered to form a federation to call upon the resources of Chicago to help them. Well, the politicians were there. City Hall was well represented. They were wise enough to realize that the way to deal with the immigrant is to deal with his organization. The labor leaders were there. The foreign press was there. But, not a single representative of the health interests of the City of Chicago was present, apparently ignorant and blissfully ignorant of the affair.

Here was a group groping for ways to improve their own health, and largely because our own program was a self-made program and in no way related to their point of view. It will be no wonder if things go there as they do in other cities. The Italians will go groping on and the native Americans will go groping on and no program can be successful until the foreign population are made full partners in it.

I could go on telling you illustrations of how the foreign-born are Americanizing themselves through their coöperative activities, their self-directed, self-governing groups, but just let me sum up in closing that an Americanization that is worthy of America must include these fundamental principles of justice, public education, free communication, and self-determination, for only as we are loyal to the best in America will we make the new Americans the best Americans.

CHAIRMAN MOREY: To me one of the most significant things Mr. Burns has said is that the American problem is not just with the foreign-born, for I believe that many a foreigner brings the ideal of Americanism to America, and he has it in his heart more than some of those whom he finds here.

Our company employed about twenty-four hundred men last year, perhaps half of them are foreigners or descendants direct, and I find them tractable. I find them not the trouble-makers. The only problem with the foreigner seems to be to give him information, to make him understand. But, his mental processes ring true, and when we Americans in America can learn what Americanization is, then we will have a very much different problem. It is not just with the foreign-born.

I think it must have been with that idea in mind that the next subject was written, "The Immigrant's Part". Only part of our problem is with the foreign-born.

We are fortunate in having with us Mr. Hans Rieg, Chief, Foreign Language Division, War Loan Organization, U. S. Treasury Department.

Mr. Rieg has had wonderful experience with the Liberty Loan floatations and he can tell as much from immediate contact with this foreign-born problem as anybody.

THE IMMIGRANT'S PART

HANS RIEG, CHIEF FOREIGN LANGUAGE DIVISION
U. S. TREASURY DEPARTMENT, WASHINGTON, D. C.

You can take iron ore, smelt it into pig iron, and roll it into angle or round, as you desire. You can take a tree-trunk, saw it in two and shape from it whatever you want. You can take a huge rock, split it or chisel it as you see fit.

You can take any inorganic substance and by mere application of mechanical skill or chemical process change its nature and its shape.

But you cannot do this with anything organic. In plant-life you can only make desired progress in the process of changing shape or character by patient application of scientific methods.

In animal-life the same applies. When we finally approach the human being, it is obvious that the process of changing, reforming, remoulding of habit, custom, sentiment and language will be slow. This process must be scientific, sympathetic, and above all based upon the coöperating and coördinating consent of him, who is so to be changed.

You cannot make an American out of a foreign-born by force, nor in a day.

Any government which will attempt to nationalize its subjects of various racial origins by forcible or arbitrary method will ultimately come to harm. This is not idle theory, but established historical fact.

There are in the United States of America more than 15 million born in foreign countries; over 14 million more are the children of foreign born. Of these 29 million, more than 50 per cent speak and read either exclusively or preferably the tongue of the country of their origin. In the aggregate, they converse in at least forty-seven different tongues. They read 1,394 publications printed in 35 different languages. The combined circulation of these publications is about 14,000,000, and more than 8,000,000 individuals read nothing else, because they can't.

Thoroughly cognizant of these conditions within our country, and having an extended knowledge of the traits, customs, and languages of these many different racial groups represented within our population—gained partly through contact with and observation of them within our own land and partly through world-wide travels in their own countries—I fully realized that in order to arouse their enthusiasm in behalf of the financial enterprises of our Government as a consequence of our entry into the war, it would become necessary to conduct a highly specialized campaign.

When borne in mind that the Bureau of Publicity of the Treasury Department was organized May 7, 1917, and the campaign for the First Liberty Loan opened, but twelve days later, it can readily be seen that time was most valuable. Within a period of three days I proposed the formation of a distinct Foreign Language Division, formulated a plan of activity and organization, obtained the approval of W. G. McAdoo, then Secretary of the Treasury, was placed in charge of this Division and started operation May 11, 1917.

Just as scarce as time, was working material. Everything had to be dug up. Authentic and up-to-date lists of publications printed in foreign

languages, lists of national organizations of all kinds with members of foreign birth or extraction, statistics on the various racial groups showing where they predominated, how engaged, their leaders, etc.—all this had to be gotten, and gotten quickly.

I did the best that could be done under the many adverse conditions and showed noticeable results in behalf of the First Liberty Loan.

Immediately after the first campaign, steps were taken to organize more thoroughly this specialization along national lines. I was authorized to make trips to the various Federal Reserve centers, in each of which a Foreign Language Division was established. In addresses before racial groups, editors and publishers of foreign language publications, etc., I drove home the exigency of organized and undivided support of the government so that by the time the Second Liberty Loan was announced, a nation-wide, highly specialized campaign in its behalf could be conducted, which reached into almost every nook and cranny inhabited by foreigners.

A special poster was designed for distribution among the foreign-born. Special publicity material was prepared. Some twenty-odd thousand organizations, both civic and church, were directly appealed to, and racial group leaders, pastors, priests, and presidents of organizations were enlisted in the campaign. All these agencies responded most willingly, and seemed to welcome the opportunity of doing something for their adopted country.

As a consequence, the response to this Loan from that part of our population was amazing. Subscriptions came not only from least expected sources, but in most surprising manner, both as to numbers and amounts.

The interval between campaigns was used to extend and intensify the organization of the existing Foreign Language Divisions throughout the Federal Reserve Districts, steadily to enlarge the lists of organizations of all kinds with a membership of foreign extraction, to keep the interest alive and increase it wherever possible—preaching loyalty, patriotism, and 100 per cent Americanism at all times.

FORTY THOUSAND ORGANIZATIONS HAVE FOREIGN-BORN MEMBERS

So that by the time the campaign for the Third Liberty Loan was launched, contact had been established with more than forty thousand organizations and with every foreign language publication in the United States. Racial group committees in Foreign Language Divisions of Federal Reserve Districts ranged in number from eighteen to thirty-seven, representing as high as forty-three distinct nationalities, their number depending upon the number of their kind within the district. Steps also were taken to provide facilities to record and tabulate the support of these various nationalities to this Loan. This was done for a double purpose; first, to establish rivalry and thereby stimulate production, and second, to enable the Treasury Department properly to give credit where credit was due.

The tabulations of the subscriptions to the Third Liberty Loan, as reported to the Foreign Language Division of the Treasury Department either directly or indirectly through the Foreign Language Division of Federal Reserve Districts, show that thirty-eight nationalities produced

\$741,437,000, or 17½ per cent of the total amount subscribed, and 7,061,303 subscriptions, or 41½ per cent of the total number of subscriptions.

The showing in behalf of the Fourth Liberty Loan was even more gratifying: \$1,114,536,350, or 16 per cent of the total amount, came from those of foreign birth or foreign-born parentage, and the number of individual subscriptions was 10,614,632 or 46½ per cent of the total number.

The response to the Victory Liberty Loan, in proportion, came up to past achievements.

Backing up most intensified organization among all these various races and nationalities, the Foreign Language Division prepared publicity material in thirty-four different languages. Special posters, pamphlets, editorials, feature stories, news items, copy and cuts for display advertisements, and personal appeals published over the signatures of racial group leaders were given national circulation. Take just one item: A lithographed reproduction in colors of the "Americans All" poster, which had been especially designed for that part of our population, was circulated to the number of seven million copies as an art supplement through the foreign language press.

From all this it is obvious that this specialized work was not only necessary, but most productive. The actual results should be measured not only by the amount of dollars produced for governmental purpose but also by their benefits to the foreign-born which, I believe, are much farther-reaching.

Let me sum up a few of these benefits:

First, it has brought the foreign-born back to the thrift and saving he had learned as a child and which extravagant America had made him forget.

Second, it tied him to this country by a new bond, and laid the foundation of a deeper, better citizenship. A Liberty Bond has nothing in common with anarchy, atheism, and soap box Bolshevism.

Third, the unification of each race among its own people and of dozens of races in a great movement like this got them acquainted, blotted out racial and religious differences and merged all in Americanism.

Fourth, it has made every native born, the so-called *simon-pure* American, who has come in touch with this ground swell of foreign-born Americanism, have a deeper confidence in the future of our country and a holier appreciation of the liberty and democracy, which those who were born here take as a matter of course. From these many peoples from many climes, now all under one flag, we now have an outward and visible sign of that inward and spiritual Americanism which is evidenced by our country's motto, "E Pluribus Unum."

However, as stated, these results achieved, amazing as they are, could not have been achieved without specialization.

To employ similar means in behalf of Americanization is obvious.

It is equally as obvious that Americanization is one of the most important tasks before us. As already indicated, we have now been made to realize as never before the importance, both as to *quantity* and *quality* of that part of our population which is of foreign birth or foreign-born

United States, and that more than 8,000,000 individuals read nothing else but such. It is their only source of information. Information begets education. Take away from them this source and you will create most fertile soil for undesired, detrimental and sinister propaganda. See to it that this source of information is made thoroughly American and clean—this can be done—and you have the desired and necessary medium of national benefit.

The invaluable service which the foreign language press rendered to the government during the time that we were at war is a matter of indisputable record. Not only the Treasury Department, but the State, Army and Navy Departments of the United States, recognize it.

Equally as valuable service can these foreign language publications render in time of peace. I consider them an absolute and peremptory need, a need not temporary but lasting, as long as we have within our midst people not thoroughly conversant with the English language or totally unable to speak it, and as long as we shall welcome to our shores for either permanent or temporary residency, peoples from foreign climes.

Well do I know that there exists great difference of opinion as to this. Let me assure you that I, as fully as you, am cognizant of the extended criticism, in many instances most severe, and by no means always just, meted out to those publications which are printed in foreign tongues.

This criticism has come from various sources. It has been prompted by many motives, and neither source nor motive has always been pure and unselfish. However, some satisfaction is to be found in the fact that equally as great men have been for it as have been against it. No matter how eminent or wise a man may be, he cannot always be right. But when it comes to the advocacy of complete abolition of foreign language newspapers, then I shall make bold to assert that no matter which the source or who the man, they are absolutely wrong.

I make the claim, as already indicated, that the foreign language press was as necessary to the successful conduct of the war as it is necessary to the safe, harmonious, and orderly conduct of the forces of our Government in times of peace. My friends, it is as necessary as a law of gravitation to the flow of the waters of the Mississippi.

However, there must be a vital and most thorough change in fundamentals and general policy. Let me sum up what I mean by this in these words:

AMERICANIZE FOREIGN LANGUAGE PRESS

What we have had have been Italian papers printed in America, Polish papers printed within our country, Bohemian papers printed within our land, German papers published within the United States, and so on down the list. And that is wrong. What we must have are American papers printed in Polish, American papers published in Bohemian, American papers published in the tongue of Italy, American papers printed in German, etc. Just as the individual who comes to us from foreign shores with the intent to live here and to benefit from the advantages of our land is expected to swear allegiance to the Stars and Stripes and mean it when becoming a citizen, so must the foreign language press become

permeated with undivided allegiance to but one country. It must be the mouthpiece of unadulterated American patriotism and its keynote should at all times be full-fledged loyalty without reservation, to but one country, the United States of America.

No objection should be had to the conveying of information pertaining to the countries from which their readers come, but serious objection should be raised to the treatment—editorially or otherwise—of matters from any other point of view but the American point. It will mean the preaching of American doctrine pure and simple. It will mean the performance of one of the greatest, noblest missions which can be allotted to any one. It will mean that the foreign language papers will drive home to their readers, conversing in many tongues, not only the blessings of our land, but also their obligations toward it. It will mean the thorough and expedient unhooking of the hyphen, gradually embracing all our foreign-born within that great big family circle of "Americans All" and for "America First"—the greatest nation and the grandest country in the universe.

CHAIRMAN MOREY: The immigrant coming to our shores incidentally comes into contact with governmental agencies, but it is only indirectly that he thus comes into contact with Americanism as a political institution, but he does come into direct and immediate contact with our industries. That is where his family is concerned. That is where his bread and butter and clothes are to come from, and he is to be taken care of. As Americanism is interpreted to him through that contact, that contact is what he thinks of America.

Our next speaker will treat of the responsibility of the industry—what the industries can do in this matter. We will be pleased to hear from Mr. H. T. Waller, who has been with the Educational Department of the B. F. Goodrich Company.

WHAT THE INDUSTRIES CAN DO FOR AMERICANIZATION

H. T. WALLER, AKRON, OHIO (FORMERLY EDUCATIONAL DIRECTOR,
B. F. GOODRICH COMPANY, AKRON, OHIO)

The title of this paper could well have been reversed to read "What Americanization can do for the Industries", and the author would be most glad to discuss a paper under this heading. However, the Executive Committee have decreed a paper on, "What the Industries can do for Americanization".—we obey the mandate.

INDUSTRY OCCUPIES THE STRATEGIC VANTAGE POINT

Industry occupies a strategic position relative to the Foreign born. Industry has needed the man with the pick and shovel, the man with brawn, the man eager to make good, the man willing to work under all conditions and at all times. The industrial progress of this Nation has its foundation built by the supply of immigrant labor. Industry, however, during

the later years has come to recognize a much greater potential force in its unskilled labor than heretofore. It has come to recognize a terrific loss due to misunderstanding; it has realized also that only as understanding is created between employee and employer can best results be secured.

Outside of Industry certain social and educational forces have been working many years to create a better understanding of the foreign born situation. Many have recognized that only as a common language was used could the best of understanding be created and maintained, and to this end educational and social workers have been seeking to develop an Americanization consciousness that would appreciate the potential value of the immigrant. As the work progressed under private and organization leadership it soon developed that in order effectively to carry on Americanization work, in order to reach positively the great army of workers it was necessary to have classes and activities conducted where these people were brought together in natural groups. This place is the industrial plant. Watch the thousands of employees as they come to and leave work. They come from and scatter to all points of the compass. While in the plant and even in the departments of the plant are gathered large groups of these men who here, at least, have a common point of interest. It is the place where their daily bread is earned, and where they are earning that which will enable them to safeguard and enjoy the future. It has been found also that of all influences that are effective in dealing with the foreign laborer the influence of his foreman leads. Consequently, certain workers in this field have endeavored to develop a plan by which the largest number of foreign employees might be most effectively reached for the benefit of industry, for the benefit of themselves, and for the benefit of the community. For, after all, the interests of the one are the interests of all three, and injure the best interests of one and you will injure the best interests of all three. *For the basic interests of Employer, Employee, and Community are identical.* What then can Industry do? Occupying as it does the strategic vantage point.

RESPONSIBILITY FOR AMERICANIZATION WORK

Industry can and should supply within its organization a person or persons charged with definite responsibility for developing the best interests of the foreign-speaking employees in the plant. No outside agency can come in and do what this agency from within can do. It is necessary that Industry shall stick to its job of production and any work that is done must be so conducted as not to interfere with production, but this has a vital influence upon production, therefore, find a man or men with high purpose, social vision, and practical common sense, who will work together with the Foreman, Assistant Foreman, and American workers of Industry. The result will be an established point of contact with the foreigner that is bound to be of tremendous value. The men responsible for Americanization in the Industry must be men of Community vision, not men who are simply creating a department and a job for themselves. This latter point of view would be suicidal to the object desired. For when it comes to the question of instruction of the employees in the

knowledge of English, the ideal is the educational leadership of the community, namely, the Board of Education and the point of coupling the public educational forces to the industrial power is a delicate one and calls for splendid leadership on both sides. Industry can do more for the promotion of Americanization than any other single agency. In fact, Industry must do more, for it is to the best interests of Industry that it should be done. The type of community in which a man lives determines more than we now realize the type of production that he turns out. There is, therefore, a compelling economic force which determines Industry's place in this great problem.

INDUSTRY MUST TAKE LEADERSHIP IN AMERICANIZATION

Today we are facing the problem of a great labor shortage due to natural causes. The fact that foreign labor is returning to Europe is a natural thing, but if Industry and the Community had paid special attention to establishing a sympathetic, intelligent point of contact with foreign labor, the result would have been the establishing of permanent homes in this country on the part of the foreign laborer, to a very much greater degree than has been the case. Only in so far as we are able to establish this personal contact are we going to be able to stabilize labor. Industry must, therefore, take a position of leadership in the problem of Americanization, and where Community Educational forces do not recognize their responsibility for adult education, then Industry must and can take the leadership, and furthermore must see to it that there is a change in attitude on the part of the educational leadership in such a way as to meet the needs of the community which they are serving. One emphatic warning is essential in connection with this problem. Force, compulsion, paternalism should be shunned as though they were a plague. We do not want American citizens as a result of compulsion. Friendship is not a thing that can be forced. Friendship is the result of sympathetic understanding. Friendship will result in the building of an ideal community. Understanding will result in the creation of an ideal industrial relationship. It is possible to secure this through the point of contact established in Industry through the agency of Americanization leaders.

COÖPERATION OF INDUSTRY AND COMMUNITY

In the coöperation of Industry and the Board of Education there is a combination of Industry and Community that is bound to react most favorably upon the Individual, the Industry, and the Community.

Industry holds the vantage point of economic leadership. The solving of this great National problem will depend very largely upon the vision of industrial leaders who recognize the tremendous value of an intelligent understanding.

SAFETY ENGINEER SHOULD PROMOTE AMERICANIZATION

Safety work in Industry is an accepted part of industrial necessity throughout this country. Just what relationship the work among the foreign speaking employees would bear to the safety problem is compara-

tively easy to analyze. Every safety engineer will say that the best safety device known is a careful workman. Careful workmen are an impossibility if they are unable to understand instructions, both verbal and written. Every safety engineer should be an insistent promotor of Americanization effort. He, more than any other single department head in the Industry should understand the vital importance of a thoughtful, understanding working force. Only as every employee is able to understand and read warnings and instructions relative to dangerous machines is it possible to cut down the fearful fatality list, which is now a fact in our industrial life.

ESSENTIALS IN INDUSTRIAL AMERICANIZATION

Industry must then supply leadership, money, and coöperation in the work of Americanization. The leaders of Americanization also must take their position with the leaders of direct production, working with them in close coöperation in order that there may be developed an industrial life based upon sympathetic understanding and mutual helpfulness.

CHAIRMAN MOREY: The purpose of this session, as indicated by our program, is to ascertain, first, what an American is and, second, what we must do to make us all Americans.

We will now have a discussion of these splendid papers we have heard and I will ask Mr. George B. Fout, Supervisor of Night Schools, Youngstown Sheet and Tube Company, to lead that discussion for us.

DISCUSSION

MR. GEORGE B. FOUT: The first I have heard of these excellent papers is in hearing them presented here this afternoon, and the speakers preceding me have so well delivered their message and given you so much food for thought that it is hardly worth while for one who is so young. I don't mean in years but in Americanization work, to tell what the essentials are in these papers.

I simply want to say to you that I have been brought into the Americanization work by circumstances over which I had no control. In a community of fourteen thousand inhabitants, 97½ per cent of whom are foreign born. I was the first American-born leader who was willing to live among them, that I might be better able to understand them and to know their needs and try to work out their problem.

And, I want to say to you men and women interested in work for the foreign born, that although I have been a Y. M. C. A. Secretary and a religious worker nearly all my life, my happiest and most fruitful years have been the three years spent in East Youngstown, which did not have a very good reputation in the estimation of a great many people because of the things that happened there.

Our speakers have brought to our attention the attitude of the American to the foreign-born man, and what the American laboring man is thinking today about the foreign-born man working in the steel industry. I think I have had a good opportunity of discerning that this last week.

I want to say to you that, whether it is just or not, I am afraid that this crisis which is on us, instead of drawing the American-born workman closer to the foreign-born—this thing that has been brought about because of false leadership is going to work for his harm rather than his good.

If we are going to Americanize, first we have to decide what is American. If I should ask you men and women here today to select the American that you would want these foreign-born to become like, whom would you select?

(The audience expressed its choice as Theodore Roosevelt.)

Now I am going to emphasize what the last speaker has brought to your attention. As I have learned to know these foreign-born and to know their minds and needs, living among them and having them come to me with their woes and troubles and knowing their heart throbs, the thing that they need and are asking and longing for is for other Americans, not like myself but better than myself, who are willing to go down among them and live there and show them what to do, and let them know that their hearts beat with *their* hearts. If we expect to Americanize them, we have to be willing to do that, otherwise their so-called leaders are going to control them as they have done in the past and will do until we are willing to do it for them.

Just a few weeks ago when they had trouble in the Catholic church down there, they sent for one of their own nationality in Youngstown—a lawyer—to tell them what to do. He came and they got deeper in the mire than they were before. They went before the Mayor with their lawyer and committees requesting him to prohibit their priest from entering the church on the next day. It being just a few days before the strike was to be called, we were concerned, and they sent for the Americanization man who stands before you to go before the committee. I went and it was about a quarter after twelve on Saturday night when the factions were brought together. They are all satisfied now and the committee said I was the only man in the community who could do that because I was a native-born American.

I could tell you many instances where the work in East Youngstown has been developed and ideals have been given without a word being said about ideals, because I was willing to work and fight and give service to them so they couldn't refuse when I asked it of them.

A great many of the industries as well as their Americanization directors are saying that we must not let religion touch this question on any side at all. I want to say to you as a Protestant that I have lived in a community that is eighty-five per cent Catholic and have been before every foreign society and have attended many celebrations held in the interest of the Catholic Church. I have always been asked to speak at the meetings and have always spoken on religion, its needs and influence, and I have had the priest come and thank me for emphasizing ideals of what America stands for in home life and church life. I am not afraid of religion. They are the most religious people I ever came in contact with and they want it.

Last Sunday we had a lot of men shut up in the mill, and some of them wanted to get up an entertainment on Sunday night—a vaudeville performance or something of that kind—because the men couldn't get out. I am thankful to say that there were some men who had grit and sense enough to say "We want a religious service". I gave them a religious service last Sunday morning and again last Sunday night and they were all so well pleased that they asked for one during the week. I want to say to you, friends, industry can be religious and you needn't be afraid of it, either. I have been religious ever since I was fourteen years old and although I am not as good as I ought to be now, I believe in it and so do most of the men, especially the foreign-born.

NEED LEADERS WILLING TO MAKE SACRIFICES

Mr. Waller struck it when he said, "We want the men and women who are willing by their lives to interpret Americanism to these people." It is not only that we want it, but they want it more than we do. That is the most important thing in this whole problem—to have a leader who is willing to make the sacrifice and work twenty-four hours in the day if necessary.

Do you know that in these years, I venture to say, I have had fifty different organizations come down to East Youngstown that have looked over the field and said: "Oh, Mr. Fout, what a wonderful opportunity you have here. I would give anything if I could locate here." I said, "Yes, not anything, but it must be everything." They wouldn't give anything at all. They went away, all of them, and forgot all about the place and opportunity.

A very attractive worker called a few weeks ago. She had been over in France. I am an old bachelor and was in sincere hopes she would come and work. After looking over the field she said: "Oh, it is just the most wonderful field and the most wonderful opportunity." I said: "Are you going to come and do the work?" "Oh, no, I am only an investigator, but I am going to send down a worker."

I haven't heard anything from that organization, though. It is six weeks ago she was there and she promised to send some one in two weeks. I have come to the point where I feel like telling all investigators, "Please stay out unless you are willing to come down and do the work that ought to be done."

Let us know exactly what must be done and what we want to do along the right lines of Americanization, and then we will get where we ought to be in the Americanization problem, but it is only going to come by the sacrifices of those who really are willing to understand the foreigner and to sympathize with him in the efforts he is making in this his adopted country.

CHAIRMAN MOREY: Now let us have a good earnest discussion. We have touched some pretty deep things today and these gentlemen who have studied this problem and presented these thoughts are here to discuss them with us.

MR. R. D. HALL (Coal Age): I am one of those foreign-born of which

mention has been made today and I have been the subject in many years of the efforts of my friends to promote Americanization. I must say that I have not as a subject been very much impressed with the work that has been done; that my Americanization as it has come has come largely from my desire for Americanization rather than from the urgent efforts of the friends with whom I have been associated who have been very anxious to change my point of view.

MISTAKES IN METHODS OF AMERICANIZATION

I consider it possibly one of the hardest things in the world to start Americanizing anybody by a process of either compulsion or persuasion. I want you to get this into your head. I don't want you to think for one moment that it should be difficult for the foreigner to become an American because I do not think it is, but I feel very much. or I did feel when I first came to this country, in the position of a little child who had lost its mother and the mother it had was poor and the conditions of life were somewhat hard, and a rich person came along and offered to act as foster mother for this child, and every night before she put the child to bed, she said, "Don't you like me better than your own mother? Am I not a richer and a better and an altogether nicer mother than the one who bore you and took care of you in your youth?"

I think it is a mistake to attempt the naturalization system on the basis of running down a foreign country. It doesn't matter how much better this country may be than any other country, and I am prepared to admit all that you argue. It creates an antagonism in any event and any one who is an antagonist endeavors to say the very best on the other side of the question. You are so sure you have a good country—and you have it—that in time he will become a good citizen, and you can get him to wean himself from his neighbors who are of his own extraction.

I think sometimes that our Americanization work tends too much towards the political end. We Americans do not want any foreigner to become a citizen, to have the right to vote, until he feels that he is an American. Our tendency has been to give the foreigner a vote before he felt he was one of us. The last thing that should be given a foreigner is a vote. He should feel deep down in his heart an affection for the United States before he ventures to cast a vote. People used to say, "Well, why don't you become naturalized and get a vote?" It always seemed to me it was a crime almost until I had been thoroughly imbued with the ideas of America to cast my vote at all. I was perfectly willing to wait until a more perfect change of heart came.

I quite agree with the speakers who say that there will always be in the heart of every man a certain degree of affection for his native land. Please remember that the man who does not like his native land will never like our native land very much.

The man who has been the bad citizen from where he came and could never feel a responsibility to his neighbor and a feeling of gratefulness to him for his goodness will never be grateful to us for our goodness. If he is an ingrate, we do not want him. The man who has a live love

for his native land still resting with him after years of living in this country is possibly very much better an American citizen for that, because it shows he can remember his father and his mother and his childhood days and his little church and all those things which were dear to him and which will continue to be dear to him as long as he lives, and if you ask him to cast those things away, you ask him to cast away the very treasure of his soul and it is wrong.

Let us remember there are things in Europe that are sacred to every man and to ask him to change his point of view and to look with despectfulness toward it is all wrong. We should lead him to a higher and better life. It is some of those people who are most devoted to their native land who are most devoted to this.

I want to say something about other foreigners I have met—Magyars. When the war was on we were running more or less patriotic material in our paper. We also had posters and things of that kind and it wasn't for any purpose but creating patriotism. It wasn't long before the Szabadsag came to us and asked that some of the stuff we had run in the basis of the paper should be taken over by them. They used those cuts again and again. I know they were performing a patriotic service, and I think the statement made by Mr. Hans Rieg was not altogether representative of the facts because I believe there was a good deal of money given by foreigners of which we had no account whatever. I think most of them are very patriotic people. I believe they are determined to help the United States in every possible way, and the very best way for a foreigner to appreciate America after he has been in the United States a few years is to go back, and I assure you after he comes back from a trip abroad, he is a better citizen. I am sometimes sorry I have only been back once. They tell me when you meet a foreigner abroad who has been in America, he shows his true Americanism in his delight in seeing you. It doesn't matter how much he waves the flag, if he feels in his heart that he loves America, that is the thing for which we are aiming.

SALESMANSHIP THE KEYNOTE

MR. EUGENE J. ROESCH (New York City): It seems to me today that the keynote of the speakers and of the last speaker particularly is salesmanship.

We in America pride ourselves on our salesmanship. We are learning that in order to sell a product, you have to know your field and you have to know what you have to sell.

Now, let us consider this proposition from that standpoint. I feel, through years of residence abroad in my engineering work and in South America, that I have been better able to present America to the foreign-born because of that, and I would suggest that every man who expects to do real foreign work avail himself of some travel or connection with the foreign element. If he doesn't get abroad, let him go into the settlements in this country and study them.

There is one thing we have to realize and that is that America, just like the English language, is a growing thing. We have not stood still.

We have our ideals but they are growing, and so America is going on like a comet, dragging on more and more, and through accretion getting other ideals. We must realize, if we give anything, the people have something to give also. Give them a chance to give of their treasure.

It was my pleasure during the war to be connected with the Scoville Manufacturing Company in Waterbury and we had a number of problems at that time. We were prepared for unrest and also for keeping the health up, and all that sort of thing. I worked considerably with the Spanish and Latins. I like them. They are fine people. They are all fine people when you come to study them. They are all human beings—we must realize that.

STUDY CUSTOMS OF THE PEOPLE

Knowing a great many of the customs of the people, I will give you just one or two instances. There was one boy who was put among some Russians. He was a hot-blooded Spaniard who carried a knife. The Russians chipped him and the altercation was carried out into the street and, of course, he was arrested for drawing his knife. Our ideals are different and the judge who sentenced him to about two months on a very one-sided hearing didn't understand the custom of the Spaniards as I did. When he was in the jail in New Haven, some lawyer, the sort of chap who preys on the ignorance of people, offered his assistance. There again we get the wrong thought. We should suppress those gentlemen. If you want to Americanize these people, get them when they are in trouble and be a real friend, and you will get them by digging deep into the roots of their soul.

This boy, fortunately, had had some contact with us and he refused the aid of the lawyer and said that he would wait until he got into communication with me. I went to see him and told him it wouldn't be long before he got out. He was ready for a little dressing and he got it. In a few days he was free and he came to me and said, "Here is a hundred and fifty dollars. If I get into trouble, or if I gamble, you just give this money to the Red Cross."

Well, I am glad to say, gentlemen, that at the end of thirty days, the end of probation, he had reported either personally or in writing every day. I made that boy a leader of a number of Spaniards.

So on, one after another—rental troubles, oppression by landlords—get them and carry the case over. Use all influence, whether legal or not, fight for them and they will fight for you and this country.

Then we came to the flu. If you will pardon, this is a little personal experience, but it will show you what can be done. We had hundreds of men quartered in barracks, quartered on what is called Golden Hill. They consisted mostly of Portuguese, Spanish, and some limited service men, all the way from two hundred fifty to three hundred fifty people sleeping in barracks, perhaps seventy or eighty on the floor. We were rather concerned about the health of these men during the epidemic and so it was my job to sell those fellows precaution and health. I won't go into details. Every man who understands the things that promote human

beings to action knows the many ways with which you can work with leaders and groups and enthuse them. But, I want to say this, that those boys cleaned their teeth, took their baths, kept their windows open at night, exercised vigorously, and not one case of Spanish influenza developed among my boys on Golden Hill. Whenever there was a case of cold, the boys came themselves for the medicine.

They have their ideals and love of their home, of their games, and they had a chance to show some of our American friends their way of indulging in sports. I remember one evening when the American girls and men of the plants, and some of the boys from the office, about two hundred of them, saw an improvised Spanish bull fight. The bull was a human being but he was a pretty good representation of a bull. It was a total surprise to me except that I knew something, but not what was coming off. I let the boys figure out their own entertainment and do their part. In that way they imbued there, some of our spirit of fair play.

JUSTICE AND FAIR PLAY

I want to say if you expect to Americanize our very big population, you must not patronize them. You must sell them the idea of justice and fair play because you know them and have studied them and have put your best front foremost. We do not do that with our foreign-born. That is our trouble. We try our best to sell our goods, but if we expect to influence the foreign element of this country, we must really sell them the American idea.

MR. M. L. FEELMER (Local Council, St. Louis, Mo.): The addresses made by our speakers, the criticisms rendered in review of these speeches, the address made spontaneously by my English-born friend over here, just brings out a thought, and that is, that after all, when we talk about Americanizing the foreigner, there is just a trifle of a feeling of superiority in us.

Now, we have some very nice nicknames. The Frenchman we call a "frog". We forget that Dumas, Balzac, and a number of others were "frogs". The Italian we call a "dago". So was Dante. The German is a "dutchman". So were Goethe and Schiller. And, so it goes all the way through.

I have as yet to hear the first speaker bring out a very important point—to sell this great, wonderful, splendid country to its native citizens. Your foreign-born citizen usually knows more about America and its institutions than you do yourself. If you want to know America, if you want to know just how wonderful, how big, how great, how everlastingly beautiful American institutions are, let some foreigner tell you why they are so wonderful. You can't realize it unless you leave your own native land and compare conditions in foreign countries with those conditions which you, by an accident, have enjoyed all your lives and have taken as quite natural and as your just dues.

MR. WILES (Director of Americanization for the City of Cleveland): As an Americanization worker, I can say there has been no movement to discredit any foreign nation or any foreign tongue or any foreign prac-

tices, as they may be practiced there; but this is America, a country of amalgamation, and all that we are after is simply to continue the amalgamating or the melting or the weaving or the mosaic, or whatever else you want to call it. We are simply trying to bring people together. We are not trying to get a fellow to forget those things he loves in his motherland!

I never speak to a group of foreign men but what I make that point clear, Mr. Chairman: We are trying to get you to learn the language of America, not to forget your own language! That is the keynote.

Let's go away from this meeting this afternoon with this one thing which we will do: Whatever Americanization may mean, I am going to begin at the beginning, and the beginning of the Americanization movement in the minds of the sanest thinkers of this country is the acquirement of the language of America by those who do not know it. That is the beginning.

Now, in your factory, in your community, in your city, if the industry, if the Board of Education, if the social workers, if the Y. M. C. A. is not carrying on a program to bring that thing about, then it is not carrying on the first step of Americanization.

I want to take exception to the first speaker. It makes me a little peeved because you say a foreigner can't learn the American language just because you can't learn French! My trying to learn French in America is an entirely different thing. These people are living in the English language, speaking the English language, thinking in the English language! I promise you that we can take any man, fifty years of age or over, who has never had a day's schooling in the homeland, and we can give him a fairly good use of the English language in a year! Then, through a longer process we will give him those ideals of America, if he hasn't had them, and I know that most of them have them before they even come to America! Then, the last thing is citizenship. Let's confer that upon him after he has been associated with the ideals of this country. Let's teach him the sacredness of that citizenship so he will vote intelligently. But, we will never get very far until we have first taught ourselves the lesson of voting intelligently!

Mr. HANS RIEG: In direct reply to your statement, Mr. Wiles, you here in Cleveland no later than two days ago had an actual and practical demonstration of what can be done with fourteen different nationalities of foreign-born within less than three months' time. I have reference to the exhibition drill of the Americans-All Squad. My friends, those fourteen different nationalities three months ago couldn't speak a word of the American language. Today they converse in the American language, sing in the American language, and drill according to commands given in the American language.

But, how was it done? Not by coercion! Not by the employment of arbitrary methods. The Colonel to my knowledge worked on that thing for two years, and one of the first things he did was, he almost daily came to my office and afterwards went to my clipping bureau; he kept at his work until he speaks rather fluently about eleven tongues. He

put himself on an absolute basis of equality with the men, but he showed these fellows. "though I am your superior officer and I have control over you to command, I consider you just as good a man as I."

Now, one more thing, again coming to the value of acquiring the language of a land. There have been and there are today, decided efforts of coercion in so far as to forbid and handicap the use of a foreign tongue. That will place in the pathway of Americanization an almost insurmountable obstacle. So, may I ask you gentlemen if you are interested in Americanization, to use your individual influence on these men in the halls of Congress in Washington and prevent them from advocating such laws. They are unwholesome! They are retarding our progress.

MR. VERMILION (Akron, Ohio): In Akron we treat Americanization as a community problem. We have coördinated every agency, not only the industries. Y. M. C. A. and all the agencies of the men, but we have organized all the women, women's clubs, home and school societies, missionary unions, and every agency in Akron today is coöperating and working on this American program: not that any of us are taking a superior attitude but the women of the city of Akron are going into the homes of these folks and sitting down and visiting with them.

We are organizing classes now. We have ninety-seven classes in operation with a total enrollment of about fourteen hundred men and women. We invite you to come down and see for yourselves the practical working of what we think is a practical plan.

I have before me here two men, plant directors of two of the largest factories representing employers of forty-seven thousand men, sixty per cent of whom are foreign-born. These two men are the point of contact between the industry and the Board of Education. The Board of Education furnishes the supervision and these men are getting the foreign-born into the classes in the industry. They are not only getting the foreign-born, but Mr. Watson called me the other day and wanted a teacher for twelve Americans who could not read or write. He has approximately one hundred colored men who cannot read or write, and they are in the classes.

This is a community problem. We cannot wait for the Federal Government to solve it. We can't wait for the State. But, you gentlemen, in your respective communities can do the same thing that we are attempting to do if you will just go about it. If you could see the eagerness with which these fellows want to get into the school, with which they want to learn English and with which they want to take the higher studies, you would get an inspiration that would make you want to get started in the work and on the right line.

CHAIRMAN MOREY: Mr. Wiles, what do you think of this matter of compulsory abolition of the foreign tongues?

MR. WILES: I think in this Americanization program, there is no reason why we should touch that at all. These groups are here, have been for a good many years. If there is anything wrong with them, it is our fault. This is a great problem of neglect. It is a great question of oversight and we have simply let things go by until they went from

germs to pus, that is all there is to it, and we haven't any time now to talk about major operations.

We have a great problem of reconstruction now. The foreign press can render me a greater service in this matter than the American because I can get a message across that I can't in the American. I use foreign speaking men and women and I use the foreign language newspapers, but the thing I am hoping for is the time, which will come, when we won't need them. If we can carry this English program through, we won't need these things.

If you will pardon the reference, I lived in a very strong German town before the war—forty-seven per cent were German. The leading newspaper was German, but the boys and girls in the high school didn't read that newspaper. They were the third generation. They read the American papers, and this paper was just about on its last legs, because the old families had passed away. The old advertisers were still using it, but the newer generation was reading the American papers. But, I say, if that will help the old folks, the Lord bless 'em and let 'em have it; but in two or three years, there won't be any demand for it.

MR. A. M. CONLIN: This talk seems to be about giving the English tongue to the foreigner who wants it. How about the foreigner who doesn't want it, the fellow who cannot read or write in any language? How are we to give it to him?

MR. ROESCH: As I said, the keynote of our problem is salesmanship. If you are going to Americanize your people, you have to study them. The first step in any salesmanship is thorough investigation of your problem. If you will investigate it in a sympathetic way, you will find a way to proceed. Take the one step and the next step will follow the same as when you are behind a closed door, you get that lock open, and when you get into the room you will know what to do.

MR. CONLIN: That doesn't answer my question. Love for your fellow neighbor is a fine idea, but supposing your fellow neighbor doesn't care to be loved. I have been associated with the foreign element for a number of years, but the farther I go the less I think I know of the problem. You can't advertise to ignorant people. You have to advertise to thinking people, that is why you have a sales talk.

CHAIRMAN MOREY: Don't you think your problem is to improve your salesmanship?

MR. PALMER (Equitable Life Assurance Co.): In reading an interesting book this morning, "Ancient Peoples at New Tasks," I came across a paragraph which, to my mind, is applicable to this question. Dr. Greenfield of Labrador says, "If you want to convert people, do something for them that they understand and get their confidence, and through some direct evidence that you are going to do something for them, educate them that you are sincere."

CHAIRMAN MOREY: Our hour is late and we must close.

For my own use, I have drawn up a little memorandum as a result of what I have heard. First, I am going to study what true Americanism is. Second, I am going to try to be an American myself. Third, I am

going to see that my company is American in its attitude, by reflecting justice and fellowship to these men. Fourth, I am going to see that my community reflects this same American attitude, and last, to do what I can to sell this Americanism of the heart and of the mind to these foreigners.

Adjournment.

General Round-Table Meeting

October 2, 1919

THOMAS STANION, Chairman

Manager Safety and Sanitation, Aluminum Castings Company,
Cleveland, Ohio

GENERAL MANAGER C. W. PRICE: I want to give myself the pleasure of introducing the Chairman of this morning's session—Mr. Thomas Stanion. He was formerly with the Commonwealth Steel Company, and now with the Aluminum Castings Company, with headquarters in Cleveland.

Tom Stanion has been one of the most valuable men in the local organization. It was Tom Stanion who was the leader of the splendid school for safety supervisors that graduated a hundred and thirty-three men here in Cleveland.

I take great pleasure in introducing Tom Stanion as the Chairman of the Round-Table Session.

(Mr. Stanion took the chair.)

CHAIRMAN STANION: I think all of you know "C. W." just as well as I do. You know whatever he says must be taken with a liberal amount of salt. (Laughter.)

The National Safety Council came into being through the need of an opportunity to interchange ideas—a need and a desire for a clearing house where the experiences of one plant could be made available for others; and naturally out of such an organization at the start there came some very lively Round-Table discussions, such as we are going to have this morning.

These Round-Tables have been continued through the various Congresses, and each year with an increasing amount of enthusiasm and interest. Some people might think we are getting so far along in our safety work and know so much about it that it is not necessary to have these Round-Table meetings any more, but such is not the case, for this safety work is a generation's job.

MECHANICAL, EDUCATIONAL, AND SUPERVISION

As we have gone along in the development of safety work, the activities have defined themselves into distinct channels. There has been the mechanical side, the educational side, and the supervision side. This morning we are going to turn our thoughts particularly to these three points. There are some who say one is more important than the other. After we have heard the discussion this morning we shall have an

opportunity of knowing better where we feel the emphasis should be placed.

Our first speaker is one who not only has made a deep study of his subject, but he has based it carefully, methodically, and accurately on the facts available. He will tell you nothing about any theories that some good people think are good. He will tell you of the facts, and the things as they are. I am happy to present to this meeting this morning Dr. Lucian W. Chaney.

IS INDUSTRIAL DEATH NECESSARY?

DR. LUCIAN W. CHANEY, UNITED STATES BUREAU OF LABOR STATISTICS,
WASHINGTON, D. C.

This is a serious question. A negative answer is greatly to be desired. If such an answer is ever to be obtained it will be because the safety men of the country have faith in its possibility and energy according to their faith. I am very glad therefore to have the opportunity to press upon your attention my conviction that no less an ambition is worthy of the achievements and capacity of American safety men.

Consider your record for a moment. What have you done already? In 1907 the severity for the iron and steel industry was not less than 21.6 days per worker; in 1910 it was 15.9; in 1913, 13.9; in 1917, 12.2 days. It should be remembered that this last figure though not much below the preceding high point in 1913 was secured under the enormous difficulties of war conditions.

You have established a descending series which if it can be maintained even at a lessened speed will approach the zero line. A preliminary figure for 1918 shows 10.9 days.

This downward trend is even more convincingly indicated when five-year periods are considered. The five-year period ending with 1911 had a severity rate of 15.0 days while the five-year periods ending in 1916 and 1917 had each a rate of 11.0 days. Blast furnaces, one of the most hazardous departments of the iron and steel industry, show a steady decline from 31.9 days in the period ending with 1911 to 16.7 in the five years terminating in 1917.

This is a good record. Can it be continued, perhaps accelerated? I am here to urge that it can and to indicate what I regard as one of the important means to that end.

Very early in my contact with the industrial accident problem two impressions began to harden into convictions. They were (1) that the accepted method of estimating industrial hazard by means of a frequency rate was wholly inadequate, and (2) that the factor of personal "carelessness" was being overstressed very greatly.

As a result of the first conviction I made an elaborate study in my first extended publication of the time lost through temporary disability. Since the deaths and permanent injuries were excluded this compilation had very little significance. From this point severity rating has progressed, due largely to the efforts of the U. S. Commissioner of Labor

Statistics, to the development of what may fairly be regarded as a standard system. This system is now used by the International Association of Industrial Accident Boards and Commissions¹ and is recommended by the statistical committee of the Council².

As a result of the second conviction I attempted, immediately, the working out of a system of severity rating in the Bureau of Labor Statistics to apply it in testing the relative effect of efforts directed toward the men and those which I included under the designation, "engineering revision."

I can do no more in the time allotted me than summarize the results of these studies. For details I must refer you to the published articles.

WHAT THE SEVERITY RATE SHOWS

It is evident, on a moment's consideration, that certain classes of accidents are much influenced by the conduct of the men, while others are more removed from their control.

I first found that in cases, such as the handling of objects and tools, where the conduct of the men was clearly a very influential factor that the frequency rate was normally high but the severity rate was comparatively low. Following the matter from year to year showed that very often a notable decline in frequency might be accompanied by stationary or even rising severity. This means that the result of effort directed to the behavior of the men is influential mainly in diminution of minor accident and may be accompanied by an actual increase in accident cost.

I then considered such causes as showed marked severity and which had, in the course of time, had a considerable decline. I found, without exception, that a conspicuous decline in severity could be correlated with definite engineering improvements. It is worth while to put some emphasis on this point. I have been diligently looking for some years for a case of important saving in accident cost which was not related to "engineering revision." I have not found one.

Let me illustrate, in blast furnaces under the old conditions "break-outs" of molten metal were distressingly common and often accompanied by serious losses of life. With improved construction, in a well built modern furnace, such events are of rare occurrence.

In a group of blast furnaces with which I was particularly familiar it was possible to trace step by step an improving severity in deaths from asphyxia and the structural changes to which it was evidently due.

In open hearths the causes most prolific in death in the earlier days were cranes and hoists, molten metal and power vehicles. Here too it was possible to trace with perfect definiteness the parallel course of "engineering revision" and a declining severity rate. Singularly enough, in the particular group of open hearths used for purposes of study, the frequency rate in the handling of objects and tools markedly decreased but severity *increased*.

¹See Bulletin 238 U. S. Bureau of Labor Statistics, Page 32.

²See Proceedings National Safety Council, 1918, Page 30.

Nowhere was a decline in the severity rates more clearly to be attributed to engineering change than in yard operation. The provision of adequate clearances, the elevation of tracks, the construction of viaducts and subways, improvements in methods of transporting hot metal, these and many other changes conspired to bring about a more satisfactory condition. Nothing at all comparable with the reduced severity due to these changes could by any stretch of the imagination be attributed to the exercise of greater personal care.

Tracing conditions thus from department and finding that marked saving in accident cost was always associated with more or less definite engineering improvement was suggestive if not convincing.

Since death is the great element in accident cost it becomes significant and important to examine the death record.

CAUSES OF FATAL ACCIDENTS

It was possible to do this in 372 cases. It was found that in 57 per cent of these some engineering remedy was suggested after the death. A group of 72 cases of later date similarly analyzed showed 58 per cent might have been saved had it been possible to apply the remedy in advance.

I have elsewhere pointed out that there are two elements of weakness in this study. They are (1) the material considered is to a considerable degree of an early date when the safety movement was beginning and when the conditions would naturally favor the discovery and remedy of a high proportion of engineering defects and (2) the judgment of my colleague in the Bureau of Labor Statistics and myself might have been at fault in studying the individual records. It was necessary to take these records as they stood. No correction or amplification of them was possible.

I determined therefore to examine some extensive records in which safety committees had set down their judgment regarding the accidents coming under their jurisdiction. These studies had been made with very great care and with every opportunity to correct imperfect records and secure all the data which could shed light upon the cases.

The results of this effort to let the safety committees speak for themselves was published in the Monthly Labor Review for December, 1918.

A SAFETY COMMITTEE'S SIGNIFICANT REPORT

The committees had gone on record concerning 1,642 cases during a period of three years. The analysis is most suggestive. The committees found that while but 7 per cent of all injuries were amenable to engineering revision 57 per cent of deaths and major mutilations could, in their judgment have been prevented by proper engineering measures. It is a rather striking coincidence that this is precisely the same percentage which was assigned by my colleague and myself to this group.

Turning now to deaths and major mutilations numbering 207, of which 68 were included in the tabulation just considered, I found that the committees had reached the conclusion that engineering remedy wa

possible in 65 per cent of the cases. No effort was made to criticise the findings of the committees. The record does not in all cases seem to fully support their final judgment. But in many such cases it is evident that the committee had additional information which had not been incorporated in the summary record.

I have thus presented in barest outline the steps which have led me to my present position on this subject. My conclusions may be summarized in the following statements:

(1) The general frequency rate is an index of the prevalence and fluctuation of minor injury. The reduction of this type of injury depends on an educational program whose final effect is to cause the men to do their work in a safer manner. A rising frequency rate may indicate one or all of three conditions (a) no educational program or a poor one, (b) a good program administered with poor judgment or with insufficient vigor, (c) industrial conditions which might for a time overbalance any program however good.

(2) The general severity rate is an index of conditions in regard to death and major injury. The reduction of this type of injury depends in very large measure upon the procedures included in the expression "engineering revision." When the severity rate rises there should be immediately a very searching inquiry for possible imperfection in the engineering program. It is almost certain to be discovered that some unobserved lacks on the engineering side are responsible for the rising rate.

THE WRONG KIND OF EDUCATION

A word about the type of educational effort. I am convinced that what may be termed the evangelistic type goes very largely wide of the mark. Nothing more significant has recently been published on this topic than the letter from a workman in the July number of Mr. C. B. Scott's Safety Bulletin. I quote: "The safety man depends too much on his talk. We employees don't need so much safety talk any more. What we need is more of the *practice* of safety in our plants."

My judgment is this, that our educational effort should be directed primarily to the development of skill rather than caution. The experienced man is at times a taker of chances to the point of recklessness. Notwithstanding this he is very rarely hurt as compared with his much more cautious but inexperienced fellow worker who has just come on the job. The evidence on this point is abundant and convincing.

I have also a strong antipathy to much of the safety propaganda because it antagonizes the men. The constant emphasis on "carelessness" as the great factor in accident occurrence is recognized by the more thoughtful workers as being unjust and injurious to them. They resent this improper emphasis.

What stands in the way of an "engineering revision" sufficiently thorough to reduce industrial death a long way toward the vanishing point? In my judgment there is only one thing. The cost. I think we have materials strong enough and men skillful enough but the price seems too great.

I must not be understood as asserting that there is not a limit beyond which industry cannot go in expending money for the prevention of death even. What I do urge is that we have gone, up to the present time, only a little way toward the reasonable limit.

The condition has in it a challenge to you safety men of America. It is for you to decide whether American industry shall distinguish itself by the breadth and thoroughness with which it applies every known and ascertainable engineering remedy to this industrial death problem.

CHAIRMAN STANION: Our next speaker is one who has had a wealth of experience in contact with men in an industry where there is an extra hazard. I take great pleasure in presenting Mr. L. A. DeBlois.

SUPERVISION AS A FACTOR IN ACCIDENT PREVENTION

L. A. DEBLOIS, E. I. DU PONT DE NEMOURS AND COMPANY,
WILMINGTON, DEL.

So long as mechanical, electrical, and physical power are applied to meet the needs of industry; so long as chemical reactions go on; so long as we continue to apply these forces, human interference with them will lead to human injury. The forces themselves are comparatively simple to understand, and they can be readily enumerated. The manner of their application to each industry, however, runs into thousands tens of thousands, hundreds of thousands, and perhaps even more.

We have something else to consider—the long list of contributory circumstances that may have almost a direct causative effect on injury occurrence. If you will take even the simple example of a carpenter's hammer and try to figure out how many different ways accidents can be brought about through its use, you will find no trouble in putting down about fifty.

Can we not, therefore, say that in the use of these forces there are a million or over a million ways in which accidents can happen? If you admit this, what are we going to do? Shall we design a million different safeguards, or shall we educate our thirty-five million working men and women in one million different ways of preventing accidents? That is the question.

Turning first to the matter of engineering revision, which I take to mean structural and mechanical betterment, including mechanical guarding. I think we shall all agree that up to this time engineering revision has been applied most successfully to these three general matters: First, to general conditions; for example, space and light. Second, to the guarding and covering of the well recognized and general hazards, such as belts, gears, cutting tools, etc. Third, to the guarding of the more serious hazards which are peculiar to the industry and which naturally attract our attention because they cause serious accidents.

It seems to me quite natural that the effect of the application of engineering revision, especially in the latter case which I have just mentioned, should be to diminish the number of the more serious accidents. But I think we shall also admit that this application affords

more protection under the conditions of normal operation than under the conditions which arise out of the necessity for repairs, adjustments, and accidental or unusual situations. And yet, I fancy that a careful analysis of the majority of our operating plants would show that the pay roll hour exposure to accidents is about one-third to the abnormal, and two-thirds to the normal conditions of work.

Furthermore, the results of engineering revision, whether general or specific, are practically worthless unless followed up by continued supervision. For instance, space and light conditions must be maintained, and safeguards must be kept in place and in good condition. Engineering revision, in itself, is but one form of applied supervision. Engineering revision without supervision is almost impossible of conception.

Turning now to the broad subject of education—safety education as meaning the control of the mental side of the situation, opposed to the mechanical and structural—we find ourselves facing about the same difficulties that we face with engineering revision.

We can, indeed, paraphrase the three most successful applications of education to our work, and if so, they will read about as follows: First, general education, such as the necessity for care and first aid, and so on. Second, special education on frequent, well recognized, and general hazards. Third, education on the more serious hazards special to the industry. This is the generally accepted program in all safety educational work, and is well defined in the developed activities of the National Safety Council. I am inclined to believe that our troubles do not come from failure to accept these principles so much as from failure to use judgment in their application.

We have reared our modern system of accident prevention on two axioms: First, that 60 per cent to 70 per cent of the accidents are due to the carelessness of the individual (and sometimes the percentage is placed even higher), and the second axiom reads that the foreman is the logical point of attack.

Now, we have all accepted this, and we have all seen it in print, and I think we all believe it. I want to ask you this question: If the employees are to blame for 60 per cent to 70 per cent of the accidents, why do we center our attack on the foreman? Your answer is that it is because we can reach the men better through the foreman, and because the men adopt the attitude of the foreman.

Admitted. But if this is true, does it not directly imply an obligation on the foreman's part, and should we not credit him with a definite share of the 60 per cent and 70 per cent of the accidents that we blame on the man? Why not say that half of these accidents could be avoided by getting the foreman in line, and therefore that one-half—30 per cent to 35 per cent—are blamable on the foreman?

RESPONSIBILITY OF THE MANAGEMENT

Now some one is responsible for the conduct of the foreman. It isn't the employees. It must be the management. If it is responsible for his conduct, it is also responsible for accidents caused by his misconduct or

his derelictions. Then, why should we not say that this 30 per cent to 35 per cent of the accidents that I want to see blamed on the foreman should be blamed not on the foreman but on the management?

You will say "Yes," perhaps, to the thought of supervision being effective in lessening accident production, but you will also say that supervision does not remove the cause of the accident. Ladies and Gentlemen, neither does the application of engineering-revision remove the cause. The primary cause of your accidents is the application of power, and you do not remove the *cause* when you surround that machinery with a safeguard.

When it comes to the actual analysis of accidents to determine the responsibility, there is a wide opportunity for divergence. A manager may be inclined to overestimate the blame which should be attached to his employees while a foreman or a safety committee may over-emphasize the importance of engineering revision. In point of fact, either engineering revision or better supervision may be remedies of almost equal value.

As an example, to show the different conclusions that may be reached let me cite the 207 fatal accidents that Dr. Chaney has just quoted. I merely want to illustrate how, if you attack the problem from different points of view, you get different results, and I am going to twist Dr. Chaney's figures to meet my needs. Purely on the basis of the accident descriptions as quoted, I re-analyzed the cases and arrived at this:

Fault of employers—susceptible of engineering revision	37 per cent
Fault of employers—lack of proper supervision.....	34 per cent
Fault of injured or fellow employee.....	22 per cent
Unavoidable trade risk.....	7 per cent
	100 per cent

This, as you see, puts 71 per cent of the blame on the management which is not greatly out of line with Dr. Chaney's 65 per cent, but whereas he has concluded that a total of 65 per cent is susceptible to engineering revision, I find only 37 per cent so attributable, and believe 34 per cent to be corrected by better supervision. This 34 per cent plus 22 per cent due to fault of injured or fellow employee almost make the 60 per cent we usually blame on the men. I think we are both right but are simply looking at these accidents from a totally different point of view.

SAFETY SHOULD NOT BE A SIDE SHOW

In the speaker's mind, the solution of this tangle of responsibility lies in the manner in which safety is introduced into the plant by the management. There are two methods: Safety may be made a part of the business of production, operation, or whatever the function of the business may be; or it may be put on as a sort of "side show," endorsed by the management. If it is a side show it will be conducted by the safety engineer as a separate little enterprise. Some men will be interested and some will not. There will be meetings, literature, and committee

but it will be always regarded by the men as something outside the big tent. The more efficient it becomes, the more will foremen and others look to it and its committees to detect hazardous conditions and have them remedied; the more often it will be said, "That is work for the Safety Department."

But compare its organization with that of the entire plant—with the foreman, for instance. How can so few men detect one million defects and five million bad practices, apply the remedies and see that they are maintained? Are they in better position to do this than the foremen themselves, providing the latter are aroused to the proper pitch of interest?

Let us trace the alternate course of development. The manager states to his men, "We will not only produce a product in quantity, of quality, and with efficiency, but we will produce it safely. The productive organization will do this. I will require it of my staff. My staff shall require it of my general foreman. He will require it of his foremen, and they in turn of their men. We have a safety engineer, and he will advise us when we ask him but *we* are responsible for results. Call your men together and explain to them, and I will see that it is followed up."

Safety meetings are called and conducted not by the safety engineer, though he may arrange the details, but by the next highest in authority in the productive organization. Foremen's meetings are called by the general foreman. A foremen's safety committee is appointed, not for the purpose of assisting the safety engineer in his work, but for the purpose of assisting the whole body of foremen. Since it is not practicable to detach the whole body for the purposes of joint inspection. The committees' findings are reported at the meetings and discussed by the foremen. It is recognized that it was the individual foreman's duty to discover and remedy such conditions prior to the visit of the committee, and not primarily the duty of the committee. The committee follows up. If the committee cannot find a remedy to recommend, the safety engineer is directed to investigate and report in writing.

It is by such means as this that accident prevention supervision can be introduced into an industrial plant as an integral part of the work, and the conflict that otherwise arises between production and safety is largely avoided.

AN EXAMPLE OF SUCCESSFUL SUPERVISION

If you will allow me, I wish to digress a moment to show you the results of what I think is one of the most interesting analyses of conditions in industrial plants. The plant in question was built for war purposes at the time war was declared on Germany by the European powers, and was designed for a duration of about a year and a half or two years. It was actually in operation for four years, and toward the end of 1918, and possibly toward 1917, not only was engineering revision at a standstill, but I believe on the downward course. In other words the plant was deteriorating very rapidly. The temporary guards that had been put up were falling apart, and had not always been replaced

medium of the committees. I'd like to hear Mr. Young's viewpoint that in his organization, the International Harvester Company.

MR. A. H. YOUNG (International Harvester Company, Chicago): have the most profound respect for the speakers who have given us talks and papers this morning. Dr. Chaney long ago blazed trails; I have visited a great many safety organizations which have been highly advertised, but never have I met the sustained perfection in safety organization that exists in E. I. du Pont de Nemours and Company. There I know that the work has begun at the top; that the management has been sold the idea.

So far as safety committees are concerned, I believe they are necessary and can be made permanent. They certainly do serve to keep up a certain necessary amount of propaganda, but more and more I am coming to the viewpoint that we have gotten past the stage where propaganda is necessary. Safety is a pretty well established and going concern. Rather than have our overhead safety organization heavy, and acting separately and specifically on the problem by itself, I believe our safety work should be concentrated within our own organization, and safety more and more an integral part of the production program.

ENGINEERS AND MANAGEMENT

I think our problem is increasingly going to be not so much with men. That is easily solved. It is standardized. The approach there is well thought out, and experiences are so great now that we can apply the lessons of the past without much trouble. But if we go higher up to our engineers in the drafting room who lay out the new plans, and ask them to consider safety, we shall go forward toward our ultimate goal much more rapidly.

Dr. Chaney and Mr. DeBlois have furnished some thought as to the possibility of accident prevention right in the drafting room, and the consideration of the design not only of buildings, but of the equipment and placing of the equipment. That exists in many concerns today. I think beyond that, that Mr. Whitney's educational work in the college is going to be increasingly important; that our engineers, when they go to the drafting room, when they first come from our colleges and universities into industry, will have a fundamental, sound conception of accident prevention.

But that isn't going to get us where we want unless the president of the concern, the general manager, the plant superintendent, the general foreman, the sub-foremen, the gang leaders, and the whole organization are thoroughly sold. I don't think we can overemphasize the importance of getting away rapidly from the habit of placing the responsibility upon the employee. I have with others preached that two-thirds of the accidents were preventable by the eradication of carelessness on the part of the individual workman. I see my error and I think we can't quickly get away from that practice and instead, hold the owners of the business responsible; it could be conclusively laid on their shoulders. Just such papers as those of Dr. Chaney and Mr. DeBlois this morning

MR. S. D. HUBBARD (New York City Department of Health): I have listened with a great deal of interest to the remarks of the two preceding speakers, but it seems to me that the correction of this situation lies in a step still further advanced than has been so far brought forward to this Round-Table.

UNIFORM STANDARDS

I believe in the adoption of standards. I believe that for a municipality or a state, or the United States, for that matter, to permit the construction of plants where accident liability is great, which safety engineers in advance can practically foresee, should be prevented.

Definite standards should be adopted by each state, and each municipality should in turn re-adopt these standards, and should see that they are made effective.

MR. E. S. CHAPIN (Pennsylvania Railroad, Philadelphia): Mr. Hubbard touched on a point which is very dear to my heart because we are operating in about thirteen states. We have standards in different states which are all different. Now, for heaven's sake, let's have one standard so we know what we're doing. I have to be a lawyer in thirteen states to know what I am doing.

MR. V. R. HUGHES (Pacific Gas & Electric Co., San Francisco): Our experience has been that our accidents from the defects in or the lack of guards are about four per cent of our total accidents. We have laid a great deal of stress on our safety committees. We have gradually reduced the accidents through these safety committees. In 1913 the fatal accidents were sixteen; in 1914, eight; in 1915, six; in 1916, eight; in 1917, five; in 1918, four; and so far this year there has only been one—out of about five thousand employees.

The cost of these accidents in 1914 was \$51,000; in 1915, \$35,000; in 1916, \$48,000; in 1917, \$42,000, and in 1918, \$34,000—so that the severity of the accidents is going down continually. We have spent about \$25,000 for guards and safety devices in that time.

MR. M. J. FLYZIK (State Safety Board of Washington, Olympia, Wash.): I am speaking particularly about mining. There is a general hazard to each industry, and with that is also a special hazard. Forty-eight to fifty per cent of the accidents in our state in the coal mining industry are due to one cause—the roof falling on the men.

The responsibility may be divided equally between the workmen and the management. The roof comes down because of the failure of the workmen to put up the wooden supports. Now, either the supports are not delivered to the workmen by the management, or the workmen fail to put them up after they are delivered. We must remove the cause. We propose to hold the management responsible for the delivery of the necessary material, and after that is done we insist that the workmen be compelled to put that material up.

I think we should pick out the special causes first. If forty-eight per cent of the accidents are due to one cause, then we in the mining industry should concentrate our efforts toward the elimination of that cause.

What is true of mining is largely true of other hazardous industries. We may have a hundred causes, but you can trace about fifty per cent of your accidents to about three or four causes.

I have arrived at the conclusion that the foreman cannot devote much of his time to accident prevention. He is continually pushing his men to get out production. Therefore, if we want to do anything along the line of accident prevention, this work should be assigned to neutral men—safety engineers.

MR. A. T. MOREY (Commonwealth Steel Co., Granite City, Ill.): I am a frank believer that the safety committee has been a wonderful factor in accident prevention. I think they are going to remain so. It is by their work that we have been bringing to the management and to the foremen their sense of responsibility. What I have heard said here this morning about putting the responsibility on the foreman and the management is simply an indication that that education of the management is being brought to a successful consummation. I have always longed for the day when the responsibility can be put right on the management, because they control the situation—but, gentlemen, don't let us get away from the recognition that we absolutely need the cooperation of the men on the job, through the safety committees.

CHAIRMAN STANION: Our time is now up. This is the conclusion of one of the best Round-Tables we have ever had. We certainly appreciate your enthusiasm and your getting up early to get here. The meeting stands adjourned.

Safety Education Section

October 3 and 4, 1919

FRIDAY NOON SESSION

ORGANIZATION MEETING

THE meeting convened at 12:30 P. M. General Manager Price presiding.

CHAIRMAN PRICE: I believe that Dr. Payne in working out this wonderful plan of systematically teaching safety to children in the schools has made the greatest single contribution that has ever been made to the Safety Movement. And I further believe that during the next twelve months the greatest contribution which the National Safety Council will make will be through its efforts to reach every school in the United States, and induce them to adopt this plan.

This meeting is called for the purpose of considering the practicability of organizing a section of the National Safety Council, to be known as the Educational Section, and primarily for the purpose of quickly reaching the schools with this great message.

I want to call on Mr. Whitney to outline the plan and purpose of this Section. No one in the National Safety Council has shown more interest in school safety than Mr. Whitney, and no one is more competent to speak on the subject.

MR. A. W. WHITNEY (National Workmen's Compensation Service Bureau): We have been feeling our way in the educational work of the National Safety Council, and taking new steps only when we felt pretty sure of our ground. We seem to see now, however, a great field stretching out ahead of us which will require our best endeavors to develop with a wisdom and energy commensurate with the opportunity.

The next step seems to be the formation of an Educational Section. The work so far has been carried on by a committee. We now need a body back of and around the committee which may gather up and focus all the needs, opportunities, and energies which it is now so evident exist.

We need a forum in which the technique of the educational problem can be discussed and developed and recorded. The problem of teaching

safety is quite as technical as the problem of guarding machinery, or of organizing shop committees, and if a forum is needed for the discussion of these problems, a similar forum is needed where the educators and those in need of the results of education can discuss the problem and the solution of the problem in detail.

The educational field, aside from the work with safety supervisors and shop foremen, which is being otherwise taken care of, falls into two main divisions: The work in public and parochial schools, and the work in technical schools and universities. It will therefore be necessary almost immediately for practical purposes to split the Section into at least these two large divisions.

Of these divisions, however, the one that is in most obvious need of the help that a section can give is that of the public and parochial schools. We have now, thanks to Dr. Payne and the St. Louis schools, a practical plan for teaching safety in the primary and secondary grades. The plan needs pushing. A section can be of some use in developing ways of approach to the schools and the public, but its main use will be for the development of the detail of teaching safety in its actual application. Most schools, most teachers, will have to be handed the plan complete; they cannot be depended upon, at least at first, to work out satisfactorily the details of its application;—I mean, for instance, such things as arithmetic examples, problems in geography and in nature work, the development of safety situations through drawings and dramatic expression, and ways of developing children's committees. A mass of such detail must be accumulated.

I conceive that one of the main functions of such a section will be to develop and classify and publish such material so that no school will be so backward as not to be able to put safety work into its curriculum.

It is easy to imagine other ways in which such a section will be useful. It is not necessary now, however, to see the whole field, only enough to know that such a section is needed. Nor is it necessary on this occasion to develop the peculiar needs of the university situation. That is another story, although quite as important and interesting.

CHAIRMAN PRICE: I am going to ask Dr. Payne, the author of this wonderful book, to express himself in regard to the value of such a Section in the National Safety Council.

DR. E. GEORGE PAYNE: I hardly know what I ought to say to this body here today. I have been speaking so much this week, and probably most of you have heard me in one place or another.

After all, the most fundamental problem in connection with the Safety Movement, as I said this morning, seems to be one of education. And the most significant part of this Movement is that of public school education in accident prevention, because after all, you know as well as I that the problem of getting the ideals and practices of safety is a matter of education.

We instill the ideals and instill them most effectively not after one reaches adulthood, but during the period of plasticity, when the child is in school and when he is being educated.

Now, first, let me say here that the public has hardly realized what a treasure they have in the teaching profession, in the body of teachers, in carrying out this Safety Movement. Whenever I talk to business men about the safety proposition in teaching they merely tell me they think the way to do it is to get a policeman to come in and talk to the children about safety, or some one else who is interested in safety. You can't teach safety that way.

In St. Louis we have three thousand teachers—three thousand school-rooms. We have about a hundred seventy-five school buildings. Think how many people you would have to have to get around, talking all the time, once each year in every school-room! You see it is absolutely impossible. Simply to go into the room once a year to ask them to observe certain rules of safety doesn't teach them anything. The teaching of safety is like teaching table manners, or teaching anything else—it is a long and laborious process.

Now, what can an Educational Section of this Council do to help get that over? It seems to me they can do a great deal. In the first place, the idea of teaching safety must be sold to the superintendents and the school men of the country. Every superintendent is facing a situation of this kind: He has in a large city two or three thousand teachers whom he has to keep harmoniously working in connection with his plan. Whenever he comes to them with a plan of introducing another subject why, they simply throw up their hands and say, "That is an impossibility. We already have fifteen or twenty."

You have to convince this superintendent that there is a way to teach safety and teach it effectively and satisfy his teachers without the additional work of another subject added to the curriculum. That is the proposition you have to put over.

Of course, we who are on the educational side taking the lead in this Movement are going to do all we can regardless of the National Safety Council or any other organization, because we are committed to it and believe in it.

After all, we have to sell the idea to the school people, and that is particularly true in the smaller communities. I think it is true in larger ones, too.

I think an Educational Section here as a clearing house can do a great deal in bringing these people to see the necessity for this kind of work. Then, I want to say further, that the point Mr. Whitney made here can't be emphasized too much. You can't put in one book everything that is to be said on this. No one man can work out the problem in all its details. We have made a starting in this direction, and school people all over the country, as they continue to work out this problem, are going to present material that will be invaluable to serve in communities where by they may select that material best fitted for the work and turn it over to Mr. Price and let him and his office do the rest in bringing it to the attention of the superintendents of the country.

I think, then, the greatest thing we can do is to assist and let the school people know we are back of it. For instance, instead of suggest-

ing that we have lecturers brought into the schoolroom, let us say to the teachers, "Here is a problem of accidents in the community. Here are children being killed and injured every day. It is your problem, and here is material with which you can help them." But don't try to take the problem away from them by suggesting that some outsider do the work for them. If you do, they cease to take interest and responsibility, and you will be holding the bag, because you can't do it on the outside. You might just as well have some one come in from the outside and lecture to the children on manners and the things they ought to do in the home and expect them to do it. The father and mother are on the job to train the child in the way he should go at home. The teacher is on the job to take care of the school activities, of which safety education is an important part, and we can't deceive ourselves about that. What we can do is to help that teacher do her job more effectively and show her that you appreciate it when she is working along that line.

That represents, it seems to me, what this division could do, and the direction to which it could devote its efforts effectively, and it would be a clearing house in which we could discuss all these problems at least once a year.

CHAIRMAN PRICE: This discussion would not be complete without some expression from our newly elected President of the National Safety Council—Mr. Richards. Mr. Richards, will you express your thought and the attitude of the Council regarding this work which lies before us?

MOST IMPORTANT WORK BEFORE THE COUNCIL

PRESIDENT RICHARDS: The Council is so new in this work that I am not prepared to express the consensus of opinion of the Council. In fact, I don't think it has really been formed. Speaking for myself—not individually, but as President of the Council—I deem it the most important work that the Council has before it now.

It has seemed to me for many years that if we could begin educating the children to be careful, to realize the danger of public, private, and home accidents—the same as the mother teaches them their prayers, and the school teachers teach them arithmetic or spelling or anything of that kind—that in twenty years from now the job of the National Safety Council in wiping out avoidable accidents would be completed.

We have a start that nobody can ever set us back on. I think it is the greatest work the Council has before it. If there is anything I can do officially or personally to give it standing before the communities in which we all live and have our interests, I am certainly willing to devote more time to it than I would be to any other matter.

I think if each one of us will only take this home to the community in which we live and do something ourselves to get it started in the schools, instead of leaving it to the General Manager or "George" or somebody else to do, we will accomplish wonderful results.

Take in the cities of Chicago and St. Louis, you have probably in the combined communities ten thousand school people. Now, think what a wonderful force it would be to the safety movement to have those ten

thousand educated people saying something to the children once a week, or once a day, or once a month, and think of the number of people that would reach! And then you can realize what this educational program can do.

CHAIRMAN PRICE: Mr. Arthur T. Morey, of St. Louis, has been one of the presidents of the National Safety Council, and is the Chairman of the Public Safety Committee of our Local Council. Mr. Morey, will you give us your thought on this subject?

MR. ARTHUR T. MOREY: Friends, this is a time I think we have all looked forward to—the formation of the Educational Section, and getting it into its own.

It seemed to be necessary to go through the process of getting the industries interested in safety work before we could get public safety on the map. As a natural part of safety, public safety work comes in with great importance in the school. I wish that those here this morning could spend a morning with Dr. Payne at the Wyman School in St. Louis, and see this wonderful method he has evolved in actual operation. I think in all my life I never spent a more interesting morning than that morning.

They have woven this safety idea all through their study. They didn't take up safety as a separate thing, but tried to weave it into the lives and thoughts and habits of the children. Their arithmetic problems involve thinking safety. Their essays, their English compositions—instead of writing on their books, "The horse is black, the cow is white," they have, "In crossing the street, first look to the left, and then to the right," or some little safety thought constructive along that line.

If we are going to get at the source of things, that is what we must do when we take up accident problems. We tabulate the accidents that have happened and put them under the classification of causes, and then try to eliminate the causes. And when we study causes, we get right back to the child life and see that if we can teach these safety ideas to the children while young, and get them into the fiber of their lives, thoughts, and habits, why, we are going to get somewhere.

There is nothing more important than the development of this Educational Section. I think the Council should be congratulated for having arrived at this point.

CHAIRMAN PRICE: I am sure we shall be interested in having the thought of Dr. Evans, the author of the Health Column in the Chicago Tribune.

DR. W. A. EVANS (Chicago Tribune): I thought when Mr. Price first talked to me about Dr. Payne's book that it was to be a textbook for use in schools. I discovered as I read it that it was a book written for teachers, and that the purpose of it was to stimulate the thought of the teachers to the end that they might learn to do a certain thing. I found, too, that you miss the philosophy of it if you read it hastily, or if you read it other than thoughtfully.

Now, I have been in public health improvement work for about a quarter of a century, and I have been engaged in teaching for nearly thirty

years. About one-half of all the deaths are due to accidents, and anything that promises materially to reduce the number of accidents will make a material reduction in the general death rate. Likewise, anything which materially reduces the number of accidents of all characters will materially reduce the rate of disability from disease, disorders, and accidents collectively.

If you read Dr. Payne's book you will discover in the field in which the Safety Council has been working, there are results that prove your work has paid. There has been great reduction in the different types of accidents that naturally or normally occur in industry or in those fields in which you are engaged, but at the same time, there has been a growth or increase in the accident rate in what are known as public accidents and, as he very clearly shows, an increase in those rates that pertain particularly to childhood.

And that is one reason for broadening your field of activity and going after children—but that is only one of the reasons. As he has said to you, childhood is the period of plasticity. In dealing with accidents, you are, as a matter of fact, endeavoring to change the habits of the people; and it is difficult to change the habits of adults. You improve the possibility of a successful accomplishment if you begin with childhood, and bend the child mind to that particular method of thinking.

What you are endeavoring to do is to create a type of alertness in the minds of the individuals. While the main theme in the mind will be the particular thing which occupies it—the trade or profession, or the line of thought of the individual—you are trying to train that individual to carry in the back of his head constantly that there are certain principles of self-preservation, which must be automatically carried out—certain hazards that must be both physically and mentally considered, and constantly considered if results are to be obtained.

In other words, it is your job to change the mechanism of thought of individuals. When you undertake to do that you are confronted with great difficulties. The possibility of successful endeavor is greatly increased if you work with children rather than with adults.

I'd like to suggest this one other thought: Children are very apt to accept the facts which are put before them as facts without very much criticism or analysis of those facts. As a general proposition, the statements that are made in the textbooks that are commonly employed are not statements which are germane to the lives of the individuals of the community; and certainly not germane to the lives of the children. The quality of the matter presented by the textbook, its avenues of approach, will be improved if in those textbooks we make use of the events that come into the life of that child—its life in the home; its life in the school; on the street, and elsewhere. We can put into the reader and speller and arithmetic and geography—and into play as well as in study—little statements of facts relating to accidents, accident prevention, and various related subjects, in place of some of the things that are there now. That would suddenly and indirectly teach accident prevention, and do it with that degree of authority that is carried to the child mind by the facts presented in the textbooks that are used.

CHAIRMAN PRICE: I think the time has arrived when possibly we are all ready to consider the practicability of organizing a Section of the National Safety Council on Education. I think a resolution possibly would be in order at this time.

ORGANIZATION AND ELECTION OF OFFICERS

MR. ARTHUR T. MOREY: I'd like to move that this meeting here and now organize itself into the Educational Section of the National Safety Council; that you as Chairman of this meeting appoint a committee to work out the details of organization, to adopt proposed by-laws for reference to the Executive Committee of the National Safety Council, and consider all of those whose presence here indicates their interest in the work as the initial members of that Section; and that we now proceed to the election of the officers for the first year.

PRESIDENT RICHARDS: I second the motion.

CHAIRMAN PRICE: Any discussion? All in favor of the motion manifest the same by saying "Aye"—contrary, "No." The "Ayes" certainly have it.

(The motion was unanimously carried.)

The form of organization which we have followed in the other sections, and I would suggest that we follow it here, is a very simple one; namely, to have a Chairman, a Vice-Chairman, and a Secretary; it being understood that the Chairman will appoint such committees as will be needed in the work of the Section.

The Chair will be glad to listen to any nominations for the Chairmanship of this Section.

MR. R. E. BLOK (Atchison, Topeka & Santa Fe R. R., Amarillo, Tex.): I move that Mr. Whitney be Chairman of this Section.

(The motion was duly seconded and carried.)

CHAIRMAN PRICE: Will some one make a nomination for a Vice-Chairman.

PRESIDENT RICHARDS: Mr. Chairman, I would like to suggest that if Dr. Payne is willing to serve as Vice-Chairman of this Section, it would be entirely appropriate that he should do so. The two men who blazed the trail for us ought to be at the head of this Section. I therefore take great pleasure in proposing the name of Dr. Payne, and I sincerely hope he may be able and willing to accept that position.

(The motion was immediately seconded.)

CHAIRMAN PRICE: I was just going to say, Mr. Richards, that we don't ask people in this movement if they will—we tell them they are going to.

(The motion was unanimously carried.)

I indicated in my outline that a Secretary to look after the details of work should be elected.

MR. C. L. LAFONTAINE (Great Northern Railway, St. Paul): No man is more interested in this Section than the man I want to propose as its Secretary. I believe he has said to you here today that he was interested—therefore he admits it. He has also said there was no question of

a refusal to serve after once being nominated and properly seconded. I therefore am going to propose the name of C. W. Price as Secretary of this Section. (Applause.)

(The motion was immediately seconded, and carried unanimously.)

CHAIRMAN PRICE: I want to say it is a very great pleasure to accept that position, and I do accept it because of my deep and sincere interest in this great movement. I want to say to you that not only individually will I do my utmost this next year to put this across, but my whole staff of thirty-five I am sure will stand by me in attending to all of the details of carrying out this plan. (Applause.)

I should be very glad to have an expression, if it is only just a word, from any one in this room in regard to this great movement that we are about to take up. I will ask Dr. Dana Webster of Indianapolis to start the ball rolling. I have known his interest in schools for a number of years.

DR. DANA WEBSTER (Indianapolis): While I have been sitting here and thinking of this question of teaching children, I have been thinking why it is that the National Safety Council and all others didn't think of this matter first when the Council was started, so that we could have been training our children all these years. I can't quite comprehend why we have missed so much—I include myself, of course.

There is another thing: There was a great deal of interest shown today in regard to Boy Scouts. I don't know but it would be a pretty good idea to have the Boy Scouts represented here next year. It would be a mighty big thing if every city throughout the United States that has Boy Scouts could send a delegate. I think that would be a wonderful thing and I should like to see that taken up.

MR. C. B. CONNELLEY (Commissioner of Labor and Industry, Harrisburg, Pa.): Pennsylvania has passed a law in the last legislature that it is absolutely compulsory to teach safety first in the public schools of Pennsylvania. (Applause.)

Now, there is much for this section to do. I feel that as far as Pennsylvania is concerned, my colleague Mr. Coke of the Americanization Department there will be only too willing to help out wherever he can in this work. Of course, we in Pennsylvania will have to because the law says so. Being a member of the School Board in Pittsburgh, and having such men as Mr. Alderdisan and Mr. Oliver—and, by the way, they were safety-first men years ago—I think we shall have no trouble. We shall be glad indeed to further or give any help we can in the other states, but as far as we are concerned, we in Pennsylvania must do our duty. (Applause.)

CHAIRMAN PRICE: In this recent scrap we had with Germany the boys in khaki across the line in Canada stood shoulder to shoulder with the American boys in winning the victory for democracy. It seems to me very fitting that Mr. Morley, the General Manager of the newly organized Ontario Safety League, should tell us whether he is going to stand with us, and what he is going to do up in Canada.

MR. R. B. MORLEY (Ontario Safety League, Toronto): Mr. Webster

made the statement that he didn't understand why the National Safety Council and other organizations did not take up this work of educating the children, and just to clear up some misapprehensions on that subject, I want to say that the Ontario Safety League started over five years ago at that end of the game.

We are great believers in the fundamental practice of teaching safety to the children. Practically all of our work has been done on a basis whereby the school boards interested paid in part for the work that we were doing in the schools. That is to say they paid for bulletins, letters, etc., I don't mean that they paid for the overhead or anything of that sort, but paid the actual cost to the state.

We are getting results with the children. There is absolutely no doubt about it at all! There is a story that some of you might perhaps like to hear, because it is a story that always strikes me as one of the classics of safety.

Some three or four years ago we went to all of the schools in Toronto and talked to children in thirteen hundred different classrooms. After the meetings we would distribute little celluloid buttons to the children. Some few days after I was in one of the schools I met a little child of six passing along the street, and she called to her friend who was just a little farther on, "Here, Liz', come on over! Here's the man what gives you the button what keeps you from being run over." (Laughter and Applause.)

CHAIRMAN PRICE: Beyond all we men can say, it is important that the women express their opinion of this great movement. The women are the conservers of child life in this world. I don't know of anybody in the room more competent to speak than Miss Nesta Edwards, who did such a splendid piece of work in Wisconsin and other parts of the country. Miss Edwards.

MISS NESTA EDWARDS (Chicago): Somebody said yesterday, "God bless the women," and so why not the men? This morning at the women's division the question came up of organizing a section for the women, and it is going to be the pleasure of that section, I know, to coöperate from top to bottom with this division that this morning is bringing to all of us such a wonderful vision.

You only have to go to a safety meeting of children and you will be on fire for safety for the teeming life of the children that sit before you.

Let me end with a story. I will steal a man's story, but I don't see him here, so I guess it will be all right. "The other day," a man said, "I had a wonderful children's meeting. I went home, and the next day the father of one of the children said to me, 'Good heavens, Charley, what did you say to my boy?' 'Why, what do you mean?' 'Well, when he went to bed he came and threw his arms around me and said, 'Dad, you will be safe for my sake.'" That child had taught him more safety than weeks of safety meetings." (Applause.)

CHAIRMAN PRICE: Do you know, friends, that in the big auditoriums of public schools of Cleveland during this week some of the eminent men of this Council have been speaking to large numbers of children? I

don't know of any one who has been more enthusiastically interested in reaching the children than Mr. Adams, of Aurora, Illinois.

MR. H. B. ADAMS (Aurora, Elgin, and Chicago R. R., Aurora, Ill.): Mr. Chairman, I believe in dreams coming true. Some years ago we started to educate the scholars in the schools of Aurora, Illinois, and I took it upon myself to visit the schools. I made little talks from the primary up through the high schools and some of the teachers met it with a great deal of disfavor because it broke into their regular routine and got the children to thinking of something besides their regular lessons.

So I met with some discouragement, but by the time I had talked to most of the schools in Kane County, the teachers began to sit up and take notice, and some of them in whose rooms I had previously spoken afterward asked whether they had offended me so I would never come back again. And today the teachers are beginning to reach out for methods of teaching their children safety-first principles.

When I went to three high schools here day before yesterday and spoke to three thousand children on safety, the principals and teachers in those high schools were so enthusiastic that they would hardly let me get to the platform to speak. When I got through they would hardly let me get out to go to the next place. You know those children are just preparing for the football season, and they have class yells and high school yells and football yells, and I introduced a yell for them, in all of those schools. I gave it to them—"Think of Safety First"—and their cheer leaders came up on the platform in each one of those schools and led that cheer and you could have heard it clear down town if the windows had been open.

The boys and girls of that age are the ones we have to interest. They are the ones who are going to take our places in this work. If we incline the twig in the right direction the tree will grow straight. You can't stop this Safety Movement—that is all there is to it!

It is like the old gentleman from the country who was on an inter-urban car for the first time. He and his wife sat in the car and they looked and saw nothing hitched to it in the shape of an engine, and the old man said, "We'll never start!" But it did start—slowly, gently, gradually, nicely—that is the way they always do, so you hardly know they are starting. (Laughter.) It kept going a little faster and faster and the old gentleman got so scared that he grasped the seat in front of them with both hands, looked in every direction, and wondered what was going to happen next. He said, "Maria, by Jove! we'll never stop."

And that is the way with this Safety Movement. It started slowly several years ago, but just look at it now! We can now reach 70,000,000 people through the schools of this country, and we are going to do it, and this is the start! (Applause.)

CHAIRMAN PRICE: Ladies and Gentlemen, when the committees worked out the program for this great Congress, they selected the four outstanding subjects that are now occupying the thought of thoughtful people. One of those subjects is Americanization. I will ask Mr. Bach, who is at the head of the Americanization Movement in Pennsylvania, to tell us what he thinks about this movement.

MR. E. E. BACH (Director, Americanization Movement of Pa., Philadelphia): There is this other side to it—linking it up with the home and in the industries with the foreign-born. I am very much interested in the foreign-born side of the whole problem. That is the thing you have been interested in to begin with, before you started this large Safety Movement, and the foreign-born are occupying your minds very largely today, I am sure.

Because of some of the things that are being said: because of some things that have happened in the last few weeks, it seems to me that the problem of safety must come back to that great institution of a common people for its solution, as have come all the great problems—the public school.

CHAIRMAN PRICE: I'd like to have volunteers now, just for a few minutes.

MR. F. S. CRUM (Prudential Insurance Co., Newark): This is a day and hour when we are thinking a great deal of the conservation of man power. Now, as a matter of fact—and we have to deal with facts in our business—by the time the population reaches the age of twenty, one-half of all who die from fatal accidents are dead. Unless we begin our safety movement before that period of life, one-half you might have saved will already be killed. That is the important thing to think about.

In New Jersey we have a state law practically requiring the teaching of safety in the schools, but it is not always in force. Now, if you will attach this Council to that movement and give it the necessary kick forward, you will do New Jersey a great service. (Applause.)

MR. J. C. CLARK (Oregon Short Line, Salt Lake City): I think that it is the grandest thing that ever happened. In my work on the railroads I have visited a good many schools. I have had a number of school superintendents ask me what interest the railroads had in safety in public schools. There are two very good reasons for this interest.

The first, of course, is from the humanitarian standpoint. We don't want to see any children injured if they can be taught to protect themselves against injury, and that is the greatest thing we can do.

But there is another reason from a purely selfish standpoint. We draw our employees largely from the towns along our road. If the schools in all of these towns will teach safety, when those boys and girls come to us for employment, we have a better class of material to draw from. They are safe to start with, and it lessens our task of teaching safety after they become employees.

I am glad, indeed, that the Educational Section has been created because I hope that they will be able to give me information, and I feel it would be a definite advantage to every railroad man and to every industry if they can outline a plan, something definite, so that we can go to the superintendent and say, "Here is your plan. Put it into effect."

MR. H. P. COFFIN (Secretary, Oregon Division, National Safety Council, Portland): Seven years ago the Public Safety Commission was organized in the city of Portland. We started in on education primarily in the public schools, and I, myself, have talked to some thirty-three thousand

children: the result being that for three months after we finished talking to those children there wasn't an accident to a child of school age in those schools. (Applause.)

Our accident records in the schools have been reduced right along, so that we have very, very few. I acted in conjunction with our fire marshal, when putting over the fire-prevention campaign, and it is a fact that we reduced our losses from \$2,000,000 down to \$200,000 a year. Figures will prove it.

The fire marshal and I gave fifteen-minute talks. When he got through with his talk, he would say, "Boys, I am going to make you all fire marshals. Every one of you in this assemblage is a fire marshal, but in your own home. Now, when you go home I want you to do your part and see if there are any fire hazards."

And in the same way I talked about accidents; keeping off the streets and safe-guarding themselves and those who depended upon them. Here is a little story that is absolutely true. One of the school commissioners was sitting at home near the grate smoking a cigar and he threw a lighted match into the waste basket. His little son jumped up and said, "Daddy, you mustn't do that. I'm fire marshal in this home and if you don't stop I'm going to report you." (Applause.)

When I spoke to a large assemblage of four thousand people at the World's Insurance Congress at San Francisco, I closed my remarks with, "Safety first should be used not in jest but in earnest. When a person sees those two words 'Safety First' it should be an incentive for that man to stop, look, and listen. It should be as sacred as the sign of the Red Cross."

CHAIRMAN PRICE: I now want to turn over the gavel to our newly elected Chairman of this great Section—Mr. Whitney. (Applause.)

CHAIRMAN WHITNEY: I want to thank you for giving me this opportunity of being connected with this wonderful work. If I were less selfish I think I should try to persuade you to turn it over to one better qualified, but I am not so unselfish as that. And besides, I have Mr. Price and Dr. Payne here to rely upon, and I could be pretty bad and get away with it with two people like that.

Mr. Webster said (I believe it was he) that unfortunately this work wasn't undertaken seven years ago. Perhaps it is in retrospect, but it seems to me this is a natural development. The Safety Movement had to be acted upon on its most objective side, and it had to get up a momentum and become a really recognized spiritual movement before we could get it into education. This is not only a spiritual movement, but it is practically a religion, and with that stamp on it, it is ready to go straight into the educational system as a tremendous, not only material, but spiritual force. (Applause.)

Mr. Price reminds me that everybody here is supposed to sign a card which has been given to you. You will then become charter members of the Section, and you will be sent literature as it comes out. We shall also expect real service from you. It is up to every one of you to go back and see if you can't put this thing into the schools in your own home towns.

MR. J. H. SNYDER (Columbus): I'd like to suggest a word. Every reform, every fight we have made against the enemy of humanity in this country has succeeded largely by putting it through the schools. We only need to look at the temperance question. The Women's Christian Temperance Union took their fight for temperance to the schools, and won. Now, starting this same way, our safety movement cannot fail.

MR. H. B. REYNOLDS (Pennsylvania Lines West): I wish to state that I took up the question of introducing safety into the schools a year ago, and Superintendent Hines of the state of Indiana has incorporated that in the teachers' manual from the first to the eighth grades as a part of the curriculum every day. (Applause.)

MR. H. E. MEGINNESS (Pennsylvania Lines West, Indianapolis): Some time ago I had the very great pleasure of addressing eight hundred Sisters of Charity, who were teachers in the parochial schools of the Sisterhood of St. Mary's of the Woods, Terre Haute, Indiana. They have placed in their schools a course of safety study, the same as Mr. Reynolds mentioned. This Sisterhood teaches in the parochial schools from Boston to Chicago. (Applause.)

CHAIRMAN WHITNEY: Is there any further discussion? If not, a motion to adjourn is in order.

CHARTER MEMBERS OF THE EDUCATIONAL SECTION

Chairman: A. W. Whitney, General Manager, National Workmen's Compensation Service Bureau, New York City.

Vice-Chairman: Dr. E. George Payne, Principal, Harris Teachers College, St. Louis, Mo.

Secretary: C. W. Price, General Manager, National Safety Council, Chicago.

H. B. Adams, Safety Supervisor, Aurora, Elgin & Chicago R. R., Aurora, Ill.

E. E. Bach, Philadelphia, Pa.

C. T. Bailey, Safety Agent, Salt Lake City, Utah.

L. E. Barnes, Ansco Company, Binghamton, N. Y.

Miss Harriet E. Beard, Detroit Normal Training School, Detroit, Mich.

Bert Bertram, Safety Agent, Atchison, Topeka & Santa Fe Ry., Arkansas City, Kans.

R. A. Beyer, Americanization Director, Central Tube Co., Pittsburgh, Pa.

A. H. Bissmeyer, The Cincinnati Milling Machine Co., Cincinnati, Ohio.

R. E. Blok, Safety Agent, Atchison, Topeka & Santa Fe Ry., Amarillo, Tex.

George F. Buehler, Great Northern R. R., 633½ University Ave., St. Paul, Minn.

P. S. Case, Union Carbide Co., Niagara Falls, N. Y.

J. C. Clark, Asst. to Gen. Mgr., Oregon Short Line, Salt Lake City.

Mrs. J. C. Clark, Salt Lake City, Utah.

G. E. Clarkson, 805 Hartje Bldg., Pittsburgh, Pa.

Harry P. Coffin, Public Safety Commission, and Secretary Oregon Division, National Safety Council, Portland, Ore.

W. Commet, 1013 Penn St., Pittsburgh, Pa.
 Clifford B. Connelley, Department Labor and Industry, Harrisburg, Pa.
 Frederick S. Crum, Prudential Insurance Co., Newark, N. J.
 A. L. Cunningham, Safety Agent, Penna. Lines West, Pittsburgh, Pa.
 Mrs. L. Luella Cox, Indianapolis, Ind.
 Louis E. DeArmand, Public Safety Commission, Davenport, Iowa.
 Edw. R. Dejon, Safety Engineer, Winchester Repeating Arms Co., New Haven, Conn.
 Miss Nesta Edwards, Chicago, Ill.
 L. C. Espersen, Claim Agent, Chicago, Great Western R. R., Clarion, Ia.
 Dr. W. A. Evans, Chicago, Ill.
 R. E. McEwen, 212 W. Washington St., Chicago, Ill.
 M. L. Fellmer, Secretary, Central Mississippi Valley Div., St. Louis, Mo.
 J. G. Fitzhugh, Galveston, Tex.
 J. E. Ford, Evansville, Ind.
 S. M. Galaty, Safety Inspector, 226 W. Jackson St., Chicago, Ill.
 Mrs. S. M. Galaty, 508 N. Humphrey Ave., Oak Park, Ill.
 G. M. Gilchrist, Groton School Board, Groton, N. Y.
 Geo. W. Greenleaf, Inspector, Indianapolis, Ind.
 Isaiah Hale, Safety Supt., Topeka, Kans.
 J. H. Hanson, Rochester Local Council, Rochester, N. Y.
 Dr. A. M. Harvey, Crane Company, Chicago, Ill.
 G. G. Hellmuth, Chicago, North Shore & Milwaukee R. R., 72 W. Adams St., Chicago, Ill.
 R. N. Hemming, Ft. Wayne & Northern Indiana Traction Co., Ft. Wayne, Ind.
 B. J. Hine, Scovill Mfg. Co., Waterbury, Conn.
 W. J. Hockett, General Electric Co., Ft. Wayne, Ind.
 Homer J. Hodson, East St. Louis Ry. Co., East St. Louis, Ill.
 William P. Howell, 333 West Houston St., New York, N. Y.
 G. R. Huggins, Finch Pruyn Co., Inc., Glens Falls, N. Y.
 C. A. Judd, Safety Agent, Atchison, Topeka & Santa Fe Ry., LaJunta, Colo.
 R. McA. Keown, Industrial Comm. of Wis., Madison, Wis.
 Miss Delight Krauss, Cleveland, Ohio.
 C. L. LaFountaine, General Safety Supervisor, Great Northern Ry., St. Paul, Minn.
 L. A. Lewis, Police Bureau, Portland, Ore.
 F. Linton, Supt. of Schools, Mingo Jct., Ohio.
 A. H. Lintz, National Safety Council, Northeastern Ohio Division, Cleveland, Ohio.
 R. M. Little, Director, Safety Institute of America, 14-18 West 24th St., New York City, N. Y.
 G. H. McClain, College of Medicine, University of Cincinnati.
 H. E. Meginness, Safety Agent, 807 Majestic Bldg., Indianapolis, Ind.
 Arthur T. Morey, General Manager, Commonwealth Steel Co., Granite City, Ill.
 Mrs. Arthur T. Morey, St. Louis, Mo.

R. B. Morley, General Manager, Toronto, Canada.
S. B. Murphy, Pennsylvania R. R., Pittsburgh, Pa.
D. R. Paddock, Indianapolis, Ind.
J. C. Kinney, Jr., College of Engineering, Milwaukee, Wis.
W. R. Rasmussen, Multnomah Hotel, Portland, Ore.
Mr. and Mrs. D. K. Rawlings, Salt Lake City, Utah.
H. B. Reynolds, Supt. Safety Bureau, Pennsylvania Lines West, Pittsburgh, Pa.
Mr. and Mrs. R. C. Richards, Chicago & Northwestern R. R., Chicago, Ill.
A. Richardson, Grand Mere, Quebec, Canada.
R. Riege, Gilbert & Barker Mfg. Co., Springfield, Mass.
E. P. Roberts, Akron, Ohio.
Harry Robinson, Crockett, Calif.
J. Albert Robinson, Providence, R. I.
Capt. J. Robbins, Windsor, Canada.
E. J. Roesch, 1556 Broadway, New York City, N. Y.
A. L. Rose, Akron, Ohio.
A. Ryder, 15 Park Row, New York City.
Robt. L. Schmidt, Louisville, Ky.
W. D. Schofield, Miami, Ariz.
H. V. Schreiber, Johnston, Pa.
Frank Shattuck, Neenah, Wis.
F. H. Sibley, Lawrence, Kans.
Carl L. Smith, Public Safety Field Secretary, 168 N. Michigan Ave., Chicago, Ill.
L. J. Smyth, Kansas City, Mo.
J. H. Snyder, Columbus, Ohio.
Herman Spoehrer, St. Louis, Mo.
J. H. Stadelman, Wilmington, Del.
Thomas Stanion, Aluminum Castings Co., Cleveland, Ohio.
W. P. Strickland, General Inspector, Long Island City, N. Y.
Geo. W. Stone, Niagara Falls, N. Y.
Mrs. J. E. Trussell, Port Neches, Tex.
J. E. Trussell, The Texas Co., Port Neches, Tex.
Harvey N. Tuttle, Pollak Steel Co., Cincinnati, Ohio.
F. M. Ward, Otis Elevator Co., Yonkers, N. Y.
Dana Webster, Indianapolis, Ind.
Carl Wiemkem, Boy Scouts of America, E. St. Louis Council, E. St. Louis, Ill.
T. G. Wilkinson, Care Elkhart Carriage and Motor Co., Elkhart, Ind.
J. S. Windisch, Brown Hoisting Machine Co., Cleveland, Ohio.
W. E. Wooley, Safety Education, Detroit Ford Motor Co., Detroit, Mich.
Earl F. Varnum, Commonwealth Steel Co., Granite City, Ill.
R. S. Vitt, Coroner, St. Louis, Mo.
Charles N. Young, National Workmen's Compensation Service Bureau, New York City, N. Y.

SATURDAY AFTERNOON SESSION

THE meeting convened at two o'clock. Mr. A. W. Whitney, General Manager, National Workmen's Compensation Service Bureau, presiding.

CHAIRMAN WHITNEY: This is the day on which we put safety education on the map. The exercises really began yesterday when a movement that has been slow in gathering momentum came to a head in the formation of an educational section.

It does indeed seem strange that seven years passed by in the life and work of the National Safety Council before this step was taken. I maintain, however, that the development of the activities of the Council has been normal and that education has come to the front at the natural and appointed time.

A miracle has happened in these years. Doubtless that little band of devoted men that laid the foundation for this structure at Milwaukee seven years ago had a lofty faith and vision of the future, but I venture to say that the imagination of no one of them comprehended the wonder and might of the stream of spiritual energy that was there unloosed. Nor can we safely prophecy with regard to its strength and purifying influence in the years to come. It is as though workmen blindly digging for a foundation had struck a stream of pure water gushing out from the depths of the earth. They thought they were building a workshop, the building turned out to be a temple.

I have been curious to explain this miracle. Safety at first sight is not an idea to conjure with, it is almost negative in its appeal and seems to limit the adventure and zest in life. Where then does it get its superhuman strength and beauty?

This is the explanation that I make to myself. Of all the riddles of a difficult world nothing is more inscrutable than an accident. What powers or processes in heaven, or earth, or under the earth are furthered by the crushing out of the life of an innocent, happy child? What manner of bargain is this in which joy and merriment, in which a parent's love and pride are bartered for bleeding flesh and ruined hopes? I give it up, it is past understanding. There is only one thing I see clearly and that is to stamp it out, to make the world over into a place where such damnable things shall not happen, to make the world a place that shall be animated by a purpose and not by soulless chance.

The other side of the bargain is to be found if at all here—in the purifying, cleansing rush of this mighty purpose. This was the stream that the workmen unearthed and it seems verily to flow from the foundation of the universe.

Two things then are explained: First, why safety education belongs in the school. It belongs there because the child has the right to have this great moral force in his life. Second, why safety education has been so long in coming. It has been so long in coming because it could not be taught as it should be taught until it had taken on this moral, this spiritual quality, until it had gained the momentum that would carry it surging into the heart of life.

I don't think I can call on anybody who is so well fitted to interpret the place of safety education in the safety movement as Mr. Little. The address of Mr. Little last year at St. Louis, and the address last night of Mr. Richards are, I think, generally felt to register the high water mark in the messages that have been brought to us in this movement.

THE PLACE OF SAFETY IN EDUCATION

R. M. LITTLE, DIRECTOR, SAFETY INSTITUTE OF AMERICA

As I have listened to Mr. Whitney and Dr. Payne talk upon safety in education I have wondered if I really had anything to contribute to the thought of the conference upon the subject. I will offer, however, what has been running through my mind knowing that it will be adequately supplemented and filled out by others. It seems to me that to approach this subject, "The Place of Safety in Education," we should first define for ourselves what is the object of education; for, unless we have a rather clear idea of what an education is for, we cannot very well define the place of safety in the organized educational work of our country.

TWO THEORIES OF EDUCATION

There are two principal theories of education, which theories we will have to deal with in placing safety and safety material in the curricula of the common schools, the secondary schools, the technical schools, and universities.

We inherit the theory of education which is theoretical and cultural; principally the training of the mind, an ideal conception of education. This view of an education is broadly held in our country notwithstanding that we are a new nation and rather a practical people. We inherit it from the past and as I apprehend there is running through the entire educational thought of our country a very strong feeling that as a new country we need the cultural values of education to be emphasized for themselves.

There is also the practical idea of an education: the dealing with things as they are in a very concrete and definite way, the endeavor to educate boys and girls, young men and women, to articulate themselves harmoniously with their environment and to deal successfully with the practical affairs of life.

These two theories perhaps could be stated in another form something like this: The purpose of an education is not to enable one to make a living but to live a large, full, and enjoyable life. This is the cultural conception of an education. The practical view of an education is that it is to equip one with knowledge and technique to make a living and to help fulfill the ordained mission of the human race, to subdue the earth and all the things which are therein and make them contributory to one's happiness and comfort. Now I think if we over-emphasize either one of these theories of education that we will not have before our minds the full object of an education. There are values in both of them, the

theoretical and the practical, the cultural and the popular. Education is not only to enable us to make a living but to live a life. The object of an education is to develop within one that mechanism of thought and power by which he can grasp the world of affairs and live in harmonious relationship with it; and also to grasp the world of thought and the abstract principles of truth and duty and feel their influence and power.

OVER-EMPHASIS OF CULTURAL IDEA

Let us think for a moment concerning the over-emphasis upon the cultural idea of an education and the neglect of the practical view. How impractical some people are who have finely-trained minds! This fact may be illustrated by one of the foremost educators of our country, a gentleman who is a student and a philosopher of the whole subject of education. Yet some years since when he was at the head of a school for education he would walk through the corridors and rooms oblivious to what was going on around him because his mind was absorbed with the abstract theories and philosophies of life. This was not only true in the institution but in his home likewise. He and his talented wife were accustomed to give lectures on education and leave their children at home with the maid. They were blessed with two active lively boys, who one day were experimenting in the bathroom turning the bath tubs into lakes on which to sail their vessels. Having turned on the water with full force they inadvertently forgot that the faucets were running and left the room and there was a flood. The neighbors in the apartments below received a copious portion of the flood, which caused them to notify their landlord that either they would move or their talented neighbors above would have to move out of the building. Some of the professors of the university said that the educators' family needed a practical education because they were so filled with the higher processes of education that they could not coördinate themselves with the cosmic processes.

Another illustration occurs to me of the dangers of having only a theoretical education in this practical world, by a visit which I made to one of our interesting New York cities where there is a fine community house in which the civic and social activities of the community are centered. After I crossed the threshold I was told that I could not visit one end of the building because it had suffered from a disastrous fire. It seems that a club of young women had had a meeting in one of the club rooms on the second floor some time before, which club was in charge of a very gifted young woman, a graduate of one of our splendidly-equipped colleges. As it was in the fall of the year they had a bright fire burning in the fireplace. When the afternoon was over the young lady in charge, in setting things in order, took the burning back log and put it out of sight in a closet without observing fire regulations. A fire broke out and destroyed one side of the beautiful building and caused the loss of many thousands of dollars. These may seem to be extreme illustrations, but really they are not, because often well-educated and gifted people are found to be most impractical.

It is quite possible in the emphasis upon the training of the mind in

abstract truth, in the beauty of knowledge, apart from the practical world of affairs, to become so out of harmony with environment as to be ineffective. The result is a lack of a well-rounded and symmetrical development of mind and character, which, it seems to me, should be the object of an education.

THE PRACTICAL TOO STRONGLY EMPHASIZED

Now take the other idea of an education, the practical—the dealing with things as they are—and put the emphasis upon it to the neglect of the theoretical or the ideal, and do we have the right object of education? I fear that we do not, and if we safety men insist that the curricula of our common, secondary, and technical schools shall place the emphasis so strongly upon material things and relationships as to dull the fine sensibilities of idealism and abstract thought, we also will weaken the educational life of our country and will not appreciably decrease accidents and certainly will not prepare ourselves against national disaster.

THE GERMAN IDEA

The one great nation of our time which has stressed the technical view of education as against the theoretical is Germany. The German people are educated, but in the last two or three generations they placed the emphasis upon technical education almost to the exclusion of the ideal and cultural values of education. When pupils had finished the grade schools most of them were allotted to various trades and vocations, some were sent to the preparatory schools for technical courses which they completed in the thirteen technical universities. When students entered the universities they were assigned courses of study and placed under professors who practically made them machines to grind out in the laboratories the secrets of Nature, that Germany might be a nation of applied science. She did become a nation of applied science in a marvelous degree, but in the over emphasis of the technical side of education much of the idealism and mysticism of old Germany was neglected and greatly lost its influence in the modern state. Not only did the General Staff of the Army and the Kaiser and the Court, but also the dominating educational opinion of Germany became thoroughly materialistic; therefore, the world cataclysm. It was perfectly clear why the General Staff should want the war and world conquest. One could well understand how the Kaiser and his advisors might want the war and world conquest, but some of us were baffled for more than two years after the beginning of the war to understand how the professors of German universities, men who were devoted to the search for truth, could themselves stand so unitedly behind the Government and General Staff for the ruthless prosecution of the war. Professor Vernon Kellog has told us why it was that the dominant mind of the German universities supported the war policy so whole-heartedly. The minds of the professors became technical and materialistic. They had embraced the Neo-Darwinian theory of the universe that the strong should rule over the weak, that by being strong there was a natural necessity to rule, and that the strong, well-equipped nation of technical skill had

not only the right but was under necessity to subdue and rule over the weak peoples, and to trample them under its feet and to destroy them unless they submitted to its rule. Germany furnishes us a tragic illustration of the results of over-emphasis upon the technical, materialistic object in education.

Neither the cultural nor the technical view of education is altogether right and both are wrong when they are separated the one from the other. Pursue an education for cultural values alone and it is a mistake, but not so great a mistake as to pursue an education for technical values alone. Either view alone is a mistake and might lead to ruin, but bring the two together and let them both be the object of our educational system.

EDUCATION FROM THE BIOLOGICAL POINT OF VIEW

I think it was the late Professor James who said in his lectures on Psychology for Teachers, that to build our conception of the purpose of an education we must recognize the great facts of biology. This idea appeals to me because I think of education in terms of life first of all. Let us consider the subject, therefore, from the biological point of view. Perhaps you may not agree with the view that we are just a development from lower levels of life and that the human family has inherited the instincts, passions, and desires of the animal life below us. But there are great fields of facts to support the view. Through the processes of evolution we have arrived as men and now constitute the human race, but we are not altogether cut off from the lower animal life and we retain many of the same traits which obtain in the animal world. Consider the subject of education from this point of view: An animal is provided with instinct, memory, and association, and by this form of education it is able to protect itself from the stronger animals, from the elements of Nature, and, marvelous is the safety practice of animals! It may be that the life of every wild animal is a tragedy as Seton Thompson affirms, but at the same time the animal has developed a wonderful power to adjust itself safely to its environment, and I doubt that 12 per cent of them die each year through accidents, which some authorities claim to be the ratio of accidental death among men.

I was sitting in my room on the sixth floor of the hotel this morning listening to the din of energy in the City of Cleveland. I could hear the thump of the car wheel as it passed over the joint of the rails, the hammer in the shop, the noise of the mills, and around and above all this a sort of symphony of sound. What was it? The energy of man's development and education which is being released in gainful occupations. But I also thought of the accidents which are taking place, the deaths which have occurred, the people who are being injured notwithstanding that this is "safety week" in Cleveland. Then I thought of the times I have visited our great manufacturing plants and have observed the men at work in the midst of moving machinery and their efforts as a part of the great constructive forces. Again, my thought turned to the congested traffic on the streets of our cities and how the thoroughfares are full of the energy and contingencies of our rapidly-moving life. To avoid accidents on

the highways, in the mills or the mines requires almost perfect mechanical organization and operation and also education of the individual to safe practices and habits which are unfailing.

We are being educated instinctively and by lessons to save ourselves amid these processes but I doubt if in the development of our artificial, man-made life we are more safe against the destructive forces than are the animals out in the forests. As I sat and looked out from the window, thinking of Cleveland and its din of energy and power moving in all directions, and people being hurt in the midst of it, I also thought of one pleasant afternoon on the French River in Canada when I was fishing for bass and of how safe the bass were in the lake that day, so far as my skill as a fisherman was concerned, and of two little mink in their glossy silk fur which came out of the rocks and swam across the river, and of the hawk flying in the blue above, the insects of the air, and the birds in the trees. As I reflected upon these contrasting scenes it seemed to me that the birds of the air and the fish of the sea and the beasts of the forests are more perfectly adjusted to their environment than men are adjusted to theirs. In other words, the instincts, associations, and memory of animals are as great, or of greater protection to them against accidental injury and death than are the instincts of self-preservation and an education for the human family. With the biological conception of education as a root idea the question may rightfully be raised—Has not our education in protection and safety lagged behind other elements of our development? It seems to me that it has. The opportuneness, therefore, the necessity, for the National Safety Council, which is gathering together the collective experience of industry for safety, to carry its message and practical methods to the schools, and for safety material to be incorporated in the curricula. Our educational processes should not only enable us to relate ourselves harmoniously to the world of affairs but also relate ourselves to the principles of abstract truth and duty and unless we have an educational system which will correlate life to our complete environment we shall not have that educational system at work which we need for the formation of our national character.

SIMPLICITY OF DR. PAYNE'S BOOK

One thing which I like about Dr. Payne's book is its primer-like simplicity. It is intended for the children in the grade schools, most of whom are below the adolescent age and in that period of life when the mind is not abstract or theoretical but receives its impressions and information from concrete facts and relationships. Only in and after the adolescent period does the mind become reflective and move in the higher sphere of abstract principles and relationships. It is wise, therefore, to provide safety material to be incorporated in the curriculum of the grade schools of a very simple and concrete nature, suitable to the needs of children who are interested in and dealing with concrete things and through them receiving their appreciation of truth and reality. This is the psychological and pedagogical value of Dr. Payne's book. He has gathered up the "Abc" material from the safety movement and arranged it in suitable les-

sons for the instruction of children to meet the practical needs of their lives. It is quite important that a child on its way to school shall have some knowledge about what to do and not to do lest it be injured. So also in the school, and at play with its companions, and in the home, and every other place the child needs instruction as to safety. The grade school is the appropriate place to teach the concrete simple facts to children, which will enable them to develop that inner mechanism of thought to grasp this outer world of controlling realities and not be hurt thereby. The Safety Council, however, should not stop with this primary instruction in the grade schools but the lesson should be carried upward into the secondary schools and also into the technical schools, colleges and universities, because in them our future leaders are being educated and trained for life's work. There our future engineers are receiving their impressions as to practical values of life. They are the students who in a few years will have charge of our great constructive processes and programs. They will be the leaders to carry forward improvements and refinements as regards the factor of safety in the operation of our industries.

SAFETY IN CONSTRUCTION

Of course every engineer calculates upon a reasonable factor of safety for construction and operation in the main, but is it not true that they have not carried their thought and imagination forward far enough to include the safety factor in all our operations? I am quite convinced that this is true. The engineer's position in business is like that of the architect or any other professional man. He must satisfy the Board of Directors and the Finance Committee of the corporation which he serves. They determine how much money can be spent on the factor of safety in construction and in engineering-revision and mechanical safeguarding. It is always a question whether or not he can carry safety to the nth degree. But there are great influences at work to awaken the intelligence and consciousness of finance committees upon this subject.

EDUCATING THE CAPTAINS OF INDUSTRY

The safety movement is enlightening the minds of the captains of industry. The forty-one State Compensation Acts emphasize the economic loss of accidents and occupational diseases. There is a growing appreciation of the value of human life and in the future it will not be so difficult for trained engineers when they submit their plans to executive and finance committees to persuade them to appropriate sufficient money to have their industrial plants constructed and equipped for safety of operation and the preservation of life and limb of the workmen.

SAFETY EDUCATION IN TECHNICAL SCHOOLS

It is quite possible in our zeal to educate workmen to safe practices and habits that we unconsciously hold them responsible for accidents in too high a degree. Careful studies have revealed the fact that the severity rate at least is more affected by engineering and revision of plant struc-

tures and equipment than it is by education of workmen. The primary responsibility for safe and sanitary work places rests upon the management. The management, however, is dependent upon competent engineering service to make work places safe and sanitary. In order that competent and conscientious engineers, imbued with the idea of safety in operation, may broadly influence the physical conditions of industry it is necessary that they be educated in the technical schools in the principles of safety and its larger values. To accomplish this object it is necessary that we carry the message of safety into the technical schools and universities, to the faculties and to the students. During the last year one of the most fundamental services which the Council has rendered was the encouragement of Dr. Payne to prepare his book for the primary schools, and also the sending of a qualified engineer to the universities and technical schools to converse with the faculties and tell them the story of safety and its need, and getting the safe practices leaflets introduced into these schools and these vital ideas at work where our future leaders are being educated. This is beginning at the source of influence in the schools where the little children are receiving the impressions which form their habits, in the technical schools where the engineers are receiving their ideas and ideals of professional service. As safety is first an attitude of mind and then a habit of life we will make more progress in eliminating accidents and prolonging life by developing the proper attitude of mind and habit during the years of education.

PLACING RESPONSIBILITY FOR ACCIDENTS

There is another thought which I wish to call to your attention; namely, that philosophy concerning accidents which holds them to be unavoidable and their cause often mysterious and inscrutable. The result is a belief that accidents cannot be prevented. The safety movement has demonstrated that they can be. The popular belief, however, is that accidents are just accidents,—something untoward, unlooked for, arising out of the contingencies of life which cannot be foreseen and provided against. It is this idea which frames the legal definition of an accident. This philosophy has even influenced the minds of legislators to declare that some things are the acts of God and we have been disposed to hold the Supreme Being responsible for some of the most unhappy occurrences in life. I am disposed to absolve the Deity from responsibility and charge the occurrences largely to the stupidity and ignorance of men. It is sort of a convenient philosophy to roll on to the Supreme Being the responsibility for things that belong to you and me in the development of our intelligence in the world of affairs. As it has been given to us to subdue the earth and make it serve our purpose there has also been given to us an intellect to be trained and educated to understand the forces of Nature and our relationship to the world of affairs that will enable us to live in harmonious relationship with all mundane things. Our educational development in this respect has been retarded and it needs to be facilitated by the safety movement. What mean our senses of sight, hearing, smell, touch, and taste, and our powers of reasoning, of memory, and of association, if they

cannot serve us to correlate our lives practically with the outer phenomena of the world. Our Creator has done his part in our endowment. We must do our part through education to enjoy the values of a harmonious life. I do not think that our educational processes will bring us to perfection, but when we recall the awful wastes that are occurring today not only of life and limb but also of material, and when we think that in a great city the hazards to life are greater than in a secluded spot where one is in tune with Nature, one cannot help but feel that safety certainly has its place in the educational system. What is needed is the attitude of mind, the practical methods and the realization of their values, and the putting of them to work, and they will help us to define and realize the larger object of education and make us a happier and more useful people. I cannot think that the incorporation of safety in the educational system will militate against the richness of life upon the cultural side.

TWO ELEMENTS NECESSARY IN EDUCATION

How can we maintain a cultural life if we do not have a healthy and whole life? The body is the temple of the spirit. The health and well-being of the body affect the vitality and beauty of the spirit. Only as the mind and spirit are educated to a proper control of the body in relationship to the world of facts and forces is the education of the mind symmetrical and complete. Educators and philosophers as well as practical people have devoted considerable time to debate of the value of the theoretical as opposed to the practical and the practical as opposed to the theoretical values of education. It seems to me that the values of both elements ought to be recognized because of the biological facts of life.

Life is not separated into compartments. Only for convenience of thought can we differentiate between the theoretical and the practical. One can hardly think of culture as belonging only to disembodied spirits but rather as characterizing a personality tabernacled in a physical organism. If one's physical organism is properly related to the physical world about him, his mind may be filled with the good, the true, and the beautiful, both of the visible and the invisible world, and he will have a healthier, safer, and happier life.

SAFETY MOVEMENT BOTH PRACTICAL AND IDEAL

It seems to me that the incorporation of safety in education strengthens this composite ideal of education. The safety movement is not only practical but it is also ideal. Much of the motive power of this great movement comes from idealism. Safety in education therefore will help to clarify the object of education and unite the practical and the cultural values and meet the needs of our great nation.

America should not become less technical on the engineering side nor should she become less cultural on the ideal side, but her technical skill should be infused with the spirit and imagination of idealism which will enrich the educational motive and beautify the entire life of our country. I hope that America will never become as Germany was, cursed by the philosophy of materialism to the obscuration and deadening of the

higher sensibilities of the mind and spirit. But America cannot fulfill her great mission without an increased technical skill which needs to be touched and infused with the spirit of idealism. We walk the earth but let us walk it in safety with our eyes to the skies.

CHAIRMAN WHITNEY: A year ago at this time we knew just as well as we do now that we wanted safety education in the schools but we didn't know how to put it in. We were in St. Louis at that time holding our Congress and we talked to the school authorities there about our need. The result was that Dr. Payne came forward almost providentially and before we knew it, had actually done what we wanted. It was an accomplished fact before we recognized it.

A plan was evolved and tried out in the St. Louis schools, and has proved successful, that seems to have completely solved the problem of getting safety into education, in the public and parochial, the primary and secondary schools.

I want to recommend this plan to the people of Cleveland. I was in the St. Louis schools, seeing a demonstration of the work when the teacher called on one of the boys to explain why they ought to be safe. He gave a number of reasons and then he finished off with what seemed to him one of the strongest reasons, that is, if St. Louis were to compete successfully in the race for population, she had to keep all her population. I think that would be a valuable thing for you Cleveland people to remember.

I take great pleasure in introducing Dr. Payne, Principal, Harris Teachers' College, of St. Louis.

TEACHING SAFETY IN PUBLIC SCHOOLS

DR. E. GEORGE PAYNE, PRINCIPAL, HARRIS TEACHERS' COLLEGE
ST. LOUIS, MO.

I hope that you won't expect from me a brilliant address, because I have merely come to tell you, as simply as possible, how the children may participate in the great movement of conserving human life.

It seems to me that this week has been largely an educational week. I came here to attend the Safety Congress, but in every session I have attended it seems to me the emphasis has been put on education and rightly so because, after all, safety is education and education is safety.

I should like without any preliminary introduction to enter into what I have to say this afternoon. What I am going to attempt to do is to give as nearly as I can a picture of what goes on in teaching accident prevention.

To be sure, it would be most desirable if we could take you into the schoolroom and see the children in action, but that is impossible. Some of you have seen the children in action and I am sure it is much more impressive than anything I could tell you of what takes place in the schoolroom.

MAKE THE CHILDREN A PART OF THE MOVEMENT

In the first place, the fundamental principle underlying our effort is to make the children a part of the safety movement just as we make them a part of the movement in the acquisition or the development of health, or in the acquisition of ideals and the practice of thrift. Our whole notion is to induct the children into a welfare movement. In other words, the children are living in a community of which they are a part and we want them to realize the ideals and the problems of that community. We think there is no bigger problem or no more important ideal than the realization of safety in the community. Underlying what we undertake of an intellectual sort is the effort to make the children responsible for the conduct of the school community.

Consequently, the whole idea is that the children shall engage in this work. The procedure is totally different in the education of a child from what it is in the education of an adult. I may tell you something that lies within your experience and you understand it and interpret it properly, but when we deal with children, if we educate them we have to induct them into the experience. Therefore, in the education of a child, we must rely much more upon getting the child into action and making him a part of it than in the case of an adult. Yet, every one of you knows that when you want to learn a thing, or when you have a problem, you learn it or solve the problem by bringing yourself to face the problem and work out its solution. You start with an interest. You get into the thing you want to solve, you go into the sources and you work out the details of the problem. That is what we are attempting to do with the children. We are making the children the central figure in the activity. The children do the thinking.

THREE METHODS IN ACCIDENT EDUCATION

There are three specific ways in which accident education is carried out. One is by introducing into the curriculum in the schools—into the various subjects such as arithmetic, language, reading, and the like—accident prevention instruction. The second is by having the children, not the adults, construct plays and the children give those plays or pantomimes illustrating accident situations such as you will see here this afternoon. The third is the organization of the whole school—not the teachers, but the children themselves,—with the idea that they shall be responsible for the welfare of the community in which they live. That, after all, is education. That, after all, is the only way education can go on.

People have not come to that view very rapidly because of the simplicity of the community of a generation ago, the community in which our fathers lived. But, in the modern, complex community, the city, you can't equip the child to participate in the life of his community by telling him what to do. You can only equip him properly or train him by allowing him to participate in that life; to live that life during his career when he is getting his education and he is preparing for those larger relations of life.

Let me give you a very few illustrations in order to make very clear what I have in mind in regard to making the instruction in accident prevention education a part of the curriculum.

ACCIDENT PREVENTION INSTRUCTION, A PART OF CURRICULUM

In the old way we learned civics—for instance about the activities of the city—by having a book and putting it into the hands of a child and letting him read about the subject under consideration and then come to class and sit in a chair and answer questions the teacher asks. We didn't ask whether it affected his behavior when he went out of the schoolroom. In fact, we never tested it very definitely to see whether the information had become a part of his life.

A lesson in civics as taught today reverses the situation. During the past year we were studying municipal activities,—the activities of the Police Department, the Executive Department of the city, the Mayor's Department, the Street Department and the Coroner's Courts and Inquests. Fortunately Coroner Vitt invited us to send a group of children to witness a coroner's inquest. The first thing was to allow the children to select their representatives to go and bring the information back to them. In the very beginning the children delegated persons to bring them information regarding things they wanted to know about.

The outcome of this visit was interesting, and was typical of what is going on in a civic class. The boys who came back said to the principal, "We must do something to eliminate accidents from this community. We must do something to see that children do not engage in those activities that endanger their lives."

The principal asked him what he had in mind. He said, "We went down there and heard the story of how the boy was killed. Two boys were going to a show and one said to the other, 'Let us take one last ride before going into the show.' How prophetic that was! One of them fell from the trailer of the street car on which he took the ride, both legs were cut off, and later he died."

This boy said, "There are boys in this school who jump on cars every week. I have jumped on them myself. We must see to it that no boy is ever permitted to do things of that kind." Isn't that accident prevention?

The principal said, "What are you going to do about it?" He replied, "I think we ought to tell the school."

"All right. Get your story ready." They got a group of children and practiced until they had a good speech. Then they began in the kindergarten and went throughout the school, and told the story they had impressed upon them.

Do you think the children of that community jump on street cars? No, because they got that story from the heart. They are learning to participate and get the experience first-hand.

And think of the ability in English that the child acquires in work of that kind! Think of the latent ability he finds in the expression of his thoughts! He learns more English in one exercise of that kind than he

learns in a month from books. Take as an illustration, some of the arithmetic problems he makes up:

ARITHMETIC PROBLEMS

"If there are 700,000 people in St. Louis and 510 are killed by accident, how many would be left? What per cent are killed?" Or:

"There are 99 people killed by automobiles and 37 by street cars. If 4 times the number killed by automobiles are killed in other ways, how many people will be left out of a population of 700,000?" Or:

"There are 464 people killed in St. Louis in the year 1918. If this number could be cut down 10 per cent by safety first, how many people will be killed in the year 1919?"

Isn't that better than to give the child a problem from a book to solve? Take this one:

"If the population of the United States was 91,972,266 in 1910 and the accidental deaths are 54,300, to what would the population of the United States be reduced by accidents alone in ten years if population did not increase in other ways?"

These are problems made by the children. Now look what the child has done in order to get the information! He has gone to every available source. He has searched out the statistics, census reports, all the information from the teachers, and he is taking it home to the parents. The parents have participated in getting his lesson for him. Aren't those problems as important as the problems you had in school?

The greatest value is that the child not only gains power in English construction but he gets a great deal of information and it must be correct information,—because the teacher sees that it is correct.—in regard to the actual accident situation, and it leads not only to the discussion in the home but in the school, of the actual statistics.

Not only is this true, but he takes those figures and throws them into tables and graphs. Isn't that the kind of problems we are interested in today?

DRAWINGS AND SLOGANS

Take drawing. You no doubt have seen the drawings here at the Armory this week, which are typical. A drawing of the American flag with the slogan, "Make it stand for Safety." "One Man at Work is Worth Two in the Hospital." "Don't taste everything you see. Safety First"—and this was a picture of a child on a chair drinking from a bottle taken from the medicine shelf. "Any Fool can be careless."

In other words, in drawing, instead of drawing scenes from nature—which is perfectly all right and I have no objections—the child draws the things with which he is familiar. I am not advocating this as the whole educational program. I am merely trying to show you what can be done in the school exercises.

SAFETY CORRELATED WITH READING AND ENGLISH

Or, take a reading lesson. In the reading class we assign newspapers and magazines as the subject matter for reading, with the purpose of

developing the safety idea, and with the idea that the children are to select an article that they think is worth while for the class to have. They know, further, that if the article selected is thought sufficiently valuable by the class, the members vote to select the article and put it in a scrap-book as a possession of the school.

Think of the stimulus to the child when he goes out to get something to share with his fellows and those of future classes that come into the school! You can imagine how much he reads, how much he discusses what he reads! Parents have told me over and over again that they have learned more about safety since this plan was introduced than they ever knew before in the schools because the parents were naturally the source and had to be able to help the children out. They had to be interested in the school work itself.

Then the child brings his article before the class. Teachers have told me that children make more progress in one lesson of that kind than in the ordinary assignment given to classes in one month.

Take the English lesson where we assign to the children a real or imaginary incident as an oral composition, and then we let it be known at the time that those who present the best selections, those who make the best effort, will be given the opportunity to present this, provided the class thinks it worth while, to the other classes in the school.

I am afraid you might get the idea that there isn't a great deal that is ideal for the children with this plan. I want to read you a few speeches that were written by the school children. The first is by a girl twelve years of age.

SAFETY SPEECHES BY CHILDREN

"There is something at this present time that must be taken care of, something that if not prevented will cause great sorrow and suffering. The boys, returning from the dangers and horrors of war, hope—long for—the safety and quietude of peace. Is this country safe for them? It is certainly not safe when two hundred twenty-five men, women, and children die each day from causes, most of which are preventable. If you can picture five schoolrooms, each containing forty-five lifeless persons, whom you might have kept healthy, helpful citizens of the United States, then you have some idea of what goes on in this country each day. We know that some of our valiant boys will not return while others will come back crippled. But there is a very great reason for this, a reason that will never in the history of the world be forgotten. Every day we see in the paper the glorious list of those who died that we might live and live better. It is only just and fair that we do our utmost to improve our country by saving the lives for which our soldiers died.

"The boy who in a careless hurry and flurry loses an arm, is he to be classed with the soldier who gave his arm? Was there a reason for him to rush heedlessly across the street to arrive at, not his destination, but an accident? He paid dearly for his act, and his parents will feel the loss as much and more than the boy himself. The man who hit the boy is to be considered. He will have the memory of it all stamped be-

fore his eyes for years. The parents, the man, and others had really nothing to do with the accident, but still they carry the responsibility.

"Now, look at the wounded soldier. At first sight of him, the loving old mother feels a shudder passing over her, and then quickly quite another feeling prevails, a feeling of pride and respect for that brave boy of hers. Every one that sees the boy shares her feelings. He is welcome wherever he goes. Now, compare these two boys that I have mentioned. See the numerous things they prove, among which one stands out strongly: that bravery or courage does not mean carelessness.

"During the last war the government found the people ever ready and willing to help. Now that this great question has come to the fore, the question of safety, can't we see our duty and do it? A tedious battle has been fought and won, and now this battle also must be fought and won. We shall be fighting in more than a just cause, fighting because people of our country are being killed by that ever-prevalent tyrant, carelessness. When we hear that people of our own nation, our brothers, are being killed, don't we feel a stirring, a quivering about us, a resolve to do our part in the work? We fought to make the world safe. We have heard that expression time and time again, and to a certain extent that has been successfully carried out, but not quite. While people suffer death caused by a tyrant, we are not finished. When we entered the last war, we went to work with the idea of winning. Very soon we saw something else. We saw that we must win quickly. As soon as this thought took root, things began to change. Very soon victory was ours! Just so it will be in this case. The sooner we get at this thing, the better. But remember, place 'safety first' first safely in your own mind and then in the minds of those about you."

That was the effort of a twelve-year girl and that was her expression. Take another of a similar character:

"Do you read the newspapers? Have you noticed how many accidents happen daily that might have been avoided? Not one day passes but what some one is either seriously injured or meets death simply through carelessness. We used to think that accidents were necessary, but now we know that it is not only possible to prevent them, but that it is our duty to do so.

"Some one might ask, 'What can I do? How can I help to promote safety?' Your teachers have given you safety rules which you should follow. Knowing them is not enough. You must use them. If the simple rule, 'always be careful,' be followed on the street, in the home, and at school, what a number of accidents might be avoided. We should be constantly on the alert, not only in regard to our safety but in regard to the safety of others.

"I am afraid some of us do not realize how important this safety-first movement really is. Let me quote some statistics to prove to you the seriousness of this matter. We think that the number of deaths in our army was great. Yes, it was great, sixty thousand. But think of it, in the year nineteen hundred seventeen, seventy-five thousand lost their lives through accident. Fifteen thousand more than in this great war! It is also estimated that one out of every eight persons in the United

States is injured yearly. And when we know that war's casualties were necessary, while those from accident were not, shall we sit by without an effort to reduce that number? Think of your own family. Would you want one of them crippled for life, possibly, through your negligence? It is a fact that the greatest number of accidents occur in the home and on the street. Out of twenty-nine thousand accidents in Chicago, fifteen thousand occurred in the home.

"Thousands of others will meet a similar fate unless we all unite to help free the country of avoidable accidents. By the combined efforts of men, women, and children, we won this war on autocracy. By the combined efforts of all of us, we shall win this great war on accidents."

If I could have the time this afternoon, I could give you many incidents of that kind of work that are coming out of classrooms every day. Let me give you a list of questions asked on examination:

EXAMINATION QUESTIONS

"Describe the correct way to get on and off a street car. What must you do on the discovery of a broken wire? What is the danger of spitting in public places? Name five public safety devices with which you are acquainted. What may the automobilist reasonably expect of a pedestrian? Give one important precaution regarding the handling of firearms. Tell how to call the fire department. What is the location of the box nearest your home? What number do you call for the police? Name five ways by which you can distinguish a careful person." That is the type of problem that acquaints the child and shows he has been studying the real problems of the community and not some imaginary one.

DRAMATIZATION

The second point, the dramatization or pantomime, will be shown this afternoon, by Cleveland school children.

THE SCHOOL SAFETY ORGANIZATION

I want to speak just one moment of the school organization, the use of the children themselves in the safety movement. The children are led to feel their responsibility for the safety of the community, not only the children in the school, but the children as they go to their homes from school and from home to school.

I went into a building a short time ago and found a group of children interested in discussing some problem. I asked them what they were discussing. They said, "We are discussing safety." I asked them whether they were doing anything to promote safety.

"Yes. We have children at all the crossings where the policemen are not stationed to take care of the primary and kindergarten children."

They told me also of an incident of the morning before in which the policeman on a very dangerous crossing had to go down to testify in a case. The children had gone there and had taken charge of the crossing and had seen that the younger children were safe. When I inquired at the school, not one of the teachers knew of it. The children had taken

care of the need because they had been led to feel they were responsible for accidents in that community.

Here is another incident: I went into a schoolroom where a group of children were meeting and discussing safety along with health and clean school yards and proper care of books, and other questions. They had their president and secretary and various committees, and the children freely participated in the discussion. They were making reports of what they had done in the past week, and one boy reported he had noticed the morning before that the policeman was not on the crossing and no committee was there. A boy quickly jumped up and asked, "Did you say you came by the crossing and there was no policeman or committee?" He continued, "What did you do?"

"I came on to school."

"Why didn't you take care of those children?"

"It wasn't my duty."

"Do you mean to say you saw those children in danger and in spite of that fact, you didn't step in and help them across?"

He said in answer, "It wasn't my duty. I was not on the committee."

"The gentleman does not seem to understand the question. I want to know whether you left those children in danger with the possibility of crippling or killing a child?" And, the room broke out into spontaneous applause that showed they felt the ethical nature of the point involved. This boy went further. "You are simply jealous because you were not assigned this duty." When once the children are made to realize their responsibility, how they take hold of it!

I could go on and give you incident after incident but I do not want to take too much of your time. I want to say, after all and fundamentally, this is a process of democracy. That is what it means to me and that is why it is so ideal. It is a democratic community of which every child is a part and he feels his part in the community. A child can't grow up and learn how to feel his part in it by mere reading.

If the children in the community are going to be able to participate in the life of the community, engage in it as a unit of the organization in an effective way, they must have experience in the schoolroom. That is what it means to me. It is a democratic community and we are training those children for life in a democracy.

(Audience expresses its appreciation of Dr. Payne's address by rising and applauding.)

CHAIRMAN WHITNEY: I wonder if I can't call on each one of you to get on the street crossing and be a committee of one to carry this message into your own home-town instead of your schoolroom.

The next thing on the program is a demonstration by the Cleveland school children of a part of this safety idea in the schools. This demonstration has been worked up entirely here in Cleveland and is under the direction of Miss Bryce, the Assistant Superintendent of one of the schools.

DEMONSTRATION BY CLEVELAND SCHOOL CHILDREN

MISS MARY HANRAHAN: It was Dr. Payne's intention that the school

children should explain this, but we did not understand that until it was too late, so please remember that I am reading the part that a school child would give.

"Science has shown us that disease is caused in a great measure by germs that have collected on the hands during work or play. These germs can easily be carried on the food to the stomach where they can get in their deadly work. In the first picture you will see a little boy with dirty hands ready to eat his dinner, but his parents are too wise to allow this. See what they do."

[The first scene depicted a family of three, the father, mother, and little boy, ready to partake of their meal. The parents notice that the boy's hands are dirty and send him to wash them. He leaves the table, washes his hands and returns to show his parents that his hands are clean. He is then permitted to eat his dinner.]

"Another way that the spread of disease can be prevented is by brushing the teeth after meals. This is equally as important as washing the hands before meals. Germs lodged in the crevices between the teeth can thus be exterminated. Let us see if the boy in the next picture has learned this lesson."

[In the second scene, there is the same family group, at the end of the meal. The boy is shown brushing his teeth.]

"This scene, I think, will fairly illustrate itself. I hope that every one in this audience after seeing it will know the necessity for using a handkerchief when coughing or sneezing and be ready to inform any one of this fact if he neglects to do so."

[In the third scene a group of girls are playing jacks, all coughing and sneezing, but using handkerchiefs to cough and sneeze into.]

"No person can be healthy unless he breathes fresh air. How is he to get it when he is not out in the open? By having the room he is in properly ventilated. We usually see to that during the day; but it is of great importance that we have fresh air to breathe during our sleeping hours. The next picture will show you what should be done before retiring for the night."

[In the fourth scene, a boy is seen opening the windows from the top before retiring.]

"Who would have thought the little fly could spread disease as it does? The tiny hairs on the fly's legs collect the germs, and then the fly shakes them off right in the most convenient place for them to begin their work. Swat the fly! This boy shows us how to do it."

[In the fifth scene, a boy with a fly-swatter is chasing flies. He shakes his head when he misses one, and nods his head with approval when he kills one.]

"Often we meet with what is apparently a slight injury; as a cut or bruise; and so pay little or no attention to it. But, how often do we have to pay for this neglect? It sometimes results very seriously. In order to avoid trouble or be on the safe side, always give the proper care to a wound, no matter how slight it may seem. Watch closely and see how it is done."

[The sixth scene depicted a mother sitting at a table when the little

child runs in to her with her finger cut. The mother immediately washes the wound with an antiseptic and bandages it.]

"How many lives could be saved if we all knew how to resuscitate a person that has been rescued on the verge of drowning! If you do not know, the two boys in the next scene will show you how."

[The seventh scene depicted one boy, who was supposed to have been rescued from drowning, lying flat on the ground, and the other boy was working to restore him.]

"How many accidents are due to carelessness at home. Let us all try to make our home a safe place to live in. Did you ever have the experience that this boy is having? I hope we will all pull out every nail that is not in its right place, as this boy will do, and so avoid accidents."

[The eighth scene depicted a boy picking up a stick with a nail sticking out of it. He finds a rock and drives the nail out.]

"Sometimes we realize there is danger in doing certain things, but through carelessness or thoughtlessness we pay no heed. Don't step on a ladder without giving it a thorough inspection. Falls from ladders often result in permanent injury or death. Let us remember the old saying. 'A stitch in time saves nine'. I hope that after seeing the next picture we will all have learned that a defective stepladder is very dangerous."

[In the ninth scene, a boy is walking up a shaky stepladder when another boy calls him down from the ladder and together they tighten the bolts, and otherwise strengthen it. The ladder is then ready and safe for use, so the boy again mounts it.]

"A frequent source of accident is the use of coal oil in making a fire. Persons may be ignorant of the danger in using oil on fire or may think that nothing can happen to them, and do what this mother and father want to do in their hurry to build a fire. The child is there, fortunately, to correct them."

[In the tenth scene when the child sees the father and mother about to use oil to make the fire, she persuades them not to by bringing to their attention an article in the newspaper which proves to them the wisdom in not using oil on fires.]

"Have you ever been guilty of dropping a match and not picking it up? More fires occur monthly from carelessly-placed matches than I could count on my fingers one hundred times. We should always have a place for everything and keep everything in its place. See what this sensible little housemaid does."

[In the eleventh scene, while dusting, the maid finds a match on the floor and places it in the match box where it belongs, nodding her head in disapproval of the carelessness of the person who dropped the match.]

"I read in the newspaper the other day of a little boy burned to death simply because his mother, either through fright or ignorance, did not use the proper method of extinguishing the flames. Maybe if she had seen this picture, that awful accident would not have happened."

[In the twelfth scene, a boy runs in with his clothes aflame, evidently. The boy is wrapped in a rug picked up from the floor and the flames thus smothered.]

"Have you ever seen children putting pins in their mouths? I have, more than once, and what a dangerous practice it is! The next picture will show you a mother at work making a dress. Instead of having a pin tray at hand, she uses her mouth for one. Her little daughter, realizing the danger, brings her a tray and so avoids trouble."

[In the thirteenth scene, the mother is fitting a dress on one of the little girls, holding the pins she is not using in her mouth. One of the little girls runs up with a tray and tells her not to use her mouth for this purpose.]

"We not only want to make our home a safe place, but we want to safeguard our lives while we are out on the streets. A very important rule to follow in crossing streets is, I think, 'Use your eyes, not your tongue'. One of the girls in the next picture is reminding the others what to do in crossing the street."

[In the fourteenth scene, the girl who is instructing the children how to cross the street, advises them to watch the traffic coming from the left until they are in the middle of the street, and then to watch for the traffic coming from the right.]

"How many of us are guilty of throwing a banana peel on the sidewalk or in the street! I wonder if we realized what a serious accident might have happened. This little girl is indeed fortunate to have escaped injury. See what she does with the peel."

[In the fifteenth scene, a little girl is walking along the street when she slips on a banana peel which another child has just carelessly thrown away. She picks up the banana peel and throws it into a waste paper box, where it can harm no one.]

"How many accidents could be avoided if bicycle riders were careful! Never try to beat an auto or street car at the risk of your life. We will show you in the next picture what a sensible rider does."

[In the sixteenth scene, the boy attempting to cross the street, looks in both directions before he does so.]

"None of us wants to be selfish, and so at the risk of health we do what this little girl in the next picture is doing. Fortunately her companion is wiser than she is."

[In the seventeenth scene, the little girl offers the other one a bite of the apple she is eating, but the latter refuses, because she knows better.]

"This next picture, I am sure, will appeal to every boy and girl in this school. We have all learned why it is necessary to carry our pens and pencils in a closed case. See what might happen if we are thoughtless in this matter."

[In the eighteenth scene, a boy is seen reading a book while walking along the street. He has a pen in his hand, which he is twirling with the point outward. Another boy, coming toward him, runs into the pen, but his coat was thick enough to save him from injury. He takes a case from his pocket and explains to the other boy that that is the proper place to carry a pen.]

"We are old enough to carry an umbrella and so must know how to do so. One of the girls in the next picture evidently must be taught how."

[In the nineteenth scene, one girl is crossing the street with her umbrella down before her eyes and, therefore, does not see the girl who is coming toward her. This girl, however, steps out of the way, but shows the other the danger of carrying an umbrella in that way and shows her that she should carry the umbrella over her head and not before her face.]

"The upper rooms of our school have appointed safety committees whose duty it is to stand at the street corners when school is dismissed to guard and caution children in crossing streets. Watch a few of the Committee at work."

[In the twentieth scene, the committee holds back or sends on groups of school children as they come to the street crossings.]

CHAIRMAN WHITNEY: That is all of that part of the entertainment.

Several have expressed the desire to have a round-table about this subject, as Dr. Payne and others are here.

MR. CHAS. B. SCOTT (Bureau of Safety, Chicago): I should like to suggest that the method of resuscitation in drowning that was shown in the demonstration is an obsolete method and that the prone pressure is the better method of resuscitation. Several men from the National Electric Light Association are here, and I should be pleased to have them give you a demonstration of this method if you would like to have it. It is the one approved by the medical authorities.

CHAIRMAN WHITNEY: I think we should like that very much, Mr. Scott.

[Two members of the National Electric Light Association come to the platform to demonstrate the proper method of resuscitation, giving the following explanation:

DEMONSTRATION OF PRONE PRESSURE METHOD

"I am supposed to have had this man cleared from the current and out of the water. The first thing to do is to take him and turn him over, putting his left arm forward, his right arm across the body, turning his head to one side, clearing his mouth of any false teeth, chewing gum, tobacco, or mucus. Then straddle your knees just behind his pockets or hip bones. Put your hands on the lower ribs, tips of the fingers just out of your sight, thumb alongside the fingers, little finger on the lowest rib. Stiffen your arms and rock forward. Release, removing the hands. Repeat fifteen times per minute, just like this.

"Now, it is very important to get your hand just in that position, no higher, no lower. If your knees are correct, you will notice that when I rock forward, my arm is perpendicular to the floor and the upper part of my leg is perpendicular to the floor. You don't want to go too far forward.

"Continue that resuscitation for four hours or until the patient is breathing of his own volition. Do not move the patient or allow him to be moved unless in very severe weather or because you are on rocky soil. After he has become conscious and is breathing, make him comfortable and do not leave him for some continued time.

"Operate on the patient right where he fell. Do not permit him to be

moved. Bring the doctor or hospital attendant to the patient and not the patient to the doctor or hospital attendant.

"Another point is that when the patient becomes conscious or is breathing again, do not allow him to get up.

"This is the method that is now approved by the Third Resuscitation Commission and by the various national organizations that have had it up. Booklets on it can be obtained from the National Electric Light Association, Engineers' Societies' Building, New York City."

QUESTION: Suppose the man's lower ribs were broken, what would you do?

ANSWER: Exactly the same way. When the lower ribs are broken, there are only two ways of resuscitation, one by the prone pressure, or Schaefer method, one by the Sylvester. In both cases they use pressure on the ribs.

QUESTION: Don't you think you would be liable to puncture your lungs by using that method if the ribs were broken?

ANSWER: In the case of a layman, it would be hard for him to determine that the ribs were broken.

QUESTION: I know of a case that had to be sent to Arizona.

ANSWER: I have handled some hundred odd cases and we haven't run into one yet where the ribs were broken.

QUESTION: In the case of electrical shock, don't you think it is better to drop them several times?

ANSWER: We don't believe in wasting the time, but I have heard that they have gotten very good results in the Queen Electric Lighting Company—they drop them three feet and drop them twice at any rate. Mr. Strickland is the only one using it to any great extent, to my knowledge. A number of other companies are not using it, feeling that they don't want to use up the time. We train our people to get to the man, flip him over, and begin work as soon as possible.

QUESTION: How long should a man keep up the work?

ANSWER: Possibly fifteen minutes. I should advise relays of fifteen minutes.

QUESTION: How long after the man has been drowned or shocked can he wait before you commence this and be successful?

ANSWER: We train them to get to him within a very few minutes. I think three minutes.

CHAIRMAN WHITNEY: Dr. Payne has to leave very soon to catch his train. Perhaps, therefore, we had better get at the discussion of his work.

DISCUSSION

DEAN CONNELLEY: We, at last, have legislation. We make it compulsory for every child in the state of Pennsylvania to become "safety first." We hope to get that much from Dr. Payne and his book. But, do not be discouraged if your school board does not approve. I will say that half of the people representing the constituents in the United States are not fit. That I know. I do not say it despairingly. We had to start at the top in order to come down. In our technical schools of

the country, much has been done. In the college work, it is just as easy for you to have a Safety-first Committee in the curriculum as a committee on advanced studies, degrees, or any other thing. It is just as easy because we did it and for five years we have had a standing committee on safety. I sincerely hope that if we in Pennsylvania can help you, you will please write Harrisburg, to the Department of Labor and Industry, and we will try to do what we can for you.

SAFETY POSTERS MADE BY CHILDREN

MR. H. J. HOBSON (East St. Louis, Ill.): I have in all of my schools, bulletin boards. The National Council formerly furnished bulletins for these boards, but have discontinued. We are now attempting to make our own bulletins. I would like to ask Dr. Payne what he thinks of that.

DR. PAYNE: I think it is a much better plan to make your own bulletins if you can. That is what we anticipate. Take the slogans of the Cleveland school children—you can't beat that work by any sort of posters you get, and I have found that where one child will look at a poster from the outside, fifty will look at one by the school children. When you put those posters by the children up in the hall, you can't get to them for children. There is the intensest interest in them.

I think it is infinitely better for the school to make the posters, although they may not be so artistic. The children look at them because they are the work of one of their fellows. In that way you get a lot of interest, discussion, criticism, and enthusiasm.

MR. SIMLEY (University of Kansas): I should like to ask Dr. Payne this: For a number of years in this safety work I have had considerable hard sledding. I have used the Council bulletins, put them up and taught safety until I have made myself disliked at times. Isn't there some suggestion that can be given us as to how we can make safety-first practical in the technical school?

SAFETY SCHOLARSHIPS

I have this suggestion: Would it be possible for the National Safety Council to provide a scholarship for men in colleges who are interested in doing something for safety first and who will put across a good bulletin or essay or who will work throughout a considerable part of the year on a thesis on this subject? Unless it is possible to get some money consideration, something practical that the boys can get hold of, I fear we shall not get a good backing.

DEAN CONNELLEY: I trust you won't go back with that kind of propaganda. Try to put enough pep into your instructors to put it across. In Pennsylvania we spend twelve million dollars every year on compensation. Now, think of that! It cost us over nine hundred thousand dollars to run our department. We have over a million injuries a year. It isn't the money, it is the human side that should be brought out! I never knew a student who sought an education who couldn't get it even though he didn't have a dollar.

CHAIRMAN WHITNEY: This is the field day for the public and parochial

schools, and I would like to ask that we confine ourselves to that problem today.

HOW TO PUT SAFETY INTO THE SCHOOLS

MR. LINTON (Mingo Junction, Ohio): Down at Mingo Junction, a steel town, we have been pioneering along this line. While we do not have safety in our curriculum, we have intended to have it. I intend to go back and put these books in the schools, and we are going to do some things!

MR. C. W. PRICE: May I ask a question? If I were talking to a school superintendent, trying to introduce safety education into a school, and he said, "That is fine from the standpoint of accident prevention; we are interested in that. But, we are interested in the educational standpoint." Strictly, what answer would you make?

DR. PAYNE: I think that the school people are more ready to accept the answer that I am going to give than business men realize. They are seeking a way. I think school people are coming to see that we have to teach health. We have to teach accident prevention not because of the practical necessity but we have to tie instruction up in order to teach it at all and make it stick.

In the matter of teaching English: we are losing so much in not using these other objectives such as health, accident prevention, thrift, etc. The war taught us that in a wonderful way. During the war thousands of outside tasks were thrown upon us. One superintendent said in the beginning that he wasn't teaching school any more, he was doing war work. I think you might take the consensus of opinion of the superintendents that they never did as much English, geography, arithmetic, and history in all their lives as during the war, and they engaged in Red Cross work, knitting for the soldiers, gathering waste paper, and all the other things.

MR. PRICE: I remember the day I visited your school I was most impressed with the enthusiasm. Do you recall any material you used that got that kind of enthusiasm I saw there?

DR. PAYNE: The discussion of health problems and practical civic problems such as I mentioned a while ago. If we are teaching civics, we are teaching live civics and not textbooks. We are letting them know what takes place in the city. We are going to have in our school a child of ten years who knows more about the actual working of the city than his father. Isn't that just as valuable as teaching something you don't know about? We are all agreed that you can't learn by memorizing something you don't understand. The difficulty of the school curriculum now, with the great variety of things is that the whole thing must be tied up to the life of the child. That is what we do whenever we bring accident prevention, health, thrift, and all these other things into the schools.

Take an adult; how many of you would sit down and work out something because somebody told you it was good for your soul? We must start with the child and with the interest of the child. He must be interested. He must do it because he wants to obtain some objective in doing

it. He is just like an adult. It is going to affect his mind and life, and if it is, it must be related to his interest and purpose. I very often say to my teachers, "If the child don't want to do what you assign him, then you are wrong and not the child."

HOW THE POLICE MAY HELP

INSPECTOR MAY (Police Department, Cleveland, Ohio): How can the police help that work in the schools? (Much applause.)

DR. PAYNE: By doing just what they are doing in St. Louis. The children call upon the policeman. They go with him and they get more information from the policeman about the Police Department than in any other way. The policeman's duties are learned from the policeman by the children.

INSPECTOR MAY: What I am trying to arrive at is this: We know every school teacher is interested in the safety of her children. Just as soon as the policeman is not at the school, the principal will call up and want to know why. What I am getting at is this: last winter we had a policeman visit every school in the city of Cleveland and talk safety, telling the children what they should do when they left the school, telling them the way to proceed on the way home, picturing to them the things most likely to happen. But, I am wondering if there were some better or more forcible way of impressing it on their minds.

DR. PAYNE: I think that is a splendid thing providing the teacher doesn't think the duty is accomplished when the policeman finishes. If she does her work, and then brings in the policeman whenever she can, that is splendid.

As I said, the children themselves find out a great deal about the activities of the policeman.

MR. EUGENE ROESCH: I know of a chap, one of the traffic men in Cleveland, but part of his time he is stationed near a public school here. Now, this chap is really a big brother to the school boys and he puts the responsibility onto the school boys themselves for maintaining order and traffic and all that sort of thing. He has his coterie of chaps so that when he is not on the corner, perhaps called on a case, they will watch the traffic, take care of the little children, and report any disorder or infringement.

I think the policemen should, and I believe they do in New York City, chum with the big boys and also the little fellows of the school and say, "Now, here, you are my representative and I put this responsibility on you." If the policeman will do that, they will be teaching a lot of civics as well as helping these boys.

While we are on the subject of what the police can do, I want to bring this matter up. I am not going to mention any particular city. I have been at every meeting here and I haven't heard a thing about getting convictions and imprisonment. Let us put ourselves on record for convictions and get the judges to back up the police. This matter is a farce when a man gets five or ten dollars for speeding and endangering lives. I myself have been nearly run over several times, and on taking

the matter up with the police, they say that they are absolutely disgusted because, when they have a clear case and have witnesses, the thing is quashed.

COÖPERATION

MR. T. B. HAYES (Upson Nut Company, Cleveland, Ohio): I want to ask Dr. Payne if coöperation of the mothers' clubs wouldn't be of good advantage with the teachers in working on this safety movement. The children, of course, are the primary object of teaching, and working through the mothers' clubs and teachers would make a good feature.

DR. PAYNE: I think you can't help but get that coöperation when you begin to teach this. Just the Friday night before I left they had a meeting with fifteen hundred present at the school, a patron's meeting in a district where they are doing this kind of work. All you will have to do is to give them an opportunity and they will do it.

MR. F. S. CRUM (Prudential Life Insurance Co.): I mark three or four papers every day as I read them, mark all sorts of accidents which we classify and file, and I pay my boy of eleven years to cut them out. That boy knows more about the daily accidents as reported in the morning and evening papers than I do. He stops and reads, while I only glance at the headlines. You couldn't hire that boy to be a jay-walker.

That just illustrates that when this matter is brought home to them daily, there is nothing to it—it is absolutely automatic.

UNIQUE EDUCATIONAL PLAN

MR. MCCLAIN (National Safety Council, Cincinnati, Ohio): I wonder if these folks would be interested to hear of our unique educational plan in Cincinnati.

I am the Secretary of the local chapter at Cincinnati and at the same time I am a member of the faculty of the University of Cincinnati. It comes about in this way: the University of Cincinnati is a municipal institution. The trustees of that University are the business men, the industry men of the city. Those men have tried to interpret the responsibilities of an education of that type to the community. In view of that, in the last eight months, they have organized in connection with the University a department known as the Department of Industrial Medicine and Public Health. That department is connected with the Medical College.

The scope of the department is this: the director of the department is Major McCord who had charge of the Base Hospital at Camp Sherman. Captain Walker, a very able man, had charge of the nitro plant in West Virginia. We have a woman, Miss Laura Sanders, who has demonstrated her worth as a woman at the University. She has been at the Teachers' College, Columbia, and the Wright Airplane Company. She used to work among the women in industry.

We are employing a man to take charge of employment relations who will go into the industrial field and develop among the manufacturers themselves, and show them the necessity and advantages of that. In

connection with that department they have a safety man. We are all members of the faculty. Besides our field work among the industries in the city, we have regular teaching jobs. This department I have mentioned takes graduates and gives them a sort of apprenticeship in these things I have enumerated.

A student will be with me a few months. I will give him the best I have in the field in industry. He will be with Dr. Walker a few months. When we get through, he is industrially trained, equipped to go into an industry of two or three hundred employees, where they can't afford to hire a safety man, or a doctor, and he will be able to meet the situation.

Here is an advantage that comes to me as a safety man being connected with the University. We have about eight hundred engineering students. I have arranged to give them a definite course in safety—we will call it lessons. If it were outside of the University, it would be called lectures—anticipating that the men will hold responsible positions later. In the Teachers' College, I have been accorded the privilege of giving them a course preparatory to teaching safety in the schools. I took my plans to the Board of Education to organize a class of teachers in the schools in the city, at least one from each building. It is hard to get them all together, but we are going to get one from each building. I am going to teach them and train them along the lines of safety as Dr. Payne has outlined. I intend to go to the schools myself to give lectures and exhibit moving pictures to give a background. We will encourage little playlets.

We have been offered the use of an already-organized club, as it is called, affiliated clubs. Each school has a little active organization that we have used for selling liberty bonds and thrift stamps. These clubs have been offered me for use in the safety work. So far as I know, and I believe I am right, I am the first man in the world (that is, taking in a lot of territory, I know) to be Secretary of a safety organization and at the same time a regular professor in a university. I thought you might be interested in that.

CHAIRMAN WHITNEY: Are there any other questions or observations? If not, we are adjourned.

Banquet

October 3, 1919

STEPHEN W. TENER, Chairman

President, Northeastern Ohio Division, National Safety Council.
Cleveland, Ohio

A. C. Brown, Toastmaster

President, Brown Hoisting Machinery Company, Cleveland, Ohio

THE CHAIRMAN: It is my pleasure, as President of the Local Council, to welcome you all to Cleveland, and to thank you for coming long distances; for coming as a multitude. I am glad to welcome you to this, the Fifth City of the United States—excluding Missouri and Alaska. (Laughter.) There seems to be a little objection to that statement. Inasmuch as I have never been in either Missouri or Alaska, perhaps I had better correct myself, so I will begin all over again and welcome you to the Fourth City of the United States, exclusive of Missouri, Massachusetts, and Alaska. (Laughter.)

THE LOCAL COUNCIL

I want to say a word for the Local and its activity. I have been extremely busy with other matters, due to labor troubles, and I confess I have not been able to attend the convention regularly, nor have I been able personally to do very much work in connection with the preparatory work of this convention, but I will paraphrase the inscription which Mr. Carnegie ordered placed on his tombstone—"Here stands a man who is able to pick men better than himself." The members of the Local Council have done their part; credit must go to the various committees, with their active chairmen, all splendid, enthusiastic workers in the cause, marshalled by that indefatigable, enthusiastic, and genial gentleman—Oscar McNab. (Applause.)

It occurred to me today, inasmuch as you were all engaged in taking part in the various activities of the convention, that very few of you have been able to visit our industries and see what is made in this city. We believe our city has made an enviable name for itself in the quality and quantity of its products all over the world. Our city is well known for the excellence of its pig iron and its peanut butter (laughter); for its automobiles and popcorn; for its wire and its wigs; for its oil and its carpet tacks; for its telescopes and its chewing gum. It is noted for its skirts and its shock absorbers (laughter and applause); for its cranes and its crackers; for its paint and its "two-and-three-quarters

per cent": for its sewing machines and its garbage cans; for its electric lamps and insect exterminators; for its grindstones and macaroni; for its brick and its mustard plasters; for its brushes and its sausages; for its chemicals and its candles; for its ships and its horse radish; and it is well known for its savings banks and its sand banks. It is well known as the home of a Rockefeller, but of no fellers who are rocky. (Laughter.) I hope I have impressed you with this, and you have put these statistics beyond the vestibule of the memory portion of your brain.

WOMEN RECOGNIZED BY THE NATIONAL SAFETY COUNCIL

Fortunately, in my position as Chairman in opening the meeting, it does not devolve upon me to address you at any length. An announcement has been handed to me which I am asked to let you have. We men are going to have a boss—the women have been recognized by the National Safety Council. Miss Tracy Copp has been made Chairman of the Women's Section. This brings her automatically to membership of the Executive Committee, which as you know is the governing board. (Applause.) Miss Kathryne Hunt, in recognition and appreciation of her work in the Chicago office, has been elected Treasurer. (Applause.)

Among those in this city who have given a tremendous lot of time to the Safety Movement is Mr. Alexander C. Brown, Toastmaster of the evening, and him I now introduce to you and take a back seat myself.

THE TOASTMASTER (Greeted with applause): *Mr. Chairman, Ladies and Gentlemen:* Perhaps some of you may know the temper and patience of a college audience in chapel on Sunday morning, and when one of the speakers of the evening asked me how long he could speak I was reminded of the remarks that the president of my college always made when the visiting clergymen asked him that question Sunday mornings before chapel. He said, "There is no limitation fixed on the length of your address, but no souls are saved after twenty minutes." (Laughter.)

PROBLEMS FACING INDUSTRY TODAY

One of the large employers of this country has said, "The personal relation in industry entered into in the right spirit gives the greatest promise of bridging the yawning chasm which has opened up between employer and employee." I think in these days of so much frenzied thinking, when we can all share thoughts with each other, it pays in the National Safety Council to give a little thought for a moment to where we stand in some of the problems that are particularly facing industry today.

The first thing we ought to have clear in our minds, as I see it, is: What is the end toward which we are striving? That sounds like a big contract, but if we will accept two premises which I think are necessary, it will be helpful to acknowledge first that the labor problem after all is nothing but one of human relations; secondly, that for any helpful solution it is necessary to approach the problem in the right spirit.

The end, therefore, it seems to me, is one of equitable human relations

based on mutual confidence; and one of the means to that end is any system or plan which will lead in that direction, entered into in the right spirit.

It seems to me the reason why so much of the thinking along these lines has been frenzied during these times of stress is the confusion as to which is the means and which is the end. We hear a great deal about many plans, programs, and systems: we hear a great deal about industrial democracy. It is difficult to give a definition of them; but where these plans of various kinds have failed, it seems to me, is primarily in the attitude of mind which has accepted them as the end and not as one of the means.

The problem is too big for any one means to be the only means of solving it. There are too many human instincts that must be administered to and must be reckoned with. And, furthermore, the very unrest that exists is not confined to any one class. We all of us share it. We all of us are dissatisfied.

I think a little article in one of the papers, which I hope not all of you at least have read when it came out, brings out the fact that the employers and the business men are by no means satisfied in their own minds. This was given as a prescription for morning exercise for the tired business man:

MORNING EXERCISES FOR THE TIRED BUSINESS MAN

"Rise at 7 A. M. Stand in the middle of the room. Raise arms slowly overhead; take deep breath and say, 'Damn the government,' lowering arms in attitude of despair ten times. Extend body flat on the floor. Cover eyes with hands; kick heels; think of the railroads and weep till dry. Kneel, wring hands, meditate upon the labor unions and groan a hundred fifty times.

"Assume sitting position, hands on hips. Sway gently to and fro. Concentrate on Mr. Burleson until a general frothing at the mouth sets in, until exhausted. Collapse on floor; grovel vigorously; think of the income tax and gnash teeth in anger.

"Observe this simple regime every morning before breakfast and you will reach the office with most of the cares and troubles of the day already out of your system." (Laughter.)

A few of these things have to be reckoned with and met in any system that is adopted; such as the instinct of monetary gain, the instinct of pride in workmanship, the instinct of leadership, of individual right, of individual obligations, which has not been emphasized nearly as much as the one of individual right—and they are equal, they should be equally emphasized. Then the instinct of family welfare, of personal improvement and comfort, and of self-preservation.

These last three instincts, it seems to me, are the point of contact which is peculiarly suitable for the work of the Safety Council—the instincts of family welfare, of personal improvement and comfort, and of self-preservation.

While safety work is performing its normal functions, it is appealing

to those instincts and forming a point of contact, between the employer and the employee, so that all the time it is doing its normal good work it is also performing a peculiar kind of team work for all other phases of work that are helpful and constructive in our labor situation. It is paving the way for all the other methods and humanitarian schemes and plans that have a tendency toward humanizing industry. That, it seems to me, is one of the big things that the Safety Council is doing for team work in this problem.

Now, speaking of the part that safety plays in team-work, we want to have emphasized the part that team-work plays in safety: and our next speaker, who is a New York banker—and we hope safety plays a part in his business—is peculiarly suited to talk on this question of team-work. He is the treasurer of the Safety Institute of America. He has been personally responsible for what the city of New York gave to him and to the organization which he has built up—a building which will be a Museum of Safety for the United States. Through an interlocking board of directors of his organization and the Safety Council, team-work has been carried on to a very great degree, and we will all be glad, I know, to hear Mr. James Speyer on "Teamwork in Safety." (Applause.)

TEAMWORK IN SAFETY

JAMES SPEYER, TREASURER, SAFETY INSTITUTE OF AMERICA

You have all heard of Charles Darwin and his celebrated book, "The Origin of Species," but I wonder how many of you have heard of the story that is told of this great man, who loved to be surrounded by his children and friends of his children. One day, these young people thought they would like to play a practical joke on the famous naturalist. They took a dead June-bug and carefully glued on the wings of a butterfly. Then they put it on a plate and brought it to the great and kindly man and asked him, "Sir, what kind of a bug is this?" He looked at it for a moment, and then said, "My young friends, this is a humbug." (Laughter.)

Ladies and Gentlemen of the National Safety Council, I do not want you to say the same thing about me, and therefore, I tell you right now, that I know very little about the technical side of the safety work, and hesitate very much to speak before such well-informed men and women, as are here to-night.

You are all experts in your field, and in these times of catch-phrases and loose talk about "uplift" and "social betterment", it is a real pleasure to meet practical men who do not try to achieve—much less promise—the impossible. You are doing a man's work, and your judgment and advice are based on personal experience, scientific study, and actual contact with your fellow-men. The fact, in itself, that the work of the National Safety Council is in the hands of practical and experienced men, and not in the hands of theorists and amateurs, however well-

meaning, should secure for it the support of everyone, whether employer or employee.

I do not want to trouble you with statistics, but it is a remarkable fact that, out of a total of 3,208,000 men called under the draft and physically examined between December 15, 1917, and September 11, 1918, there were about 950,000, or nearly 30 per cent found to be disqualified partly or totally, at that time.

Now much of this disability was due to insufficient care and under-nourishment, when these men were children; how much to insanitary conditions in the homes, or unhealthy conditions in factories; how much to accidents, sustained on the highways or in the workshops; and how much to carelessness of the workers themselves, I do not know; but that much of all this could have been prevented and should be prevented, is evident. Not only is man-power of very great importance in time of war, but the conservation of man, and woman power, also, is equally important, economically, for works of peace.

It is not necessary for me before an audience such as this, to speak of the purely humanitarian side of your efforts. Every one here wants to see all of his fellow-beings contented, as far as possible. No one can afford to forget in these days that, if human beings become physically unable to support themselves, those so handicapped are not only a financial burden to the community, but easily become dissatisfied with the existing order of things and their dissatisfaction breeds discontent and worse. It is therefore "good business" in more ways than one, to prevent sickness and accidents to men and women and children.

SAFETY WORK PROMOTES COÖPERATION

There is another weighty reason why the work that you are doing should appeal to every one, and that is, because it tends—like nothing else—to bring labor and capital together, to assure coöperation in a practical, natural way. The easiest way to do this is for employer and employee to consider together non-controversial matters—matters that are clearly to their mutual interest; and what can be more so than the health and physical well-being of the workers? The workers naturally are interested in it, and so must the employer be. There is no twilight in this zone and, when men once find that they agree on certain aims and measures, it does not take very long to have them discuss other more difficult points, like hours of work and wages, and to recognize one another's legitimate aspirations, their rights and mutual obligations.

In our own country, blessed like none other with natural resources, we have seen, during the last fifty years, a marvelous development of industries. American energy, American inventive genius, and American capital and brains have been devoted very largely to producing, at low cost and in great quantities, those things which the people need in their daily life; all of which has resulted in very substantial benefits to all. But in this tremendous effort, made in competition with other nations, it would seem that the welfare of the men and women and children engaged in producing these very things, has perhaps not always

received sufficient attention, at least up to the last ten or twenty years. The Peace Treaty, as you know, has one special article establishing international organizations for the purpose of improving labor conditions. The next twenty-five years will see the efforts which your association—in coöperation with the workers themselves—is making for their well-being crowned with growing success.

Each century has had its distinctive feature of progress,—sometimes only discerned by subsequent generations. But one thing is apparent even to-day: Never since the world came into existence, were there so many men and women who, realizing their obligations, are devoting their time and thought unselfishly to the betterment of living conditions of their fellow-beings. I believe that the result of such pioneer teamwork of coöperation will be more satisfying for all concerned, than any benefits that may come through enforced rules and legislation. But in any legislation dealing with these matters of public health, accident prevention and liability, the advice of the National Safety Council should be sought and heeded, both by State and Federal authorities.

Ladies and Gentlemen, we are living in serious times, but let us be careful not to lose our sense of proportion, as to events in which we take part. One is apt to overrate the immediate difficulties that confront one, not remembering similar dangers of the past successfully overcome, and to be startled at any novel way that may be proposed for their solution.

Will you forgive me one moment if I remind you of the program of the Populists in 1892-93 only about twenty-six years ago? The platform of this "People's Party" proposed certain changes, which frightened many of our people and seemed to them absolutely revolutionary and fraught with danger. The distress and financial stringency then existing made the "People's Party" call for "free and unlimited coinage of silver and gold" at a fixed ratio, for an "increase in the circulating medium", and a "national currency, safe, sound and flexible."

You all know, Ladies and Gentlemen, they are wrong as to the "free and unlimited coinage of silver", and the majority of our people decided, at the subsequent election, that they were wrong in that remedy; but the "national currency, safe, sound and flexible" we have since got, through the Federal Reserve Bank Act, worked out by experts who knew better how this aim could be attained.

Another thing the Populists demanded in 1892 was "a graduated income tax". Well, we got that. They also demanded that "postal savings banks" be established by the Government: These are here. Another thing they asked for was the election of United States Senators by direct vote of the people: The Constitution has been amended to that effect. They also asked for "rigid enforcement of the existing eight-hour law on Government work", and "sympathized with the efforts of organized workmen to shorten their hours of labor". You know what great progress has been made in that direction.

There are certain other things that the Populists advocated, namely that the "Government should own and operate the railroads in the interest of the people", and also "that the telegraph and telephones like

the Post-office, should be so owned and operated." I do not know exactly what they meant by the words, "in the interest of the people." We have lately had a little experience with such Government operation and, in spite of able management, it has not proved satisfactory to our people. On the other hand, the people who own railroad securities are well aware that the policy pursued by Federal and State authorities during the last half-dozen years or so towards the railroads, has not been "in their interest", nor in that of the country as a whole—to put it mildly.

At that election in 1892, out of about twelve million votes, the Populist Party received approximately one million. There was one other party that received less, about two hundred sixty thousand votes, and that was the Prohibition Party; nevertheless, prohibition has since been written into our fundamental law. While some of us do not like this amendment very much, it will doubtless be a substantial factor in preventing accidents.

There is one other measure which it is expected will soon become a National law, and which was not even in the platform of any party then: that is Woman Suffrage and that also should help your work.

I mention all these to remind you that what to many seems revolutionary at a given moment, gradually may come to be accepted and regarded as justified, and that all these progressive changes under our well-tried form of Government, have been brought about in an orderly manner and by peaceful means, as becomes a free, self-governing people.

PERIOD OF UNREST

To-day, the whole world is still under a nervous strain and the situation is certainly fraught with danger. In order to win the war, each Government had to keep its own people keyed up to a high pitch. Many vague and specific promises for a better state of affairs to come were made; but, alas, many a hope thus awakened is doomed to disappointment. At the same time, the destruction of property and human lives had, at least, to be condoned. While some of the present unrest is due to these general conditions, it may be caused also, in part, by the natural desire of some employees to secure a more equitable share of the large profits which their employers made, or are supposed to have made, during the war. Many men, not only among the working people, are dissatisfied and are trying to better themselves, the more ignorant ones not being too careful as to the means to that end.

There always have been, and there always will be, others who will use such dissatisfaction and unrest for their own purpose, just as there always will be some who remain blind to the signs of the times in which they live, and fail to recognize changing conditions. It must, however, be clear to anybody who stops to think, that the high cost of living can surely not be overcome by the curtailment of production, be it through strikes or through shortening the hours of work. This is the wrong remedy and must bring the opposite result. It would indeed be a misfortune for the workers themselves and for our country, if the radical

element were to prevail now, even if only for a short time. But, I do not believe it will. Whatever may happen in other countries, it will not happen here! I have too much faith in the common sense of the American people.

OUR PROBLEMS AND OUR OBLIGATIONS AS A NATION

After a while, when our nerves have calmed down, we will surely continue to make sane progress, as we have in the past, in the solution of the differences between capital and labor in an orderly manner, after considering and deciding what is really best to be done not for any one class, but for the welfare of the people as a whole.

Whether we shall insist on laws for compulsory arbitration, for forbidding strikes, in the transportation industry or by those in the employ of the Commonwealth; whether we shall insist that combinations of labor, (which are as legitimate as combinations of capital) shall be subjected to the same laws and restrictions, and that the leaders of both shall be punished for any abuse of trust; whether we shall insist that labor should share more directly, not only in the profits, but also in the management of large enterprises; whether any or all of these proposals are to be embodied in the law of the land, nobody can tell at present.

But this we all know: The relations between labor and capital cannot be adjusted by the suppression of the right of free speech on the one side, or by the destruction of property on the other, and I also believe that the American people will insist that every one shall be free to work where and as he chooses, and that the savings and property of every citizen, large or small, shall be protected against attack from whatever source.

Ladies and Gentlemen, one word more and I am through: Thanks to our fighting men on land and sea, and competent leaders, and to the work in the factory and on the farm, to the efforts of a united nation, our country has won this war, and, with enhanced prestige, is now the great creditor nation of the world. Whether there be a League of Nations or not, whether we are in it or not, our advice will be sought, and our voice will be heard in the large international questions which the future will solve. But it is not enough that today the United States is the richest and perhaps the most powerful nation. If we want to have real weight and use our full influence for Peace and Humanity in the future, we must show to the other nations of the world, first of all, that we will not tolerate mob law here, and that we are able to make orderly progress ourselves. The coöperative work that you of the National Safety Council are doing is one of the most practical and patriotic steps to that end. We have to give a living example of the real spirit and discipline of a true democracy. If we want to help maintain order and peace abroad, we must show the rest of the world that we can maintain order and peace at home.

THE TOASTMASTER: I am sure the Congress will wish me to thank Mr. Speyer for his courtesy in coming to us, and to assure him that

when New York grows large enough for the Congress, we shall be glad to meet there. (Applause.)

I think you all know Mr. Beyer very well. Well, Mrs. Beyer is as enthusiastic in safety work as "Dave" Beyer is. She has, however, done us one discourtesy, which she is going to endeavor to make up tonight. Her debut was made in New York City in the Metropolitan Opera House—her debut to America; but her debut to the Safety Council, and only the start of many pleasures which we hope she will give us in the future, will be given tonight. Mrs. David Beyer. (Applause.)

"SAFETY LAST"

By MRS. D. S. BEYER

(MARIA CONDE)

Is your engine unprotected?

Safety last!

Are the plans for guards rejected?

Safety last!

Pat it gently on the gear,

By the middle of next year

You will likely not be here!

Safety Last!

Never label stairways "Danger,"

Safety last!

Do not warn the passing stranger,

Safety last!

If you tumble down the stair,

Break your leg or muss your hair,

It's a fine excuse to swear!

Safety Last!

Is your emery wheel a menace?

Safety last!

Has it blinded Mike or Dennis?

Safety last!

Never worry, never weep,

Do not groan when you're asleep,

Compensation bills are cheap,

Safety Last!

Song by Mrs. Beyer. (Prolonged Applause.)

THE TOASTMASTER: Mrs. Beyer, the National Safety Council hopes you will continue not only with your verses of "Safety Last", but in other ways to make Safety First last. (Applause.)

In connection with safety work, there is a great deal being done, in good ways and other ways, as welfare work; but the other day I noticed

for the first time that welfare work had extended to the farm, and like welfare work in industry, it was carried out on behalf of the producers. It was called to my attention in this clipping. The headline is: "Milk cows to music. Increased amounts obtained by this method at the Electrical Exposition prove that music has power to induce a cow to yield extra amounts of milk."

"A test was made here at the Electrical Exposition. Cows which were milked to the accompaniment of phonograph music were said to have given from ten to twelve per cent more than their average yield. (Laughter.) Classical music seemed to be most appreciated by the cows. (Laughter.) One of the Holsteins under the influence of the compositions of Mozart and Beethoven gave forty-five quarts of milk in twenty-four hours."

That is welfare work that pays. (Laughter.) That also makes clear what some critics of welfare work mean when they say that insincere welfare work is simply a dodge for milking the producers. (Applause.) Safety work, fortunately, has never been so criticized. It started with nothing but the inspiration, the vision, and the determination of its pioneers. It had no figures to prove that its inspirations were correct.

The next speaker, who is one of our pioneers, has become now, after his many years of constructive service, the President of the National Safety Council.

(The audience immediately rose to their feet with cheering and shouting, and sang "For He's a Jolly Good Fellow".)

THE TOASTMASTER: He was elected. I think, because from the start he would not accept the statement "It can't be done." His confident belief that it could be done leads me to read to you a few lines by Edgar A. Guest on the subject "It Couldn't be Done" because of their appropriateness to our new and beloved President:

IT COULDN'T BE DONE

Somebody said it couldn't be done,
But he, with a chuckle, replied;
That "maybe it couldn't" but he would be one
Who wouldn't say so till he tried.
So he buckled right in with a trace of a grin
On his face. If he worried he hid it
He started to sing as he tackled the thing
That couldn't be done—and he did it.

Somebody scoffed—"Oh, you'll never do that.
At least, no one ever has done it."
But he took off his coat, and he took off his hat,
And the first thing they knew he'd begun it.
With a lift of his chin, and a bit of a grin,
With never a thought that he'd rue it,
He started to sing as he tackled the thing
That couldn't be done—and went to it.

There are thousands to tell you it cannot be done,
 There are thousands to prophesy failure.
 There are thousands to point out to you, one by one,
 The dangers that wait to assail you.
 But just buckle in with a bit of a grin,
 Then take off your coat and go to it,—
 Just start in to sing as you tackle the thing
 That cannot be done—and you'll do it!

The Safety Movement no longer has to depend upon the inspiration and vision of its pioneers. It now has figures, facts, and statistics to prove that that vision was correct. And when I say statistics I do not allude to the definition some one gave to the group which may be divided into plain lies, damn lies, and statistics. (Laughter.) I think Mr. Price's statistics are beyond that criticism.

The determination of our new President, this determination that has won him the success he has so richly deserved in all these years of service, reminds me of a story that is told by Mr. Charles Schwab.

He tells of a young colored soldier in a training camp outside of New York City, during the war, who had been working very hard for many months without any rest or recreation. When he finally secured a furlough he quickly spruced up and started out of camp. He was stopped by the sentry, who asked him for the pass word. "Pass word? Pass word, corp'ral? I ain't got no pass word." "Well, you can't get out of here without the pass word." "Well, I'se got a furlough." "A furlough won't let you out of here. You've got to have a pass word to get out of here. And, furthermore, you can't get back without one if you did get out."

"Well, corp'ral, I'se got a furlough. I'se got an old mother up in heaven. I'se got an old father in hell, and I'se got a sweetheart in Hoboken. And, pass word or no pass word, I'se goin' to see one of them three before this day's out." (Laughter.)

I was told that whatever I might say about Ralph Richards, the wheel horse of safety, the Abraham Lincoln of the Safety Movement, could not possibly do him justice. I will ask him to speak without further introduction, as soon as we can get sufficient quiet from this audience who will greet him when he rises, so he may be heard. Mr. Richards.

(Greeted with prolonged applause and cheers.)

THE COUNCIL—PAST AND FUTURE

R. C. RICHARDS, PRESIDENT, NATIONAL SAFETY COUNCIL, CHAIRMAN, CENTRAL SAFETY COMMITTEE, CHICAGO & NORTHWESTERN RAILROAD

Mr. Toastmaster, Ladies, and Gentlemen: I should be less than human if I did not feel deeply the very kind reception that you have given me tonight, and the approval you have given to the action of your Executive Committee in electing me to the highest office in the gift of the National

Safety Council. The Council has twice signally honored me much beyond my deserts. Three or four years ago, very much to my surprise and astonishment, when I was attending one of these dinners, the toastmaster announced that I had been made an honorary member of the Council. I thought then, as I do now, that there is no honor that could come to a safety man that he should appreciate more than being elected an honorary member of this great Council which has done so much for the conservation of human life.

Tonight, when I am again honored by the Council, my heart is too full to tell you how much I appreciate it; but if giving to you my best efforts in the splendid, wonderful work the Council is organized to do, will make you understand how much I do appreciate what you have done for me, you can depend upon it that that work will be performed. They say that the only prayer that is ever answered is the prayer of labor. I will give you the best I have.

You have all discovered by reading the program tonight that it was intended that some one else—my eloquent friend Bob Campbell—should speak, and that I am simply here as a filler-in. Nobody will regret more than this audience that I was drafted to take his place. I feel a good deal like a friend of mine who was called upon unexpectedly on an occasion like this, to act as I have been asked to act, and on the way home he met one of his friends who knew what he was going to do. The friend asked if he had his audience with him. "Yes, for three blocks." (Laughter.) "But owing to my early training as a sprinter, I distanced them after the three blocks." (Laughter.) I hope my effort won't meet with the same kind of reception that his did.

REVIEWING THE PAST

Seven or eight years ago, my friends, the National Safety Council started on a journey. I think some great educator said, "All the world stands aside for the man who knows whither he is going." The National Safety Council knows whither it is going. It is destined to a place, a station, on the great road we are following, known as conservation of human life. We started with a party of thirty-seven, in charge of Bob Campbell and Billy Cameron, and as we moved along year by year, instead of people standing aside and getting out of our way, they have dropped into our ranks: and with Morey and Palmer, and Van Shaack, and Price, the party has grown in six or seven years from thirty-seven to thirty-seven hundred or more. And every year, with your enthusiastic cooperation and assistance (and you know every great movement in the annals of the world was a triumph of enthusiasm) that party will grow until it numbers tens of thousands, and no place will be large enough to accommodate our Congress, until we ourselves build such a place.

And can't you visualize what that place will be when our party grows to the right number? I surely can! And I believe you can. The Safety Movement is bound to grow; is bound to succeed because it is right, and anything that is right must necessarily succeed.

When "Safety First" was first heard of as a phrase, we people who

welcomed it enthusiastically were dubbed as dreamers and fanatics by the wise and hard-headed men of our country. But like many things that have been mentioned in Mr. Speyer's paper this evening, it has come true. We want to remember, ladies and gentlemen, that this thing didn't just happen; it didn't just befall; it wasn't done in a day, or a month, or a year—but in a flight of years. And ten or fifteen years from now we shall look back and count the achievements that have been accomplished in conserving that one priceless thing that no man or woman has ever been known to sell—men sell most anything else, sometimes for money, sometimes for glory, sometimes for ambition—but no man or woman has ever been known to sell his life or limb. And because we are striving to save that priceless thing, the greatest asset that our great nation has—the lives and limbs of its people—we are bound to be successful. We are bound to meet with the approval not only of our own hearts and consciences, but of the hearts and consciences of all the people of these United States.

TWO OBJECTS IN VIEW

The National Safety Council has two objects in view, in addition to saving life and limb, and that is to furnish service that will aid everybody in doing what we are trying to do. Nothing that has ever been published by the National Safety Council has been copyrighted. Everybody is privileged to use our ideas and our information, no matter who or where he is.

The next great thing that we have to do, Ladies and Gentlemen, is to educate the people. We commenced by educating the men in industries, because that was where an awful waste of human life was going on. It isn't necessary for me to tell you how much of it there has been in the past, but we all know that since the organization of this great movement and this wonderful Council that we have been making rapid steps toward the reduction of that great waste of life and limb—that this country was suffering every year. And now, in the Educational Section that was organized today, we are commencing where some people thought we ought to have commenced in the first place, but the time was not ripe for it. We had to demonstrate, first, that we could do something in order to get the support and assistance that was necessary.

That wonderful book which Dr. Payne has written tells us that every year, in the parts of this country where they have registration of accidents, and that is only 70 per cent of the country, over 10,000 children under ten years of age lose their lives in an accidental way; and that 250,000 of them under ten years of age are maimed or permanently crippled. And so, because that illuminating book has forced us all to realize how much and how necessary it is that something should be done to educate the children and the public in general, this Council has determined it will take up that work.

The other great work we want to do this year is the work of in-

creasing public safety—on our highways, our streets, in our theaters, and everywhere the public goes.

Those two things, Ladies and Gentlemen, will be the two things, as far as I am concerned, that we will devote our best efforts to in order to bring about a satisfactory remedy. This Council tonight has representatives from nearly every state in the union—from thousands of communities. There are over two thousand people registered, which does not include our wives our sweethearts and our sisters. And if every one of you men and you women—God bless you!—will make it your individual job when you go home to see the superintendent of your schools, to confer with your board of education, and take with you a copy of this book written by Dr. Payne, and explain to them some of the things that are contained in that book, and show them the necessity of doing something to put a stop to this waste of child life, this maiming of children, the result will be wonderful. I want all that hear me tonight to pledge themselves that they will do something along that line. Don't leave it to "George" or to the General Manager, or to his able assistant, or to myself—but do it yourselves! And then see how much happiness, content, and pride it will bring to you to know that you have succeeded in doing something that has saved some child in your community.

Ladies and Gentlemen, if you could see what I have seen during the last thirty-five or forty years in the investigation and settlement of accident claims—that regiment of widows that have passed through my office, some of them with three or four children tugging at their skirts, that regiment of old, gray-haired fathers and mothers who have lost an only son on whom they were dependent, and that vast army of maimed and crippled people—you would realize as I do how necessary it is for each and every one of us to do something individually to help the safety cause. Our friend Whitney, who has devoted countless hours to starting this idea, and Dr. Payne have blazed the way. It is up to us now, my friends, to follow in their footsteps, take advantage of what they have shown us, and do something for the benefit of the child life of the nation.

I just want to say one thing more. The Toastmaster has told us that no soul was saved after twenty minutes and the church has been telling us for centuries that the most important work in the world is the saving of souls. If it is, certainly the next most important work is the saving of life and that is our work.

During that great war, which happily for us ended victoriously, there was one little poem written that has always appealed to me—more, I think, than anything else I have ever read. It was written by Colonel McCrae of the Canadian forces, whose body now lies in Flanders fields:

IN FLANDERS' FIELDS

In Flanders' fields the poppies blow
Between the crosses, row on row,
That mark our place; and in the sky
The larks still bravely singing fly,
Scarce heard amidst the guns below.

Local Council Officers' Session

October 3 and 4, 1919

C. W. PRICE, Chairman

General Manager, National Safety Council

FRIDAY MORNING SESSION

CHAIRMAN PRICE: Every time I think of the work of the local councils and all that it involves, I think of what my friend, Raymond Robins, said when he returned from a trip in the Men and Religion Forward movement. He was all flushed as he came off the train, and he stood up on a chair and began speaking: This is what he said: "Friends, these are great days. Things are certainly coming to pass." That describes exactly the way I feel.

Looking back over this past year, we see it has certainly been a great year. Looking forward to this coming year and considering the possibilities in this local council movement, I think every man in the room is keenly aware of the fact that it is growing more and more every day. We can literally say, Gentlemen, that these are great days, and that great things are not only coming to pass, but have already come to pass.

Rochester and Pittsburgh and then St. Louis made a greater contribution to the safety movement than they dreamed of. Little did the people who helped to organize those three movements dream how the demonstration of what can be done in a community would really grip that community and get every man, woman, and child interested. Little did any of us dream that that could be done. We wouldn't have believed it a year and a half ago, and yet the demonstrations that have been made in those three cities, and now in Cleveland and now in Cincinnati and then in Portland and in Kansas City—those demonstrations are bringing to our minds the thought, as we have never had it before, that it can be done. Unbelievable things have been demonstrated to be possible.

I want to speak of the organization of two local councils, because we don't want to forget the smaller cities that have been organized with a permanent secretary, one of which is in Delaware with headquarters at Wilmington with the du Pont Company as sponsors and backers, with Mr. Reed as the Secretary and Mr. DeBlois as being one of the prime movers. Mr. DeBlois is a member of our Executive Committee and one

of our influential men in Council affairs. Then there is the council at Bellingham, Washington, which is the fifth local council to be organized in that state. We hope that, possibly during the coming year, with the backing of the new safety board which is represented at this Congress by Dr. Kloeber, there will be a permanent secretary at Seattle, and that that permanent secretary may take care of the other local councils and get even better work out of them than they have been able to perform during the past year.

I have almost said what I was going to say at another point, that at the last Congress we had three cities, Rochester, Pittsburgh, and St. Louis, with permanent secretaries, and this year we have added Portland, Kansas City, Cincinnati, and Cleveland. We must not forget Cleveland. From present indications we are practically certain of Chicago. Mr. Harold McCormick has agreed to call together about thirty millionaires as soon as they get back from their vacations and raise \$30,000, and if he does we are going to have a local council in Chicago that will be a model, we hope.

The Executive Committee is considering—and I think it is going to be realized—a plan by which there will be a joint arrangement between the Safety Institute of America and the National Safety Council, so that a local council will be organized in New York City with headquarters at the Safety Institute and with the Safety Institute acting as the agents of the Council, to take care of Yonkers, Northern New Jersey, and Long Island. This will probably constitute the biggest and most important local council that will be organized. I think I can say with confidence that that will come to pass. The action of the Executive Committee last night leads me to believe that it is now only a question of detail. I think that is going to be the biggest thing we will do this coming year.

Duluth is very promising. Mr. McDonegal, who is the President of the Duluth & Iron Range Railroad, a powerful and influential man in Duluth and interested in many things, has promised to call together a group of men as soon as the labor difficulty is over, and if he does we are sure of getting the money. So I feel pretty sure of Duluth. We have been flirting with Buffalo, and I have been down there. The Chamber of Commerce seems to be taking the matter seriously and has appointed a special committee for the purpose of considering ways and means of raising \$10,000 and engaging a permanent Secretary. I think the examples of Rochester and Cleveland are getting to be a little irritating to Buffalo.

That brings me to a point where I can say, Gentlemen, that every city that organizes makes it easier for the next city, and I can say to you truthfully that this thing is developing just as fast as we can possibly take care of it with our present field force. Looking forward to the next year, we practically have at hand now all of the work that we possibly can do during the next twelve months in organizing these big centers that we have spoken of.

There is Mr. Smyth over there. Mr. Smyth was a newspaper man

and he helped Uncle Sam clean up that little bunch over in Europe. Mr. Smyth has done some of the best organizing work in Kansas City. And there is Mr. Coffin of Portland. And there is Lintz. The demonstration here in Cleveland is sufficient evidence of what Lintz can do. I don't want to miss an opportunity of speaking of our neighbors across the line, the border cities, represented by Captain Robbins over there. He was mixed up in that quarrel, too, about four years. If I were to characterize Captain Robbins I can only use one expression which perfectly describes him, and I would have to use the expression we used in the old McCormick works, "He has the guts," and he is putting it across. After only three months, and after hobnobbing with secretaries like Lintz and Fellmer, he went back and had the nerve at the very outset to organize a Safety Week in the five cities. I happened to be invited to go up there, and do you know they didn't have a single accidental death during that week in the five cities? That shows what it is possible to do, Gentlemen, when you have got the guts and the backbone to take hold of it and say, "We are going to do it and do it just the same as we said, 'We are not going to take a year to get going in this war, but we are going to do it in thirty days.'" In this movement we want to get the guts and the courage, because we have the big idea, and if we believe in it we are going to go to it and do it. Captain Robbins believed in it and he went back and did it. It was one of the most wonderful demonstrations I have ever seen, with so little preparation, so little time to develop a community spirit.

HIGH SPOTS OF THIS YEAR'S EXPERIENCE

Now I want to line up the high spots of this year's experience, because nobody else will. It seems to me the outstanding things in this last year's experience that were really significant to us were looking forward to the future. There was the school for Safety Supervisors conducted in the four cities, a school including fifteen lessons with some of our very best men, men like Oartel of Pittsburgh, for instance, as the speakers or teachers. There were fifteen lessons which covered the fundamentals of safety. They were carefully prepared by our Engineering Department. I don't think our Engineering Department has ever done anything so well as the preparation of those lessons. They were very brief, written in popular newspaper English, but including the very essence of the whole proposition, the meat of the cocoanut. The pupils were furnished copies of those lessons. At the end of the course a banquet was given with proper speeches, and engraved diplomas, each one with a little blue ribbon around it, were presented.

One of the interesting things about this school was that, immediately after writing a letter to the plant manager outlining the purpose of the school, the character of the lessons—that this school was prepared really to train a man for the position of safety inspector and give him the fundamentals—the manager became thoroughly interested. Nothing else that we have ever done brought a response from the general managers so promptly and heartily as the proposal to establish these schools.

Before Mr. Lintz came on the job, I went out before here in Cleveland. A splendid school was conducted here and it had the largest percentage of attendance. The students were one of the finest groups of men that we had. This school was started even before the local council was well organized. The idea of offering a course which is complete, which covers the fundamentals, which will prepare a man for the work, is a very popular plan, and I think I can say that in all the history of the National Safety Council we have never rendered to our members a service so definite, direct, and tangible, as that rendered by these schools. I don't think there is any qualification to that statement at all.

Now so successful were these schools that we have conceived the idea of turning our foremen's meetings into foremen's schools.

We are now preparing ten lessons out of the fifteen, carefully selected with regard to the work of the foremen. Those lessons will be written in very simple style, but they will give every foreman all that a foreman needs to know about safety in such a way that the foreman will believe it. He will have a complete set of lessons. He will have a diploma that he can hang in his office. I believe, Gentlemen, that the foremen's schools will be equally popular with the managers, and I believe they will render equally definite and tangible service to the foremen. I think all of you are aware, as I am aware, that we are never going to get anywhere in this efficiency movement, this industrial relations movement, until we have better educated and better trained foremen, because the attitude of the workmen depends on the attitude of the foremen. We are all waking up to the fact that the foreman is the keyman absolutely. I think we who have been in the game for a long time, and who have met thousands of foremen, are impressed and depressed, as I have been, many times. I suppose I have spoken to a thousand meetings of foremen, and always I have been impressed with their low average of intelligence—good men but with very limited education, very limited outlook, and practically no contact with the outside. I believe that this service to foremen is going to be an important development in the local councils.

The big thing in the future local council is going to be not industrial safety, but public safety. I can see it every day. Industrial safety is taking its place in the regular organization as a part of production, and there will be less and less need for propaganda work such as we have had to do during these years, because it is recognized as a matter of profits. Just as fast as we can convince the manager that it makes money and is good business, he is going to give it the place which the companies with which we are so familiar are giving it, and we don't need any further propaganda.

But public safety, school safety—those are the things that will call for a continuous campaign just the same as we are continuously campaigning for better morals and better health and so on: and it means the education of the rising generation.

I don't think any one who has not been close to the work can appreciate the opportunity for the permanent secretary. I know it has been a revelation to me. The demand for a man who can devote all of his time

to the service of the members has been well beyond the possibilities of these splendid men to serve our members, and there is simply unlimited opportunity to go into plants, incident and meet the superintendent and those who are interested in safety and at home with them and help them work out their own extermination and stay with them in the right road. There are unlimited opportunities to go to the members' meetings and in this way to keep up interest, because the interest many times wanes when they have to live on their own initiative. Our members welcome the inspiration that comes from their secretaries. There is wonderful opportunity to go into the plants as our secretaries have done, and with a portable motion picture machine have moving picture meetings at noon time.

Now I am almost through. I don't know whether I should say it or not, but I am going to, because it is in my heart. I can't tell you how much I appreciate personally the splendid service of our three field secretaries. I have often said to their faces and behind their backs, that I never expect to have better men as long as I am manager of the National Safety Council. They are men who have been pioneers in safety work, who have been pioneers in this large movement which has come during the last few years, and I want them to know, and I want you to know, how much the officers of the Council appreciate their service, and what splendid possibilities there are in that service as we develop these things. They go into a city and spend a month to help work out the organization and then work with the secretary, until they acquaint him with the experience of all the other cities. These field secretaries meet with the permanent secretaries every three months in conferences and give the permanent secretaries the benefit of their experience. In this pioneer movement we are doing just what we have done in the National Safety Council; we are pooling our experiences. Then there is the exchange of letters and reports, going the rounds of these permanent secretaries, so that one man knows what all the others are doing. We are gradually working out standards so that we can go into a city with a program—one of these field secretaries can—which promises definite results. It isn't a theory, but it is a fact that has been tried out in other cities and can be recommended.

Now I have talked longer than I thought I was going to talk, but it is because I feel so keenly the possibility of this thing. It is beyond our strength or our time or our ability. We are going to have more opportunity, and it is coming now. We don't have to go out and do any more missionary work. If we take care of the things that are coming to us, that are thrust-upon us—if we meet those, we are going to do mighty well. I think that will be true of every local council. I know that Fellmer will back me in this, that if you meet the things that are right before you, you will have more than you can do. This thing is so full of possibility, and this demonstration in Cleveland—which I am sure is a convincing evidence of what can be done in a community which was not very radical on safety six months ago—is really remarkable. This was a good, solid, conservative sort of community, not very radical on safety.

but look at it now. It is a wonderful demonstration which has come here.

THE EXPERIENCE OF A LARGE CITY IN LOCAL COUNCIL WORK

CARL L. SMITH, PUBLIC SAFETY FIELD SECRETARY,
NATIONAL SAFETY COUNCIL

My contribution, I am told, is to give you the experience of a large city in directing a local council, and to visualize to you those things which have been found to be successful in instilling Safety into the community life. We are fortunate indeed, and I am particularly fortunate, in having the experiments of a number of large cities that have accomplished effective Safety work the past year from which to draw the experiences to present to you.

PERSONNEL OF THE EXECUTIVE COMMITTEE IMPORTANT

In starting the organization of a local council, too much care cannot be exercised in selecting the men who are to compose the Executive Committee. Men should be selected to fill these positions, especially the offices,—such as the president, vice presidents, chairman of the finance committee, and treasurer,—from among men who are prominent in the community. I have found in my personal experience, and in my observation of the work in other cities, that success comes easier when the men who comprise this committee are men of prominence. Personally, I believe that the president of a local council should be some manufacturing head, or a prominent representative of a large public utility company, such as the president or general manager of a prominent company in the district. There are many reasons to confirm this theory. If the head of the local organization is a man well known and occupying a high position in the manufacturing world, he naturally commands great respect, and it is very easy for him to get the cooperation of other industrial presidents and managers. Especially is this so in the beginning, when a city is just starting its work.

In every city that I have gone into the past year I have found there are one or two, or sometimes three men who, when they endorse a proposition, speak for practically all industrial plants of the community. It is our problem to interest these men. Our experience has proved that when we do reach these men we have a better and more substantial organization, and it has been found, I might say, comparatively easy to get their interest. We have made enough demonstrations, as shown by the development the past year in our Local Councils' work in large cities, to be able to lay before the big men the picture of just what can be accomplished by organized safety work in a community.

CHAIRMAN PRICE: That is a very important subject. It really determines the success of your local council.

MR. G. E. MORGAN (Employers' Mutual Insurance Co.): I want to as-

whether the men who were selected as the heads of your organization down there were the large contributors, or were they the men who interested the large contributors to start your plan for the first year?

MR. CARL SMITH: In a great many cases they were both the large contributor and the man who was interested in the work. If he is the head of a large manufacturing plant, he is naturally in position to make a large contribution. In most cases the man at the head made a substantial contribution. He was big enough to do that to set the pace.

SAFETY ENGINEERS PLAY AN IMPORTANT PART

By saying that big men should comprise the Executive Committee, I do not mean to slight in any way the executive ability and efficiency of our safety engineers in the community, for they are a deciding factor in the success of the work; but as the old saying goes, and which we have been following out in industry—that we should not place square pegs in round holes—so it is in this regard. Safety engineers are qualified to do a certain specific work in community safety. They are especially valuable as chairmen of our districts, and a certain number should be included on the Executive Committee. This is the system that is now being followed out in Pittsburgh, St. Louis, Rochester, Cleveland, Cincinnati, Kansas City, San Francisco, Portland, Windsor, and other cities that are organizing local councils with paid secretaries.

CHAIRMAN PRICE: May I add this word to that? One difficulty has been that the executive committees have been made up almost wholly of the men just under the general manager. I believe every one of the local councils knows that it has meant a great deal to them to get some really influential men in it. I have had it in my field experience over and over again. There would be splendid young men, splendid working material, the very backbone of a working organization, but lacking just that backing, that influence which puts it across in a big way. That is a very important point.

PAID SECRETARY A NECESSITY

MR. CARL SMITH: The experience of the cities that I have just named has proved beyond question that a paid secretary to handle the details of the work and direct the activities is so important and so far ahead of the old plan of a voluntary secretary, that it is hardly necessary for me to take your time by offering any further reasons why this should be done. Suffice it to say that the results obtained in these communities speak for themselves.

In St. Louis, the first year of their organization, accidents and fatalities in industries were decreased 57 per cent. Industrial, public, and home accidents as a whole were decreased 16 per cent in 1918; and the report of the Coroner of St. Louis shows a reduction of 18.5 per cent for the first eight months of 1919 over 1918. In Pittsburgh, according to the report of the State Department of Labor, accidents and deaths in

Allegheny County, the first year of the organization, were decreased 33.1 per cent. Prominent men, such as the Coroner of St. Louis and the Commissioner of the Department of Labor of the State of Pennsylvania, have gone on record to the effect that the safety work, as conducted by the National Safety Council, with the paid secretary in these communities, was largely responsible for results.

CHAIRMAN PRICE: It might be well to answer questions in regard to the type of men who make good secretaries. It makes or breaks, you know. Will you outline your ideal of a secretary, the kind of a man whom you would get for \$3,600 or \$4,000, or \$5,000 in some of the big cities?

MR. CARL SMITH: In the first place I think that a secretary of a local council must have initiative to put over his ideas. He is a secretary, is in the background, and is not presumed to be in the limelight. Nevertheless, the secretary is quietly directing the work of the whole organization. If he is that kind of a man, he is going to be able to get his Executive Committee to work with him. He should give them all the glory. He should be humble when it is wise to be humble, and he ought to be there with the punch when it is proper to be there with the punch. The ideal that we have is so inviting to big men that you just have a mighty easy job. They will be delighted to do the work for you because they want to do something for the community.

HELPFUL TO HAVE BACKING OF CHAMBER OF COMMERCE

It is very helpful to have the support of the Chamber of Commerce in conducting community safety work. In St. Louis the Chamber of Commerce contributes the office space, the salary of a stenographer, furniture, lights, telephone, and other incidental expenses. They have found that the Safety Department is one of their liveliest activities. It secured for them more publicity than any two or three other departments. It also gives direct service to their members as every man, woman, and child is interested in safety and the welfare of the city. Presidents, past presidents, and chairmen of membership committees of Chambers of Commerce have told me that in soliciting membership for their organization, the subject of safety was one of their most appealing talking points. By having the endorsement of the Chamber of Commerce, they are really sponsoring your work to the industries of the community.

There is a lot of argument on that point: whether we should be affiliated with the Chamber of Commerce or whether we should be independent.

MR. P. S. CASE (Niagara Falls): We find in Niagara Falls—and I presume it is common to a good many other cities—that the Chamber of Commerce is regarded as an organization of capital and their benefits are largely benefits to the capitalistic members.

MR. CARL SMITH: It all depends upon your local Chamber. Chicago has a real Chamber; the Advertising Club is affiliating with it. St. Louis has a real Chamber of Commerce. I think there is one in Rochester. It depends on local conditions. If the Chamber of Commerce is a

big organization in your community, get into it; if it hasn't the standing it should have, then stay away from it.

CHAIRMAN PRICE: Am I right in assuming that in practically all cases the Chambers of Commerce are known among the labor leaders as a sort of neutral body and not against labor as the Employers' Associations are?

MR. E. P. ROBERTS (Manager of the Engineering Society of Akron): I have a good many dealings with the men in the ranks both in Akron and Cleveland, and I think the average man on the street has the impression that the Chamber of Commerce is against labor.

CHAIRMAN PRICE: Then you want to keep away from it.

MR. ROBERTS: I believe in the Chamber of Commerce thoroughly, but the man on the street does not.

MR. CARL SMITH: You understand that regardless of what Chamber of Commerce you are allied with, you maintain your independence. It simply helps you along with the overhead expense. The direction of your department is entirely up to you and to your committee in every case.

MEETINGS OF EXECUTIVE COMMITTEE OFTEN—OTHERWISE NO ENTHUSIASM

I am fully convinced, after my experience in St. Louis, especially in arranging for the Congress, as well as my observation of the workings of executive committees in other cities, that it is vital to the success of the work that executive committees meet weekly. It enables them to keep in touch with the movement and to take an active part in doing some of the work. After all, success depends on getting the Executive Committee-men to really do some of the work. The secretary is employed to attend to the details, but he must have the expression of his committee in order for him to be sure that he is on the right track. It is great encouragement to a secretary to have twenty-five or thirty members of the Executive Committee get together once a week. In the average community it is very easy for men to get together at noon-day luncheons. They have to eat, and as one man said a short time ago: "I attend a great many noon-day luncheons, but I know of no meeting that I get more genuine pleasure in attending than the meetings of our Local Council Executive Committee." Why this statement? Because, after all, he realized that this cause was representing an ideal that is to be found in but few organizations. The members of the Executive Committee become intelligently interested just in proportion to the active work they do.

MR. L. J. SMYTH (Kansas City Council): In starting a movement, how are you going to get the kind of men you want on the Executive Committee to go to the weekly luncheons? I find, for instance, that the men we want for an executive committee usually has three or four luncheon engagements almost every day in the week, and it is hard for them to decide which one to fill. I haven't yet been able to find a day in the week when I can reach all of the members of my committee, and I have a comparatively small committee.

MR. CARL SMITH: After you have gone along for three or four months,

that won't be the case, because when your committeemen meet, they will attend it in preference to any other luncheon engagement. If you get forty per cent of your committeemen to attend your weekly luncheons, you are doing well. Of course, the attendance will fluctuate—you won't have the same men each week. But they keep in touch with you by the minutes, and you get what you want: that is, you get action on matters which you present to the committee.

MR. M. L. FELLNER (St. Louis Council): There is one point which the speaker brought out which I find quite important, and that is to provide copies of your minutes for those who do not attend your meetings. I have had more favorable comment on that than anything else which happened in the Executive Meetings.

MR. G. H. MCCLAIN (Cincinnati Council): I want to know how you get these temporary committees into existence at the start of things?

MR. CARL SMITH: You know when you go out to purchase a house or purchase anything, you look it over carefully, and you usually select the best you can find. That is the way we do with these men here. We select them with regard to their abilities along particular lines. Then we go to see them and sell them the idea. We sell them on the thought that they are the one person in Kansas City or Cincinnati who can turn the trick. It takes some persuasion, perhaps, but eventually they come along because they see that this is an unselfish work, and everybody is in it for the good of the city; the civic idea grips them and they accept. That is the way you get them.

MR. MCCLAIN: Are those appointments or selections verified by the organization later?

MR. CARL SMITH: Yes.

MR. MCCLAIN: You pick the men and get the committee into existence.

MR. CARL SMITH: Yes, it is obvious that the secretary is going to be the "goat." It is up to him to see that he surrounds himself with the proper people in order to put the job over. The secretary is really the one who selects these men in the beginning.

MR. L. S. BRAINERD (L. T. Block & Co., St. Louis): I think another good thought in picking this Executive Committee is to have as much of a diversified group of men as possible. That is, from diversified interests, diversified employments. Have some from public utilities, some from iron and steel and some from wood working, etc.

ACTIVITIES

MR. CARL SMITH: There are two classes of activities that should be conducted by a local council—some activities for the fall and winter months and some for the summer months. The reason for this is obvious. There are things that will appeal to superintendents, foremen, safety engineers, and workmen in winter that will not appeal to them in summer; and there are activities in the summer that will not appeal to them in winter. The one thing we all, of course, try to do is to have something new all the time to keep the interest aroused in a community. Here I want to say that in planning these activities we often make the mistake of

planning too much—more than we can possibly do. *Do a few things well.* This spells success. There are just a few things that one can do, and if they are done well, they will get results and enough results to satisfy any manager that he is getting dollar for dollar for the membership dues paid.

The mistake has been made in believing that a lot of activities should be launched at one time in order to let the people know that you are doing something, and the result has been that they usually have resulted in failure. It is much better to do one or two things and have them done in a big way, than it is to do a half-dozen things in a small way.

Fall and Winter Activities.—The most successful activity we have held the past year in any of our large centers has been the School for Safety Supervisors. This experiment was tried in St. Louis, Pittsburgh, Rochester, and Cleveland. Four hundred and sixty-four men were graduated from these schools and were given certificates. The schools were attended by plant managers, superintendents, safety inspectors, foremen, and members of the shop safety committees. The course consisted of fifteen lectures.

In most of these cities a chairman was appointed to take charge of the school, and let me say that this is one of the secrets of the success of the schools. In St. Louis a general manager of some big plant was designated to act as chairman. Experience has taught us that it is necessary to have a man with plenty of "pep and punch"—our chairman had the "pep." When the men attending the school see that they have such a leader, they are very responsive. The secretary should keep in the background. He is only there to see that the details are taken care of. Committees were appointed by the men themselves to help handle arrangements in conjunction with the chairman. They took care of such matters as providing entertainment—sometimes a quartette, sometimes a pianist, sometimes a vocal solo. In other words the men realized that this was their school. After the close of the course in all the cities in which it was given, alumni societies were formed, and monthly meetings were held.

As to some of the results accomplished—the General Superintendent of the St. Louis Transfer Company, P. J. Kelleher, stated that as a result of the lecture on Plant Lighting, given by Mr. C. W. Price, General Manager of the National Safety Council, he had made an inspection of all his garages and barns and had installed a new and up-to-date lighting system. As a result of the lecture on Resuscitation, given in St. Louis, there were several cases reported where lives had been saved because a man who had taken this lecture had been near and offered assistance. One case, I recall, was in Cleveland, and the man was employed by the American Steel and Wire Company.

In St. Louis, the secretary kept in touch with every student by writing a letter each week to those who were present and also to those who were absent. In this way personal touch was maintained with the men, and I assure you it was appreciated by them.

MR. M. L. FELLNER (St. Louis Council): Mr. Smith fails to mention that at these schools we distributed registration cards, and that was the

reason he had such close check-up on these fellows. He would write them, "You missed that splendid lecture last night," and it would make the fellow keen to come the next time.

CHAIRMAN PRICE: Did you write a letter to the manager about the attendance of his men?

MR. CARL SMITH: Yes. It is well to do that as a news-letter of service to members. Suppose that Mr. DeBlois would come to speak on some definite subject, and a big crowd was there. We would send out a news-letter to the manager like this, "Five hundred attended supervisors' school last evening." As a matter of fact that was done. The Secretary of the Chamber of Commerce wanted to know if that was true, because it hit him right between the eyes. The presidents and general managers of the plants will want to know it also, because if the school has grown to that extent they will want to learn more about it.

Foremen's Meetings. Next to the Supervisors' Schools the most important activity is monthly meetings for foremen. A chairman should be chosen for this work just as a chairman should be chosen for the Supervisors' School. The superintendent of a plant who is well known and a favorite among the foremen would be preferable. It St. Louis last year, in a series of foremen's meetings held in a large hall of the Street Railways Company, with a seating capacity of 2,000 people, they drew an average attendance of 1,800 superintendents and foremen. You ask how this was accomplished? I can state positively that it was caused by three things:

1. There were 550 men enrolled in the Supervisors' School. Most of these men were executives in charge of other men. They were appealed to and were pledged to see that the foremen in their plants attended the meeting.

2. An effective letter was sent to the manager each month, containing tickets patterned after the ordinary theatre ticket, for the manager to distribute to the foremen. On the back of each ticket, was a program of the entertainment to be given in conjunction with the speaker's name and the subject on which he was to talk.

3. The chairman of the foremen's meetings was a man who could tell a few good jokes and make the men feel that they were all of one large family and that they were coming together once each month for a great purpose, and at the same time they were receiving information that would tend to make them more efficient and give them greater opportunity for service to themselves and to their fellow-men.

Splendid results in obtaining attendance have been accomplished in Pittsburgh, Rochester, Cleveland, and other cities.

That is a valuable point. You should have a chairman who can get up and arouse the enthusiasm of the men.

MR. L. J. SMYTH (Kansas City Council): Can those foremen's meetings be made a combination of school and round-table? Is there time enough in one evening in a comparative short session to crowd it all in?

MR. CARL SMITH: Oh, yes. And another thing that struck me as very interesting last year: a great many of the supervisors who attended the

weekly meetings insisted upon attending the foremen's meetings too. In the first place, they wanted to see how many of the foremen of their own plants attended. In the second place, they wanted to enjoy the entertainment and the big program just as well as any one else. So there was plenty of time for discussion, as you say, and it made a very interesting evening.

CHAIRMAN PRICE: Would you say that at least half of the time in a foremen's meeting should be reserved for round-table discussion?

MR. CARL SMITH: I wouldn't say half of the time. I would say the better plan is to have a definite time to start and a definite time to finish; a definite time for the lecture and a definite time for discussion. In the supervisors' school we allowed thirty minutes, no more. The men soon get to know that they have only thirty minutes for discussion, and that they have to speak up and start it. It made no difference how hot the discussion was; when the time came for closing, we closed.

Managers' Meetings. It has been found advisable to hold about four meetings in the form of a noon-day luncheon for managers and plant executives. The speakers at these meetings should be men who will be able to talk on subjects in which managers are interested,—such as "Health and Efficiency of Employees," "Employees' Representation," "Labor Turnover," "Employment of Men," etc.

It has been said that managers would not attend noon-day luncheon. In St. Louis an average attendance of 275 was obtained. In Rochester, Cleveland, and Pittsburgh good results were had. Some have thought it impossible to induce the managers to attend these meetings. This is not true. If you have a good speaker and if the meeting is properly advertised the managers will respond. All notices of such meetings should be addressed to the manager, and the invitation should include his plant executives. A policy that proved very effective was to mail an invitation to the manager, enclosing a post card, asking him to state how many places he wanted reserved, and then the day before the meeting check up these cards against the list of invitations mailed. Those who had not replied were called on the phone and personally asked to attend, stating the importance of the meetings. It is not necessary for the secretary to do this detail work. He can turn it over to his stenographer or any other help in his office. I remember one instance in getting out a crowd for a managers' dinner the young lady, in one hour's work calling over the phone those who had not replied, received requests for 67 plates. As the manager is the man who must O. K. the membership bill each year, you naturally want to reach him in some way and tell him the fact that you are doing something worth while for the welfare of the community. In order to make a local council successful the manager must be educated in safety as well as the foremen.

MR. POLLARD (International Harvester Co.): What has been done with reference to getting superintendents' meetings?

MR. CARL SMITH: They attend the supervisors' school.

Motion Picture Service. One of the activities that is appreciated by the manager, safety engineer, and workmen of the plants is the service

of a motion picture machine and films for noon-day and evening shows. Most of the districts are now supplied with a portable motion picture machine and some motion-picture films. Letters are sent out from time to time to the managers in the district, stating that this service is available to them and that the secretary will be glad to arrange for the showing of a film that will be in his office for thirty days. Experience has shown that after these letters are mailed, in a very few days enough bookings come in to keep the motion picture-machine in use for three or four weeks at a time.

Secretary's Service. The paid secretary can find himself a very busy man in giving individual service to plants,—such as inspections, talks to foremen and workmen, assisting safety engineers, in organizing the plant and many other calls for his services too numerous to mention.—if he will but send out a letter from time to time to each manager comprising his membership.

Summer Activities. Experience has taught us that it is well to discontinue all meetings for managers, safety engineers, and foremen during the months of June, July, and August. The reason for this is that we find early in the spring every one is interested in getting in the garden, or putting the eggs under the old hen, going fishing, playing tennis, or what not, and the appeal to attend meetings in the evening is lost. Summer time is here and they want to enjoy it as much as they can, so they turn their minds into other channels.

Boat Excursion. However, there are a few things that will appeal to them in which they will be glad to take an active part. In St. Louis, this summer, they conducted a very successful boat excursion for superintendents, foremen, and safety engineers. In fact a great many managers attended. Posters were distributed in all the factories, and tickets were sent to the managers. Many concerns bought tickets and distributed them gratis to their men. In other words, they held a community safety boat excursion.—nearly 2,000 went on the excursion.

Picnic. In Pittsburgh, the Carnegie Steel Company held a picnic with a barbecue, games, band, shows, and safety speakers. Mr. Phil G. Fenlan, Safety Engineer of the Duquesne plant of the Carnegie Steel Company, told me there were 15,000 men, women, and children in attendance.

Open Air Shows. The Park Department in every city, my experience has proven, welcomes the coöperation of the Local Council in giving open air shows to the children of the community. Usually the shows are given on the playgrounds or in the parks. The city authorities are always willing to provide seats and assist in the preparations. There are always people in every city who will be glad to help in the way of entertainment. Community song leaders are delighted to assist. The months of June, July, and August are, of course, preferable months for this entertainment as the schools are closed and the children are free to be amused and instructed. Posters and tickets distributed through the plants are good ways to advertise these shows.

PUBLIC SAFETY

Personnel of Committee. In beginning public safety work in a community, the personnel of the committee is very important. There are men in every community who, because of the position they occupy in public life, should play an active part in the work of public safety. It would be sheer folly to attempt to organize a committee without such men as the Director of Public Safety, Director of Streets and Sewers, Chief of Police, Judges of the Courts, Circuit Attorney, Director of Parks and Public Buildings, representatives of prominent manufacturing plants, automobile clubs, team-owners' associations, transfer and taxicab companies, etc. Many individual men in public life have attempted to organize public safety work and have failed because it was purely an individual idea. To have community safety, every organization in the city which is obviously interested in safety, should have certain specific work to do. The safety committees as conducted in St. Louis, Pittsburgh, and Cleveland are made up of men who are representing such organizations and such work is assigned to them as they are especially qualified to do because of the organizations they represent.

Essentials in Industrial Safety and Public Safety. In industrial safety we have found that there are five essentials that are really the governing factors in the success of safety work in industrial plants, namely: manager, foreman, safety engineer, shop safety committees, and the bulletin boards. We also know that to have successful safety work in industrial plants, the manager must put the safety idea on the map, and so it is with public safety. There are five essential things that must be done.

1. The Mayor of the city must believe in safety and that it is a good thing, and be willing to request, over his signature if necessary, the prominent men of the community to serve on the Public Safety Committee.

2. The policeman is to the neighborhood which he patrols the same as the foreman is to his men. He is responsible for the protection of the citizens on his "beat," and just as we have had to educate the foreman to his responsibility, so shall we have to educate the policeman. We are hoping to do this by having schools for policemen, where each will receive ten lectures on Safety Work as applied to his job.

3. The secretary of the Safety Council in the community is to the community what the safety engineer is to the shop. He must keep in touch with the needs of the community and his Public Safety Committee, and wisely pilot the ship.

4. A Vigilance Committee, composed of prominent men of the community, takes the place in Public Safety of the workmen's committee in the shop. These committees are organized by first having five men appointed on the committee. These five men meet and adopt a pledge card which every one signs before becoming a member. They are then each given a number and thereafter known by that number. Each is supplied with a number of report cards on which he reports careless practices occurring on the streets. These cards, after being filled out, are

sent to the Secretary of the Complaint Board of the City, or Chief of Police, who then takes the matter up, either personally or by letter, with the person concerned. The complaint card is filed by license number of the car. Should a second offense be reported, more severe measures are taken. Each one of the five men agrees to name five more men and be responsible for their instruction, thus making a total of twenty-five men. These twenty-five men sign the pledge, and after a little experience, each names five more men, making a total of 150, and so on. The number of men involved are as many as it may be deemed necessary to select.

5. *Bulletin Boards.* After all is said as to the success of the safety work in Industry, we all know that the bulletin boards in the various departments still play an important part in the prevention of accidents. The pictures and stories that are put on these boards from time to time visualize to the workmen the part they themselves must play to reduce accidents, and are a great factor in selling the men the safety idea.

If we are to reduce accidents on the streets and curb the speed maniacs it will be by visualizing to them the pictures and stories of the 60,000 lives that are lost each year in public accidents, so that the fifth essential in Public Safety is bulletin boards in garages, service and gasoline stations. In Pittsburgh, St. Louis and Cleveland the plan is to have these bulletins posted on the boards at least monthly by the policeman on the "beat", the board to be electrically lighted, with glass front the same as used in industry, and to be marked the property of the city. Attached to the board it is planned to have a tin box with the words "Traffic Rules and Regulations. Take One"; these boxes to be kept full with the little booklet of the traffic rules and regulations of the city. This will insure a permanent distribution of the law so that the old excuse of the driver not having an opportunity to get a copy of the traffic law will be done away with. It will surprise you to know that in St. Louis for instance, although there are 35,000 automobiles running around the streets of the city, that only 5,000 copies of the traffic law had been printed for distribution in the last five years. We know that bulletin boards in garages and gasoline stations will get results, and I might cite as an example the experience in East St. Louis where Mr. D. E. Parson, General Manager of the East St. Louis and Suburban Railway Company, posted bulletins on Public Safety in the public garages and gasoline stations promiscuously without any attempt to make it a dignified presentation, and as a result of his efforts collisions between automobiles and street cars were decreased 50 per cent.

I have here a copy of the Pittsburgh and Cleveland plans for Public Safety, giving the personnel of their committees and the work assigned to each committee, which is patterned after the work laid out by the Public Safety Committee in St. Louis. Copies of these plans can be secured from Mr. G. E. Clarkson, Secretary of the Western Pennsylvania Division of the National Safety Council, 704 Frick Building, Pittsburgh, and Mr. A. H. Lintz, Secretary of the Northeastern Ohio Division of the National Safety Council, 310 Chamber of Commerce Building, Cleveland.

SCHOOL SAFETY

"School Safety," as many managers of plants are expressing it today, "is the very essence of safety work in a community. When you start to teach the children you begin to get at the fundamental basis of accident prevention work." We are indebted to Dr. E. George Payne, Principal of the Harris Teachers' College of St. Louis, for the first book written on this subject, which will show a teacher how to include safety instruction to the child in the present school curriculum without adding a new study. The school people in the communities that I have visited are very anxious to get this work started, and it is one of the things that our Secretary in our Local Council can offer the managers of the plants in his district in the way of service that will be appreciated by them.

FINANCING A LOCAL COUNCIL

You are perhaps familiar with the way in which these local councils are being financed. If not, it will be interesting to you for, after all, money is needed to carry on these activities and the more money the community has, the more successful it is going to be in safety work, just as the more money a plant spends in perfecting its safety organization, the more efficient its organization is. In St. Louis the plan of assessment is based on the number of employees. An assessment of 10 cents per employee is made for the first thousand and 7 cents for the excess. This has been found an equitable plan and sufficient to finance the work. In Pittsburgh the local work is financed by a double due assessment. In Rochester it is taken care of by the Chamber of Commerce through a Community War Chest. In Cleveland, Cincinnati, San Francisco, Portland, Kansas City, and Windsor the work for the first year is being financed by contributions made by the big men of the city in order to make a demonstration as to what can be done in community safety, and after the first year the method to be used is to follow the assessment plan on the pro rata system, as used in St. Louis.

In making plans for a paid secretary to undertake the work in a community, let me just say there is nothing so discouraging to the secretary and every one else as to be handicapped by finances. The time to get the necessary money is at the start. In making the estimate of the cost, and preparing your budget, make it high enough so that you are sure it will cover the cost of the work of the year without slighting the service.

CHAIRMAN PRICE: I am glad to see my good friend Morley sitting over there looking pious—he is here from Canada. Mr. Morley is the General Manager of the Ontario Safety League and the Canadian National Safety League. We are very glad to have you come over here and tell us what you think of this man Smith and what he said.

MR. R. A. MORLEY: There are certain points that Mr. Smith has brought out that might possibly be worth while for the members present to have some of our experience on, because our experience now spreads over nearly seven years.

EXPERIENCES OF ONTARIO SAFETY LEAGUE

Mr. Smith brought out the importance of the Executive Committee, and I think that perhaps we have been more particularly lucky in the Ontario Safety League—we have been very lucky in the type of men we have had. We have gone in strongly for presidents of concerns, not forgetting, of course, the labor organizations, the automobile associations, etc.

So far as the labor end of it goes, Gentlemen, I want to say that you cannot lay too much stress on getting results out of your labor men. The labor men are tickled to death to come to your Executive Committee meetings and meet with the men who are presidents of concerns, etc. They get their point of view and it is the old, old story about safety work being the greatest ground that there is for carrying on proper and satisfactory industrial relations.

Now as to the Executive Committee meeting once a week: I don't agree with Mr. Smith. I think that once a week is too often, and in our experience once a month is plenty; that is, after you get working. Of course, at the outset you may have to have meetings seven days a week, but after you get things going, the Executive Committee has laid down certain policies and has become acquainted with the man who is doing the work—that hard-hearted Secretary who is so very essential—after they become acquainted with him and his methods, I think that you get your best results out of having your meetings once a month, not once a week. I say that after several years' experience on the job, but I think that you ought to have a definite date. For instance, ours is the first Monday of every month, absolutely regardless of anything else being pulled off—except a public holiday. We have a meeting on that day, and as I say, you get results.

I don't suppose there is any need to elaborate on that need of a paid secretary. You have to have a man whose daily bread is, to a certain extent, dependent on what he is doing. He is going to take a darned sight more interest in the thing than if he were simply putting in an hour or two a day for what he considered the good of the cause.

Mr. Smith also mentioned the question of the secretary having the necessary punch. I remember on one occasion the president of the organization making a statement to our secretary and the secretary looked over at him and said, "Dr. Hughes, that is not so." Dr. Hughes said, "Oh, I thought it was." He took it very nicely, too.

You brought out, sir, the question of the importance of public safety work, and I think your public safety work must be made the basis of your big appeal to the community at large. You are going to get your results from the community at large, through your public safety work; and the most important part of the public safety work in our experience is the school work; it is the keystone of your whole proposition. You carry on your school work, and you may not get results for ten years or you may get results tomorrow.

In that connection I would like to tell you a story of Mr. Cushing, who came into our office about three years ago from Thorold, a compara-

tively small place near St. Catharines. He said, "I understand you issue school bulletins. Can we get them at Thorold?" I told him that they could. He said, "What do they cost?" I named some small figure. He said, "I am not a member of the school board, but I want to get them." I asked him where his interest came in. He said, "I am interested because my company is one of the comparatively big employers of labor in our small town, and we feel that, if the children in the schools to-day are taught school safety, street safety, safety in the homes, and various other types of safety, when we get them in our plant they are going to be safe operators, and it is going to be simple to teach them industrial safety."

That is one of the big points of your school work. You can't lay too much emphasis on it. We have carried on our school safety in a various number of ways. We use motion pictures. We have school bulletins which we put in the class rooms every week, and once a year we distribute a letter to parents. Those are all things that have been done time and time again by somebody else, but when you get a combination you are going to get results.

In connection with that school bulletin, I want to put this thought into the heads of some of you. Your school board is going to pay a great deal more attention to your school bulletins and to the work that you are doing in the schools, provided they have some financial interest in it. We have been very lucky in regard to our school work. For instance, the Board of Education in Toronto this year allows us to spend up to \$600 on school bulletins and on that annual letter to parents. Once a quarter or once every half year, whenever we need the money we send them a bill and say, "Gentlemen, up to date we have spent so much money." At one of our meetings not long ago in Hamilton, the Chairman of the Toronto Board said that they were allowing us \$600 and that they were going to double it next year. We get \$200 a year from the Halifax, Nova Scotia, Board for the bulletins.

That feature of paying for the bulletins has two excellent points to my mind. In the first place, as I said before, you get more effect from stuff like that when it is paid for, and in the second place you get the money.

I want to finish up with a remark about the question of finances. With some of the local councils the question of finances may not matter, but it seems to me, as Mr. Smith brought out, it is a thing to which they must at some time or another devote a considerable amount of attention. In our campaign, at least in Canada, we have two features with our finances. In the first place, we have got to get the money. In the second place, we have got to spend that money to prevent accidents. Those are the two features of the financial end of a safety campaign, to my mind, and you can't get away from either one of them. I laid down a policy years ago when I took hold there that we wouldn't buy a damned thing unless we could pay for it. Lots of things we went without simply because we did not have the money to get them with. But our credit is good, Gentlemen, we can get anything we want now in the city of Toronto.

As a wind-up, I want to tell you two or three incidents. We have a peddler in Toronto who, every year, for six years, has sent us his little \$5 check. He is a man who is listed in the city directory as a "peddler." Because of the work we are doing he thinks we are worth \$5 a year from him. We have had contributions from all types and all classes of people. As I explained to you, we have had money from the Board of Education. We have had, in the six years that we have been at work, a total of \$10,000 from the city of Toronto.

The last thing I want to leave with you, Gentlemen, as the climax is that this year the province of Ontario, in view of the work we have done and the work the people hoped we would do, has made us a grant, without any strings of any description, of \$10,000, and that is more than patting one on the back.

CHAIRMAN PRICE: Mr. Morley has a right to speak with authority on school safety, because that has been emphasized during the last few years in the work in his city.

I remember during the first year of my service as field secretary, that one of the very bright spots in that experience was a four day visit I made at Niagara Falls. I remember that they had twelve members of the National Safety Council when I went there, and we found, on investigation that there were twelve other companies that were worth mentioning that were not members of the National Safety Council. We set a goal of having every company in Niagara a member, and we started out every morning with pep and ginger and determined not to fall down. Inside of three days we had the other twelve and that was one hundred per cent.

One of the men who was most active in that little drive and in organizing that local council, who is now and has been ever since, one of the men who has made it one of the most successful small councils, is Mr. P. S. Case of the Union Carbide Company. Mr. Case, we are glad to have you here. Come up and tell us how you did it.

THE EXPERIENCE OF A SMALL CITY IN LOCAL COUNCIL WORK

P. S. CASE, UNION CARBIDE COMPANY, NIAGARA FALLS, N. Y., SECRETARY-TREASURER, NIAGARA FRONTIER LOCAL COUNCIL, N. S. C.

The experience of a small city in Local Council work should, I believe, have a value from the standpoint of determining the policies of other councils which materially outweighs its historical interest. Our experiences in Niagara Falls Safety Council, though novel and intensely interesting to ourselves, were, I assume, a repetition of those of most locals. With this idea in mind, I am limiting the intimate details of our experience at the Niagara Frontier Safety Council to those which will best serve to "point a moral rather than adorn a tale."

A Local Council is or should be essentially a service organization. By this, I mean, an organization which justifies its existence by virtue of the

services it renders to its members. My experience in Local Council work has led me to believe that the most vital requisite of a Local Council's success is that it devote a considerable if not the major portion of its energies to rendering special service to its members.

There is at all times, and more particularly at the inception of a Local's activities, a necessity for a number of routine activities which are valuable to the members collectively. The Local Council, however, never becomes indispensable until it ascertains what the individual members consider their personal problem in safety work and effectively helps them to meet that problem.

Niagara Frontier Safety Council was organized under rather unique and favorable circumstances.

ORGANIZATION OF A LOCAL COUNCIL

In October, 1916, I attended the National Safety Council Convention in Detroit. There were, at the same time, several other representatives of Niagara Falls industries on hand. One day somebody mentioned that the representatives of the Buffalo plants proposed forming a Local Council in our district to embrace both Buffalo and Niagara Falls. At once we began to discuss the proposition of Niagara having its own Local, for we did not feel that Buffalo was conversant with the peculiar problems in our Electro-chemical Industries. In other words, there seemed no chance of an organization in Buffalo securing the intimate knowledge of our personal problems, which we have already mentioned is essential to a Local Council becoming a true service organization. We then bespoke Mr. Cameron and Mr. Price and arranged tentatively for a Local Council at Niagara.

It became evident, on returning and canvassing the plants in town to see who were already council members, that only a small portion were receiving the benefits of belonging to the parent organization. This being the case, Mr. Price devoted a considerable portion of his time at Niagara to securing new memberships and we have more than once congratulated ourselves that we did not fail in a single instance of "selling our service."

After organizing our Local and helping us conduct our first foremen's meeting, Mr. Price of necessity left us to our own devices and thereby hangs a tale.

Pursuing our original idea, stated at the outset of this paper, the effectiveness of a Local Council's efforts depends on the quality of its service. The mere fact that it has a service to offer, be it foremen's meetings, or school for safety supervisors or what not, is of no significance unless this service is of intrinsic worth to the members. In other words, the Local must effectively meet the member's personal problems.

Almost without exception the Foremen's meetings have a function to perform for every industry. Executives' meetings have their place also as do schools for safety supervisors and workmen's mass meetings, etc. These are collective functions that can best be performed for a group of plants by a central organization. There are, however, a vast number of special problems which come up in the individual experience of every

plant which are, in the main, more vital to the success of its safety work than some of the general considerations just mentioned.

The Council's organization in Chicago has long recognized this fact: witness the Sectional Bulletin Service, the Sectional meetings of this Congress, the Safe Practices leaflets on special hazards, the Information Bureau, etc. A Local Council to be successful must duplicate this type of service if it is to have a genuine value to the members.

Our early experience after Mr. Price assisted us to organize was highly successful. We had several foremen's meetings during the winter of 1917 and 1918 which were well attended and favorably commented upon.

A BUDGET AND A POLICY

Buffalo had at the same time, organized a Local there and on comparing notes, we found that our progress was favorable as compared with theirs. There were two things, however, which we had failed adequately to provide for—namely, a budget and a policy. The former we successfully solved after considerable deliberation on a five cents per employee per year basis; but the latter involved principles of service which I have already outlined and was the main reason for our re-organization which I will detail later.

Our early activities involved the expenditure of considerable money which was advanced to the organization by two large member plants in town. As our organization began to take form, we got together and decided on an assessment of so much per employee per year on the various members as a fair system of raising funds. We were able, moreover, at five cents per man to raise more than enough funds for a year's activities together with a fund to retire the loans which had been advanced us during our early organization. We were, however, without a definite policy which included special service to our individual members and this together with our inability to maintain an effective voluntary organization, particularly during the recent war, contributed to the necessity for re-organization.

In order to render the high class of special service to individual members on which the existence of a Local Council depends, it is necessary to maintain a paid organization at least in part. There is, of course, a certain amount of routine stenographic and clerical work which under a voluntary organization is divided among the various officers. Such an arrangement will function, after a fashion, but has the permanent disadvantage of no centralized filing and record system. When, however, we attempt the personal relations which involve visits to member plants, conferences, follow-ups on meeting notices, membership drives, etc., it is altogether beyond the possibilities of a voluntary organization to accomplish. Unfortunately my knowledge of Local Council work does not extend to a personal acquaintance with a permanent secretary's work. Aside from the functions of a Local Council which are obviously impossible to perform in any other way, there is of necessity a mass of other problems with which a permanent secretary would deal. These are present in any Local Council problem and are peculiar to the group of industries concerned.

I am, therefore, not in a position to state just what we have left undone at Niagara which we ought to have done with a paid secretary, but there is no doubt in my mind as to the fact. With this in mind, that in order to render a high class of special service, a Local Council must maintain in part at least a paid organization, Niagara's experience was typical.

During the winter of 1917 and 1918 we again held foremen's meetings which though excellent in quality were not properly attended and we began to cast about for a reason for this falling off in interest. In the first place, owing to our lack of a paid secretary, we were not in a position to follow up properly our notices of meetings. Then too, we were not making any additions to our membership which might have contributed to maintaining a keener interest in our foremen's meetings. This condition was unavoidable for the same reason although the field was very promising. I might state at this point, that Niagara's industries were almost without exception on 100 per cent war work and the labor and production problems were absorbing all of the time of our voluntary organization. In addition, we were entirely out of touch with one another's personal problems, largely because we were too busy with our own and all of these factors militated against the formation of the necessary constructive policy.

By the fall of 1918, we had reached the limit of our capabilities under our original organization. It was obvious that a re-organization had to take place in order to build something that could render real service and it was equally obvious that this had to be a paid proposition at least in part. So in the fall of 1918, we turned our attention to the successful experience of the Rochester Local and began to study their methods of doing business.

REORGANIZATION AND BROADENING OF ACTIVITIES

There had, in the meantime, been a Chamber of Commerce organized in Niagara Falls and we decided to duplicate, so far as possible, Rochester's relation between the Local Council and the Chamber of Commerce. The details of this arrangement, of course, took some time and not until the spring of this year did Niagara Falls Safety Council become part of the Niagara Falls Chamber of Commerce.

It is axiomatic that even an organization which renders a very distinct and valuable brand of special service to its members must broaden its activities to enlarge its organization in size and effectiveness, if it is to continue to exist. I notice in a recent executive service bulletin from the Chicago office a fine collection of valuable data on Employees' Representation which is evidence of the recognition of this fact by the central organization.

The idea of Safety work is so intimately connected with employees' relations in general, that without losing its identity as safety work, it may well include a working knowledge and supply of information in these other directions. I suggest that all Local Councils seriously consider the possibilities of service to their members which lie in the inclusion of a moderate amount of attention to employment, hygiene, employees' repre-

sentation, and recreation problems in a Local Council's program of activities.

Niagara Falls Chamber of Commerce is seriously considering this phase of industrial needs in the form of what will be known as an industrial council. This council will be in charge of a paid secretary who is part of the Chamber's regular staff and together with safety work will give his attention to some of the other problems mentioned above. As this involves a considerably greater financial outlay than Local Council work alone the plans are taking some time and will not be operative until later in the year.

Having heard our experience such as it is, I hope you are convinced as I am that a Local Council is primarily a service organization the effectiveness of whose efforts depends on the quality of its services. That it must render a progressively efficient and genuine service to justify its existence which in turn is only possible through a paid rather than a voluntary organization. That the work of a Local Council must be progressive in its nature and extend in the direction which the needs of its members demand, presumably to those other branches of employees' relations which are daily becoming more and more important.

DISCUSSION

CHAIRMAN PRICE: I am particularly anxious to occupy the next hour in a discussion of the problems of the small local council. I would like to discuss first the problem of the local council that will probably not be able to employ a permanent secretary.

I think the lame spot in the program of our local councils' sessions last year was that we allowed the consideration of the larger local councils to overshadow everything. We know how to solve the big city problems, and we don't know how to solve the other. Thus far in these sessions, we have not added very much to this problem. I have selected Mr. Case deliberately believing that he is as competent to answer those questions as any one. We haven't all the light, but we have a little, so let us see if we can get at anything that will really be of help to us in solving this problem.

Niagara Falls has done better than most other small cities and Mr. Case is very frank about its failures. He hasn't been nearly so frank about its successes.

MR. DEBLOIS (Wilmington): I would like to propound a question at once. What place in the inauguration of a small local council would you give to publicity? I don't mean simply newspaper articles, sporadically, but a general knowledge in the community of the existence of a local council, what its purposes are, etc.

PUBLICITY

MR. CASE: I don't think there is any question that publicity is the finest thing that you can have. There is no question that you should have one hundred per cent interest in a small town by all concerned,

both manufacturers and the general public. In a small community you have got to get everybody or you are not going to get along. You need the influence and you need the money. The more publicity you can get, the better it will be. Safety is essentially an advertising and selling proposition. I think publicity is the word every time.

MR. DEBLOIS: Let me continue that, if I may. In starting the thing, would you start with publicity, concentrate on that before you undertook actual work?

MR. CASE: My personal knowledge or feeling in that matter and I don't pretend to speak from great experience—is that in almost any activity results speak almost louder than anything else you can bring forth. A moderate result to back up your publicity is an excellent thing. I wouldn't get the cart too far before the horse.

MR. DEBLOIS: We have just been going about six or eight months in the Delaware Council. We have Mr. Case's problem of a small community. There are three or four very large concerns having central headquarters, the du Pont Company, for instance. There are no large manufacturing interests. We have concentrated sixty per cent on the publicity. We started with perhaps six members of the National. We haven't really gone out to sell a membership. The Membership Committee hasn't called more than one meeting and hasn't got to work yet. We have let publicity sell memberships. It has done it because we sold newspapers first. We can get anything we want in the paper now. That means not only two or three columns, but the front page, if necessary, and editorials. They are hungry for the stuff. We have sold it to the editors personally. The labor paper has given us as much as two whole pages in one of its weekly issues. We can feed it anything. That has sold us to date about thirty-five memberships, active memberships, and it is going to keep right on selling them.

The point has now arrived where they are asking for a little something for their money. We have given three good meetings, one with Forster, one with Price and one with Carl Smith. But we must give them a little more, and we are going to feed that to them now. But meanwhile in our opinion, that publicity work has got to be kept up one hundred per cent, and because we are a state council and not a city council, we have got to sell the state papers, such as they are, down to the last little local town with a weekly news sheet, just as much as we sold the city papers. That is the reason I wanted to bring that out.

CHAIRMAN PRICE: That is a good point, but you admit that you have to deliver?

MR. DEBLOIS: We have to deliver something.

MR. LINTZ: Speaking of publicity, I am always interested to learn just how you brought the council before the people with respect to getting these members? Did you advertise the council itself and what it does in a direct way?

MR. DEBLOIS: I really have misled you that publicity sold these memberships. In launching the thing, we had to select the only non-partisan organization as a sponsor. That was the Chamber of Commerce. The

only other organization professedly non-partisan, was the Manufacturers' Association, which was regarded by the labor interests as anti-union.

The Chamber of Commerce really hasn't taken any active part in the work. When we sold the idea to the Manufacturers' Association through the Chamber of Commerce, they promised one hundred per cent membership. Actually they got about twenty-five. But they didn't get it through the efforts of their secretary, but entirely through our newspaper publicity.

That is the way we started the thing, through the Chamber of Commerce as a sponsor at a luncheon, which brought the matter to the attention of the Manufacturers' Association at one of their regular meetings, to the Compensation Board, which took but passing interest in it, and to the labor unions, Central Labor Union, and the Labor Herald, which are with us one hundred per cent strong.

CHAIRMAN PRICE: Mr. DeBlois, do you think that you can carry on the program that will include a foremen's school instead of a safety supervisor's school, and a real effective public safety campaign, for instance, a week's drive, including the city officials and also this publicity that you have spoken of, without a paid secretary?

— PART-TIME PAID SECRETARY —

MR. DEBLOIS: I wouldn't say that we didn't have a paid secretary. We are dodging the issue. One of my assistants, Mr. Read, who unfortunately was called back to Wilmington, is giving sixty per cent of his time. He is experienced in safety work, is an experienced organizer, and had something to do with the sporadic safety drive that was organized by one of his ex-assistants in the city of Nashville. His time is paid entirely by the du Pont Company. He really is a part time secretary and I arrange his duties so that he can devote a portion of his work to that.

CHAIRMAN PRICE: Do you think that is a practical plan? I had in mind bringing that up, the possibility in Niagara of securing a man like Mr. Case whose company is interested, whose time could be spared, possibly paying him a salary for that time and in that way overcome the weakness of the plan?

MR. DEBLOIS: Here is the proposition. I think it is a perfectly workable one in other communities. We have these three large powder companies which have their main offices in Wilmington. They derive very definite advantages from the local council, both to the men in the organization and to the status of the organization in the community. There was a little feeling in the community against these big fellows, and the big fellows don't want that. It is not hostility but it is just a little aloofness. The big fellows want to be mixed right in with the community and they welcome anything that will strengthen the community relations. Every time it was necessary to raise pay or salaries the other fellows around the town said. "Oh, well, these big fellows are hogging all the market and spoiling all our wage schedules." Therefore, the activities of a local were welcomed.

Now, then, when you come to assess those large companies for dues, you cannot assess them on the payroll basis, because they have very few payroll employees there, practically none. So we went to them with this proposition (there are two small ones and one large one): "Now you two small ones give us \$100 annually which we will consider straight dues to the local. It is not a donation, but it is the value of the services that you will derive for your employees, and your own position in the community. Mr. Large One, we will also take \$100 dues from you, but we will also take the services of one of your men." That went over without any trouble at all. They saw that they were going to get more in service than could be paid on any normal dues schedule.

CHAIRMAN PRICE: Is there any such possibility in Niagara? Is there one company sufficiently large to spare the time of one man?

MR. CASE: I think that it is possible. I must say, in all frankness, that I think it is fundamentally wrong, because there was a certain wise man who said a long time ago that a man "cannot serve two masters," but at the same time it is a very good makeshift, and provided we have the whole-hearted enthusiasm of the concern to which this part time man belongs, I think it could be accomplished. However, I do not believe we would come to the point of accomplishing what we could with a full time paid secretary.

CHAIRMAN PRICE: About how many employees, roughly, have you in Niagara Falls.

MR. CASE: Probably 25,000.

CHAIRMAN PRICE: Do you think that Niagara in the next two or three years, is large enough to warrant the employing of a man at \$3,000 or \$4,000? You have got to have just as good a man there as anywhere? What do you think is the practical solution of the Niagara problem?

PERMANENT PAID SECRETARY

MR. CASE: Personally, whether it is good judgment or not, I am sold on the idea of a permanent paid secretary. I think, and I have the opinion of the Chamber of Commerce to back me, that by including certain other functions in relation to the spreading of general information on employee relations, the overhead could be borne properly. In other words, members could take out their service in other things besides safety, but whether that agrees with the policy of the Council or not, I am not in position to say.

CHAIRMAN PRICE: Don't you think, Mr. Case, that with the very rapid development of public safety which I think is bound to come in the next two or three years, because of the large increase of street accidents and because of this school safety that is coming now—don't you think that all of the citizens, including the industrial managers, will appreciate that there is a big community problem that is bigger than the service that might be rendered to the individual plants? Even in a community of your size there is a big job for a good man. It is a bigger job than we had thought when we considered this only as possibly a service to these industrial concerns.

MR. CASE: I think that is very true. It is a very pleasing development that public safety is becoming so large a part of the local council's work. I thoroughly agree with Mr. Price's former statement that industrial safety is becoming such a part of the regular routine of affairs that it naturally develops that we take more interest in public safety, and I believe thoroughly that in Niagara there is a possibility for such a man.

CHAIRMAN PRICE: Mr. Smith, what is your thought in this matter.

MR. CARL SMITH: My thought is that the failures have been due to the fact that no one man has had sufficient time to give the necessary attention to the work.

There are four or five problems in the small cities: a definite program, school for supervisors, school for foremen, school safety, and, perhaps, public safety.

CHAIRMAN PRICE: Would you say that Niagara should have a school for supervisors or a school for foremen?

MR. CARL SMITH: It ought to have both. You have just mentioned twenty-five thousand employees. That would bring you a revenue of \$1,250, and if that were increased to ten cents per employee, it would give you a revenue of \$2,500 a year. I would say it could be easily raised. If you had as secretary a man who was interested enough in the idea to see that the program was carried out, I believe that you could find a very good woman, a high grade stenographer, who could tend to the office details at a salary of \$90 a month and carry on the program for you with your assistance. That would develop, perhaps, into a paid secretary at \$3,000 a year. But your problem is to put over some direct activities in your community this fall.

Start with \$2,500 as your budget. Get your high grade woman who will do the bulk of the work in the office, and she can handle the details for you with you as the secretary to guide her. In all of our small cities the problem has been the sending out of the notices to the foremen, to the managers, checking up and seeing that they attended the meetings. She would take care of all those details. You would simply have the responsibility of carrying out the idea. I think that is what we are going to have to decide upon. Certainly we must have a program. Publicity is all right, but we must have down on paper definite services to give these men.

CHAIRMAN PRICE: I think that Smith has said something there. I think I said something, too, when I spoke of the enlarging field in even a small community. It is big: it is much bigger than we have thought it in the last two years. A year hence, aren't we going to see it big enough and aren't the people going to see it big enough so that there is ample room for a paid secretary in a small community, even smaller than Niagara, Mr. Case? What do you think of that, Smith?

MR. CARL SMITH: Yes, it will come.

MR. DEBLOIS: I absolutely foresee, when we take up public safety work this spring that this man who is now part-time paid secretary will have to devote his entire time to safety work. But part of his salary will be deducted from the fund which we are looking forward to raising

for public safety work. We have about 125,000 population, but with public safety work it means a full time paid secretary with a stenographer and office assistants.

CHAIRMAN PRICE: I want to get your reaction on this. I remember when I attended a meeting of some eighty business men in Cincinnati where we were launching the financial campaign, that the chairman, Mr. Geier, who is one of the outstanding young general managers there, made this point: that we want right now to get under one organization all of these things that are going to make for industrial peace and betterment—safety, health, industrial relations, the housing problem. Let's not split it up. Let's get a good man. Isn't that what we are going to come to in a small community? We want peace; we want right industrial relations; we want safety on our streets; we want safety instruction in our schools; and we want the active coöperation of our civic organizations.

As this thing grows, and it is growing by leaps and bounds, this problem of bringing about good conditions, this meeting of the crisis that we are in the midst of now—aren't we beginning to see that even in a smaller community than Niagara Falls there is a great big job for a big, broad, strong man? There is a job for such a man to work out an organization that will not only take in this narrower field that we have been talking about, but that will also take in this whole field.

MR. MORLEY: I think the majority of those present don't appreciate the value of public safety work as a money-getter. We have lots of men in Toronto, perhaps one hundred, who don't get anything at all out of the contribution they make every year to our work. A few days ago I was accused of doing too much direct advertising for the Ontario Safety League, but what I said in rebuttal, so to speak, was that we had to do a certain amount of that in order to hold the interest of these people who would not give up their good money unless they knew that we were doing good work, and that we had to advertise what we were doing.

Gentlemen, public safety work gives you a chance to get money from the average banker who may not directly care about industries or anything else. He may have no interest in school safety; he may have no children, but for a community proposition he will give his money.

CHAIRMAN PRICE: I am interested in getting Dr. Payne's reaction. He has been active on the Executive Committee down in St. Louis. I think, Doctor, your thought on this idea of the larger problem, including not only safety and sanitation but the whole question of community welfare, would be helpful.

DR. PAYNE: I came in during the midst of this discussion and hardly know what you have said. Take our own local council. There are a lot of us who are very glad to do a lot of things. We have all sorts of points of contact, but we haven't the time to initiate activity and carry it out in so far as the details are concerned. For instance, I am Chairman of the Committee for the Speakers' Bureau, and there is a great deal that I can do there, if we have somebody who really does the work, but otherwise I couldn't do it at all. Therefore, in a town of 50,000 a man

would have his hands full taking care of this work. And if you had such a man as Smith or Fellmer, I think he would get the funds to carry it on with.

CHAIRMAN PRICE: This is the point I want to really get at now: in a small community of say 25,000, don't you think that in addition to the industrial problem, let us say, that there are a dozen plants, that the community problem, the school safety matter, and getting the cooperation of all the civic organizations and the city officials and all, is big enough even in that community to warrant the hiring of a good \$3,000 or \$4,000 man to take care of the situation?

DR. PAYNE: Absolutely. And I think that when once hired he would demonstrate his worth, if he is that type of man, to the community. Take the problem of school safety alone—I mean teaching it in the schools. I am thoroughly committed to the feeling and to the view that the only fundamental way to handle this is to take children and develop them in ideals and habits of safety. Whenever you once do that you have cared for the problem.

Take an instance that the public is hardly conscious of. This whole prohibition movement is due almost wholly to the fact that the Women's Christian Temperance Union about thirty years ago got into the schools the teaching of temperance. Most of it is unscientific—they call it "scientific temperance." Its effect in a few years, although very poorly taught, was that you got a body of people in the United States large enough, just as soon as these children came into the period of voting, to abolish the liquor traffic. It wasn't what they thought about it or what they knew about it, but it was what they felt about it. And the way they felt about it was what they said and talked about as children.

You have the problem of teaching safety, as I said in the committee this morning. There are only a limited number of situations in which accidents occur and those situations are very definitely known. The way that accidents are prevented is by persons being careful. Carefulness with reference to each of these situations is just a matter of habit, and those habits are formed, not when we are adults, but when we are children.

Our habits are practically formed by the time we are twenty. We form no habits, practically, after we are twenty; and that is why this problem of safety is such a difficult problem—because our lives, so far as habit and skill is concerned, are formed before that time. Therefore, the school proposition alone would take up much of one's time. If he worked it out in the way that it has to be worked out. The teamsters must get the notion of safety. They are just like a body of teachers were yesterday; they had no idea that there were more people killed by accident in the United States during the period of the war than were killed on the battlefields of France. They were absolutely amazed and appalled at that situation. So you must get that notion over to them.

CHAIRMAN PRICE: I think every man in this room appreciates the enormous value of school safety as a part of this community effort.

Now I want to get Ward on his feet over there. Ward is from Yonkers.

I don't know when I have met a fellow like Ward in a community. He is a combination of a Tammany ward heeler, a Methodist preacher, a business man, and a born leader. He is an Irishman. Now supposing, Mr. Ward, you weren't hitched up with New York and that you were isolated so that you would have to handle Yonkers alone, do you think that Yonkers could afford a good paid secretary at \$3,000 or \$4,000 a year, who would take care of the whole safety and sanitation work, industrial relations, community betterment, and similar activities?

MR. FRANK WARD (Yonkers, N. Y.): There was a thought which ran through my mind when Mr. Smith was talking. In Yonkers we have a Commissioner of Public Safety. In other words, we have a department there which is responsible for the safety of the city of Yonkers. I was wondering whether it would be well to submit a proposition to the council or mayor there to have the city defray a portion of that expense, and make it less burdensome on the industries and the other institutions around there or the people who would be likely to contribute to such a fund.

However, I do believe that with the number of manufacturing industries we have there it would be possible to gather from them and some of the other people who are interested in this particular subject a sufficient amount of money to overcome the secretary's expense. I have listened with a great deal of pleasure to the remarks that have been made here about that particular thing. I firmly believe that a high-grade man is absolutely necessary. I remember very well, Mr. Price, the time you visited Yonkers. In order to save a lot of time and to make a more congenial affair of it, I invited all the managers of all the industries in Yonkers to our plant. We had a lunch room there. Mr. Price talked to them practically while they were eating. They were there four or five hours before they got through, although they came with the understanding that they would only be there thirty or forty minutes. I have noticed during Liberty Loan campaigns when I had visited the various plants that every one of them is practising safety to the fullest extent, and they are proud of it, and they will tell you about it. They all have records of their accidents, and I believe, with the interest that was displayed by those various industries, that it will be possible to gather a very liberal contribution for the furthering of that particular subject.

I was very glad to hear Dr. Payne speak the way he did about the school part of it. I had never really appreciated that there was so much good to be done. I have thought along those lines somewhat and I can see it is positively true that you must start with the child. He doesn't start after he is twenty years of age to formulate the principles that you try to pound into him before he reaches that age.

We have been handling the matter this way in the New York Council, and I believe it has been a very crude way. We have depended upon the people who have attended the meetings to advertise it. In other words, New York Council is peculiarly located. It isn't like any one of the individual cities such as Rochester, Cleveland, or St. Louis. We

cater to a radius of twenty-five miles over in Jersey and down Staten Island, up in Westchester County, and in the past winter, owing to the courtesy of the Safety Institute, we have been able to have a meeting every thirty days. We have had six meetings during the winter and special speakers at each one of those meetings. They have resolved themselves into round-table discussions which have been very interesting. The attendance at these meetings has been very good. One meeting was devoted entirely to the ship-building organizations in that section. But up to this time we have been dependent upon the people who attended the meetings to go out and preach the propaganda and gather the new ones in.

MR. DEBLOIS: I was wondering whether in the smaller communities the liability insurance companies could be of more value than they are in promoting the local safety council work from the industrial side. In our state they have a great big hold on the state, and while they are active in the organization, and one of their engineers is vice-president of the Council today, still I feel that either in the financial end or in the securing of memberships through their own insured, that they ought to be of very material help. I think there is a field for development.

CHAIRMAN PRICE: Don't you think, Mr. DeBlois, that very soon now public safety is going to become so recognized that we will be able to get a contribution from the city and possibly, also from the Chamber of Commerce?

MR. DEBLOIS: I think we have got to get it in Delaware.

MR. G. E. CLARKSON (Secretary, Western Pennsylvania Division, Pittsburgh): We have had already three meetings of our public safety committee. Our first meeting was a very large one. We considered it very large. We have about eighty-five men, interested in all affairs of life, nearly. At the next we had about forty. That was during the summer months. The next one was held just a few weeks ago. At our last meeting we were able to get two members of the City Council and also one or two of the Executive Board of the Chamber of Commerce. We carried our program out according to schedule, and asked our committees to report. About half of the seventeen committees reported. Then we called upon one member of the Council and one from the Chamber of Commerce. The member of the Council was a man who is quite influential in the Council. He has been connected with it for a good long time, and he is otherwise a public spirited man and influential in the civic and political life in Pittsburgh. He said, "To my mind, this thing is more worthy than a half dozen other things that we are spending a whole lot of money for, and I will say to you that if you will bring the matter properly before the Council, I, for one, will vote for it." Certainly we were very much encouraged by the moral support, at least, that we got from the Council. That was followed by General Logan, Chairman of one of the important committees of the Chamber of Commerce. He, by the way, is a member of the Executive Committee, and he said in effect that this organization should become one of the regular activities of the Chamber of Commerce.

As yet we have not followed out these suggestions. We are waiting for the psychological time. There is one reason why we are waiting. Another reason why we are waiting is because we haven't had the time. We in Pittsburgh are just as much too large as you in Niagara are too small. We ought to have at least three or four local councils around in our Pittsburgh district as large as your council at Niagara Falls.

But the reaction out of this public safety work is this: when we get started and get sufficient momentum, get to doing things you know, I think the others will follow. These smaller communities will follow right in line, and just simply ask and demand that they have a paid secretary. I believe that we ought to be willing to give it to them.

CHAIRMAN PRICE: Capt. Robbins, you look as if the spirit were moving you and you were just waiting for a chance to talk.

CAPT. JACK ROBBINS (Windsor, Ont.): I think that what I have to say will interest the gentleman from Niagara. In my little place—

CHAIRMAN PRICE: How many folks are there in those five cities of yours, Captain?

CAPT. ROBBINS: There are about 65,000. It is comprised of five little cities. I want to show you the interest the mayors of these towns took in this matter. I went to one mayor, the second mayor I visited. I said, "We want you on our Safety Committee." He said, "No." I said, "What? Don't you men believe in safety?" He said, "Yes, but I want to be in the first place," and it was true of every one of them. We couldn't put the fourth man on at all until we convinced him that it was for the benefit of the community at large. He wanted to be first. That was our trouble.

I think that we have met in our four cities nearly every question that Mr. Price put this morning. Take, for instance, the Chamber of Commerce. I believe the Chamber of Commerce has done more work for our local council than any other organization.

CHAIRMAN PRICE: I believe you are right.

CAPT. ROBBINS: We are going to stick with them.

The next point is the Executive Committee. We got the big men interested. We sold them the idea. The public were rather indifferent. They would say "We believe in it," but they wouldn't get up out of their seats and do anything. I started them going, and when they saw that there was a man there who meant to put it over, why they got out and did everything they could to put it over. Mr. Price knows it. The Executive Committee is in my brain right now. Why? Because I waited until safety week to see who worked and those who didn't work I didn't want, and I have got the workers and the big men. They comprise my Executive Committee.

Next was the foremen's school. Already we have 32 plants asking why the devil we don't start the foremen's school, because we had promised it a long time ago. I couldn't do it until safety week. There are 32 plants that have promised, and that have each guaranteed five men. We shall have an audience anyhow.

Mr. Price, Mr. Morley and Mr. Little came to our city and spoke.

What was the result? The next morning, without making an assessment or anything, \$2,000 came in my mail. It was exactly \$1,900. We didn't spend a lot of money in publicity. We talked to them first and got them interested. Then we gave them the publicity and we got the results.

You know with us there is traffic coming from Detroit, which is the second biggest city in regard to automobiles. They drive over on the ferries and, of course, in each of the cities there are different rules and regulations. We made the big record of no deaths and no serious accidents. The only accident that we had was to a young lady. One of the big steamers loaded with steel pulled away from its anchor and hit a ferry boat. The lady fell and broke her leg. That was the only accident we had in that week.

On Monday of the next week a little child who attended my picture show on Saturday was killed. The mother said, "That little girl is a safety girl and knows all about safety," but she got killed. She was walking on the right side of the road, but a man who hadn't taken the interest in safety, who hadn't been taught safety, was on the wrong side of the road and killed her.

In so far as the police are concerned, already we have had twenty-eight convictions. They were twenty-eight cases where the maximum fine was assessed. We are following the example set by St. Louis. We are going to get them if they don't pay attention to the driving laws, and make the city safe. They are going to get it, and they know they are going to get it, and the police are behind us. It is so all through Canada, and not only in my place.

We made 50,000 small two-minute talks. We give them to the retail merchants. They put them in each package. Each home which bought groceries or anything had one of those talks. We thought 50,000 would be enough. Before I came away, the retail merchants asked for 200,000. They will pay for them and give them out all the year.

The paid secretary is the only thing. We have had a certain amount of money promised us by the Manufacturers' Section of the Chamber of Commerce, but as a man said to me in a plant, "What is the use of taking care of me inside the plant when you would have me go outside and get killed by a machine?" He is right. We have to have public safety. You know each little town has its own council. They were composed of different nationalities and they were all indifferent. I spoke to all of them, and before I came away the mayor of the biggest of those towns came to me and said, "Put your proposition up to us as a body for public safety."

CHAIRMAN PRICE: In all my experience in field work I have never had any instance that came anywhere near illustrating so well what could be done in a small community as this, because this is small and all divided up. But when you have a real man there at the head of the thing with the time, you can put it across.

This thought came to me as I have been sitting here: The trouble with all of us who have been worrying about this small town proposition is that we haven't seen this thing big enough. Isn't that the secret?

We haven't grasped the bigness of this thing, even in a small town. There is a real place for a real man in every community. Now, if we are so slow, how can we blame citizens for being so slow?

The thing that I am carrying out of this meeting this morning is the need to convince myself of the bigness of this thing, to make myself believe that even in a small community we must have a paid man. We are going to put this across in the small community just the same as in the large city, and we are not going to sit here helpless and hopeless wondering how we are going to solve the problem.

MR. E. E. BACH (Director of Americanization for the State of Pennsylvania): All of this discussion has been very interesting to me, and I want to give you this one suggestion: that you can still fortify yourselves further along the line of public safety by tying up closer with the State departments of each State. We are just about to tie up with the great public school systems of Pennsylvania along the line of first aid, with a course in first aid. Now why not get busy with your program on public safety and take it up with the superintendent of schools? It can link up very nicely in that way and it will be put over with power back of it.

Speaking of the other extreme—the small town with the single industry and with that industry owning the entire town, property and all and controlling every activity in that town—

CHAIRMAN PRICE: That was your problem?

MR. E. E. BACH: Yes, but it seems to me your point of attack there will be with the head of that particular industry, and you can quite easily carry out every feature of the most generous plan that you can possibly conceive if you once have interested the head of that particular industry.

MR. FELLNER (St. Louis): There is one thing that we always have to do. We will have to get the authorities of the civic activities, as well as our industrial activities, to realize that after all, the greatest number of accidents happen in public life, not in industrial life. That is quite natural. The exposure is larger, the number of hazards is larger, and once you sift that down and draw it out in heavy lines it is very easily shown.

FRIDAY MORNING SESSION

HOW TO CONDUCT A SCHOOL FOR SAFETY SUPERVISORS AND FOREMEN

THOMAS STANION, MANAGER, SAFETY AND SANITATION, THE ALUMINUM CASTINGS COMPANY, CLEVELAND, OHIO

It has taken the average farmer many years of experience to appreciate the true meaning of these lines written by an Indiana young man who had left his father's farm:

I left my dad, his farm, his plough,
 Because my calf became his cow;
 I left my dad—'twas wrong, of course—
 Because my colt became his horse.
 I left my dad to sow and reap,
 Because my lamb became his sheep;
 I dropped my hoe and stuck my fork
 Because my pig became his pork;
 The garden truck that I made grow
 Was his to sell, and mine to hoe.

Too often the daughter or son labored hard with things apparently their own only to have them sold by the father and the money added to the family purse. Just as state schools have been one means of demonstrating to the father what the boy or girl can accomplish when given an interest aside from work on the farm, so the schools for safety supervisors and foremen have helped industrial managers to realize what they, the safety supervisors and foremen, can accomplish along accident prevention lines when given the proper place in the work of the plant.

Important as is this effort, there are but few places where schools have been conducted as a city or community affair. These few were primarily for safety supervisors but foremen were usually welcome. Little effort has been designed especially to reach the foremen. Not a few companies have had classes or clubs for the instruction of foremen but these were usually for production affairs with safety instruction as a part of the course. Schools conducted for a community must obviously be of a different character from those held by a company for here there is no semblance of the company authority to inspire attendance. They are on a purely voluntary basis and must of themselves create and hold the interest. The doctrine of Safety First is no new preachment. It was born with the animal kingdom and since the earliest days of the human race, we have been taught by experience and precept that self preservation is the first law of man. Experience has been an expensive teacher and those gaining her lesson have not always seemed to profit thereby. The precepts have been true to best practice but their presentation more or less haphazard with this result—we have today a generation of adults who do not know how valuable an asset Safety First can be in their lives and how simple its application to the every day and ordinary rules of life. Fortunately for succeeding generations our public schools are grasping the opportunity of service by inculcating the Safety First idea in the minds of little children in a way and at a time when it will make the lasting impression.

PROBLEM OF TEACHING ADULTS

The problem then of the school for supervisors and foremen is complicated by the need of presenting to adults the same fundamentals that are now being given to children in the lower grades;

to adults who largely have not had extensive education. Obviously, these adults must have the lessons set forth in practical form and any theory so clothed in daily usages that its value will not be ignored. The training given in the school for safety supervisors and foremen should be so correlated to that in the public schoolroom that the father can encourage his son and the son awaken the interest of the father.

The subject of this paper might be interpreted as a combined school for safety supervisors and foremen. Yet there is a fundamental difference in the approach that should be made to these two classes of men for, theoretically, the foreman functions as an executive while the safety supervisor assists and encourages by ferreting out the accident hazard and recommending the proper course for its removal, and keeping alive generally the practice of Safety First principles. While these differences exist and they can well be recognized in presenting the lessons, yet the guiding principles for the work as a whole are the same. What is said about the school in general can apply to one as well as to the other. It is the same sort of interest to be aroused and maintained and like methods can be used.

Taking as a premise that accident prevention work is the best entering wedge into that limitless field of employees' industrial relations with the management, what better could be chosen than this as the first subject for treatment in special classes for practical industrial men. Realizing, too, that safety supervisors are largely drawn from the ranks of foremen and further, that as a class they, the foremen, have been neglected in an organized effort for general advancement, it is fitting that this initial effort to spread safety knowledge should be primarily for them. There are organizations for engineers of various sorts; for managers; for agents of every description; but remarkably few associations for foremen intended for their advancement and better mutual acquaintance. The safe way is always the right way to do a job and if this group of men are given a comprehensive training in the safe way, a general improvement in their work is sure to result.

SUBJECTS AND SPEAKERS

The primary reason for these schools is to present in comprehensive and interesting ways the fundamentals of accident prevention work, with a secondary and almost equal reason to afford the student a broader viewpoint. To give a course of lectures which might well be a part of any technical school curriculum and yet couched in terms of and intermingled with practical affairs such as will maintain the continued interest of shop men. The subjects chosen should in themselves be worth while—each a vital stone in the Safety First foundation. The speakers should not only be skilled in their respective subjects but able to hold the attention of their hearers with their delivery as well as the wealth of experience out of which they speak. These classes are quick to detect the imitation from the real in the presentation of the subject. Anything that can be used to illustrate the lectures,—either pictures, models, or

samples,—is of value. A little color makes an impression and helps to carry the message. The lessons should be real. They should show careful preparation and be conducted in a dignified and orderly manner. It should be realized that the school as a whole will get only what is put in and that the members of the class will soon catch the enthusiasm of the leaders. On a basis of drawing out the thought of the class, more will be accomplished than by handing information to them. Interesting items, data, and other facts, briefly stated, are valuable as suggesting means of tackling similar problems in their own plants or factories. All that can be done to encourage the safety supervisor or foreman toward solving his own problem strengthens him accordingly and will put his safety work on a firmer foundation. After all—to guide the thought and action of the pupil in self expression is not only the function of the school but the highest goal of the teacher.

Following the discussion of the lesson as a whole or the treatment of each major part of the subject, there should be an opportunity for questions from the class. Too much importance cannot be attached to this phase of the work. There will doubtless be a hesitancy at first in putting forth these questions, but under a genial atmosphere this will pass away and the members of the class take advantage of the expert knowledge available. Even though their questions may seem simple they should be answered with all the information at hand. Besides the questions, value is derived from a recital of experiences by members of the class even though some of the results had not been so successful as desired. Good always follows from a frank discussion by men who are handling a common problem.

THE CHAIRMAN

Assuming that this school or class is conducted by a Local Safety Council, the chairman of the meetings might well be some other than the executive secretary of the Council. His time is too valuable for this detail. Some one interested in the community safety work, with experience in handling meetings, who will set aside the evening regularly for the class, would be more desirable; preferably a man who has had active experience as a shop executive or safety supervisor and can thus appreciate the shop viewpoint. His interest in the class should be such that he will feel responsibility in its success and will be diligent in his efforts to conduct the class in an interesting manner. Much enthusiasm can be aroused and maintained and the social side of the meetings encouraged. The meetings should start at an appointed time and last not more than one hour and a half. Once a week has proven successful as the frequency of the meetings and on any night that will not conflict with some special local affair. If the classes are held in a community where certain nights have, through long established custom, been used for lodge meetings, such nights should be avoided. So far as possible, the attention of the class should center on the subject for that evening although announcements will have to be made. In this, the secretary can assist as well as in obtaining the record of attendance, distributing the lesson

outlines, and such things,—all of which help him to get acquainted with the various members and be better able to push the community safety work as a whole.

When the time seems right, the class can be encouraged to organize by electing officers. This will tend to arouse interest, afford a medium for transacting business for the class to act as a unit. Then, too, this class can be a power in carrying through other activities of the Local Council such as executive luncheon meetings; superintendents' and foremen's district meetings; and workmen's rallies by backing them up in their respective plants and arousing the interest of the proper people. In fact, such work will bring beneficial results to the class as a whole because of the additional interest the members will find through these efforts.

Although there are some limitations in selecting speakers, the field is so broad and the general interest in safety work so keen that the proper ones can always be secured. It hardly need be mentioned that one poor evening leaves an impression that requires several splendid programs to overcome. Some of the subjects that go to make up a well-rounded course may seem in themselves uninteresting because the beginner cannot appreciate their value. One is Accident Statistics, their Compilation and Use. It requires some experience to appreciate the value of carefully recorded facts surrounding each accident. All of us are too prone to minimize the importance of the thing in hand and it is not until some little time has elapsed that we see its value. By special attention color can be given this meeting and interesting side lights thrown out to show how great is the subject and how real the value of carefully prepared records, both to show as time goes on in which direction progress is being made and to present an accurate statement of how accidents occur in the particular plant.

PRINTED OUTLINES OF SUBJECTS

Printed outlines giving a general resumé of the subject are supplied for distribution to the class as a service of the National Safety Council. These can best be given out at the close of the meeting and, added to the notes a man has taken will make a good reference for the subject. The outlines are arranged for filing in a loose leaf folder. Few samples or specimens have been used for general distribution in these classes although this offers a field that might be developed to good advantage.

The location of the meeting place merits careful consideration. Some years ago one of our industrial centers started a class in English-for-foreigners. A fine room in a good building was secured, located not far from the center of the district where the prospective scholars lived. But only a very few attended. After no little investigation it was learned that the meetings were not held in a place frequented by these people. Another room was secured—this time on a street that was one of their direct paths of daily travel. The class was a success at once for they found it easy to "drop in." Although not to so marked a degree, yet

the principle involved applies to this class as well. A building that is used for other meetings or gatherings that these men attend would be the best selection.

Thus far the course has been covered by fifteen lessons substantially as follows:

1. The Importance of the Manager's Cooperation in Promoting Safety
2. Plant Conditions—Arrangement, Order, Lighting
3. Design and Construction of Safeguards
4. What the Foremen Can Do to Promote Safety
5. Bulletin Boards, and Other Ways of Reaching the Workmen
6. Workmen's Inspection Committees and Meetings
7. Electrical Hazards
8. Eye Protection and Safe Clothing
9. First Aid
10. Labor Management and Safety—Physical Examinations—Instruction of New Men—Labor Turnover
11. Plant Sanitation
12. Accident Records, How to Compile and Use Them
13. Fire Prevention in Relation to Safety
14. Qualifications of a Safety Engineer, His Duties and Opportunities
15. General Review and Experiences

The field which they cover can, like the whole safety program, be divided into the two major parts, viz.: Mechanical and Educational Safety. True to the program for other safety work, the order in which these subjects are usually taken up shows the two groups intermingled—not following through the entire educational group before any mechanical subjects are introduced or vice versa. The reason for this is obvious; both classes of the work must be undertaken at the same time and run concurrently if real progress is to be made. Nor can either lag behind the other any more than one can be emphasized to the exclusion of the other and have a successful campaign. A works manager once asked of his assistant who was somewhat familiar with safety work this question: "Is it true that 80 per cent of the preventable accidents can be eliminated by care on the part of the worker and that only the other 20 per cent can be stopped through mechanical guards?" Upon being told that such was true, he replied that the effort of his plant had better be directed solely toward the 80 per cent item *first* and then at a later date go after the 20 per cent. No comment need be made on the inherent fallacy of such a plan. Safety is a thing of mutual benefit to worker and company to be secured by the joint cooperative effort of the two. The management must take the lead by giving visible evidence of the sincerity of its intentions. Such can only be expressed through mechanical guards or engineering revision. Just so far as the company takes this lead will the workers be encouraged to follow. It is indeed quite proper that the two main themes in the course should be developed hand in hand. They cannot be separated and are mutually dependent. Though the results expected from each part are not on the same scale, yet they are of equal importance.

GENERAL REVIEW AND EXPERIENCES

The value of the last lesson—General Review and Experiences—cannot be overestimated. By the time this subject is reached, the members will have had opportunity to put to practical tests the points they have gained from the course. A chance to tell how they have succeeded or failed will be timely. There will be eyes saved from the proper use of goggles and protectors; burns avoided; fingers uninjured because of effective guarding; shop lighting revised; resuscitations; and in fact, almost every phase of the work will come up for discussion. In the arrangement of this meeting, too, careful planning will bring its reward.

It has been aptly said that the business of a school is to "bring the knowledge of the past into the service of the present." This expresses concretely the aim of a school for safety supervisors and foremen. To avoid pioneering. What would not the early leaders in the Safety First realm have given for such instruction as is now included in any one of the lessons? How much searching and experimenting, and how many failures would have been avoided? Yet such information was not to be had. Our technical schools had not sensed the need nor had any college developed its courses along these lines. The University of Hard Knocks solved the problem and perhaps it is well that such is the case. Those who first were concerned with its solution were practical men who needed the ideas expressed in shop terms. In fact, although the members of these classes may not have college degrees, they are hard-headed business men and will appreciate this training in so far as it gives them points and ideas which they can readily adopt or adapt to their definite needs. No silver-tongued orator who can ascend to filmy heights of theoretical methods need come before them. His schemes might not stand the acid test of adaption to the average shop. That these men may have the inspiration of the practical experience of successful men and the enthusiasm that comes from a class learning things together, is the real aim for the instruction. Of value, too, for the safety man are the pointers that can be thrown out on side lines—the ideas that will start his thought along another line and assist him in some problems not definitely a part of his safety work.

Were there not definite results to be had from these classes, their existence would not be justified. First of all such a class is one of the best services a local council can render its community. No other organization is so able to conduct such a school. Its value will be felt in the safety work of the district as a whole as well as in the plants and factories directly represented in the class. Recently one of our local councils was soliciting funds for its year's budget. A certain company had not been inclined to cooperate but some of its supervisors had joined the safety class. Later on this fact was made known to the management and their attitude changed. Here was a definite service from the Local Council and a goodly check was forwarded at once. Next, the lessons on the part the management has in the work do get home to the proper officials with the result that the company realizes the true relations of

affairs; that is—first of all, a careful management before careful men can be expected. Lastly, the definite accomplishment through explicit knowledge gained in class. Instances of lives saved after the class had been given the demonstration on the simple method of resuscitation are not uncommon. Who knows what suffering has been saved because an effective guard or protector was used after the safety man had carried back a lesson from the class? The benefits are far reaching. No one can measure all of them and yet there are enough visible to justify all the effort. Incidentally, there is a general broadening for all who attend.

DIPLOMAS AWARDED

To dignify the course and that the members of the class may have something to show for their efforts, the National Safety Council awards a diploma to each one who satisfactorily completes the series of lessons. This usually means attendance at 75 per cent of the lessons and a statement that the outlines for those not attended have been read. The diplomas are greatly prized and the graduation thus afforded has been found to be a valuable affair, giving an opportunity for a special social evening with its attendant benefit of better acquaintances.

The future of these schools is indeed bright. The science of safety is stretching into broader fields, affording the safety supervisors better means for developing their work. This they are following with diligence and enthusiasm. With the foremen undertaking definite instruction in safety and grasping the opportunity of a closer working relation with their men, which this work affords, they are not only boosting accident prevention but are entering the day of a better understanding with their men through the best possible approach. The spirit in which these activities are being undertaken insures their success.

DISCUSSION

After reading, "These classes are quick to detect the imitation from the real in the presentation of the subject," which occurs on page 235, the following discussion took place:

CHAIRMAN PRICE: One of the secrets of success of your school here was the character of men who addressed it, wasn't it?

MR. STANION: Yes.

Following the reading of the sentence, "Good always follows from a frank discussion by men who are handling a common problem," on page 236 the following discussion took place:

CHAIRMAN PRICE: I believe you start about a quarter past eight and close at ten. About how much time would the presentation take and then how much is left for the round-table discussion?

MR. STANION: The presentation required about three-quarters of an hour, and from a half to one hour was reserved for discussion as the meeting desired.

CHAIRMAN PRICE: I remember the night on which I gave a little talk on shop lighting at the school. It was a very simple thing. I think there

were seventy-five or eighty-five questions during the hour and a quarter. They kept me on the floor steadily, and at ten o'clock they were still going strong. Every question that was asked me by those men was a question of a practical nature, such a question as a practical man would ask who wants to go home and put in a lighting system.

I gave it in four schools and the questions were very much the same. It is wonderful how it brought out the discussion. For instance, a man wanted to know how to light an overhead crane. They were all practical questions. One of the things that I would suggest, if you conduct a school, is that the speaker stop at the end of each little section of his talk. For instance, I would cover the subject of reflectors, showing the fundamental principles of the design of a reflector, and the difference between inefficiently designed reflectors and efficiently designed reflectors. Then I would stop and the students would ask questions.

MR. STANION: That is a mighty good point: that the speaker must know his subject. He may think, because he is talking to a group of men from a shop or plant who have not been trained in school, that they are not going to follow him as closely as another audience might, but don't you believe it. They do. You would be surprised at the comments following the meetings. If a speaker isn't right up to snuff the men know it and they say so.

ENTHUSIASM CAN BE AROUSED AND MAINTAINED

Following the reading of the sentence, "Much enthusiasm can be aroused and maintained and the social side of the meetings encouraged," on page 236 the following discussion took place:

CHAIRMAN PRICE: Don't you think, Mr. Townsend, that one of the important factors in the St. Louis success was Mr. Stremmel?

MR. TOWNSEND: The personality and enthusiasm of Mr. Stremmel was certainly a wonderful factor, and when we came down to the last meeting in the course and he stood there and showed such a perfect grasp of every one of those subjects, as he held a sort of examination of the whole thing, it was a revelation to me.

CHAIRMAN PRICE: Mr. Townsend has a little diploma hung up in his office somewhere, showing that he graduated from that school. He is with the International Shoe Company. It is wonderful—the spirit and enthusiasm that the students got in that thing.

Following the reading of the sentence, "It hardly need be mentioned that one poor evening leaves an impression that requires several splendid programs to overcome," page 237, the following discussion took place:

CHAIRMAN PRICE: I wish you would emphasize, if you will, the point that you have some money available to bring in outside speakers. I think that is important. You don't depend on local speakers, do you?

MR. STANION: The program in Cleveland was made up with eighty per cent of the speakers from the outside, and when it was necessary to pay the expenses of those speakers, the local council had funds available for that. In most cases, however, the speakers come at their own expense.

CHAIRMAN PRICE: I wanted them to see the type of men who addressed your classes.

MR. STANION: We had Mr. Oartel from the Carnegie Steel Company. His subject was, "The Duties and Opportunities of a Safety Engineer." Then we had Frank Morris, Mr. Rasmussen, Mr. Smith and Mr. Price, all of the National Safety Council. Mr. Rice, of the Pittsburgh Railway, was there and Mr. Scott of Chicago.

MR. H. L. ROBINSON (Worcester County Council): I would like to ask Mr. Stanion if there is any preparation required by the members, home work, etc., that would be objectionable to the average foreman?

MR. STANION: Our course required nothing of that sort. The outlines were distributed after the lesson had been given and he was expected to go over that at home, but there was no check made to see whether he did or not.

MR. H. L. ROBINSON (Worcester County Council): Is the topic for the evening the same subject as covered in that outline or paper that the National Safety Council sends out?

CHAIRMAN PRICE: Oh, yes. He must be assigned to that particular subject. Not only that, but the speaker is selected because he is strong on that subject.

MR. H. L. ROBINSON: Will the National Safety Council furnish a list of speakers on whom we can draw?

CHAIRMAN PRICE: Oh, yes. We try to persuade them to do it; we make it our business to help every school get speakers.

I think, Stanion, you might give your own thought about handing out the lessons before or at the lecture. There is a point there that ought to be brought out. Why didn't you give the lessons the week before?

MR. STANION: Our point in giving out the lessons or pamphlet after the speaker had finished was that if a man had it in his hand sometime before he would be less likely to pay attention to what was being said by the speaker. He knew he was going to have an outline at the end, and he was free during the meeting to pay attention to the speaker.

CHAIRMAN PRICE: I think Smith or Rasmussen told me at St. Louis they found there was an inclination (when the men had the outlines in advance) to say, "Oh, well, I know all the speaker is going to say, and I guess I won't go." There was not very much of that, but just enough to make it wise not to give out the lessons in advance. Let them take the lessons home as a sort of review of the important points. The Council furnishes the lessons. There are ten lessons in the foremen's course, and fourteen lessons for the supervisors' schools.

Following the reading of the sentence, "Of value, too, for the safety man are the pointers that can be thrown out on side lines—the ideas that will start his thought along another line and assist him in some problem not definitely a part of his Safety work," page 239, the ensuing discussion took place:

MR. STANION: Right there, Gentlemen, a great deal of benefit has been derived in shops where the safety engineer has shown himself interested in something beside safety. For instance, one of our leading safety men found a type of hammer, the head of which was set in rubber. The

rubber setting took up the shock as the man used it. He thought immediately that that would be of benefit to the production people. It would help them, though not especially from the safety standpoint. He took it to them and they liked it, and he rose in their estimation because he could bring something around beside safety.

Mr. Stanion then read the remainder of his paper.

VALUE OF POPULAR SONGS

MR. RASMUSSEN: Would you mind telling these gentlemen what the singing of that safety song did for the school?

MR. STANION: Yes, with apologies to St. Louis. (I wouldn't dare say that we started the song.) We would sing that song, which is a parody on "Hail, Hail, The Gang's All Here," every evening. It gave an enthusiasm to the meeting to start it in good shape.

MR. FELLMER: Did you ever make them whistle?

MR. STANION: We had them whistle one night.

CHAIRMAN PRICE: If somebody had told me two or three years ago that you ought to have singing at a school of this sort I would have said, "No, no, that is out of place." Those St. Louis fellows strike the thing that catches the middle-class fellow right here (indicating the heart). Maybe it is a Southern trait, the Southern atmosphere—what is it down there that you fellows seem to get?

MR. FELLMER: We are real folks.

MR. RASMUSSEN: I had some doubts in my own mind as to the value of that singing while we were conducting that school here, and one evening Mr. Stanion was out of town and he asked me if I would take charge of the school. There was an opportunity to demonstrate whether my idea was any good. So I purposely omitted the singing. The whole lesson went through very nicely, but just before the close one man got up and said, "We didn't have our song."

CHAIRMAN PRICE: That song puts the pep into you. Going out in membership campaigns is one of the toughest jobs that you have. It takes the heart out of you, and every morning in St. Louis when we would jump into the automobile we would say, "Are we downhearted? Hell No," and we put it over one hundred per cent, didn't we, Fellmer?

MR. FELLMER: Yes.

CHAIRMAN PRICE: I think I agree with what Herbert Spencer said. Some one has called him the "Giant Intellect." He said, "We are very largely controlled in our lives by the emotions and only in a very small degree by our intellect." I think some of us are just a little highbrow, we are not quite human enough; we don't hit that other fellow where he lives. Those Southerners down there seem to get that chord and we Northerners will have to copy it.

We have plenty of time for discussion and this is a very valuable presentation of what I consider the essentials, and I wish you would ask questions of Stanion. There isn't anything that is on the program that is more important than this because the foremen's meetings and the safety supervisors' meetings are the backbone, absolutely, of your local

council work which is going to appeal to your manager and get his support.

MR. H. L. ROBINSON (Worcester County Council): Is there any maximum or minimum whereby the class will be most successful? That is, you wouldn't want a class smaller than fifteen? If you have too small a class you won't accomplish very much, and on the other hand can you get too large a crowd?

MR. STANION: I would say that that would be a problem to meet as the conditions justify. If you had only fifteen you could arrange a course for fifteen. If you had fifteen hundred you could arrange a course for fifteen hundred.

MR. RASMUSSEN: In a condition such as you have, couldn't you invite some of the plant superintendents?

COMBINE FOREMEN'S AND SUPERVISORS' CLASSES

MR. H. L. ROBINSON: I think that we couldn't limit it to supervisors because in most of the plants there aren't more than a dozen all told who have safety engineers or supervisors. We would have to combine the foremen's class with the supervisors' class.

CHAIRMAN PRICE: I am very glad that you mentioned that. If you don't agree with me please say so. I was in Grand Rapids and Flint and I have recommended that they have only one school,—foremen and safety supervisors—with the idea that there is a small group of men who are going to be safety inspectors and they could be handled in a class supplementing the course.

MR. STANION: I wonder whether any one got the impression that the school in Cleveland was only for safety inspectors and supervisors. Such was not the case. One of the most enthusiastic members we had was the president of an automobile company.

CHAIRMAN PRICE: Would you say that seventy-five per cent of those men will not devote themselves exclusively to inspection?

MR. STANION: Sixty or seventy-five per cent.

CHAIRMAN PRICE: I think that has been the case in St. Louis.

MR. BROWN (Brown Hoisting Machinery Co., Cleveland): One of the directors in my company attended and missed only one meeting. My particular point of view was the value of having the superintendents and the assistant superintendents attend the schools as well as the safety man, because the school, by its nature, to a certain extent is elementary. It can't carry any subject through in all its branches, and the safety engineer can study out the details by himself later. Your safety engineer will not get proper coöperation unless the superintendents have somewhat more than just the elementary teaching that you would give to the foreman. For this purpose, however, the superintendents will not need the post-graduate course required of the safety engineer.

CHAIRMAN PRICE: Then too, Mr. Brown, in the part which is devoted to your safety engineer and to the superintendent, too, you are talking to him about what he can do with the foreman, which is a very important problem, of course.

Mr. Brown, have you more confidence in this idea that we are talking about as a result of your experience here than you had at first? I know you were very optimistic, but has your experience confirmed the valuation you placed on this thing?

MR. BROWN: There isn't any question about it. As you say, it pays every day of the year.

CHAIRMAN PRICE: This movement is twelve years old and the experience of each of these Congresses is a revelation to all of us. There is a wonderful volume of experience that is locked up in the heads and lives of all of us fellows who have been in the game. What a wonderful thing it is, and what an intensely practical thing it is to put all that splendid experience into this simple form, boil it down and in fifteen lessons put it across to these key men—not twenty-five things that you ought to know, but six things that you ought to know. That is literally what the school does. It takes the experience of twelve years and puts it into simple form so that those men, without going through our experience and struggle, can get the essentials at once, without all that experimentation that Mr. Stanion has told about. When I think about it in that way, then the value of this school idea comes to me. I don't think we have ever done anything that compares to it in practicability and in service, direct service to the industry. Aren't there some more questions?

MR. TOWNSEND: I would like to emphasize two or three things. Of the five hundred who were in attendance at our classes (although so many didn't graduate) I don't believe more than ten per cent of them were safety engineers or supervisors or men who expected to devote their whole attention to such work. They consisted of foremen, superintendents, and mechanical engineers from different plants, and I feel that there was a great value in having these men in attendance.

CHAIRMAN PRICE: I think that is a splendid point. I am thinking, Rasmussen, that we ought to change the name of that school and call it a school for safety supervisors and superintendents.

MR. TOWNSEND: It is so essential that you have the mechanical engineer interested along these lines because he has to cooperate absolutely with the safety engineer.

I want to speak of another thing in reference to these topics. In general, the men who presented those topics in the St. Louis School held pretty closely to the outlines that had been provided, but a few of them didn't; and I know as I sat there trying to get all that I could out of the lecture and listening to those presentations, on one or two occasions I felt when a man was through that he had not given us very much, but before we were through with the discussion and the questions, the whole thing had been thoroughly brought out, so that we felt that we had the full benefit of the subject.

I want to ask Mr. Stanion this question. Did you lay any emphasis on the entertainment features of the evening to attract the people and give them something outside of the subject itself?

MR. STANION: We had nothing of that sort. The fellows came to the meeting on Monday night. We sang the song, got down to business,

and when we had finished with the discussion, there was a little chatting around and then we went home.

CHAIRMAN PRICE: What do you think of that entertainment feature?

MR. TOWNSEND: Sometimes we would have a solo or instrumental music or a quartet, besides our song which was led by Mr. Stremmel. Sometimes we had a moving picture, a safety film—something of that kind.

CHAIRMAN PRICE: That would occupy just a few minutes.

MR. TOWNSEND: It would probably take twenty minutes or half an hour at the most. I felt that this was a really important feature in winning some fellows who perhaps weren't so much interested in the safety proposition or the school lesson, but who would come for the entertainment feature and remain for the other also.

CAPT. ROBBINS: I would like to have you tell me whether our idea is wrong. You know we have just started. We have sent notices to the managers asking that they be present. We also have gone on the theory that a man has guts enough to think that he is going to be the manager or foreman sometime. We are not limiting it to foremen or safety supervisors at all. Anybody who wants to come in and thinks it is going to benefit him is more than welcome at our meetings.

CHAIRMAN PRICE: I think you are on the right track, Captain. You are always right, Captain.

MEN HIGHER UP SHOULD SET EXAMPLE

MR. E. P. ROBERTS (Manager of the Engineering Society of Akron): I want to emphasize the importance of the men higher up setting the example. In the case of Mr. Brown here, whom I happen to know, he sets the example to his men, and they in turn set the example to the men under them. But that doesn't always happen. For instance, in a plant I have recently been connected with, I have seen some of our higher men set very bad examples on safety. There are lots of automobiles going out at closing time over the sidewalk. They ought to have a watchman there. Those men high up don't set the proper example in driving out. I think it is very important that they should set that example.

Also in connection with hospital work: the men higher up should set the example in going to the doctor or the nurse for slight scratches. We are continually preaching that to the men, even with a slight scratch. If the men see some man higher up having a slight scratch attended to, it is an example to them which is very important.

MR. J. H. HANSON (Rochester Safety Council): With reference to the idea of entertainment at the safety schools: it seems to be pretty general throughout the north here that fellows want to get down to business. We took a vote in our school and they voted against any sort of entertainment. With the foremen it is entirely different: they want it. It may be due to the hospitality of the South that they heed that little entertainment in St. Louis to put the thing across.

CHAIRMAN PRICE: Mr. Stanion spoke of the tangible results, reported

in writing or verbally. of what those pupils actually did in their own plants. That is one of the most encouraging things in this whole business. Seventy-five per cent of the pupils who graduated have gone home and done something substantial.

TESTIMONY AND REPORTS

As an example of what I mean: I was going up to the speakers' table there at St. Louis and three men stopped me and said, "Mr. Price, you will be glad to know what happened after your lecture on lighting. We have torn out all the old lighting in our plant and equipped it with new lighting." That made me feel good. I felt as though that trip was worth while. I know that Swift and Company organized Workmen's Committees and reduced their lost time accidents 50 per cent before the school closed. Did you not have a night of testimony in one of the schools?

MR. FELLNER: We didn't have a night of testimony in the supervisors' school, but we sent out a circular letter and asked for the reports, and about one hundred letters were received in reply. They contained some of the most wonderful things that you have ever heard. At one of the plants they operated a good many punch presses and they had fifty-seven varieties. It was one of these plants that had grown up from time to time as an auxiliary to another business and had never been organized. One of the young men in that plant turned himself loose. They placed a great value upon what he had learned about good housekeeping in the first place. He had all the windows cleaned, established dead lines for aisle space, and got the other foremen into the game. He found a couple of carloads of rubbish in that plant.

His firm was thinking of building a new structure: when the president came through and found out what had been done he cancelled the idea of having a new plant. The accident reduction in that plant was forty-five per cent. After S. J. Williams' lecture on fire prevention, I was present when they conducted a test of the extinguishers and we found Mr. Williams' statement that forty per cent of them were inoperative was correct. Under the head of good housekeeping we discovered that most of the extinguishers were hung where a fellow couldn't get at them unless he had an airship. We planned that differently.

The most wonderful thing that was done was when this young safety supervisor came in and asked me what I would advise him to do about his stairway, which was about four stories high. I could have told him the solution right off, but I didn't. I just threw out a hint or two and then let him go to it. I found the stairway whitewashed from top to bottom, with a large light at the top and one at the bottom, so that there was always daylight on the stairway.

There is one thing that never can be emphasized too much, and that is that a man must know whereof he speaks when he goes to address a school, or when he goes to address the safety supervisors' or inspectors' committee. I met one of these committees in the American Steel Foundries Company in Granite City, and it was the most wonderful

experience that I have had in all my safety work. There were seventy-five men: Of course, they had the able leadership of Mr. Stremmel to pilot them along. You should have seen the fellow feeling, the idea that they were all just folks and not workmen or foremen or manager or secretary of the local council—there was no ceremony there, every one was in his shirt sleeves—why they even addressed the negro as Mr. Brown. The questions which were fired at the speaker and at Mr. Stremmel and myself kept us jumping, but when we got through we all voted it was the most wonderful thing that ever happened.

Just to give you an idea of it: they had a smokestack used for carrying off gases, and this stack had to be reconstructed. They reconstructed it on a concrete base and put a steel stack on top, thinking that while they were about it they might make it possible to carry off as many of the gases as possible and preventing the gases from getting into the plant. One of the ordinary workmen on the committee got up and said, "I stopped the taking down of the scaffold on that stack before I came into this meeting." The construction boss was in the meeting. He said, "Yes, he stopped me and said he would bring it up at this meeting." This workman said, "We surely can place twenty to twenty-five feet more concrete on that foundation and carry the gases over the roof of that building. Six men whom I know of are in Colorado now getting their lungs treated, and the doctor tells me that their lungs are in the same condition as the lungs of a soldier who has been gassed over in Europe." He was just a common workmen, Gentlemen.

MR. COFFIN (Portland, Oregon): In the largest cities, in the East especially, there are any number of public buildings and large buildings many stories high, and they are managed as a rule by a chief engineer. Now those engineers control the lives of a great number of employees, and there are a great many hazards that are pertinent to a building of that kind. Could they not be included?

CHAIRMAN PRICE: Yes. Usually the local council has adopted the plan of making the attendance upon the school a privilege of membership in the council. I don't mean to say that that is the rule that you have to follow, but I think we will agree that that is advisable, so that if the owners of this building were members of the council, they would get an invitation to this school.

MR. SANFORD (General Electric Co., Lynn, Mass.): I wish to emphasize what in my opinion is the need of the foreman getting a good, strong, safety education. We had for some time safety inspectors who were covering the entire plant. They were inspecting the individual machine equipment in the various foremen's departments, but we found that a man might report that his machine wasn't just right and the foreman would say, "Oh, well, the safety inspector will get that; keep on using it until he tells you to shut it down." That has been changed as far as the foreman is concerned. Each department foreman is made absolutely responsible for conditions in his department. He can work that out in his own way, either by appointing an inspector or by requiring the assistants and gang bosses to share the responsibility.

We still have the inspection service. We have, for instance, two men who spend all their time on the 100 or 150 cranes throughout the plant. They are not responsible to the foremen as the crane repairs are handled by the maintenance department. Everything in the plant which is handled by the maintenance department, such as cranes or elevators, is reported to the maintenance department for attention.

CHAIRMAN PRICE: I would like to ask you one question. Do you think that there would be a place in Lynn for a school where the foremen from all of the plants would meet?

MR. SANFORD: Lynn is just about evenly divided—General Electric Company and the boot and shoe industry. These two different industries would probably have specific problems which would be widely different.

CHAIRMAN PRICE: Those lessons have to do with the fundamentals. Don't you think there is a value in getting foremen away from their own plant and meeting other foremen under entirely different conditions and in an entirely different atmosphere? You can't get this in any kind of an inside foremen's meeting.

MR. SANFORD: I think that might possibly be worked out.

CHAIRMAN PRICE: That is the point that we are discussing here. It doesn't make any difference how good their foremen's meetings are. There is a value in getting the foremen away from their own plants and getting them to meet other foremen. It is surprising how few foremen visit other plants.

MR. FORTUIN (Lehigh Valley Council No. 5): We have had no school, although our council has been very active in other respects. Yesterday I attended a meeting of the Cement Section. Mr. Josse, another St. Louis man, stated at that meeting that he and some of his men attended the school at St. Louis. A man was injured in their plant through electric shock and due to the lessons they received at this school they saved his life. That brought home to us the importance of starting a school down our way. I can say to you now that we are going to do it.

CHAIRMAN PRICE: That makes me think of the thrill I had when a fine young man about as tall as Mr. Brown and as good looking as he is walked up to the table at the Cleveland school and received his diploma. Someone pointed him out to me and said, "That man saved the life of a man which would have cost the company \$5,000." I said, "If we have done nothing else in Cleveland but that, it is worth while."

MR. JUDD (Omaha Council): We haven't yet done anything toward giving the lessons that you have spoken of here. It is our intention to start a school just as quickly as we can get the papers. Our intention is to get out among people who are not members of the council, see if we can't get some of their foremen or superintendents to attend these meetings, and in that way win the membership of the company. We have called on several of them and they are undecided whether they want to go or not. We reasoned that if we can go and get these men and show them the value of these lessons that we will win the support of the man who is at the head of the company. That is the way we intend to go at it. I am going to try to see if I can't start a school of this kind in my

own plant. We have in the neighborhood of fifty or fifty-five foremen. We are new: we have never tried out anything at all and the information we are getting here is certainly valuable.

CHAIRMAN PRICE: Mr. Rasmussen says that Omaha is coming and coming strong.

AN ALUMNI ASSOCIATION

There are a few things that I want to summarize. In all these schools I think we have formed what might be called an alumni association in order to hold the class together. The graduates appoint their permanent chairman and secretary. They meet once a month for two purposes. In the first place they are going back to their plants to try these things out and naturally they get into difficulties. Once a month they have the opportunity to come together and with a leader like Stanion or Stremmel, they can ask him questions about their own problems and then go back to their plants and take a new grip. That is an invaluable thing. Then there is a great deal in having the feeling that you are not alone. There is nothing so discouraging to a safety engineer who is just starting. I remember when I started with the Harvester Company I was absolutely alone. To have a feeling that other people are standing with you and you can lean on them for experience is a tremendous help to a new man. To have a speaker who will supplement or enlarge some industrial relations subject makes a very interesting program. I think that is a very important thing. It holds your group together.

Then the third point—and this is very important—we are literally developing new timber out of these men, timber with which to build a local council organization. They are men who have been isolated to some extent, but they are the best kind of men and they have this fresh interest and this vital contact with the thing itself. If we can hold these men together in these schools and keep them interested in the local council we have some real workers. I remember that in St. Louis they increased the attendance wonderfully just through the efforts of these people. That is worth while, I think.

Next year I am going to bring up this same subject. It is certainly by far the most important thing, the most important development in our local council work. There is no question about it at all, and one of the things that has wonderfully encouraged me is this: it is what we put into a letter to a manager that a school is to be started, that a series of fifteen lessons is to be given, covering all of the essential things that a superintendent or a safety engineer needs to know in order to do the work, a school in which there will be passed along the experience of other companies by these good teachers and that quickly, in fifteen weeks, and that this man will be given a diploma. It appeals to them. There is something thoroughgoing and systematic about it. It covers the whole ground. It isn't just a hit and miss meeting of foremen, and it has been successful in every town where it was conducted. I believe we have struck an idea absolutely. It is the opinion of fifty men, with whom I have talked, that the foremen's school will be popular because it is more thorough.

FINANCING A LOCAL COUNCIL.

Mr. Pardee was not here to discuss the financing of a local council. Mr. Brown, who has been the chairman of the committee to raise the finances for Cleveland is especially interested in that subject, and I know that the rest of you are. I don't know whether I could lead off with just a few ideas that are in my own mind in regard to financing, but I want to express one thought in regard to financing a new city. For instance, we are going up to Duluth. There is a great, big new territory, practically untouched. Mr. McDonegal up there is going to call together a few influential men and they are going to raise \$10,000. We have found from experience that we must get a little money to bridge the first eight months or year in order to make a demonstration. I never appreciated that so much as I did after the Congress in St. Louis. It happened to be my pleasure to go with Smith and visit all but three members of our council, meeting the managers and telling them what our new plan was and that we were going to increase their dues double and sometimes threefold, to cover the local expenses. Smith and I used to joke and say that we didn't sell more than six of them. We didn't have to. Simply the story of what we were going to do, and the fact that we had made a demonstration, that wonderful demonstration of safety week, was all that was necessary.

Now I have such faith in this idea, and I feel that the need is so great, and I feel that the industrial managers are so keenly aware of the fact that the whole industrial relations movement hinges on the education and development of their foremen, that I believe you can in any town get the money to have a six months' demonstration on this school idea and other things. You can then go to the business men and work out permanent financial support such as they have in St. Louis.

In a word that is my central idea. Mr. Brown, I would like to have you talk and ask questions and start this thing going.

MR. BROWN: I can do only the second part.

Assuming that you have financed the first eight months through contributions, isn't it desirable to remove the council entirely from any necessity of soliciting contributions in the future?

CHAIRMAN PRICE: Absolutely. You haven't put it on a permanent basis until you do that, and that means, Mr. Brown, that you must have the influence of some big man who knows the general managers. We did that in St. Louis. We took the time to sit down and tell them what we were going to do. That can't be done in a wholesale way very well. We found that going to the man personally was the thing we had to do.

MR. BROWN: The thought occurs to me that now the local councils are spreading so rapidly throughout the country, and there are more and more cities all the time who are having permanent paid secretaries, that it would be desirable to have the dues made universal throughout the country, based on the number of employees regardless of whether they had a local council or not, a local secretary or not. In other words, raise the dues to the National in order that a rebate may be sent from the National to those cities where there is a local council. The cities

that are doing the intensive work are those which have a paid secretary, and a great deal of that work is building up a fund for the National Council—in other words, securing members that the National Council doesn't have to solicit at all, thereby increasing its revenues. That increased revenue can be used by the National Council in its intensive work to get members in other localities where there is not a permanent paid secretary. It seems to me that instead of burdening the localities that have a permanent secretary with the national dues and an additional amount for their local, no matter how you put it, whether it is all in one or in two sums, if it is a larger amount than members pay in cities which have not a local council, it would be more equitable to charge the same dues of all and then rebate a certain amount to the secretarial cities.

CHAIRMAN PRICE: Let us assume then that there are five hundred industrial centers in which we would hope local councils would develop with paid secretaries, and we would estimate that in each one of those we would want \$10,000.

MR. BROWN: I am talking about the second year.

CHAIRMAN PRICE: Yes, I say the second year, and your thought would be to raise our dues sufficiently to raise that amount which, if pro-rated around, would support a secretary?

MR. BROWN: It is based on the success of the Red Cross Plan.

CHAIRMAN PRICE: That is an entirely new thought. I am thinking of this, Mr. Brown, that the dues of the council were raised fifty per cent not long ago, and, of course, it is a very radical thing to raise dues very much in an organization like ours. In the first place you would have to make a very substantial raise. You would have, roughly speaking, to double the dues to accomplish what you have in mind. Supposing you did that. We will say that I am a man down in Texas and you have deducted from my dues. You must explain why, and you say it is to support these local councils. I reply that I am not anywhere near a place where I can get help from a local council, and that I don't believe I can help support a local council in Cleveland.

MR. BROWN: The St. Louis plan has proved that you would not have to double the dues.

CHAIRMAN PRICE: The dues were more than doubled in St. Louis.

MR. J. H. HANSON (Rochester Safety Council): We had to treble the dues.

MR. BROWN: Of course the National Council wouldn't have to do anything as large as that even if it did require doubling the dues for the local, because it would have the dues to draw from somewhat more broadly than from any one town. You would not only get those increased dues from the town where the council employed a secretary, but from all the other districts also.

MR. RASMUSSEN: Wouldn't the communities which have no permanent organization—for instance, Duluth—complain about helping to pay for a local service that was rendered the people of Cleveland?

CHAIRMAN PRICE: I can't tell off-hand the spread of our membership, but we have a large number of members who are isolated in little towns

and small centers where there isn't much probability of developing a local council.

MR. BROWN: I have talked with Tom Stanion about it and he has practically convinced me that the present method of financing the local council is the proper method, but there are others I want to talk with. I am not bringing this out necessarily as my own point of view.

If that is not the proper plan, would you think a suitable coöperation from the national organization might be this: that, for every new member secured, a certain proportion of his dues for the first year be rebated to the local which has a paid secretary, on the theory that all of that expense has been assumed by the local in securing that member and has thereby relieved the national of that expense? The theory is that the local should be paid in that measure for securing that member whose dues for all the years in the future will go one hundred per cent to the national. It would also stimulate the securing of new members by the local council because of the particular benefit they would get from the new members, rather than from increasing their funds by contributions from the present members.

CHAIRMAN PRICE: We have done substantially that, only in different form. For the first year we give them twenty per cent of all dues, old members and new alike. Whether that would amount to as much as your plan of simply confining it to the new, I can't say.

MR. BROWN: Will you repeat that?

CHAIRMAN PRICE: If you had two hundred members in Cleveland, say, when you started, you would be entitled during the next twelve months to twenty per cent of all the old members and the new. If you have had a local council here and had that twenty per cent that is another matter, but to-day in Duluth when a local is started it will get twenty per cent of all the dues of all the members we have had up there for years.

I would like to make two points there. In the first place I never did anything easier than to go to those 125 managers and ask them to make such a marked increase in their dues. I never in my experience have had anything sell so easily as that. Why? Because there has been such a tremendous demonstration. Now, I believe, after this week, Mr. Brown, that if Mr. Lintz will select men like yourself, who know the managers on whom you want to call, and if both of you will go to see those managers, you will put it across just as easily as we did in St. Louis, because you have had a demonstration here that will convince anybody who is open-minded. I never did anything easier than to raise that money in St. Louis.

There is something in the people of a city supporting its own local activity. You know we take more interest in a thing that we give directly to. It is our baby, you see, and I am a manager, maybe, and I am giving a couple of hundred to this local council in Cleveland and I therefore have an interest in it. It is a very direct contribution toward a specific thing.

MR. BROWN: I was only bringing out that where that is done, the local

is performing certain services that are no longer required from the national. Therefore, could not the amount of the contribution that went directly to the national be reduced?

CHAIRMAN PRICE: I forgot to say that in addition to this twenty per cent that we are giving, we are also sending our field secretary to spend a month with your local secretary. This is our contribution to your local council. It doesn't cost you a cent. We are glad to make that contribution.

Then the third point that I want to make is that we have a surplus of \$45,000 and we don't want to increase it. We have brought it up to a point where it is comfortable; it will bridge us over three months, and we have now brought our budget up to our income. We are giving all the service that we can out of \$153,000, and therefore we couldn't subsidize the locals without cutting out some of our present service.

However, Mr. Brown, I am very optimistic about the other plan. I believe it is easily possible for you to go to the members of the council here after your splendid demonstration and get the money. I believe that managers are so alive to the need of doing something, and as one man said to me after one of the meetings in a city where I spoke before some rich men to raise some money—he said, "Price, all you have got to do is to go tell the story of what St. Louis, Cleveland, and Pittsburgh have done. Just that story of actual accomplishment is enough to convince any business man who is at all progressive." I believe in this thing; I believe it has such intrinsic worth, it is so practical, that we ought to be able to sell it. Lintz, it is up to you.

Mr. LINTZ: Nobody knows it better than I do.

CHAIRMAN PRICE: Let's hear from some others.

Mr. J. H. HANSON (Rochester Safety Council): We had a special committee appointed to look into this thing and thrash it out because we had this problem come before us last fall. This committee brought in a decision that a budget should be made up which would include both the cost of the public safety campaign and the regular industrial work. They found that it took seventy per cent of that budget to conduct public safety work, and it was the conclusion of the committee that the cost of the industrial work should be borne by the industries.

CHAIRMAN PRICE: You mean the public safety work?

Mr. HANSON: No, the industrial—that should be borne by the industries, by an assessment of say seven to ten cents per man, and that the public safety work should be borne by the city, the Chamber of Commerce and the Automobile Club. It was proposed to go to the Chamber of Commerce, to the Automobile Club, and to the city authorities, to ask a certain amount which would cover this budget. We are financed at the present time in an entirely different way—we draw from the community chest.

CHAIRMAN PRICE: I want to add a chapter that Hanson didn't put in there. I want you to get this, Mr. Brown. The council financed the experiment in Rochester during the first six months, putting up \$5,000. I spent two weeks with Harvey just at the close of the six

months. We went to the industrial people—now mind you—to raise enough money to finance the local during another six months' period, and it was very easily raised because of the demonstration.

MR. BROWN: I think that that statement by Rochester brings out a very important question that is likely to be asked by industrial managers. "How much of my contribution is simply public service work, and how much of it is real industrial work?" The answer is that thirty per cent of what he gives us is used for the part that he is most interested in, according to that statement.

CHAIRMAN PRICE: My experience is that industrial managers—I won't say they are equally interested—but they certainly are very much interested in public safety.

MR. BROWN: I don't mind that myself, but I think it brings out the necessity of going to others than simply the industries for help. You have a good argument that the community must take the responsibility in the support of the movement.

CHAIRMAN PRICE: I still insist that the backbone of the financial support of your local council, both public and industrial safety, is going to be in your big industries. The big bulk of your money is going to come from those people.

MR. MCCLAIN (Cincinnati Local Council): In conducting a public safety campaign such as they have here in Cleveland this week, this idea occurs to me: suppose we made a lot of little lapel tags or banners and the school children sold those on the streets for ten cents apiece—is that a good idea or is it not?

MR. STANION: That would cheapen the whole thing.

MR. LINTZ: I wanted to inject a thought there: Mr. Hanson made me think how enthusiastic the automobile clubs are. I have had the pleasure of associating with Mr. Caley, our local secretary, and I have had several very interesting conversations with him. He told me, "Lintz, I am with you. I know it is a good thing. If it is five hundred or one thousand remember that the Automobile Club is with you." I think that enthusiasm can be made to grow.

Fortunately the Cleveland Automobile Club has adopted its own insurance department. We have a better chance of getting support than we otherwise would have.

MR. FELLNER: There are two absolutely definite activities. One is the industrial activity; the other is the public safety activity. You must finance them in two budgets and that is what we are going to do in St. Louis. We are not going to disturb our industrial budget at all. The public budget will be secured by calling together those most interested: department stores, transfer companies, the city authorities, and groups of that kind. It is going to be put on a permanent basis, not on a contribution or charity basis.

CHAIRMAN PRICE: Do you mean to tell me that you are not going to take any money out of the fund that is secured from your seven and ten cent assessments?

MR. FELLNER: We can't afford to.

MR. LINTZ: Have you given any thought to a basis of establishing dues for public safety work?

MR. FELLMER: Not yet, but we have been figuring on establishing a regular basis of dues.

THE PITTSBURGH PLAN

MR. CLARKSON: The Pittsburgh plan of financing industrial safety work is to double the dues to the National Safety Council, but when we formed our Public Safety Committee, we insisted upon keeping the Public Safety budget absolutely separate from the industrial budget. The plan is this: to raise \$15,000 for public safety work. We have assurance of financial support from the city, from the county, from the Chamber of Commerce, and from several other sources, such as the Board of Fire Underwriters, and the Street Railway Co. Of course, the Street Railway Co. is an industry and it belongs to the industrial class.

CHAIRMAN PRICE: Sometimes the street railway companies are more interested in public safety work.

MR. CLARKSON: I am going to classify them later.

We are going to the street railways and the public utilities and the large corporations, because they, as large corporations, are interested in public safety, very much interested, and, as a matter of fact, we believe over there that the large industries are not paying enough dues. They are public institutions. Take for instance the Carnegie Steel Company, the Jones & Loughlin Company and other similar companies. They are public institutions; there is no getting around that. They owe a duty to the public; hence we are going to pass those corporations for contributions. That is the way we expect to get our finances for the public safety work. That is, the city is going to give so much, the county is to give so much, and the Chamber of Commerce so much; such organizations as the Board of Fire Underwriters and the fire insurance companies are especially interested. Then we are going to the industries, the large industries, and ask them for a contribution to take care of our first year's work. That is the way we plan to raise our finances to carry on both of these functions.

But, in connection with our industrial work, we can't raise our dues again for we feel that would be suicide; we have got to concentrate on getting new members.

CHAIRMAN PRICE: Mr. Brown, I am going to use you as a barometer to indicate to me whether we are getting anywhere. Have you had your questions answered? Have you a clear idea of how you ought to finance the council here? Aren't there some doubts still in your mind?

MR. BROWN: Yes, but I don't think that any one in this room will say that they have it solved. I think, however, that it is concealing the issue when you say that the money that you spend for public safety is

CONTRIBUTIONS OR DUES

not derived from contributions but is derived from dues. You get those dues from those who are particularly interested in public safety rather

than in industrial safety, like the bankers and the professional men and the rest of them. You call them dues.

CHAIRMAN PRICE: No.

MR. BROWN: St. Louis calls them dues, but they still are contributions, because dues are only those funds that come back with the direct benefit to the employees of the companies that pay the dues. And when you call them dues for a banker, that proportion of his dues that applies to thirty or forty or one hundred that he may have in his bank, that part is dues, but the rest is contribution.

If a lawyer, who has no employees, pays \$100 for membership in the local council, you call it dues, but it is a contribution. There is no use trying to cover that up. I don't mean that that isn't wise and proper, but I think it is better to show that it is a direct contribution for the public safety work.

MR. EUGENE J. ROESCH (New York City): I think I can offer something which may be helpful to us here.

CHAIRMAN PRICE: What is your connection, Mr. Roesch?

MR. ROESCH: I have been organizing the printers of the country, and I have some experience along this line. In my connection in Europe and South America, I have always been very interested in safety, and in New York City, preparing for the war emergency, I organized perhaps the largest classes in this country in accident prevention.

We are interested now in the salesmanship of our proposition, and we should take this as a real salesman and study our problems properly. In the first place, wherever you have a direct benefit you want to call it dues, and I would suggest that you have some means of pro-rating it.

CHAIRMAN PRICE: We have that.

MR. ROESCH: Where people have indirect benefits, they have also just as great moral obligations and they should do their share, but do not call it a contribution. If you do that, you are going to set up a wall immediately. Call it subscriptions, and have a definite basis for those subscriptions. We have gotten a budget of about a million and a half—printers who formerly paid \$20 or \$30 a year for their work are now paying \$2,000 and \$3,000, and they are doing it gladly, because they see their benefits, and the allied industries are never allowed to think of making a contribution at all. They make a subscription and they really see some indirect benefit. I think you should keep away from that word "contribution". I feel you will get much better results if you call it a subscription.

DISTINCTION BETWEEN PUBLIC AND INDUSTRIAL SAFETY BRANCHES

MR. TOWNSEND: I would like to say a word that would make a little clearer in the minds of some the distinction between the public and industrial safety branches of local council activities and why in St. Louis we feel that it is the proper thing to raise a separate fund for the public safety work. We are offering there in the public safety work a definite service, which is distinct from that which we offer to the industries in the industrial section. The chauffeurs' school is going to be largely

patronized, and it is awakening a great deal of interest. The school for patrolmen is going to be of a great deal of interest. The bulletin service at the filling stations for automobiles, the bulletin service in the public schools, and various other things of this type will advance public safety. These things have got to be financed, and it is going to take a definite budget to finance all of them. We feel that it would not be just to attempt to draw from the budget for industrial safety. But instead of going to these manufacturers, as we have in the past, we will go to them, of course, but also to these other groups, the transfer companies, the department stores and these people who have many automobile trucks on the streets, and we will ask them for their contributions—and I think we will call it, not a contribution, but a subscription.

We feel that we are going to put it over with a lot of enthusiasm in the future and the people will see the justice of its being a separate fund.

MR. COFFIN (Portland, Oregon): I believe that I can speak from experience as far as public safety is concerned—

CHAIRMAN PRICE: Mr. Coffin used to be the head of the Public Safety Commission in Portland.

PUBLIC SAFETY COMMISSION OF PORTLAND

MR. COFFIN: That was an organization of prominent citizens officially appointed by the mayor. We were financed by the city council, as well as by the Chamber of Commerce and public utilities. We started in our work about five years ago, and every one knows the work that the Commission has done in Portland. It has become national in its scope. We raised \$4,000 a year in that work when we first started. With the large increase in automobiles we still cut down the accident record. Our deaths from street accidents decreased from an average of 29 or 30 a year—we cut it down the first year—to five a year. In our fire prevention work, as you all know, we cut the losses from two million to two hundred thousand. That is on record. So that in starting now in industrial safety, it seems to me that that should be kept entirely separate from the public safety function, because the city, the city officials, and the public utilities are vitally interested in public safety. Of course, it will work in conjunction with and be under the management of the National Council, but the two will be kept separate.

CHAIRMAN PRICE: The time is approaching when we must turn McClain loose or we will have trouble.

We could go on here for an hour discussing the form of this thing, how we could work it out. That is a very important detail. We might get somewhere, but the two things that I think are important for us to carry out of this meeting are: First, that this work we are doing is absolutely practical, it meets in a successful and effective way a crying need in our streets and in our homes, as well as the industries, a need that every thinking citizen is rapidly coming to realize. Secondly, we have a plan here which has been tried out. We have worked out definite lines of service such as this school that we are talking about and this public safety that was outlined yesterday by Mr. Smith, and which has

been so splendidly demonstrated here. If we are going out to get this money we must have faith in the thing that we are trying to sell. That is fundamental to every salesman. I used to be a salesman. I sold shoes. I couldn't have sold shoes if I didn't believe in them.

I personally am obsessed with the value of this thing, and when I go out to sell a membership I go into a manager's office with faith sticking out in my eye. I don't believe I could sell a membership at all if that were not the case. If I have had any success in cracking hard nuts—and they always take me to the hard ones—it is because I profoundly believe in the value of this thing. It is growing every day. There are wonderful possibilities that are locked up in these activities which we have discussed this morning, foremen's and superintendents' meetings, possibilities that we haven't caught a glimpse of in this public safety. It is coming by leaps and bounds.

Think of the story that Capt. Robbins told yesterday. That is a new chapter and there will be a new chapter next month. If we have the faith in this thing we are going to go out and sell it. I think it is very important that we should know how to put it before these people whom we are going to approach. For instance, one of the things which we did in Pittsburgh was to get out a little folder outlining the whole plan and activities, so that in convenient and brief form it can be put into the hands of all these men you are approaching and they will get the story. Give newspaper publicity constantly to the school and the other things that we are doing, so that these men whom you are going to approach will be fully informed in regard to the activities of the council and the value of it.

Another point I want to emphasize is that when you go to those men, go to them personally and go to them with some one who knows them personally. We went to twenty people and we got twenty subscriptions. Why? Because the man whom I was with knew every one of those men. If you, Mr. Lintz, will take Mr. Brown to see Mr. Mather of Pickands & Mather, you are going to come away with the bacon, I tell you.

I think that we can properly go on to the next subject, although personally I would like to spend more time on this. The thing is so new that we are practically engaged in pioneer work. It is growing by leaps and bounds. It is a wonderful experience that has come to us in the last year. I feel as if I had just started in safety work. This thing is opening up so fast. The next year we are going to come back with stories of wonderful accomplishment.

At every one of our sessions we always like to exhibit one of our new babies. One of our newest babies is Cincinnati. In that city, there is in operation a very unique plan of connecting the local council with an industrial medicine department newly organized in the University of Cincinnati. It opens up an entirely new experiment and the more I get into it the more I am impressed with the possibilities of it, I am inclined to think that Cincinnati has added a new chapter. You have gone St. Louis one better, and Pittsburgh, too. Now McClain, get up and see if you can prove it to them.

THE CINCINNATI LOCAL PLAN

G. H. McCLAIN, SECRETARY, CINCINNATI LOCAL SAFETY COUNCIL

A good deal has been said in all these meetings about the educational side of safety. The educational side of safety, to my mind, is *the* side. Of course the thing develops into ramifications that nobody can see the end of when we go to talking about the educational side of it.

We have a condition in Cincinnati that is unique, as Mr. Price has said. In view of the fact that it was somewhat radical and unique, I will go into details. I may spend some time on things that aren't very interesting to you, but if they get tiresome just raise the flag and I will stop.

Last winter in February, Mr. Victor T. Noonan, who has cut a wide swath in safety work in this State, held a get-together meeting in Cincinnati at the Sinton Hotel. Considerable enthusiasm was demonstrated there, which, perhaps, is a little out of the ordinary for Cincinnati. Cincinnati has been a dark spot in safety work for some time. At the conclusion of the meeting there was a very decided demand for some sort of safety organization. The leaders in that town had been aroused and demonstrations had been given them that it would pay them to be interested, so this demand came for a local organization. There were two schools, as it were. Some people wanted just a local safety league. At that meeting were Frank Morris, Dr. Otto Geier, Mr. Lew Palmer and some others who were directly interested in the National Safety Council. These men whom I have named were on the Board of Directors. They foresaw the advantage of organizing a chapter to be affiliated with the National Safety Council. In other words, a regular local chapter. That much was decided on, after this meeting was over.

JOINING SAFETY WORK TO INDUSTRIAL MEDICINE AND PUBLIC HEALTH

About the same time another activity of somewhat similar nature was developing in the city. There are some very fine public-spirited people in Cincinnati. Among the professions there were some men who were dreaming of the organizing of a department that would be known as the Department of Industrial Medicine and Public Health. This was the dream of Dr. Holmes, Dr. Fred Lander, Dr. Otto Geier. Dr. Geier conceived the idea of linking up this safety work with this department which was then being organized.

About that time, I believe, we called in Mr. Price. Mr. Price came and after going through the thing pretty thoroughly he said, "Well, it looks interesting as an experiment." He has signified that I am an experiment, or that I typified this experiment in Cincinnati.

It was decided finally that the local safety secretary should be a member of this new organization. I believe I shall explain the details of this organization inasmuch as it is new and is being looked at from every angle all over the United States.

Dr. McCord, who was Major McCord in the medical corps of the base hospital at Chillicothe, was asked to take charge of this new department. Dr. McCord had, to use the common term, made a name for himself over

there and had attracted considerable attention. He took charge of the department and aided in the organization. I must say that Dr. McCord brought with him every army rule and tradition there is and he certainly can lay out things on a military basis. He is my boss and I know.

Another factor in this work was the industrial physician. We finally succeeded in getting Captain Watkins who had charge of all sanitation, hygiene, and medical work at Nitro, West Virginia, where he had about twenty doctors and seventy-five or eighty nurses under his jurisdiction. He is a man who, I believe, knows all that is known in industrial medicine and public health work. This man was for nine years in the Public Health Service of the United States. He has taken over this work of industrial medicine. One of his chief functions will be to render a service in that field to the industries of the city. I must say that in Cincinnati we have some places that need a half dozen such men right now.

Another division of this department is the service that we are giving to women in industry. We have secured the services of Miss Laura Sanford. It may be that some of you people know of Miss Sanford, who was for a long time with Columbia University and later with the Wright-Martin Company. She will spend her time on problems relating to women in industry, bringing to the attention of the management conditions as she finds them.

We have Captain Walker, who was a very active bacteriologist at Camp Sherman, and in Europe too, to take charge of the bacteriological work. We are to have the coöperative service of a dentist in oral hygiene. We are taking on an expert in employment management. We are going to attempt to educate a lot of these men, these industries in Cincinnati, to the advantages of modern methods, because we are woefully lax in that regard. I might say right here that we have a rather peculiar condition. The city of Cincinnati, a city of perhaps a half million people, has only three or four factories which employ more than two thousand people. There is a great list of factories employing from fifty to two hundred and three hundred men. So we have a real problem there, and a good many of these fellows are old timers; a good many of them have taken the business from their fathers, and it is pretty hard to show them the light.

SAFETY A REGULAR DEPARTMENT OF THE UNIVERSITY

Last—and I don't know whether to say least or not—is the Safety Department. This department has been recognized as one of the regular departments of the University of Cincinnati. I have the distinction of being the first local secretary who is also a professor in a university. Gentlemen, I am the only specimen alive in the world to-day. But after all, is it an experiment?

CHAIRMAN PRICE: You are, a little later on, going to tell what McClain is going to do in the university?

MR. MCCLAIN: I am saving the best for the last.

Cincinnati University is a municipal university, maintained by the regular educational fees of the taxpayers. The trustees of Cincinnati

University are business men and the industrial leaders of the city. These men are forward-looking and public spirited enough to reach up into the clouds, as it were, and interpret the responsibilities a municipal university should have to the community.

Now I will try to answer the question you have asked. Where does the safety man come in and what is he going to do?

Here are the advantages, as I see them, in this connection. We have about 800 engineering students in the university of Cincinnati. A large number of those students are what we call coöperative students. I think Cincinnati University is a pioneer in what we call coöperative education. A large number of those boys go out and work in the factories in Cincinnati and in the immediate vicinity, Dayton, Hamilton, Middletown, and Springfield, for two weeks. Then they spend the next two weeks in the University. I have the opportunity and the plans made to teach these young men safety. These men who will be in a few years the foremen, the superintendents, the managers in that city and community will have this thing in their skins so deep that they will never lose it. And that is my responsibility.

Now you all know that a man has a very high regard for the things that he learns in his particular college. He thinks his college is just a little bit better than any place else, and that is perfectly all right. Now if I am able to go before these young engineers and say, "Men I want you to know that you are the first college men who are being trained by a member of the faculty who is a regular safety man," I believe that it will make an impression on those men which they will never forget. I am going to teach them along the lines of these foremen's meetings. I am going to utilize those lectures to a certain extent and blend them with college experiences, and I think they will be very valuable.

CHAIRMAN PRICE: How many students are there in the engineering school this year?

MR. McCLAIN: About eight hundred all together.

I want to introduce, as far as I can in the technical side of their training, safety in machine design and things of that kind.

TEACHING SAFETY TO TEACHERS

Here is another advantage that I think that I have. There is a college of education or a teachers' college connected with Cincinnati University that trains from eight hundred to a thousand teachers. I have arranged with the dean of that college to give a series of eighteen lectures, a credit course of eighteen lectures or lessons—I call them lessons down there, which, of course, is more appropriate in the school—on this question of safety, which is based in a general way on Dr. Payne's experiment in St. Louis. I go just a little bit farther. I intend to do a little field work. I want to take some of these teachers out on the street and I want them to see with their eyes what the hazards of the street are. I want to take them through industries. (This is the latter part of the course, after they have become thoroughly interested in safety.) I want them to get it from the big, broad, viewpoint. Then I want to give

them one or two lessons in the mechanics of safety. I want to emphasize such things as railroad signals, elevator protection, railroad gates, bells and signals, stop and go signs, everything that has to do with the mechanical side, and the rules that go with them.

So much for the teachers. Here is another important thing. In my connection with the university—

CHAIRMAN PRICE: You forgot to speak of the school teachers who are coming, one from each building.

MR. MCCLAIN: I am going to speak of that. I went to the Board of Education with a plan for public school teaching based on Dr. Payne's experiment. I almost hesitate to call it an experiment now, because it is no longer an experiment, it is a proven fact. I went to the Superintendent of Schools. I said, "Dr. Condon, I want to call together one teacher from the various buildings of the schools." Then I told him about creating a class for professional credit, and giving them a course so that they can apply the teachings of Payne's book. Immediately it met with his approval. I said, "I want your permission to make the rounds of the schools to talk to the students en masse for ten or fifteen minutes, to give a background to the teaching of this question of safety in the schools. It will dignify and emphasize the local teachers' work." It instantly met with his approval—no objection whatever. Furthermore, they placed at my disposal childrens' committees and things of that nature which were already organized in the school to be used as vehicles of safety.

It is my intention, men, to emphasize this question of school safety in the school. I spent five years as a teacher. Sometimes they say, "pedagogue" but I just like to be known as a teacher. I enjoyed it immensely. I can live a half dozen lives if I can get around to the young people. I think that I can go into those schools with my little moving picture machine occasionally and give a little lecture to back up the teaching of the local teachers, to emphasize that, and I believe that we are going to get way yonder in our results.

That, in a way, outlines my program. You men have the advantage of me because you can come here and stand up and say, "We did this and we did that and we did the other thing. We had so many men in our classes, etc." All I can do is to stand here and swell up my chest and boast about what I am going to do. I really believe that I am going to do it, because I never undertook any other proposition in my life where everybody has so whole-heartedly handed me the right hand of fellowship and said, "McClain, we are with you; you are all right; go to it; is there anything we can do to help you?"

CHAIRMAN PRICE: That means a lot.

MR. MCCLAIN: Just to illustrate: in the city of Cincinnati there is a very fine social service organization. The citizens will soon go into a campaign to raise a little over one million dollars to carry on social work in the city. We went to the federation of these social agencies and we carefully cultivated their support, and they give us anything that we ask.

The other day the man who has charge of the Better Housing League called me up and he said, "McClain, can you come down some day and give a little talk to my visiting housekeepers? This question of home safety, as you have emphasized it, has impressed me very much and I believe that if you will instruct these visiting housekeepers a little bit, their activities will be a little broader." You know I am not going to overlook a chance like that. That illustrates just how we are being treated.

So much for our connection with the university. On top of that we have our regular industrial service which you men have already been working on and have proved successful. We are laying our plans now for our supervisors' schools. I expect also to have the foremen's schools. I got on the job in August. I was very anxious to try my strength. I was so interested that I couldn't hold still much longer, so I decided to have a big foremen's meeting to let them know we were in town. I am a little chesty about this too. I knew but few of the industries in the city. I made no personal calls. We sat down and wrote letters, attached a little blank at the bottom, requesting so many tickets to this foremen's meeting, and we had some 1250 odd men out in Emery Hall, the biggest hall in the city. Then I thought, "Well, you are off now and you have got to keep it up." That gave me a little encouragement.

FINANCED BY BUSINESS MEN

The thing that will interest you is how this thing is financed. This whole department (we speak of it as a unit because in making up our budget for this department we included about \$7,500 for safety activities) will spend, I imagine about \$35,000 a year. A group of business men accepted the responsibility of financing it. In other words, they said, "You fellows go ahead and do your job, and you don't need to worry about the finances. We will take care of them."

Well, these men simply guaranteed our existence and told us to get on the job. They have raised practically all the money, or will have done so shortly. They are going to all the industries of the city and are getting subscriptions. I emphasize that word "subscriptions" in the light of what has been said. They say to a man, "We will have a man for you who will teach you employment relations; we will have a man for you who will come in here and help you improve conditions for your women; we will have a man come in here who is an expert in safety; we will have a man come in here who is an expert in industrial medicine. Put down your \$200, and if you don't get all this service it will be because you don't ask for it. It is there for you."

Our finances really aren't worrying us very much. This period of financing is to cover five years. When a man puts his little old \$200 down for this year, it means that he has got to come across the next year and the next year. Later, if the department has demonstrated itself of true worth to the community, the university will make some plans of financing it through the regular channels.

The money that was raised was taken to the trustees of the university and given to them to administer.

Have I left out anything?

CHAIRMAN PRICE: I want you to emphasize one point, that practically all of these boys who are working two weeks on and two weeks off in the shops—two of them hold one job—are absorbed into the industries and occupy important places.

MR. McCLAIN: I don't know whether any of you men are directly in contact with this coöperative system of education. It is working out to be a huge success to the young man who can't advance money for his education. He works two weeks and goes to school for two weeks. We have found it to be a wonderful thing in Cincinnati. These men, as you readily see, are going out into the industries and are going to carry this microbe of safety with them, because I am going to put it into their heads so tight that they will tell their foremen about it; they will tell the men around it. It will be one of their hobbies. To me, that looks like a mighty big field for spreading this gospel of safety. It looks to me like throwing a stone out into the center of a pond. The waves go out and out and out until they reach the shore on all sides.

(Mr. G. E. Clarkson, Pittsburg, took the chair.)

CHAIRMAN CLARKSON: All right, gentlemen, you can now shoot questions at Mr. McClain.

DISCUSSION

A MEMBER: I would like to ask whether you have included in your program a little publicity work whereby other universities in this country will be kept in touch with the work which you are doing. I had the pleasure some time ago of making a safety inspection of one of our largest universities. I was astonished at the lack of consideration that was given to safety in their laboratories and in their methods of teaching.

MR. McCLAIN: I might say that I understand the Council will make some effort in the next few months to spread propaganda to all the active universities of the country on this question of teaching safety. It is going to start a campaign to educate the universities. That may be a little far-fetched, but the fact is that they should start right there.

MR. L. J. SMYTH: How much of your program can be carried out in a state university? For instance the University of Kansas is close to our council in Kansas City, and it has offered coöperation through Prof. Sibley, the head of the Mechanical Engineering Department. In what way could a university coöperate with a local organization where the university is forty or fifty miles out of town, but draws on the city for a great many of its students?

MR. McCLAIN: How close are the relations between the university and the city?

MR. L. J. SMYTH: Very close. Although the university is in Kansas it is very close to Kansas City, Missouri, and the relation is a very close one. We want to get their coöperation but don't know just how to go about it.

MR. McCLAIN: I think one of the things that is coming very shortly is this: Universities are going to give credit for a certain safety engineering subject. I believe this will come first in the mechanical engineering schools. It strikes me that the first thing to do is to put in a course in safety engineering, and in that course not only stay close to the technical side of it, but also go into the various phases of it, how it relates to the employee and to the employer and to the problems of the foremen, because these men are all going to be executives—I wouldn't exactly say all of them, but the executives of industry will come from them.

CHAIRMAN CLARKSON: In Pittsburgh we have the Carnegie Institute and Pittsburgh University, both of which are connected with industry. Their directors are the large managers and officers of the large industries, and I have no doubt that if we would just start out in Pittsburgh as you have started in Cincinnati, we could affiliate with either of those universities. Of course, Carnegie Institute of Technology is one of the largest technical institutions in the country, and Pittsburgh University is somewhat like the Cincinnati University—it is one of those coöperating schools.

MR. COFFIN (Portland, Oregon): Has anything been done toward putting in a course of safety engineering in the curriculum of these technical schools?

MR. McCLAIN: Not to my knowledge.

MR. H. L. ROBINSON (Worcester County Council): I think the Massachusetts Institute of Technology has made a little start along that line. I am not able to state just how far they have gone, but I have received circulars from which I infer that they intend to go into safety engineering, perhaps in connection with their mechanics course.

MR. McCLAIN: It seems we are right on the edge of the universities taking this thing up. Our mail every morning brings in inquiries from the whole United States on our method of procedure. This is particularly true of the fact that the entire department of Industrial Medicine and Public Health is attracting nation-wide attention. It is new and an experiment, and people are anxious to learn how the plan is organized, what we are going to do, and what our relations with the university are.

MR. FELLNER (St. Louis Council): Let me suggest, from the experience of Mr. McClain and the other gentlemen, an idea which I have in my mind? Why not have the local secretaries in communities where there is a university, and where the local council is conducting a safety supervisors' school, offer to the engineering department of the university the use of that school to its students, and in that way get the safety idea implanted in the heads of these prospective executives?

MR. McCLAIN: That is a very good idea indeed.

Adjournment.

LOCAL COUNCIL REPORTS

BOSTON SAFETY COUNCIL

W. C. SWIFT, PRESIDENT

Works Manager, Standard Woven Fabric Co., Walpole, Mass.

E. M. COFFIN, SECRETARY-TREASURER

Staff Engineer, Associated Industries of Massachusetts,
1034 Kimball Building, Boston, Mass.

The New England Safety Council at a meeting early in the year, decided that its activities were, in a measure, duplicating those of local councils already established at Worcester and Springfield, and therefore, at a very spirited meeting decided to disband with the understanding that the Boston Safety Council would conduct the activities carried on in Massachusetts east of Worcester County.

The carrying out of this program led to the organization meeting of the Boston Safety Council, June 12, 1919. Forty-eight delegates representing industrial and other organizations were present. Mr. W. L. Robinson, secretary of the Worcester local, outlined very clearly the activities started in the center of the state, and Field Secretary Rasmussen of the National Council was present and gave much valuable advice and assistance. The Compensation Rating and Inspection Bureau was represented by Mr. Magoun, General Manager, who gave a very pointed talk on the value of safety work in reducing compensation premiums through the Massachusetts Experience Rating Plan.

Our second meeting was held, June 27, with an attendance of thirty-nine. Mr. Victor T. Noonan, who comes to Massachusetts from Ohio, where he was director of industrial safety, gave us a very fine talk on "Indifference, the Great Ally of Accidents". The following discussion was led by Edwin Mulready, Commissioner of Labor in Massachusetts, with very general participation.

At the meetings of the Executive Committee it was deemed best to defer further activities until the end of the vacation season, when general membership meetings will commence and community gatherings for foremen and employees, with speakers and moving pictures, will be facilitated.

CENTRAL MISSISSIPPI VALLEY DIVISION

C. B. HARDIN, PRESIDENT

United Railways Company

M. L. FELLNER, SECRETARY

St. Louis, Mo., September 15, 1919.—Following the adjournment of the Congress of 1918. Mr. Carl L. Smith as Permanent Secretary of the Cen-

tral Mississippi Valley Division of the National Safety Council began the practical organization of the Division's work. A permanent organization was effected and the following officers and committees installed:

President: C. B. Hardin, United Railways Co.; Vice-Presidents: George Aurien, Mississippi Glass Co.; D. E. Parsons, East St. Louis & Suburban Railway Co.; Philip Stremmel, National Enameling & Stamping Co. Plants; Secretary: Carl L. Smith, St. Louis Chamber of Commerce; Treasurer: Herman Spöehrer, Union Electric Light and Power Co.

Committee Chairmen—Boy Scouts: Major H. H. Simmons, Scout Director; Complaint Bureau: E. G. Marsh, Secretary Complaint Board; Educational and Schools: Geo. P. Knox, Assistant Superintendent of Instruction Public Schools; Finance: Arthur T. Morey, General Manager, Commonwealth Steel Co.; Fire Hazards: Wm. G. Panzer, Chief of Fire Department; Industrial: J. C. Josse, Continental Portland Cement Co.; Legal: Hugh K. Wagner, Attorney and Counselor at Law, 503 Fullerton Buildings; Liability Insurance: Walter D. Thompson, United States Casualty Co.; Membership: Paul F. Gutmann, Mississippi Glass Co.; Parks and Public Recreation: Nelson Cunliff, Park Commissioner; Police and Traffic: Barney Verheyen, Assistant to Chief of Police; Program: Walter S. Gemmer, Scullin Steel Co.; Publicity: W. B. Weisenberger, St. Louis Chamber of Commerce; Public Safety: Charles M. Talbert, Commissioner of Streets and Sewers; Public Utilities: C. Howard Stewart, Assistant to Secretary and Treasurer Laclede Gas Light Co.; Sanitation: Dr. G. A. Jordan, Assistant Health Commissioner; Speakers Bureau: Dr. E. Geo. Payne, Principal, Harris Teachers' College; Statistics: Dr. R. S. Vitt, Coroner, St. Louis.

District Chairmen: L. S. Brainard, Utilities Indemnity Exchange, St. Louis, Mo.; J. W. Costley, Granite City Steel Works Granite City, Ill.; H. C. Davis, Wagner Electric Company, St. Louis, Mo.; Homer J. Hodson, East St. Louis & Suburban Ry. Co., East St. Louis, Ill.; Edward C. Friedewald, Kolb Coal Company, St. Louis, Mo.; H. F. Hecker, Monsanto Chemical Co., St. Louis, Mo.; Dr. Heber Robarts, Belleville, Ill.; E. A. Robertson, Laclede Steel Company, St. Louis, Mo.; Duncan C. Smith, Aluminum Ore Company, East St. Louis, Ill.; J. C. Townsend, International Shoe Company, St. Louis, Mo.

SCHOOL FOR SAFETY SUPERVISORS

The first activity undertaken was the institution of a school for safety supervisors and a course of fourteen lectures on the following subjects:

1. Safety and The Manager: The Importance of His Support and How to Get It—W. E. Worth, Superintendent, Chicago Tunnel Co., Chicago.
2. Design and Construction of Safeguards—R. J. Young, Manager Department of Safety and Relief, Illinois Steel Co., Chicago.
3. Plant Conditions; Arrangement, Order, Lighting—C. W. Price, General Manager, National Safety Council, Chicago.
4. What the Foreman Can Do to Promote Safety—Frank E. Morris, Safety Engineer, American Rolling Mill, Middletown, Ohio (Present, Regional Field Secretary, National Safety Council).

5. Bulletin Boards, and Other Ways of Reaching the Workmen—W. R. Rasmussen, Secretary Western Pennsylvania Division N. S. C. Pittsburgh (Present, Regional Field Secretary, National Safety Council).
6. Workmen's Inspection Committee and Meetings—M. L. Fellmer, Commonwealth Insurance Company, St. Louis.
7. Electrical Hazards—F. H. Reid, Bureau of Safety, Chicago.
8. Labor Management and Safety; Physical Examinations, Instruction of New Men, Labor Turnover—A. H. Young, International Harvester Company, Chicago.
9. First Aid—Dr. R. S. Vitt, Coroner, St. Louis.
10. Eye Protection and Safe Clothing—Fred M. Rosseland, Safety Engineer, National Safety Council, Chicago.
11. Plant Sanitation—Dr. G. A. Jordan, Assistant Health Commissioner, St. Louis.
12. Accident Records, How to Compile and Use Them—Frederick M. Crum, Assistant Statistician, Prudential Life Insurance Co., Newark, N. J.
13. Fire Prevention in Relation to Safety—Sidney J. Williams, Secretary and Chief Engineer, National Safety Council, Chicago.
14. Qualifications of a Safety Engineer, His Duties and Opportunities—J. A. Oartel, Carnegie Steel Co., Pittsburgh.

were given to a class which had an enrollment of over four hundred and an attendance of over three hundred on the average. These fourteen lectures were followed by a general Review and Experience Meeting and the course closed with appropriate graduating exercises, May 22, in the form of an informal dinner at the Planters Hotel at which occasion General Manager Price distributed diplomas to two hundred and twenty-five graduates (graduates being such students as had attended at least 75 per cent of the lectures). The first lecture was given in the Directors' Room of the Chamber of Commerce with an attendance of one hundred and twenty students. After the first lecture it was found necessary to secure larger quarters, and through the cooperation of the Union Electric and Power Company the subsequent lectures were held in the splendid auditorium of that company on Twelfth and Locust Streets, and this auditorium was filled to capacity (450) on several occasions. This course of instruction has been productive of a great stimulus for safety in the industrial plants of St. Louis and wonderful results have been noticed in some plants that had never before paid much attention to organized, systematic safety work. The classes were in charge of Mr. Philip Stremmel General Superintendent of the National Enameling and Stamping Company's Plants, whose enthusiastic methods and strong personality were one of the most potent causes for the wonderful spirit prevailing among the members of the class. The members were composed of young men in minor executive positions, such as traffic men, employment men, shipping clerks, etc., through the ranks of superintendents and work engineers into the ranks of executives and managers. After the close of the school two meetings were held; one in the form of a dinner lecture on the newly passed Work-

men's Compensation Law at which Mr. H. C. Davis, Assistant Treasurer of the Wagner Electric Company, and one of the members of the class, delivered a very comprehensive lecture on "Workmen's Compensation". The other meeting was in the form of a get-together social, at which the Ford film "The Only Way" was shown and a beautiful class pin adopted and plans were made for the participation of the class in a boat excursion to be given by the Superintendents' and Foremen's Organization.

SUPERINTENDENTS' AND FOREMEN'S MEETINGS

Four meetings of superintendents and foremen were held on the following dates:

January 30, 1919. Mr. Rasmussen's experience in reducing accidents at the plants of the American Smelting & Refining Co., Omaha—W. R. Rasmussen, Secretary, Western Pennsylvania Div. N. S. C., Pittsburgh.

March 4, 1919. Opportunity—Victor T. J. Gannon, United States Department of Labor, Washington

March 31, 1919. Playing The Game—J. C. Townsend, Safety Engineer, International Shoe Co., St. Louis.

May 12, 1919.—Key Men—Philip Stremmel, General Superintendent, National Enameling & Stamping Co., Granite City, Ill.

A musical and entertainment program was given in addition to these splendid lectures. These meetings were attended by an average of eighteen hundred superintendents and foremen and their wives and were very enthusiastically and interestingly arranged. Mr. J. C. Josse of the Continental Portland Cement Company was in charge of this feature of the work. Under the auspices of the Superintendents' and Foremen's Organization the Council arranged for a Boat Excursion on the Steamer St. Paul which took place on Saturday, August 23, and proved very successful. A total of over fourteen hundred participated in this outing and the afternoon and evening was spent in a great get-together family-style excursion.

MANAGERS' MEETINGS

The following Managers' Meetings were held with enthusiastic attendance of executives and managers from all the industries of our district:

February 21. Labor Turnover in Relation to Safety—A. H. Young, International Harvester Co., Chicago.

April 10. H. C. Davis, Assistant Treasurer of Wagner Electric Co. and Dr. R. S. Vitt, Coroner, substituted for Mr. R. M. Little, Director of the Safety Institute of America, New York City, who did not arrive in time to deliver his lecture on "Conservation of Man Power."

May 22. The Missouri Workmen's Compensation Act and Its Application—H. C. Davis, Assistant Treasurer, Wagner Electric Co., St. Louis.

MOTION PICTURES

The Council purchased a moving picture machine and the film "The Outlaw". It has been shown in plants of members all over the district and has proven of material value in the work.

SPEAKERS BUREAU

The Division maintains a bureau of speakers in charge of Dr. E. George Payne, Superintendent of the Harris Teachers College which furnishes speakers for clubs and organizations. A good many addresses were delivered by this bureau to organizations, especially before Parents' and Teachers' Associations. The service of the secretary was also freely rendered for addresses on safety topics before assemblies of workmen and superintendents as well as other bodies.

PUBLIC SAFETY

At the beginning of March a systematic campaign was begun toward the furtherance of Public Safety, under the chairmanship of Mr. A. T. Morey and with the following Sub-Committees: Vigilance; Street Cars; Statistics; Complaints; Playgrounds; Automobile and Legislation; Schools; Bulletins and Publicity; Police.

The Public Safety Committee inaugurated regular monthly meetings in the form of a dinner at which questions pertaining to Public Safety are taken up successfully. These assemblies have assumed the character of a civic institution of St. Louis and are attended by not only the members of the Central Mississippi Valley Division interested in safety, but by the heads of financial, mercantile, transportation, and civic interests of our city. We have had present at these meetings members of the Board of Police Commissioners, heads of our educational institutions, Chief of Police and his staff, the judges of our courts, prosecuting and circuit attorneys, etc. Under the cooperation of this committee the laws and regulations affecting traffic and other phases of public safety have been promoted, and great results have been obtained. The enforcement of a one-hour parking ordinance in our city which reduced the number of automobiles parked in the congested district by over 50 per cent and thereby facilitated traffic very materially, while reducing the chance of accident, is directly traceable to the work of this committee, as is the establishment of the whistle signal system by the traffic police. The cooperation of the civic authorities of St. Louis is whole-hearted and we can safely say that these authorities have been made into safety enthusiasts. Astonishing results are being obtained by means of the Vigilance Committee which is composed of a number of the best business men of St. Louis and the purpose of which is to report violators of traffic rules to the City Bureau of Complaints which diplomatically calls the alleged offenses to the attention of the offenders and is very successful in getting offenders to promise more careful handling of vehicles in the future, while at the same time establishing a record which could be used in proving to automobile drivers repeating previous offenses that it is inadvertent carelessness on their part which makes them transgressors. So far there has been no occasion to use this record in court. One of the judges of our city courts stated that since his tenure of office in April, he has only had one repeater brought before him.

The Daily Press of St. Louis has been tied into the work of the Public

Safety Committee in a very gratifying manner. All the papers giving a great deal of publicity to the work of the Division.

RESULTS

From figures obtained from the Coroner's Office the number of inquests held in the city of St. Louis for the first eight months of 1918 was 1140—For the same period of 1919 this number had decreased to 1010, a decrease of $11\frac{4}{10}$ per cent. For the same period the automobile deaths in 1918 were 61 and in 1919—51, a decrease in number of 10, and, in percentage of $16\frac{4}{10}$ per cent—This in spite of an increase in automobiles from 23,000 to 41,000, or 78 per cent. Industrial fatalities decreased from 110 for the year 1917 to 46 in the year of 1918, a decrease of 58 per cent. and according to the statement of the Coroner's Office present figures indicate a further decrease in the neighborhood of 20 per cent.

SCHOOL SAFETY

With the assistance of the Home Office, Dr. E. George Payne, Principal of the Harris Teachers College compiled a syllabus on safety to be taught in the curriculum of all the schools in St. Louis.

On June 15, Mr. Carl L. Smith assumed his new duties as Public Safety Field Secretary of the National Safety Council and Mr. M. L. Fellmer was appointed Secretary of the Central Mississippi Valley Division to succeed him.

PROJECTED ACTIVITIES FOR 1919-20

School for Safety Supervisors consisting of the following sixteen lectures, one General Review and Experience Meeting, and four Round-Table discussions:

November 28—Safety and the Manager, the Importance of His Support and How to Get It

December 5—Safeguards

December 12—Shop Lighting

December 19—Reaching the Foreman—What He Can Do to Promote Safety

January 2—Bulletin Board

January 9—Workmen's Inspection Committees

January 16—Head and Eye Protection

January 23—Plant Sanitation

January 30—Layout of Buildings and Machinery

February 6—Fire Protection in Relation to Safety

February 13—Electrical Hazards

February 20—First Aid

February 27—The Movement for Better Industrial Relations, Its Development and Significance

March 5—The New Employee—Instruction in Safety, Physical Examination, Continuity of Employment

March 12—The Foreign-born American

March 19—Qualifications of a Safety Engineer—His Duties and Opportunities

SCHOOL FOR SUPERINTENDENTS AND FOREMEN

In accordance with the plan of the National Safety Council there will be a School for Superintendents and Foremen consisting of ten lectures, as follows:

1. Handling Men (a general lecture on foremanship)
2. The Foreman's Place in Accident Prevention (including introductory statement of the safety movement as a whole)
3. Design and Construction of Safeguards
4. Plant Sanitation—Arrangement, Order, Lighting, Sanitation
5. Educating the Workmen (including bulletin boards and instruction of new employees)
6. Workmen's Inspection Committees
7. Eye Protection and Safe Clothing
8. Electrical Hazards
9. First Aid
10. General Review and Experience Meeting

MANAGERS' MEETINGS

We are projecting four or five meetings of the same high character as held during last year. The details of the subjects and speakers have not as yet been decided.

SCHOOL FOR CHAUFFEURS

Under the auspices of the Public Safety Committee, a School for Chauffeurs will be established, at which the following six lectures will be given by competent speakers:

1. Rules of the road—parking regulations and traffic rules
2. Mechanical hazards and efficient driving
3. Hazards of the streets
4. Accidents, statistics and reports
5. Safe operation of automobiles and trucks
6. Qualifications of a safe and competent chauffeur

The project is to give to members of the Chauffeur's Class a diploma similar to the one given to graduates of the Safety Supervisors Class of 1919.

STATISTICAL BUREAU

Plans are being perfected whereby all public accidents will be reported to the office of the Secretary and there statistically tabulated as to causes and circumstances. Industrial accidents, at least as far as they produce fatalities, will be treated in like manner.

BULLETIN BOARDS

The Public Safety Committee will endeavor to establish bulletin boards in all public garages and gasoline filling stations in the city and providing suitable bulletins through the National Safety Council.

Eighth Safety Congress

BUDGET

The activities planned call for a total budget of approximately \$14,000 for the year 1919-1920 to be equally divided between the Industrial and Public Safety sections.

CHICAGO SAFETY COUNCIL

HARVEY G. ELLERD, PRESIDENT
Armour & Company, Union Stock Yards
CHARLES H. DAVIS, SECRETARY
Commonwealth Edison Company

The program of meetings was delayed several weeks because of the "Flu" epidemic. All of the meetings except the first were joint safety dinner meetings with the Illinois Manufacturers' Association. The chairman for each meeting was appointed by the joint body. The Executive Committee held regular meetings, each member taking an active part.

The general meetings held during the year follow:

November 27, 1918. Meeting called to order by President Fred M. Rosseland. Report of Nominative Committee received and the following officers unanimously elected to serve until June, 1920:

President: H. G. Ellerd, Armour & Company; Vice President: H. L. Krum, International Harvester Co.; Secretary: C. H. Davis, Commonwealth Edison Co.; Treasurer: T. E. Barker, Miehle P. P. & Mfg. Co.; Executive Committee: the Officers and W. E. Worth, Chicago Tunnel Company; H. M. Webber, Chicago Telephone Company; F. M. Rosseland, National Safety Council. The meeting was then turned over to the chairman of the meeting, H. L. Krum, who introduced the speaker of the evening, F. A. Carlisle, Manager, Friedlander Brady Knitting Mills. Mr. Carlisle gave a very interesting talk on the important subject "Women in Industry." A detailed discussion followed the address, during which Mr. Carlisle answered many questions.

January 29, 1919. "Reconstruction Plans Based on War Time Experience," Chairman William Beye. "From the Standpoint of the Employee," by John Walker, President, Illinois Federation of Labor. "From the Standpoint of the Employer," by H. F. Perkins, Division Manager, International Harvester Company.

February 26, 1919. "State Fund Insurance," Chairman, President H. G. Ellerd. "Objections and Defects of State Insurance," by R. T. Caldwell, of Dysard and Caldwell, Attorneys, Ashland, Ky. "Destructive Tendencies in America Today," by M. T. McKee, Secretary, National Council of Insurance Federations, Detroit, Michigan. The discussion of this subject was exceedingly interesting. Mr. Caldwell's address was printed in pamphlet form and Mr. McKee's speech was printed in "Manufacturers' News."

March 26, 1919. "Working Condition Service, U. S. Department of Labor," Chairman, A. H. Young. "The Scope, Function, and Purpose of this New Governmental Agency," by Grant Hamilton, Director General. "Division of Labor Administration," by W. M. Leiserson, Ph. D., Chief of Divisions. Mr. Leiserson made a big hit with his straight-forward statement of the fundamental truths of Industrial Relations.

April 15, 1919. "Industrial Surgery," Chairman, Doctor L. P. Kuhn. "Fifteen Functions of Industrial Surgery," by Dr. Loyal Shoudy, Chief Surgeon, Bethlehem Steel Company. "The Present Deficiency of Surgical Treatments and After Treatments of Accidents," by Dr. P. B. Magnusson, Medical Director, Industrial Commission of Illinois.

May 7, 1919. "A Get Together Dinner Meeting," Chairman W. E. Worth. "Entertainment During the Dinner," by Daw and Russell, Entertainers, and Quartette of the Commonwealth Edison Choral Society. "What Is Our Job?" by R. C. Richards, Chairman Central Safety Committee, Chicago & Northwestern Railroad. Motion Pictures: "The Outlaw" (Courtesy, Liberty Mutual Insurance Company); "Fit to Fight" (Courtesy, U. S. Public Health Service); "Careless America," (Courtesy, Universal Film Mfg. Company); "Experience Meetings," 4:30 P. M. "Advertising Safety to Your Men," Chairman, H. L. Krum. "Proper Treatment of Advertising Matter," P. A. Power, Advertising Manager, Benjamin Electric Company. Mr. Power pointed out the advantages of placing stress on treating subjects from the positive, rather than the negative viewpoint, because of the psychological effect obtained. General discussion followed.

The attendance at each meeting averaging about 300 (attendance at one meeting was 700), clearly indicated that the subjects considered were timely and important. During the Spring efforts were started to bring about a better financial condition which would enable the Council to employ a paid safety engineer secretary. Progress was necessarily slow, but it is believed that financial arrangements will be completed this fall.

Tentative plans were made by the Executive Committee to hold a series of district safety meetings but labor conditions seemed to render such meetings impracticable and they were postponed until a later date.

Much of the success of the work during the year was due to the personal work of Executive Committeeman, W. E. Worth (who is also Chairman of the Industrial Relations Committee of the Illinois Manufacturers' Association), and of the Chairman of our Program Committee, A. H. Young.

The Safety Banner, inaugurated by the Chicago Safety Council in 1917, was continued throughout the year. It is acknowledged to be a valuable means of informing members of safety dinner meetings, items of local interest, and as a desirable medium of communication between the Executive Committee and the Membership.

DETROIT SAFETY COUNCIL

J. H. GOLDIE, PRESIDENT

Cadillac Motor Car Company

H. T. BARNES, SECRETARY-TREASURER

Lincoln Motor Car Company

The Detroit Local Council held but one meeting during the Fall of 1918, due largely to the influenza epidemic. The subject discussed was

We are the dead. Short days ago
We lived, felt dawn, saw sunset glow,
Loved and were loved, and now we lie
In Flanders' fields.

Take up our quarrel with the foe.
To you from failing hands we throw
The torch; be yours to hold it high.
If ye break faith with us who die
We shall not sleep, though poppies grow
In Flanders' fields.

There is an old hymn, that wonderful hymn of ours—The Battle Hymn of the Republic. The last line of that hymn "As He died to make men holy, let us die to make men free," I want to paraphrase for the benefit of this little talk that I am trying to make to you: Let us remember that as our men fought and died across the seas to insure the liberty and freedom the founders of our government established, let us live to make their children and their children's children safe. (Prolonged Applause.)

THE TOASTMASTER: Mr. Richards, in thus closing the formal part of the program for this evening, I am sure that all of these ladies and gentlemen desire me to tell you that we not only know, as you have said, that we have a principle that is right, but that we have leadership which is right, and we will follow you every step of the way. (Prolonged Applause.)

"Coöperative Accident Prevention." A most interesting talk was made by Mr. John A. Oartel of the Carnegie Steel Company.

At the annual meeting, January 15, 1919, the following officers were elected: President, J. H. Goldie, Cadillac Motor Car Company; Vice-President, J. M. Eaton, Lincoln Motor Company; Vice-President, C. G. Axtmann, Detroit Insurance Agency; Secretary-Treasurer, H. T. Barnes, Lincoln Motor Company; Program Committee, R. A. Shaw, Ford Motor Company; Membership Committee, E. F. Lingemann, Hudson Motor Car Company.

The February meeting was the best attended dinner meeting ever held by the Council, 228 persons being present. The subject was "Dangerous Practices" and Mr. R. M. Little of the American Museum of Safety was the principal speaker.

The subject of the March meeting was "The Value of Uniform Accident Records," and the Employment Managers' Club was invited to attend. It was suggested that a joint committee be appointed to investigate the value of including an employee's accident record with his employment record. After due consideration the committee felt that such a plan was not advisable at this time.

No meeting was held in April, but on May 16, a meeting was called to discuss plans for assisting in the Public Safety Campaign which the Detroit Police Department and the Detroit Automobile Club were to hold during the month beginning May 20. Much credit is due Mr. George Walters, Secretary of the Police Department, Mr. Charles T. Bush of the Detroit Automobile Club, and Mr. F. E. Morris, Field Secretary of the National Safety Council for their untiring efforts in behalf of the campaign. There is no question as to the success of the campaign but it is felt that an even greater result would have been obtained had the campaign been held to one or two weeks rather than a month.

Plans for securing a permanent secretary for the Detroit Safety Council were discussed during the campaign and it is hoped that definite action may be taken this Fall.

EAST CHICAGO SAFETY COUNCIL

J. C. SMITH, PRESIDENT
Inland Steel Company, Indiana Harbor, Ind.

E. O. M. REDDIN, SECRETARY
Hubbard Steel Foundry Company, East Chicago, Ind.

November 7, 1918. Safety Engineers' meeting. Mr. W. F. Grebe spoke on "Accident Prevention." Attendance, 10.

December 12, 1918. Workmen's meeting. Mr. S. J. Williams spoke on "Accident Prevention." Moving pictures were shown. Attendance, 95.

February 6, 1919. Workmen's meeting. Mr. Arthur H. Young spoke on "Workmen and the Safety Movement." Moving pictures were shown. Mr. James Johnston, Scotch comedian, in monologue, songs, and dances, and music by the East Chicago High School Orchestra.

EAST ST. LOUIS SAFETY COUNCIL

D. E. PARSONS, PRESIDENT

D. C. SMITH, SECRETARY

Safety Engineer, Aluminum Ore Co.

Things accomplished by the Council during the past year, for the city of East St. Louis, are as follows: Fifteen plant men have been attending the Safety Council in St. Louis during the past winter; coöperation has been effected with the executive committee of St. Louis, financially and otherwise; we have placed in the public schools of this city books on Safety, and have secured the coöperation of all principals in the teaching of Safety to the children, much along the lines followed by Dr. Payne in St. Louis; attractive bulletin boards have been maintained in all schools and public garages, filling stations, etc.; a selection of bulletins has been sent to the various places; considerable work has been done along fire prevention lines through posters and through work in the various plants; monthly meetings have been held, where various plant problems have been discussed, and, at our last meeting on Friday, September 26, a special committee was appointed to meet with some of the city executives for the purpose of interesting the public in this work.

We were late in getting started this year, on account of the activities in St. Louis, and most of our finances and individual work went to that side of the river. Much that takes place in St. Louis along the Safety line is naturally carried to the East side of the river.

ERIE SAFETY COUNCIL

O. G. HITCHCOCK, PRESIDENT

Hayes Mfg. Co., Erie, Pa.

M. C. GOODSPEED, SECRETARY-TREASURER

General Electric Co., Erie, Pa.

The work of the Erie Local Council for the past year has been in the main a following up of the work done in previous years. Practically no new work of any kind was attempted. Meetings were held each month during the winter season which were fairly well attended. Two of these meetings took the form of inspection trips in local plants with a very much increased attendance. The discussion and program, however, at these meetings had to be very limited.

One public meeting was arranged, the speaker of the evening being Mr. R. M. Little, of New York.

The Executive Committee is trying to hold a rally directly following the annual meeting of the National Safety Council, at which time reports of the Cleveland meeting will be given and an attempt made to line up the membership for better work during the coming year.

Eighth Safety Congress

LEHIGH VALLEY SAFETY COUNCIL

MORRIS FORTUIN, PRESIDENT
 Pennsylvania Cement Co.

J. R. MULLIGAN, SECRETARY-TREASURER
 Bethlehem Steel Co.

The fiscal year ending June 30, 1919, was the most successful experienced by Lehigh Valley Local Council since its inception five years ago. Despite the fact that monthly meetings were discontinued during the fore part of the fiscal year due to war productional activities on the part of the membership, the resumption of the monthly meetings beginning with the Annual Public Meeting in December and continuing through the six month period ending in May, showed the membership enthusiastic and intensely interested in the work.

Lehigh Valley Local Council has banded together in its membership over sixty industries in the Lehigh Valley, represented by 103 individual memberships. The attendance at our monthly meetings during the latter half of the fiscal year was never below 90 per cent of our membership, which showed a lively interest in the subjects discussed.

December, 1918—Bethlehem, Pa.. "Rehabilitation of Injured Men."

January, 1919—Easton, Pa.. "Accident Prevention."

February, 1919—Allentown, Pa.. "Importance of Uniform Accident Statistics."

March, 1919—Bethlehem, Pa.. "Importance of Safety Committees in Accident Prevention Work."

April, 1919—Nazareth, Pa.. "Provisions of the Revised Compensation Law."

May, 1919—Easton, Pa., "Industrial Morale."

NORTHEASTERN OHIO SAFETY COUNCIL

S. W. TENER, PRESIDENT
 American Steel and Wire Company, Cleveland, Ohio

A. H. LINTZ, SECRETARY
 Cleveland Chamber of Commerce

The activities of the Northeastern Ohio Division have been somewhat limited since the report rendered last year until the appointment of the permanent secretary the latter part of April, this year. The inactivity of the members last year, naturally, was due to so many important officers being called to the assistance of our Government during the great War. During 1918 new officers were elected to further the work in view of securing the services of a permanent secretary.

The permanent secretary took up his duties on April 23, 1919, at which time he immediately assisted in formulating a complete new executive committee. The committees elected on May 16 to handle new local

matters were as follows: Annual Congress, Oscar McNab; Boy Scouts, John K. Doan; Churches, Rev. E. R. Wright; Clubs and Organizations, Fred H. Caley; Districts, C. E. Pettibone; Education and Schools, G. A. Green; Entertainment, L. B. Bacon; Finance, A. C. Brown; Fire Hazards, M. R. Marshall; Industrial Relations, E. L. Brady; Inspection, Safety Codes and Safeguards, H. L. Weeks; Membership, B. W. Nutt; Plant Organizations, O. J. Lewis; Program, Thomas Stanion; Public Utilities, W. F. Weh; Public Safety, F. E. Waite; Publicity, R. M. Wheeler; Safety Week, T. B. Howe; Sanitation and Health, Dr. H. L. Davis; Speakers' Bureau, W. R. Carson; Workmen's Compensation, A. L. McKee.

Active work on the Annual Congress and Safety Week was started about July, 1919. From this time on, the time of the secretary and the executive committee was occupied in making ready the latter preparations.

A School for Safety Supervisors, comprising fifteen lessons, was conducted, starting on March 31, with one lesson a week. There were 137 students who completed this course and were graduated on July 7. The entire program for the graduation exercises was unique in that the arrangements for the evening were all taken care of by a committee which was elected by the class. The main address of the evening was delivered by Mr. C. W. Price on "The New Ethics of Business." The enthusiasm displayed at the graduation exercises, which were held in the form of a banquet, can well be appreciated when you learn that there were 125 present, notwithstanding that there was a street car strike on in Cleveland at the time.

The class has since been called together by the class officers to be told of the plans for the Annual Congress and Safety Week, and the same enthusiasm was prevalent at this meeting, and many volunteered to serve on the Local Reception Committee during the Congress.

The secretary, in conjunction with Mr. Thomas Stanion, Chairman of the Program Committee, and the district committees, conducted three very successful foremen's rallies, with an excellent program, uniquely arranged, and had very good crowds at each.

The Local Council held two monthly meetings for plant executives during May and June. The first of these meetings was addressed by Mr. R. M. Little, Director of Safety Institute of America, New York City, on "Forethought vs. Afterthought in Safety." The other was addressed by Mr. C. B. Auel, Director of Processes and Standards, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., on "Safety and Industrial Relations." A very large attendance was present at both of these meetings and proved to us that our prospects for meetings of this nature in the future are good, and it is evident we will have good crowds. We hope to proceed with these meetings on the average of one every two or three months during the winter.

The secretary has also given moving picture Safety shows and talks to foremen and safety committeemen at about fifteen plants.

It being necessary to start work in connection with the Annual Congress and Safety Week about the last of July, all other local activities were set aside with the exception of this work.

The Public Safety organization for the City of Cleveland has been completed, and the Mayor of the City has personally named and written to various influential men to serve on the respective Safety Committees.

OMAHA SAFETY COUNCIL

H. A. JOHNSON, PRESIDENT
Omaha Gas Company

E. E. JUDD, SECRETARY-TREASURER
American Smelting and Refining Company

The Council has had one Foremen's Banquet, has held four meetings at various places throughout the city, and has taken in 13 new members.

PHILADELPHIA SAFETY COUNCIL

H. B. HARMER, PRESIDENT
JOHN P. MUDD, SECRETARY-TREASURER

The Local Section opened its program for the year of 1918-19 with a very successful meeting at its headquarters, the Engineers' Club, in Philadelphia.

Dr. Francis D. Patterson, Chief, Division of Hygiene, Department of Labor and Industry, who is well known in both National and Local Council circles, addressed the November meeting on the subject of "Reconstruction and Rehabilitation." A great deal of the text of Dr. Patterson's paper has since been published in magazines, newspapers, and publications of the state of Pennsylvania.

The second meeting was held in December. The subject for discussion was "The Woman in Industry." Introduction was made by Mr. J. J. Coffey, Supervising Inspector, Department of Labor and Industry. A very interesting discussion followed, in which representatives from very nearly all the large manufacturing concerns of Philadelphia participated. In general, the discussion was topical in form and considered the following phases of the subject:

1. Laws governing her employment
2. Moral protection
3. Physical comfort
4. Safety

Prior to each meeting of the Safety Council, an informal dinner is held in the dining room of the Engineers' Club. Through the courtesy of various members of the Local Council, music is furnished. The societies affiliated with the Engineers' Club have purchased a piano, which is used on these occasions. Needless to say, a splendid spirit of good fellowship prevails at these informal dinners and many subjects other than safety enter into the discussion. Sometimes near the close of the dinner, the strictly routine business of the Council is gone over and finished so as to give the entire evening to the paper and discussion.

Mr. J. F. Conner, of the United Gas Improvement Company, gave an excellent lecture, entitled "Dangerous Practice," at the February meeting. His talk was profusely illustrated with lantern slides. At this same meeting, Capt. Matthew J. Shields, Field Representative of the American Red Cross, talked on "First Aid and Sanitation."

At the March meeting, Mr. Harry A. Mackey, Chairman of the Interstate Compensation Board for Pennsylvania, presented a paper, entitled, "Three Years' Administration of the Pennsylvania Workmen's Compensation Act." As the manufacturers at large were interested in a revision of the current act, Mr. Mackey's talk proved to be of the most vital interest.

Mr. Arthur Sellers, Chief Deputy of the Coroner's office in Philadelphia, at one of the meetings gave an informal talk on "Industrial Accidents in Philadelphia".

A special feature of the meeting in the Spring was the demonstration of the various safety devices. Such articles as goggles, protective face masks, leggings, and machinery guards have been shown at the meetings.

Mr. L. A. DeBlois, Safety Engineer, E. I. du Pont de Nemours & Company, Wilmington, Del., spoke at one of the meetings on general safety matters. The very large attendance which marked this and several previous meetings showed the increasing appreciation of the Local Section by the manufacturers of Philadelphia.

"Accident Reporting and Recording" was the title of a paper given by F. S. Crum, Assistant Statistician of the Prudential Insurance Company of America. This meeting concluded the activities for 1918-19.

SEATTLE SAFETY COUNCIL

B. W. SAWYER, PRESIDENT, AND CHAIRMAN PUBLICITY COMMITTEE
Brace and Hergert Mill Company

T. H. BOYD, SECRETARY, AND CHAIRMAN MEMBERSHIP COMMITTEE
Safety Engineer, 948 Henry Building.

Since our last annual report, the Seattle Safety Council has continued to conduct a vigorous Safety Campaign in the establishment of its members. Active safety committee work and lectures to the employees have been constantly maintained in each plant, periodical safety meetings and banquets have been provided, with a large attendance from each firm, with the result that our activities in the direction of accident prevention have been kept alive and constantly before both employer and employee.

We now have enrolled, a membership representing approximately 5,000 employees in the lumber, shingle, sash, door, box, and metal trades industries in Seattle and immediate vicinity with a bright prospect of a very material increase at an early date.

The Seattle Safety Council was created by a group of local employers in January, 1918, following which, application for charter was made to and favorably acted upon by the National Safety Council.

The Executive Committee selected Mr. T. H. Boyd, Chief Claim Adjuster and Investigator of the State Industrial Insurance Commission of Wash-

ington, as its Safety Engineer, to organize and operate the same. Immediately an intensive Accident Prevention Campaign was inaugurated and since the above mentioned date, we have devised and installed 1,564 safeguards of various designs, all of which was in addition to the requirements of the State Factory Inspection, to which each of our plants was subject. As a result, accidents in our member establishments were actually reduced 50 per cent plus during the first year's operation, while our statistics for the current year indicate a most gratifying condition and a still further reduction. This statement is endorsed by the State Industrial Insurance Commission of Washington.

The safety engineers of the various chartered Safety Councils in this State, realizing the necessity for a movement sufficiently broad in scope and with proper police power to cover all industries in the State included in the forty-eight different classifications of industry and coming within the purview of the Workmen's Compensation Act, and having in mind the particular need of a carefully drawn and equitable merit and demerit rating system, more than a year prior to the convening of the last session of the legislature, drew up the fundamental principles and framework and had drafted into legal form for presentation to the Legislature, a bill which resulted in the present state safety law, creating the State Safety Board. This is considered one of the most finished and up-to-date pieces of industrial legislation ever placed upon the statute books of any state and wonderful results are predicted from its application and enforcement.

Subjoined are the present officers of this Council:

President. B. W. Sawyer. Brace & Hergert Mill Co.; Vice-President, H. C. Hilke, Seattle Cedar Lbr. Mfg. Co.; Treasurer, E. T. Verd, Bryant Lumber Co.; Secretary, T. H. Boyd, Seattle Safety Council; Executive Committee: Alvin Schwager, Schwager & Nettleton Lbr. Co.; Wm. A. Whitman, West Waterway Lumber Co.; F. F. Hopkins, Seattle Boiler Works; Chairman Program and Education Committee, A. D. Cross, O. B. Williams Co.; Chairman Public Safety Committee, W. A. Steigleder, Bolcom-Canal Lbr. Co.; Safety Engineer, T. H. Boyd, Seattle Safety Council.

WATERBURY SAFETY COUNCIL

R. S. SPERRY, PRESIDENT
Scovill Manufacturing Company

B. J. HINE, SECRETARY-TREASURER
Scovill Manufacturing Company

The activities of the Waterbury Safety Council may be briefly summarized for the year ending July 31, 1919, as follows:

A business meeting for members was held December 20, 1918, at which the following officers were elected:

President, Roger S. Sperry; Vice-President Ex-officio, W. H. Sandland, Mayor; Vice-President, Whitman W. Bowers; Secretary-Treasurer, Burton J. Hine.

A complete executive committee as well as chairmen of the various committees were also elected:

Plans for the work to be carried out were discussed and arrangements for financing the Local Council made by voting to add 10 per cent assessment to the membership dues of all members.

A meeting for superintendents and foremen was held January 30, 1919, with an attendance of about one thousand. A program consisting of speaking, moving pictures, and singing proved very successful.

A general public safety meeting was held February 27, 1919, at which about one hundred and fifty were present. An excellent program of speaking, lantern slides, and singing was carried out.

A meeting for all employees, including foremen, was held April 24, 1919, about 250 attending. Two subjects, "The Neglect of Slight Accidents in Factories" and "Goggles and Their Uses in Safeguarding the Workman" were covered by the speakers, illustrated with photographs. Music was furnished, and moving pictures shown.

An open air meeting for the general public was held May 23, 1919, in the evening, about eighteen hundred attending. Two good speakers covered the subject of "General Public Safety" after which moving pictures were shown. Music was furnished by the Chase Companies Band.

Exhibits included a lineman receiving a shock, simulated by flashlight powder, at the top of a pole, and being lowered down, afterwards receiving first-aid treatment. Also, of a man being struck by a trolley car, who was also carried to the platform for first-aid treatment.

Interest in the Local Council has been stimulated during the year through the efforts of the Chairman of our Publicity Committee in connection with the various meetings, and with the increasing of our publicity work we are expecting to increase our membership. During the year, an important membership, that of the City of Waterbury, has been secured.

Great credit is due to those who have served on the committees during the year in making the meetings so successful. Our council having been in existence but a short time, the work of the committees demands considerable time and effort which have been cheerfully given.

WORCESTER COUNTY SAFETY COUNCIL

J. F. TINSLEY, PRESIDENT

Vice-Pres. & Gen'l Mgr. Crompton and Knowles Loom Works.
Worcester, Mass.

H. L. ROBINSON, SECRETARY-TREASURER

Manager Employment Service Department.
Crompton & Knowles Loom Works, Worcester, Mass.

Our regular Fall meetings were resumed in October, 1918, at which meeting we had Mr. John Higgins, at that time President of the New England Safety Council, in which he spoke of the necessity for each local

Council working out its own plans under the supervision of the National Safety Council the same way the local draft boards handle their work under the Provost Marshal Organization.

Since then, regular monthly luncheon meetings have been held on the first Monday of each month, at one of the local hotels, and these meetings have averaged between twenty-five and thirty members at each meeting.

One of our general meetings was held at Fitchburg, following which a trip was taken through the plant of the Simonds Manufacturing Company, where many interesting things were observed in the manufacture of saws.

The last meeting of the season was held on a lake at Webster, where we had a shore dinner and general good time. Previous to the meeting, a trip was taken to the plant of the S. Slater & Sons, Inc.

It was planned to have such trips during each year, in order that the members may become better acquainted and to lighten up the serious sides of accident prevention.

In order that every one could get the most good out of the local Council, we organized a round-table group to make a study of definite types of hazards. Each group has a chairman and hold meetings once a month, reporting the results of these meetings at the general meetings. The groups are divided as follows:

1. Eye and Safe Clothing Section
2. Machine Tool Section
3. Wood-working Section
4. Power Transmission and Electrical Hazards
5. Foundry Section.
6. Construction Section

By having these various sections, we get away from generalities and each member can attend the groups in which he is interested.

We have also formed the Consulting Engineers' Committee, who may be called on by any interested concern in Worcester County for advice of any kind on safety, and who are prepared to make an inspection for any concern and recommend guards wherever necessary.

Several of our members have had evening safety meetings for their own employees, with very satisfactory results, the attendance of some of them having been as large as five hundred.

The Local Council itself, held a Foremen's Safety meeting during the Winter, at which Mr. R. M. Little gave a very interesting address.

Our plans for the coming season are to collect accident data from each of the concerns every month and to compile this data, returning to them a comparison of their own lost time accidents with the average for the whole county. We consider that this will enable us to have some definite figures to show prospective members, and will also cause a little competition among our members to decrease their accidents below the average.

On the whole, the activities of the Worcester County Local are well on the way toward making an alive Council and a benefit to all the members and to the community.

Safety Bulletin Luncheon

ROUND-TABLE DISCUSSION

Friday, October 3, 1919

FRED M. ROSSELAND, Chairman
Safety Engineer, National Safety Council, Chicago

THIS luncheon round-table meeting was arranged for the purpose of discussing some of the essential features of a good safety bulletin, and suggesting improvements in the bulletin service of the National Safety Council. About 100 delegates attended. The discussion was spirited and interesting, and was limited in its extent only by the necessity of adjourning to avoid conflict with the general session in the afternoon.

SIZE OF BULLETINS

The Chairman described the Council's present practice of issuing, in the general series, one large bulletin (17 by 22 inches) every alternate week, and on the other weeks three small bulletins (8½ by 11 inches), with an occasional double-size bulletin (11 by 17 inches) where necessary. The sectional bulletins are practically all of the small size.

In the discussion which followed, it was generally agreed that bulletins of different sizes are desirable because they help to prevent the bulletin board from looking always the same. When a vote was taken, it appeared that two of the men present were limited to small bulletin boards which would take only the small-size bulletin. One other expressed his dissatisfaction with receiving a large bulletin every two weeks. All the others present indicated their approval of the present policy.

TEXT VS. ILLUSTRATIONS

This, the Chairman stated, is a never-ending question. The Council endeavors to use illustrations as much as possible, but a certain amount of text seems to be necessary, and in some cases quite a little text is needed to make the bulletin intelligible. It is very seldom that the Council issues a bulletin consisting entirely of text, and in such cases the number of words is as few as possible.

In the discussion of this matter, several speakers remarked that, in spite of what the Chairman had said, they thought many of the Coun-

cil's bulletins still contained too much text. Such a bulletin does not command attention unless it is signed by the company. It is all right for a company to issue typewritten or printed bulletins consisting largely or entirely of text, over its own name; but National Safety Council bulletins, which cannot be signed by the company, must consist almost entirely of illustrations in order to hold the attention of the workmen. A series of pictures is better than an explanation in words.

The Health bulletins in particular should be illustrated wherever possible, rather than consisting entirely of text, as they now do in most cases.

The meeting voted almost unanimously that the amount of text on National Safety Council bulletins should be still further decreased below the present practice.

GREWSOME BULLETINS

The Chairman stated that every little while the Council receives a criticism from some member on the grewsome bulletins which are issued occasionally. To such a criticism the Council always replies that while such bulletins are admitted to be unsuitable for posting in a department where there is no great hazard and where only women are employed, and perhaps likewise in some other departments, most of our membership find an occasional bulletin of this sort very helpful and we therefore continue to issue them.

One member present stated that he had made a special effort to ascertain the opinion of the workmen themselves, on this matter. In 126 shops which he visited he received an unfavorable comment in only thirteen cases.

Other speakers agreed that bulletins of this type, if properly prepared and issued not too often, are a powerful means of attracting the attention of workmen who are not moved by any other sort of appeal. The meeting expressed its agreement with this view of the matter.

HUMOROUS OR CARTOON BULLETINS

The Council has received some criticism, the Chairman said, because of the occasional humorous or cartoon bulletins that have been issued recently. It is said that Safety is a serious subject which should be treated in a serious manner.

In this discussion it appeared that some of those present agreed with the criticism just mentioned. Others, however, emphasized the fact that the average man will look at a cartoon where he will not look at anything else: bulletins of this type attract attention and add variety to the bulletin board. When a vote was taken, a large majority of those present favored a continuation of the Council's present practice of issuing occasionally—not too often—a bulletin of this type, provided always that the bulletin is so designed that it will not appear to ridicule or make light of the Safety idea.

A, B, C Session

October 2, 1919

PHILIP STREMMEL, Chairman

Superintendent, Hot Mills, National Enameling and Stamping Company,
Granite City, Ill.

CHAIRMAN STREMMEL: I attribute largely our success of the school for Safety Supervisors in St. Louis last year (which you all know was the largest class in the United States) to the fact that we started promptly at the stated time and finished, irrespective of how interesting the meeting was, at the closing time. We never permitted ourselves to go a minute over the time. What was the result? The men knew what to expect. The men knew that we would start on time and they were there, and they knew they would get out on time, and therefore we never permitted our meetings to drag, and they were full of life.

As you know, this is an A, B, C session, and it is primarily for safety engineers and safety supervisors. To my mind the safety engineer and the safety inspector are the two vital men for safety in the plant. And so I am glad to see this splendid representation of men here this morning who have come to listen to men who have had experience along these various lines. It now gives me pleasure to introduce to you Mr. C. B. Hayward.

MR. HAYWARD: In taking up this subject I want to have you note particularly that it is the essentials of the safety organization and not the details that this talk is going to cover.

THE ESSENTIALS OF A SAFETY ORGANIZATION

C. B. HAYWARD, DISTRICT SAFETY MANAGER, LIBERTY MUTUAL INSURANCE
COMPANY, PHILADELPHIA, PA.

When it comes to laying out and putting into action for practical operation, an organization the purpose of which is the reduction of accidents through the elimination of existing hazards, and the bettering of working conditions, in a plant, the problem involves executive, adminis-

trative, and practical ability, not different from that shown in other productive channels. The development of this work and the efforts called forth in this specific phase of Industrial Relations, provide an interest and an outlet for the energies of every man following this branch of engineering science. It is taken for granted that he has had the proper training for understanding the possibilities of this industrial necessity.

INITIATIVE, TRAINING, AND GOOD JUDGMENT REQUIRED

The same quality of initiative, training, and good sense or judgment are required in the handling of a Safety Organization as in any of the various other departments of a plant. The directing of safety activities, making it a result-getter, is no soft job. The fruits of your labor are absolutely what you make them, and hard work only will bring you success. Safety Engineering is most important to the industry that employs you, and calls for the best in man if the best results are to be obtained.

Hence, in presenting this subject before you, let me have your attention to this one fact: Safety work is a man-sized job and the essentials mean much or little according to whether or not you intend to carry the activity to a successful finish. Know your work—keep your fingers on the details—keep in touch with what others are doing in other plants—watch the opportunities and make use of them to keep the work interesting and impressive.

THREE ELEMENTS

There are three elements in the essentials of a safety organization which are distinctive in that they are simple and basic in their scope. They form the very foundation of our plan and are not only necessary in the commencement but are still more important in the continuation of its existence. They are elements of support, analysis, and action.

THE ELEMENT OF SUPPORT

The successful operation of safety work in any sized plant hinges upon its director or keeper. I repeat for your benefit this last statement: The proper functioning of safety engineering activities centers around the man who is its responsible head. You who are here today are, to all intents and purposes, the men whom fate has ordained to carry out this work, making it an asset in your respective plants, and the element of support, the faith and backing you require, may mean more than you realize. Let us, therefore, analyze what the safety engineer needs in the way of support before we go into the details of carrying on the organization.

Official Recognition. First, there should be no doubt about which side of the fence the general manager or head of the plant is playing. He should feel the responsibility of its success and be an absolute believer in and follower of safe practices. Furthermore it must be known throughout the factory that the highest official supports the new movement in all sincerity.

Foremen. Second, the foremen or men in charge of men should be let known by their words and actions that safety is considered by them as

part of their duty to the employees as well as to the employer. The support in this game against chance is of vital importance to the outcome of the issue.

Employers. Third, the support of the employees must be obtained and maintained through practical and common-sense methods. They will not lean to scientific, theoretical, dreaming practices put to them in a complex manner. Sound judgment with simplicity will reach and keep them.

The first item of these three is most essential to safety organization and must be secured by the one who is to do the organizing before the work is started. The other two can and should be obtained soon afterward. I once heard one of the foremost safety men in the country state that once a plant had the first two of these elements of support within its walls, it had its safety organization. Experience has proven that there is a completed truth in this statement and it will be vouchsafed for by any safety engineer who has been through the mill and won his spurs.

THE ELEMENT OF ANALYSIS

Taking up the next step in the development of this general plan the element of analysis should be in sequence of importance. The details of the work resulting from an analysis of the efforts to be applied in various lines, make it simple to understand where the energies of the organization are expended. In other words, this answers the question. Of what shall our work consist? It might be said in a general visualizing statement it covers three fundamental and vitally important phases of activity: Supervision, plant inspection, and safety education. These three subdivisions are in reality the product of our safety department and are applicable to any size of plant whether there be 50 employees or 5,000 employees within its jurisdiction.

Supervision. The first item mentioned, that of supervision, may be carried on by a general committee comprised of only a few persons in positions of authority and meeting once a month, or may be superintended by a safety engineer and a corps of assistants who work under the guidance of a general committee. The personnel of this supervisory board and the time given to the work at hand should be determined by the size of the industry, the hazard of the operations and the number of employees. Comparison with industries of similar size and commodity for the market, which have had some experience with safe practices, is also a deciding factor in making this activity of economic value to your company.

Plant Inspection. Considering the second subdivision, inspection of the plant, and referring to supervision methods just mentioned, it is not difficult to see that the same range of operation is also possible under inspection. From weekly or periodical inspection in the smallest industry, the work may be broadened to daily and constant scrutinizing of working conditions by a full time safety engineering department in the larger plants. It is necessary in either case to make a study of accidents that have happened, learn their causes and locations, assist in

construction of guards, etc. These are the details that proportionately require a greater amount of time as the size of the plant increases.

Safety Education. In taking up item number three of the analysis, the safety education of employees, it should be understood that in the actual work done by the safety organization this item is the most important of the activities. Because most accidents are due to carelessness, the great problem rests with the instruction of employees in safe practices. The details of this work should be regulated to the size of the industry as in supervision and inspection. I might take the time to go over all these details but it is not necessary. The main thing to remember is that this safety education is an important essential in the organization.

THE ELEMENT OF ACTION

The element of action is the third and final essential of my outline on the requirements of a successful safety organization. It might be called sincerity of operation. It might be described as carrying out the details to a finish. If you intend to put a safety organization into action, make it a real part of the plant's existence. This element has that bearing upon the whole plan of making it a live activity or a dead issue. The vim, pep, or whatever you wish to call energy, that is shown by the general manager, the safety committee, and the safety engineer must be of such stable quality that interest never lags and the work never gets stale. The incentive to make your plant an ideal one in which to work and one where accidents are not known, should exist ten years from now as well as at the present moment.

CONCLUSION

In conclusion, the main fact I wish to emphasize for your attention is that this presentation of the subject before you is simple in its fundamentals and inclusive in its outline. The essentials are what you need and what you at this time should understand. It is unnecessary to enter into details for you can cover these through reference to safe practice standards in use throughout the country. You can get much of this information from other discussions at this very congress. The object of this discourse is to present to you facts that deal with the building up of a successful safety organization—facts that are self evident and clearly defined. Support you must have; analysis is the basis of engineering; and action is red blooded American determination.

CHAIRMAN STREMMER: I think we all agree with the speaker in the closing words of his paper. I will now call upon the second speaker on the program. Mr. Fellmer, the Secretary of the Mississippi Valley Division of the National Safety Council, who will speak to us on "The Foreman—The Determining Factor." I am very sorry to say that Mr. Morris is ill and cannot be with us. He wrote me a letter a week ago and said "I am looking forward to my trip to Cleveland when we shall see each other eye to eye." We have had Mr. Morris at our plant on a number of occasions to speak to our foremen and to our safety committee.

THE FOREMAN—THE DETERMINING FACTOR

M. L. FELLNER, SECRETARY, CENTRAL MISSISSIPPI VALLEY DIVISION,
NATIONAL SAFETY COUNCIL, ST. LOUIS

The foreman is the keystone of the arch of safety in an industrial plant.

Let's first see what a foreman is. A foreman has been placed in his position because he knows the work to be done in his department, from the practical side. That is one requirement. The second one is that he has been placed in this position because a superior officer in the organization of the plant realizes that he is a man who can teach others to do the particular work to be done in that department. In olden times a foreman was a man who was running around—the old English term is an "over-seer". That term implies a man who watches the other man perform his duties—a sort of a prodder, to keep them going. And also in the times of an abundant labor supply the foreman was given a great deal of leeway in the manner of handling the men, and he very often handled them very much more forcibly than elegantly. He very often handled them by kicking them around and kicking them out at his own sweet pleasure. These times have fortunately passed and the foreman is now an entirely different rock in the structure of safety. The best term that I have heard applied to the job of foreman was applied by the United States Shipping Board during the war. They called their foremen "leaders", and that is what a foreman really ought to be. He ought to be the leader of his department. He ought to lead his men, not drive them. That brings us to the point of a foreman being the making or unmaking of a safety campaign.

In one of our Round-tables in the Central Mississippi Valley Division in St. Louis, a young foreman got up, after it had been impressed upon the foremen present just how necessary it was for the foreman to instruct new men in his department in the specific dangers of their occupation—the young man got up and stated that he had not done so in the case of a supposedly experienced operator of a certain machine. He had put him to work because the man claimed that he was experienced on that intricate machine, and when the foreman returned to look after the new man he found him with his hand practically severed, by reason of a hazard which was peculiar to that machine and with which this otherwise experienced workman was not familiar. This foreman then declared that thereafter he would never be too busy to instruct a new man in the particular dangers of his job.

FOREMAN MUST WATCH NEW EMPLOYEES

If you were to see a graphic analysis of the accidents of any large concern, as to causes, places in the plant, hours of the day, and term of service of the men involved, you would find that your line representing men in the employ of the company during the first month is the longest of all. This is quite reasonable. When a man comes into a plant, he

isn't always of the highest mentality and he is more or less bewildered. He is over-timid, and the first thing he knows he gets hurt.

Then my studies of the frequency of accidents in plants prove that after the first month you will find a downward curve in the number of injuries happening to new employees, until the first effect of the hurt gets worn off. Then a fellow becomes familiar with his surroundings, familiar with his work, and by about the twelfth or thirteenth month of his employment the curve gradually begins to increase again. It is a strange thing, but in several analyses that I have made of the accident records of large concerns, I find just that to be a fact.

That increase of the curve is strictly attributable to the foreman. It is strictly a lack of supervision on the part of the foreman that brings this about. The foreman has a thousand and one reasons to be continually supervising his men in the execution of their duties, but the one reason that very seldom is brought out to the foreman is a rather selfish reason. The foreman, as far as the department and its output are concerned, is the employer of laborers under him. They are directly amenable to his direction. The efficiency of a foreman and his gang is gauged by the cost of production in that department, and the cost of production is affected by the cost of accidents. So, from a selfish standpoint, if the foreman keeps down the cost of accidents in his department, he naturally proves to his employer that he is an efficient man because his cost of production is correspondingly low.

A foreman who does not pay attention to safety is simply standing in his own light. When a foreman employs a man, or a man is sent to the foreman for employment, no matter how experienced the man is in the work for which he is employed, he has to be taught to do the work of that particular plant in the particular way of that plant in a manner profitable to that plant. Only then is he a valued employee. Then it devolves upon the foreman to take every new man and break him in to do his work in his way in a manner profitable to the plant or department. If he omits safety in the primary education of that man, and the man is hurt, he has to go through the same proceeding again and break in another man. This increases the cost of production.

SAFETY AND EFFICIENCY

Now there is another thing: If a foreman does pay due attention to the safety work, the men very soon will think that he is really concerned about their physical welfare while at work, and they will feel free to come to him and offer their suggestions as to the betterment of conditions in the department, and it will bring about a better feeling of understanding and confidence between the foreman and his direct charges; and by and by when safety begins to permeate that little subdivision of the plant, the foreman will find that these men will caution each other against dangers and will produce a very favorable record of accidents. And again, the foreman having brought about that state of affairs in his department, will be free to devote more time to the actual production of his department, thereby further increasing his efficiency

and putting himself into line of promotion. So those are the selfish reasons for the foreman to put his shoulder to the wheel and make safety an actuality in his department.

Unless a foreman does just these few things, unless he is able to command the respect and the confidence of his men toward the safety organization, you may have the biggest prizes, you may have anything that you can schedule, and your safety organization is going to be a fluke. The foreman, as our esteemed Chairman has said, is the "keyman" of the situation. He is the man about whom the entire organization of any plant revolves, though his position in the organization may be a subordinate one. By reason of his direct contact with the men and his position as a transmitter of the wishes of the men to the management, he stands right at the keystone of the arch. He is the keyman. If you take him out of any organization, your organization is bound to fall in efficiency and in safety.

CHAIRMAN STREMMEL: There is no doubt about it, gentlemen, the foreman is the determining factor. The foreman today fills the most important position in the plant. Why? Because he is the personal representative of the management. He is the salesman who is selling the ideas of the institution to the men. The men have a conception of the institution to the extent that the foreman imparts the knowledge of the same to them, and therefore there is no question but that the foreman is the determining factor in any manufacturing establishment. It gives me great pleasure to introduce the next speaker, a man who was one of our lecturers last year in our school of Safety Supervisors in St. Louis, a man who gave us a very interesting message, Mr. W. R. Rasmussen.

METHODS OF PROMOTING SAFETY EDUCATION IN A PLANT

W. R. RASMUSSEN, REGIONAL FIELD SECRETARY, NATIONAL SAFETY COUNCIL

During the year and two months I was in the Pittsburgh District and in the six months that I have been out as Regional Field Secretary for the National Safety Council, I have visited approximately 1,500 plants, and the most surprising thing to me during that year and eight months has been to see how few organizations really get the maximum results from bulletin boards. Why do we put up bulletins? I would ask you this question: Why does a commercial house advertise? I think we have it right there.

You know that practically every large concern, whether large or small, spends a great deal of money for advertising. We can't pick up a daily newspaper, a magazine, or a periodical of any kind but we see some very high class advertising. I attended a meeting of advertising men a short time ago at which one gentleman stated that there were more brains put into the advertising game than any other profession known.

Now if it is good business for the commercial man to advertise—and I think it has been proven that it is—why isn't it good business for the

safety engineer to advertise? You have something to sell. You can't lay your merchandise on the table as the commercial man can, but you can lay your idea on the table—and how are you going to get them across with the great mass? Simply through advertising, and your advertising medium is your bulletin board.

KEEP BULLETIN BOARDS ATTRACTIVE

If you were a commercial man and you expected to derive real benefits from your advertising you wouldn't write a half page advertisement, hand it over to the newspaper, and let them run it indefinitely. You are paying big money for that space and you would want to utilize it and get as many messages across as you possibly could. You would be very careful as to the location of that advertisement. You wouldn't want it in some place where nobody would see it. Why does not the same thing apply in advertising safety in our plant? I met a young man about two weeks ago on the Pacific Coast, and as I walked into his plant I noticed an old dirty wall, full of smoke and grease. There were a lot of old dirty bulletins on the wall. Some of them were torn, and it looked to me as though they had been up there for a year. I said to him, "Why don't you get some real bulletin boards, something that will attract the people?" He replied, "They don't read them anyhow; they don't pay any attention to them. Anyway I am only trying to reach workmen." That was amusing. Could you expect any self-respecting man to go up and read an old, dirty, torn bulletin? When he said that he was only trying to reach the workmen, I wondered whom these high priced advertisements are trying to reach. We are trying to reach the same men.

What is the best method of using bulletin boards? I should say to have a really active bulletin board, something that will appeal to the men. Usually the best color for a bulletin board is our safety color. I would have it painted green on the outside. I would have it glass covered. I would have a light at the top so that it would shine down and the bulletins would stand out. I would have the inside of the board in white, and I would have a removable back so that I could have different material on each bulletin board, which I could take from one to the other and keep on down the line until I had changed them all.

How often should these be changed? I should say at least once a week; oftener if you can, but at least once a week. The reason men don't read bulletins in plants is because they become an old story. There is nothing there that is interesting to them. They have probably read them once, but that is all. The boards have gotten dirty, and the men are used to seeing the same old thing there and hardly know that it is there.

WHAT TO PUT ON BULLETIN BOARDS

What shall we put in the bulletin boards? Of course we all get the National Safety Council bulletins. We want to put them in, but that is not enough. You have got to have something local, something about your own plant interesting to your men—for instance, bad tools that you find. Put them in the bulletin board, and tell the story about where

you found them and what was liable to happen if their use had been continued. Very often you have broken goggles. Put them in the bulletin board and tell the story. Tell whose eye was saved by that pair of goggles.

A short time ago I was in a plant and saw an old, run-down wheelbarrow—as dangerous as anything could be. It was standing underneath the bulletin board and the story was pasted inside of it, where it had been found and all about it. That was the first time I ever saw a wheelbarrow used as a bulletin, but it was mighty good material.

Very often you find an article in the newspapers describing some accident that has occurred in a neighboring plant, or perhaps a plant at some distance, but something that might occur in *your* plant. Paste it on a large sheet of paper and draw an arrow pointing to it and let the men go up and read it.

This kind of bulletin boards is not the only kind. I have found that a great deal of good can be derived from blackboards and chalk. These also must be kept very much alive. You can tell stories of different things that happen in the plant, not only safety but other things that you would like to have the men know. For instance, if a man is sick, ask somebody in that department to go to see him, put his name and address on the board. Put on the board the number of accidents you had the same week a year ago and try to beat the record. If you can't find anything else, there are a lot of safety slogans. Use them—they are good.

WHERE SHOULD THEY BE PLACED?

Where should bulletin boards be placed? There is another thing that a great many organizations get away from. I have seen more bulletin boards at the front gate than anywhere else. They put them there, and when a man is going out or coming in he is usually in a hurry to get to his work or to get home, consequently he never sees what is on that bulletin board, unless it is something that can be seen at a glance. I would say, place the bulletin board right where he is working. True, he does not read it every time he passes there, but every time he looks up it is a reminder. These men don't get hurt on purpose. They get hurt because they forget, and if you have that bulletin where, whenever they look up, they will see it, it will remind them to be careful.

I find an honor roll a very good thing. Start the first of the year and put up the names of all the departments in the plant with a sign something like this, "These departments have gone so far this year without an accident." When they have an accident draw a black line through the name of that department, not heavy enough so that you can't tell what department it is, to show that it is a disgrace, that they have had an accident. You will be surprised how hard those men will work to keep their department on the honor roll.

In getting men to wear goggles I have found this a good illustration to them. Take two glass eyes and put them on a small bulletin board, with a pair of goggles, and this slogan, "Which would you rather wear—these or these?"

THE "DIRTIEST PLACE" SIGN

Every organization has more or less trouble in keeping the plant clean. I believe the best method that has been tried is a sign about twelve feet long, about one foot wide, stood up on two horses with these words on it, "This is the dirtiest place in the plant." Whenever you find a dirty place, have the sign put there, but it isn't the safety engineer's job to put it there. (Laughter.) Have a committee, which will be appointed through one of your Safety Committees, and call it the "Dirty Plant Committee," or some similar name. You can occasionally go around and tell them about some dirty place that you saw, but let them place the sign because you don't want to get in bad.

The whole proposition of bulletin boards is to keep up the men's interest. It isn't only the bulletins that you put on the bulletin board, but it is various ideas that you can get hold of that will get enthusiasm into the men. For instance, I saw this used, hung right over the front gate as the men went into the plant, "We have gone so many days without an accident." The number of days was changed each morning. If they forgot to change the number of days there would be somebody in the Safety Office asking them what had happened.

Another thing is a big target at the front gate, with rings around, each ring representing an accident. A block of wood painted red is a good color because that designates danger. If you have one accident put it in ring No. 1. If you have two, put it in ring No. 2 so that the men can see that somebody got hurt. The men want to know all about it, and the secret of your success is to get the men talking about it.

In getting out a bulletin to the foremen this has been a good method. Take all the foremen in your plant and make a list of them, then the number of men each foreman has, the number of hours those men have worked, the number of accidents each one has had, the number of days' loss each one has had and the percentage of lost time. Put the best man on top and the poorest man down at the bottom. Hand one of those to the foreman every month. Let him see where he stands and you will be surprised to see how the man at the bottom will get up to the top next month. That shows whether the foreman can prevent accidents or not.

I think you have an idea of bulletin boards—that it is advertising, advertising safety in your plants. Get the best methods that you can possibly think of, put it on the basis of advertising, and I am sure you will get it across.

CHAIRMAN STREMMEL: The statement made by our speaker that more brains are put into advertising than any other line of business was a remarkable statement to me, and it proves to me that we are living in an age when education is the foreword, and we realize more and more as we go along the value of education. Those who are leading the forces of unrest today have realized that for some time and they have used it to a great advantage in the form of propaganda, education, and that is what the safety movement has to be largely a matter of education, a matter of advertising.

It again gives me great pleasure to introduce our next speaker who was also one of our lecturers before our school last winter at St. Louis. This speaker gave us the closing message of our school year, and it was agreed by all who attended our school that he was the speaker of the season. It gives me great pleasure to introduce to you Mr. John A. Oartel.

WORKMEN'S INSPECTION COMMITTEES

JOHN A. OARTEL, CHIEF, SAFETY BUREAU, CARNEGIE STEEL COMPANY,
PITTSBURGH, PA.

In discussing the subject of Workmen's Inspection Committees, I shall treat it under two heads—"The Man" and "The Job." We hear a great deal today about selecting the man for the job. Why not do so in our safety work, which surely ranks in importance with any work that is being carried on in the world today? What type of man should we have to serve on workmen's inspection committees?

THE MAN

Intelligent men. In using the words "intelligent men," I do not mean men with the training of the schools or anything of that nature. I mean men who are at least fairly familiar with the safety work, with the process or operation which they are called on to inspect, and with the hazards incident to that operation or process. A mistake that has been made in the past has been that we have not lined up men with the big idea of safety. I have known men in the mill in the old days—steel blowers, open hearth melters, and rollers—who absolutely refused to impart any information along their particular line to a beginner. They feared if they did so that after a time the beginner would learn all about the process and they themselves might be displaced. They were afraid of their jobs. If I were called upon to appoint workmen's inspection committees, the very first thing I should do would be to call the committee together in a meeting and impress upon them the bigness of their job. I should get the best safety enthusiasts I could, lined up to come and talk to them—men like C. W. Price, R. M. Little, and A. H. Young. I should have that speaker tell them that they are about to engage in a mighty big undertaking, no less a task than the saving of human life. The next thing I should do would be to instruct these committees thoroughly in all the hazards pertaining to the particular operations of their department. How do we go about it now, in most cases? A letter is sent from the office to the foreman appointing John Smith, Tom Jones, and Sam Brown, on the Workmen's Inspection Committee for the next six months. Is it any wonder that their work is slipshod and ineffectual?

Men of good common sense. Under this heading I want to include a number of qualities which I have not the time to discuss in detail. They should be men of tact and discernment and should understand human nature. They should have the courage of their convictions, as

they may sometimes be called upon to take issue with those in authority. They should be men of likable dispositions and broad sympathies, who have the power to draw out other men. They should also be of a mechanical turn of mind, if possible, as they may sometimes be called upon to devise safeguards where they are needed. In this short summary, you may think that I have perhaps set the ideal too high—that the type of man I have described does not exist in the ranks of Industry. If you should make that statement, it would be only partly true. As long as we do not set up high ideals that call for the best there is in a man, just so long will our work and attainments be mediocre and we shall fail to accomplish deep and lasting results.

THE JOB

The work of inspection committees, in my opinion, should follow two general lines, namely, inspection for mechanical hazards and for dangerous practices.

Mechanical hazards. The safety movement has already borne much fruit in the way of engineering revision, but perfection has not yet been attained, and a great many accidents are still caused by improper construction and lack of safeguards. We cannot hope to expect much suggestion in engineering improvement from the workmen's inspection committees, unless such glaring conditions exist that they should be apparent to everyone. We can, however, expect much from inspection committees in the way of correcting dangerous processes that do not require the services of a trained engineer. Some of the best safeguards that I have ever seen and that have by their installation protected certain very hazardous processes have been devised and developed by ordinary workmen. If we take our workmen entirely into our confidence they will surely come along with suggestions for safeguarding that will be beneficial alike to employer and employee.

Dangerous practices. We learn from our study of accident statistics that accidents occur to new men in the ratio of six to one. Here then is work for the inspection committees. I do not desire to intimate that the entire instruction of new employees in Safety should be left to the inspection committee. Not at all. That is the foreman's duty. The foreman who today does not take every new employee, or delegate the duty to someone else who is trustworthy—the foreman who fails to instruct every new employee in the hazards of his position, is no longer fit to be foreman. He may be good at getting out production, but unless he conserves the lives and limbs of his workmen he is a liability instead of an asset to his company. I think, however after the foreman has done his full duty to the new employee in the way of instruction, there still remains a great deal that can be done by the workmen's inspection committee. What more efficient work, what nobler work, can be done by the workmen's inspection committee, I ask you, than to prevent the accident? This can be done very effectively by the committee taking charge of the new man and "mothering" him for a certain length of time until he learns the job thoroughly and is familiar with every hazard and

dangerous practice. I would like to see a demonstration of this plan in a plant that has a high accident rate. In a plant of this nature, the committee would take charge and watch the new employee so closely that he could not make a false move of any kind. If this could be done, I am sure it would result in a reduction of accidents.

When we have done our duty to the new employee, our work is only partly done. There still remains the old timer, who because of his familiarity with the process, becomes careless and thoughtless. I have known men of this type who disregard all safety rules. They are a law unto themselves. They persist in taking a chance. They perform their work in a way that results in accidents to themselves and their fellow workmen. They generally do this in the absence of the foreman. He does not hear of it until an accident has occurred. There is a certain hesitancy on the part of all workmen in reporting practices of this nature to the foreman, but a practice like this if persisted in will undermine and wreck everything that has been done in safety education in that particular shop. Here is your proposition—whether to allow a man of this type to run wild and wreck your entire organization or to report him to headquarters as you would a man who is running wild on the streets shooting up the town. Workmen's inspection committees may solve some of these problems by reporting such men to the foreman or superintendent. By advice—by admonition—by even holding a man up to ridicule before his fellow workmen, a man who engages in dangerous practices may be made to see the error of his ways and turned from them.

I shall now outline briefly some of the ways in which some of the large companies carry on the work of their workmen's inspection committees.

CAMBERIA STEEL COMPANY

"In our plant we have nineteen safety committees composed of three men each, and their instructions are to make a thorough inspection of their department at least once a month and send us a written report. Their duties in addition to this consist of making an investigation of all serious accidents and spreading the safety spirit throughout their department all the time. After each committee makes its report we have an inspector go out from our office, look up the various items, and have orders placed at once to have them rectified. In some cases items found have already been ordered.

"These committees change every two months and consist of foremen and sub-foremen as a rule. Some of them do splendid work, but as you know, we cannot always pick just the kind of men we would like to have in this work. These men are chosen and appointed by their own superintendents who notify us of their appointments. At the close of this two months' period we award a \$10.00 prize to each committeeman whose department accident percentage shows improvement over the previous twelve months. The committee having the highest average improvement are awarded a grand prize of \$20.00 each. We find this cash award a great incentive for our men to carry on their safety work."

AMERICAN STEEL AND WIRE COMPANY

"The workmen's inspection committees that we have been using in our plants in the past are known as Mill Safety Committees, and are composed entirely of rank and file workmen. The committee generally consists of three members, who serve from one to three months, one man being kept on from the previous month to act as chairman of the committee. Members of these committees are chosen by their respective foremen, the Chairman of the Permanent Committee designating the foremen who are to appoint a member of the committee each month. These men are picked from the better class of workmen, those who are wide awake and familiar with the operations of the plant. The membership is not restricted to English speaking workmen, however, at least one foreign-speaking workman being placed on each committee.

"This committee makes an inspection of the plant once a week, and renders a report to the Chairman of the Permanent Safety Committee. These men are encouraged to observe and report any unsafe practices, as well as hazardous places and defective equipment.

"Each member of the Mill Committee is given a safety button when he is placed on the committee, which he is permitted to keep after he has been discharged from the active committee. This button indicates that he has served on the committee, and when he is discharged from the active committee, he is instructed to consider himself still a member of the safety committee and to do all in his power to promote safety in the mill.

"We have found these committees to be a very valuable asset in our safety work, and have received many useful suggestions from them.

"We are at the present time changing our organization and substituting departmental committees for the mill safety committee. There will be one of these committees to each department of the mill. The committee consists of the shop or department head as chairman, and from three to five workmen. The membership of this committee should represent, in so far as practicable, the various occupations in the department. The chairman should be permanent, but there should be a rotation of the remainder of the membership, the service of each member covering not more than three months.

"It is the chief duty of these committees to make safer and better working conditions for the employees in their department.

"They make a study of the general conditions, departmental and occupational hazards and practices, and endeavor to encourage the cooperation of other workmen in reporting promptly for correction any existing unsafe conditions, practices, or hazards through which personal injury may result.

"These committees meet at least monthly with their chairman, for the purpose of making a formal inspection of the department, or inter-department inspections, review accidents, suggest remedies, physical or operating, and they render a full report of the meeting with their recommendations to the Chairman of the General Safety Committee."

BETHLEHEM STEEL COMPANY

"The safety committee organization comprises four divisions or classes, three of these divisions being composed of qualified Safety Committeemen.

"1. *The Permanent Safety Committeeman*—One in each department, who has charge of all first aid and safety committee work there, and is responsible for first aid equipment, safety bulletin boards, and the distribution of safety literature throughout his department. He makes written reports of accident investigations in his shop. He is under the supervision of the Division Safety Inspector, and is compensated at the rate of \$5 per month, for the detailed attention he gives this work in addition to his regular shop duties.

"2. *The Departmental Teams*—Taking a course in First Aid and Accident Prevention, and who qualify for this work by completing the course with the Annual First Aid Meet.

"3. *The Active Safety Committeemen*—This group assumes their duties upon completion of the course, and serve for one year, or until the next First Aid Meet. In company with the permanent safety committeeman they make an inspection of the shop once a month.

"4. *The General Safety Committeemen* (Once a Committeeman, always a Committeeman)—Those who have served for one year as active committeemen. This group are the auxiliaries of the active committees, but do not make the monthly inspection of the departments.

"*Instruction of Safety Committeemen and Training in Accident Prevention*—You cannot qualify a man for Safety Committee work over night, safety committeemen are not born that way. A man may be naturally careful and prevent accidents to himself, but he must be trained in accident prevention if we expect him to look out for the other fellow. Neither can we expect long service in the shop to qualify a man for accident prevention work. Very often he has grown so familiar with the danger that he does not see it for himself, much less point it out to his fellow worker. Men must be trained to see the causes of accidents and near accidents in order to prevent them. Such training must come from a detailed study of the unsafe practices and hazards of a particular department. Safe practices covering the various operations are dwelt upon. Departmental accident statistics and accident investigation reports are used. Photographs and prints showing accident causes, help in the work. Current literature is quoted on the subject under discussion, and interchange of ideas encouraged. Much stress is placed upon the attitude and spirit of the committeemen in approaching a fellow worker on accident prevention work, realizing that accident prevention through education is a persuasive proposition rather than a command. A part of each first aid instruction period is devoted to this work.

"*Safety Committee Activities*—The safety committee organization is the natural agency for all human relations work in the plant, and the effectiveness of this organization can be largely measured by the degree to which it participates in plant human relation activities. The recent Liberty Loan Campaign in the Bethlehem plants, and in the subsidiary

plants of the Bethlehem Steel Corporation, was conducted by the Safety and Welfare Department. Twelve hundred of the fifteen hundred sellers at Bethlehem were members of the safety organization.

"Night school education, athletics, recreational centers, the injured, the sick, the unfortunate, all plant activities of the human element are within the realm of the safety organization. If the problem of the employer and employee is to be solved finally, the solution should naturally come through the medium of such a democratic organization trained to be considerate and helpful to the other.

"A study of the accident statistics at Bethlehem covering the last three years of the unorganized accident prevention period, 1911-12-13, as compared with results of organized work covering the period, 1914-15-16, shows an Accident reduction as follows:

Lost eyes	33.65 per cent
Amputations	41.5 per cent
Fatal	10 per cent
Average reduction for all causes.....	23.38 per cent

"This reduction despite the fact that accident causes were many times increased due to War productional activities."

CARNEGIE STEEL COMPANY

In our own company, we have inspection and safety committees composed of both foremen and workmen. At each plant there is a general or central safety committee, composed of department superintendents and assistant department superintendents. The superintendent of the plant, or his assistant, is chairman of this committee. In each department, there is a committee composed of the foremen of the departments. The department superintendent or his assistant, is chairman of this committee. In each section of the department, is a committee composed of workmen, with the foreman as chairman. The committees composed of superintendents and foremen are permanent; those of workmen serving for a period of six months. The duties of the workmen's committees are to have jurisdiction over the section in which they are employed. They are required to inspect for both mechanical hazards and dangerous practices. There is a very close connection and cooperation running through the entire membership of these organizations. The matters discussed by the general safety committee of the plant are handed down to and discussed by the department committees, and by them, to the workmen's committees. All recommendations from the workmen's committees are referred to the department committee, and if necessary, to the general safety committee of the plant for approval. We find that this system of safety organization gives good results. The superintendents and foremen form the backbone of the organization. They assume the responsibility, outline all policies, and direct the work. The workmen have their part in inspecting and looking after their own little corner.

How thoroughly should a plant be organized? Some statistics that I have gathered along this line may be interesting. I have found that a

comparison of eleven plants of the same company showed that the plant that had the most men on safety committees in proportion to the force, had the best accident record. The proportion ranged from one safety man to every thirteen employees, to one safety man to every one hundred seventy-three employees. The plant having one safety man to every thirteen employees has maintained the best safety record in the company for four years. The other plant is near the bottom of the list. You may draw your own conclusions. To sum it all up, the same things that bring success in any field of endeavor will bring success in accident prevention. These things are—organization, leadership, energy, tact and last but not least, good horse sense.

CHAIRMAN STREMMER: I want to say a word about the man who just read this most interesting paper. It shows what the safety game will do for a man when he once becomes interested in it. Mr. Oartel today is Director of Safety for the Carnegie Steel Company which employs something like 50,000 men. This man entered this plant, as I understand it, became interested in safety, and in order that he might know more about it and come in close contact with it, accepted a position at a reduced salary (he being a married man with a family) in order to get his start in the safety game, and today he is holding a very responsible position. It shows what the safety movement is doing for many, many men. I could tell you this morning a number of cases where young men have gone into safety work because they were interested and had a vision of the possibilities of it, and today have gone out holding responsible positions in various industries at splendid salaries.

For instance, one young man five years ago was a time-keeper in one of the steel plants working at \$65 a month. Today he is holding a responsible position in the safety field, receiving \$4,000 a year and traveling expenses. So there are any number of men whom I could tell you about, just like this one individual, who have had a vision of the possibilities of this safety work, who are giving it their time, thought, and attention, and are going into the work and are making a success of it.

Now it gives me pleasure to introduce the next speaker, who was also one of our lecturers in our school last year and gave us a most interesting message at that time.—Mr. Sidney J. Williams.

THE FUNDAMENTAL PRINCIPLES OF SAFEGUARDING

SIDNEY J. WILLIAMS, SECRETARY AND CHIEF ENGINEER, NATIONAL SAFETY COUNCIL, CHICAGO

The first half of our subject is—what shall I guard? The second half is—how shall I guard it?

If you want your plant to be 100 per cent safe, the answer to the first question is—guard every moving part, wherever located, on which a workman might be injured if he came in contact with it in any way or from any cause whatsoever. If the moving part is in a place "where nobody ever goes," remember that some one is likely to go there sooner or later, in connection with the repair or maintenance or alteration of the ma-

chinery itself or of the building, or for some other reason which you cannot anticipate. You probably have heard the classic story—a perfectly true story—of the man whose heel was cut off by an unguarded gear 14 inches below the ceiling. The man was standing on a scaffold, working on another shaft nearby; to brace himself he placed his foot against the shaft on which the unguarded gear was located, his foot slipped, and was caught in the gear. Many similar examples could be quoted of accidents occurring in out-of-the-way places. Recognizing this fact, the Illinois Steel Company rule book—to mention only one example—requires that all gears, wherever located, must be enclosed.

You may be puzzled by attempting to apply this principle to the guarding of overhead shafting and belts. Many shops contain miles of overhead shafting which it is almost a physical impossibility to guard. On the other hand, oilers and repairmen are frequently injured, sometimes fatally, on unguarded overhead shafting or belts. The only solution is, if the shafting positively cannot be guarded, to prohibit absolutely any work on such overhead transmission while it is in motion. Repair work, shortening of belts, etc., can be done during the noon hour or at night: oiling likewise—or better still, install automatic oilers, or oilers which can be filled from the floor by using a special oil can with a long spout. For details, see the National Safety Council's Safe Practices pamphlet on this subject.

A gear or belt or other dangerous moving part which happens to be located below a table, or in some other place where it is partially hidden, is not thereby made safe. Someone occasionally must reach under the table to sweep or repair the floor, or to oil or repair the machine. Someone may slip or stumble so that his arm comes in contact with a gear or belt which would be safe for the workman standing in his normal position. The immigrant totally ignorant of machinery—and it is hard for us to realize the completeness of the ignorance on this subject, on the part of foreigners brought up in farming districts—may deliberately put his hand or his finger into an opening that looks interesting, just to see what it is. If he finds that "it" is an unguarded gear, it is easy to say that the accident is his own fault—but that does not relieve our obligation to pay his compensation nor does it restore him to his vacant place in the gang.

What I have said of gears and belts applies equally well to any moving part on which a man might be injured—counterweights, cranks, reciprocating parts such as a planer bed, and so on; also, of course, to the operating point of machines.

CHARACTERISTICS OF AN EFFICIENT GUARD

The second half of the problem is—as already stated—"How shall I guard it?" Here are a few points to remember:

1—A safeguard should be so designed and constructed that it will prevent ALL accidents on the part guarded—not only accidents to the operator while at his regular work, but also to the operator or passers-by in case they slip or fall or carelessly touch the machine.

2—The guard should not interfere with production. If it does, it is liable to be taken off. In designing a guard it is generally wise to consult the man who will use it.

3—In general, the guard should be attached to the machine and not to the floor; if attached to the floor, use a connection which will interfere as little as possible with sweeping.

4—The guarded part must be easily accessible for oiling, inspection, and repair. The door or removable section provided for this purpose should be hinged or otherwise attached to the remainder of the guard, or to the machine. If not, it is likely to be left off permanently.

5—The guard should not interfere with cleaning and sweeping around the machine. It should, therefore, be kept generally about six inches above the floor.

6—The guard should be strong enough to resist injury and keep its shape. A light, flimsy guard soon becomes bent and is discarded. A substantial guard is cheaper in the end.

7—Incombustible guards are preferred. Wooden sockets, soaked in oil, may become a serious fire hazard. Metal guards are neater and wear much better. "Metal guards look as if you wanted to; wooden guards look as if you had to." Guards may be made of cast iron, sheet metal, wire mesh, expanded or perforated metal, or slats. Where subjected to acid or fumes, wooden guards may be necessary.

8—It is desirable to interlock the guard with the operating mechanism, where possible, so the machine cannot be operated unless the guard is in place.

9—A safeguard can often be so designed that it will also serve to prevent wear on the parts guarded—for example, a solid gear enclosure.

Let us consider the application of these suggestions to the design of gear guards. Cast iron guards are preferred because they may be made to fit more snugly, present a better appearance, and protect the gears from dust and injury. In shops having similar gears on several machines, the cost of patterns and cast iron guards will be no greater than the cost of "built-up" guards. A cast guard of one machine may be used as a pattern for making guards for similar machines.

Guards for a variety of machines, and in many sizes, may be more cheaply made of sheet metal. In large guards, an angle iron is used to make the joint between the flat sides and the curved part of the guard. In smaller guards this joint may be made by cutting projections (like saw teeth) on each side piece and bending these over to form a smooth curve. The joint may then be made either by spot welding or by riveting. Short pieces of angle iron may also be used to form the joint—about $\frac{3}{4} \times \frac{3}{4} \times \frac{1}{2}$ -inch angles, one inch long, 3 inches or 4 inches apart.

Gears should be completely encased; or where this is impracticable, should have a band guard with side flanges extending inward beyond the root of the teeth. If there is a spoke hazard, the gear should be completely enclosed, or filled in between the spokes.

Belts, flywheels, shafting, and large gears are often guarded by an openwork, rather than a solid enclosure. Such guards should be so de-

the efficiency of the operator. The real safety engineer will, where necessary, study the operation of a machine until he understands it as well or better than the operator himself—as well as the foreman, the superintendent, the master mechanic; and then he will apply their brains and his own in working out either a guard, or a change in the machine, or a change in the operation, which will remove the underlying hazard and make the operation intrinsically safe.

DISCUSSION

CHAIRMAN STREMMEL: Now we have five minutes for discussion on each subject presented this morning. We will start with subject No. 1. "The Essentials of a Safety Organization."

RULE BOOKS

MR. ROBINSON (California & Hawaii Sugar Refining Co.): Is a book of rules desirable for every organization? We have about 1,500 employees. Probably about fifty per cent are foreign born. I would like to know if it is a good policy to try to introduce a book of rules for every employee, necessitating the printing of that book of rules in different languages?

MR. McDONALD (E. I. du Pont de Nemours & Co.): We cover that subject in this fashion, sir. We make a study of our particular department, find its particular hazard. We then go ahead and perfect what we term "House Rules," governing that house operation. That is done through our various plant operations and we have found it very successful. When a new man comes into our organization, he is instructed by the foreman in the hazards of his occupation along the lines mapped out in these safety rules.

MR. A. L. THOMPSON (E. I. du Pont de Nemours & Co.): I would like to add to what has been said about safety rules. It has been the practice of many concerns to get too many rules in the book. The fewer rules you have for house rules, the better it will be. A man never reads a long list, but if you will make those rules just as short and snappy and few as possible, you will get better results.

CHAIRMAN STREMMEL: Are there any companies represented here today who offer a reward of any sort to any employee who memorizes the book of rules on safety?

MR. THOMPSON: I don't know whether any of the Illinois Steel Company men are here or not, but they had a practice when I was with them some years ago that the men had to stand an examination on the safety rules, and after they stood the examination they were given a watch fob designating that they knew the rules.

CHAIRMAN STREMMEL: Does anyone present require the members of the Safety Committee to be thoroughly conversant with the book of rules before they are made a member of the Committee?

MR. THOMPSON: I think all of them do. I know the Du Pont Company

does. I wouldn't stand for a man on a Safety Committee who doesn't know the book of rules. As Mr. McDonald has said, we have house rules in the majority of our plants. Our general rules, of course, govern all plants. We specialize on particular house rules in the explosives department and those have to be memorized by the men before they are put on the Safety Committee, otherwise you wouldn't feel that a man was competent to serve on the Committee.

CHAIRMAN STREMMEL: I know many plants where the men do not know the rules. How many just simply ask your foremen to select men and have them appointed to the Safety Committee?

(The attitude of the audience indicated that none of them did this.)

CHAIRMAN STREMMEL: The five minutes are up.

THE FOREMAN—THE DETERMINING FACTOR

CHAIRMAN STREMMEL: Any questions or remarks on this subject? This, to my mind, is the most important subject that you have before you this morning. The foreman or the foreman's organization in any plant can make or break the safety organization to a large extent. Interest your foreman; get them vitally interested in safety, then you have the cooperation of your foremen with your safety committee. If the foremen have an indifferent spirit toward the safety cause, then your safety committee is handicapped in its work within the plant. I know foremen and you know foremen who have stated openly that safety is "all bull," and they haven't been interested in it at all. You know and I know that it has been a very difficult matter to interest the average foreman in safety because when we selected men for the position of foreman in days past we selected a type of man who possessed qualifications different from those which we require of them today. The type of man, whom we select today as a foreman is a different type of man from those we selected in days past. In days past we selected men who, if they could fire a lot of men, were considered good foremen. The more men he could hire and the more he could fire, the more valuable we thought he was to us as a foreman, but that has changed and today it is just the opposite. The foreman who can hire the least men and keep the most men within his plant, who can have the least turnover, is the man whom we want. He must be a leader of men. A leader of men must have certain qualifications, and therefore the standard of efficiency for foremen today is higher than it ever was, simply because he is the dominating factor in your plant. And the efficiency of your plant, the efficiency of your safety movement in your plant, depends largely upon the personnel of your foremen's organization. Therefore he is the determining factor in many respects, not only in safety but in efficiency and many other things. Therefore the question of selecting foremen is one of vital importance to any management today, especially due to the great unrest within our plants, and wise is the management who can select men who are leaders of men and who possess the necessary qualifications.

WHO SHOULD INSTRUCT NEW MEN?

MR. ERIC (Sparks-Withington Co.): In our plant we have a Methods Division and an Efficiency Department. I would like to know what part they should play in the instruction of operators. Our Methods Division studies the operations and efficiency of the machines. Is it advisable to have that department instruct the men as to safety and the use of guards, or to have the foreman do it?

MR. A. L. THOMPSON (E. I. du Pont de Nemours & Co.): I consider that instruction from the foreman is better than from the efficiency man, because the operator works directly under the foreman and not under the efficiency man. The operator does not feel that he is responsible to the efficiency man, where he does feel that he is responsible to the foreman. I have a couple of "areas" in my plant where a new man gets a general idea of his work before he is turned over to the house in which he is working. The foreman in the house where he is working is required to go over the rules with him and instruct him in his work, and a report comes in from the Safety Department that such and such a man has been instructed and by what foreman he has been instructed. We follow that up once in a while by going round and picking that man up and questioning him on the rules and asking him why he does so-and-so and his reasons for it. Then we see what kind of instruction he has received. I think you will find, at least I have found, that the instruction from the foreman is the best.

CHAIRMAN STREMMEL: There is another point: a man to be a foreman in deed and in truth must be well-informed about his job and if he is well-informed about his job and is able to instruct his men in any part of the operating of his department, if, when a man goes to him for any information whatsoever, he is well-informed about his job—it immediately creates confidence within the men who are under this foreman's leadership, and establishes a point of contact that is very valuable from the standpoint of efficiency in that department.

The time is now up and we will pass on to the next subject. "Methods of Promoting Safety Education in a Plant."

WELL PLANNED BULLETIN BOARDS BRING RESULTS

MR. MEACHAM (Goulds Mfg. Co.): It may be of interest to some of our friends here to know what we are doing along bulletin board work which I consider one of the most valuable means of education. When we started with our safety work we had six or eight bulletin boards, large clumsy affairs, strewn about over a great area and lots of the fellows didn't see them. They were too far away from them. About six months ago we had made up some small boards, about eighteen inches wide and two feet long, painted black. We had about twenty-five of them made and put them up in each department, where each man couldn't help but see them, and at the top of each board we put "KEEP YOUR EYES ON THIS BOARD." We kept that sign there for six months. At the end of six

months we put on this slogan, "ALWAYS BE CAREFUL—THE A, B, C OF SAFETY."

We put up in each department on these boards the bulletins that referred to the special hazards of that department. For example: a man in the pattern shop or a man in the shipping room is not particularly interested in a molten metal hazard, but he does want to know about the hazards of his department. Right there let me say that I think that good safety work consists more in telling men about the results of getting hurt rather than the hazards of their department, because nine times out of ten the man knows more about the hazards of his own occupation than you do.

Now with regard to department competition. I have had a little experience in that and it hasn't been altogether to my credit. We employ about eleven or twelve hundred men and we are divided into different departments. We have six plants and I conceived the very fine notion, as I thought, of pitting each department against the other in the matter of accident reduction. I found this, that while the accidents went down, the number of accidents reported decreased, they decreased because the fellows didn't want to report them for fear of spoiling the accident record of their department.

You have got to look out for that. So we immediately started a foremen's competition, based on the number of accidents that the foreman found necessary to send to a physician for treatment, and I think in the light of my present experience that that is about the best way to get at it. If you start this competition business, be careful.

MR. PERRY (Eastman Kodak Company): Another example of bulletin boards will be of interest to you, I feel, in an industry reaching about 11,000 people. Within the last two months our antiquated open bulletin boards of wood have been replaced with a series of steel, glass-faced bulletin boards, illuminated, having the standard removable back. The backs are changed in half of the board, the board being of double construction. The backs are changed every day in one half, and from once to twice a week in the other half. The usual bulletins can be roughly divided into those two classes, messages to put across every day, and messages which it is desired to repeat for two or three days.

These new bulletin boards are getting the messages to the people. Previously they were not reading the bulletins posted on the old boards, which were often torn. But these new boards have bulletins put up in a clear, bright-colored manner. Most of them are printed on a regular printing press. They are attractive and neat, and I think the general idea includes a lot of the brains that the advertising people are claiming. It may be that the safety engineer could utilize some of the advertising man's brains to a lot of advantage because these new bulletin boards are working.

CHAIRMAN STREMMEL: The time is up. We will have to pass on to the next, "Workmen's Inspection Committees." There, to my mind, is a very important subject, not only from the standpoint of safety, but also from the standpoint of efficiency.

MR. CHRISTY (International Harvester Co.): I would like to ask for a little information. Perhaps some of these brothers here can help us out. Do you use a regular form for the use of the Safety Committee?

MR. MEACHAM (Goulds Mfg. Co.): The merit rating board of the State of New York provides a special form to be used for that purpose. There is a form for the safety inspector, there is a form for the various safety committees, and there is a form for the foreman's Committee and the General Committee. Those forms are in use in our plant.

SPECIAL TRAINING FOR SAFETY COMMITTEEMEN

MR. MULLIGAN (Bethlehem Steel Co.): Just a word with reference to the special preparation for men for safety committee work: The Bethlehem Steel Company feels that men must be prepared for safety work, and for that reason has instituted a course which has been carried on now for the fifth year, a course of five months of two hours per week on company time, one hour with the instructor and another hour with rehearsal. The work given in this course is one-half first aid work and the other half accident prevention work. The accident prevention work is based upon at least a four year history of the department from which the particular Committee comes. As a result of this course the Bethlehem Steel Company have particularly trained for safety committee work over a five months' period, four thousand men during the last five years.

This last course just completed last Saturday culminated with the graduating exercises in the form of first aid meetings, with upwards of 1,000 men.

During the time of their preparation they are not regarded as safety committee men because we feel that they are not qualified for the work. After the course is finished they go on as active safety committee men for one year or until the next group is prepared. After serving one year they move over into the General Safety Committee. All of the safety committee men in the shop are led by one man known as the permanent safety committee man whose position does not change and who is paid, for the attention he gives to this work, a bonus of \$5 per month. With the safety committee in the different classes, the permanent committee man who has charge of the work in the shop, the active committee who serve for a period of one year and the general committee—we never lose sight of a man. We believe in the slogan, "Once a committee man, always a committee man."

CHAIRMAN STENMEL: The time is up, Gentlemen. The next subject is "Fundamental Principles of Safeguarding." Here is the opportunity for some of you men who are just starting out in safety engineering and safety inspectors' positions to ask some questions.

GUARDS INCREASE EFFICIENCY

MR. HUGHES (Pacific Gas Co.): I have hardly found a place where a guard reduced or interfered with the efficiency of the machine. With reference to railings, especially on a dam: we find the men cross that dam

much more quickly with a guard rail. They will always hug the rail going along.

MR. COFFIN (Public Safety Commission, Portland, Oregon): I believe that one fundamental, basic problem here in the safeguarding of machines is to commence at the fountain head. The laws of the various states vary in prescribing certain safeguards, but it seems to me that if these various accident and industrial commissions and those who are responsible for safeguarding the plants could get together in a congress and prescribe certain regulations, then they can go before the various manufacturers and safeguard these machines before they are sent out to the various plants throughout the country.

CHAIRMAN STREMMEL: That brings us to our time for closing. I am sure that you will all agree with me that this has been a very interesting session. I am sure that you and I will say that it was "good for us to have been here." I take it that the men who have been in this A, B, C session this morning are men who are safety engineers, safety inspectors, officials or foremen or superintendents in the plants—they are men who are striving to know more about the safety game.

OPPORTUNITIES OF THE SAFETY ENGINEER

I want to say to the safety engineer and the inspector especially this morning these few words: this presents to you the greatest opportunity that you have ever had in your life. If you will study the safety game, if you will enter into the work with enthusiasm, if you will have a vision of its possibilities, I will predict for you, if you will pay the price, that within two or three or four years you will be a bigger man, a better man, a stronger man within the plant where you are employed; you will be in a position to demand a greater remuneration; you will be in a position to fill a more responsible position than you are filling today.

Let me bring home this thought to you. What is the safety movement? It is simply answering in the affirmative the question, "Am I my brother's keeper?" We are our brother's keeper, and let us remember that.

And men, how can you be a friend to man? By putting forth an honest effort in your respective positions as safety engineers and operators, to see that at all times you have safety first, last, and always! The meeting is dismissed.

would require an appropriation on the part of the company you represent. Think this matter over and later on we may develop the idea during the year and correspondence will be forwarded to you on the subject. Your opinion will be asked then, and whether or not your company would be willing to appropriate a certain sum in addition to the dues for the purpose of supporting such an office.

I would also like to call your attention to the entirely new departure in accident prevention work established this year—that of teaching safety to children, and through them reaching the parents.

Gentlemen, I want you to use every effort in your home town to try to put that thing across. You can get a copy of Dr. Payne's book from the headquarters of the National Safety Council. It is something that is really a radical departure. It is well worth while, and if you will put it in towns where you have plants, the children will reach the parents, and the parents will finally get that safety idea, instead of scoffing at it, as some do at the present time.

I have attended a number of the meetings of the Executive Committee of the National Safety Council, of which I am a member by virtue of my chairmanship of this section. I want to take this occasion to advise you that never has a body of men worked together in such perfect harmony for a common cause. The men of the executive committee never once consider themselves or their individual interests in taking measures for the development of the great idea. Gentlemen, this Council will prosper—it must, because it is right!

(The report of the Chairman was accepted.)

CHAIRMAN LYNCH: Gentlemen, the next order of business is a paper by Mr. A. L. Kaems, Deputy Industrial Commission of Wisconsin, Madison, Wisconsin. I believe, is far ahead of a whole lot of our other states on the subject of safety and safeguarding. I am sure Mr. Kaems will have something very interesting for us.

MR. A. L. KAEMS (Industrial Commission of Wisconsin, Madison, Wis.): Mr. Chairman and fellows, I have been assigned the subject of punch presses, and I believe it is a real question, because we know in Wisconsin that punch presses have given the Safety Department of the Wisconsin Industrial Commission more trouble than any one machine in the metal trade, for the reason that the accidents are all serious.

DIE CONSTRUCTION—THE REAL SAFETY OF PUNCH PRESS WORK

AUGUST L. KAEMS, ASSISTANT TO SAFETY ENGINEER, INDUSTRIAL
COMMISSION OF WISCONSIN

Punch presses give the Safety Department of the Wisconsin Industrial Commission more trouble than any other machine in the metal trades, for the reason that the accidents are always serious.

In 1916, 27 per cent of all the accidents in the metal trades were caused

by punch presses, and 48 per cent of all the serious accidents resulting in permanent disability in the metal trades were on punch presses.

In 1915, there were 1,988 days lost in temporary disability and 18,900 days lost in permanent disability. In 1916 there were 4,037 days lost in temporary disability and 61,140 days lost in permanent disability. In 1917 there were 5,685 days lost in temporary disability and 77,680 days lost in permanent disability. In 1918, there were 5,229 days lost in temporary disability and 82,250 days lost in permanent disability. For the first six months of the present year there have already been 2,135 days lost in temporary disability and 47,850 days lost in permanent disability.

These figures show how dangerous the work on punch presses is. All accidents on these machines have increased from year to year. In 1915 there were 141 accidents; in 1916, there were 326; in 1917 there were 341; in 1918 there were 381; in the first six months of 1919 there were 187 accidents.

Various reasons were given for these accidents, such as carelessness, disobedience, inattention, sleeping, and so on. In only two cases, the firms admitted that the accident was due to the improper setting up of the machinery.

We admit that more machines are in use today than ever before and that more kinds of work are being done than ever before; but as we have worked on safeguarding these machines, we should have held our own if the mode of our guarding was correct, but the figures I just gave show the increasing seriousness of the punch press problem.

I can remember when the first gate guard was demonstrated to us, showing that if even a lead pencil was left under the gate on the bed of the table, the press could not be tripped. We thought that guard would eliminate accidents, but it didn't.

Then came the two hand trips. When that was demonstrated, we thought that surely would be the thing to stop accidents, but accidents occurred just the same. Then came the automatic sweep guard which we thought would eliminate accidents. Yet we see that accidents have increased from year to year. This is due to the fact that we are not guarding right. Manufacturers are doing their work in the same way and they are now trying to devise some mechanical way of stopping the accidents. This is wrong, and I can prove it.

WHY SO MANY ACCIDENTS HAPPEN

Why have we so many accidents on presses? The answer is simple enough. It is because the operator must put his hand underneath the dies either to place the material in on which he is working or take it out. This can be easily overcome if we work out ways to place material in the die without using the hand, and to take it out in the same way. This is not very difficult to do, and it is my purpose to show you how it can be done.

Where the work is done in the proper way, we have succeeded in stopping accidents. How did we do this? Why, by building safe tools to do the work with and forgot all about the mechanical guard, and we will

have to go a step farther and plan presses for certain jobs so they can be done in a safe way.

I have in mind a plant in which thirty fingers were lost during 1917; eight in one day. Yet by building safe tools, there has not been one finger taken off in 1918 nor in 1919 up to this time. This surely is a wonderful record and it has been accomplished by just building *safe tools*.

Let me demonstrate to you how this was done. For instance, in re-drawing cups, the operator had to place the material in the die. The right way was for the operator to take hold of the cup on the sides, but in working fast, he sometimes missed his hold and then placed the index finger of his hand inside the cup, when the ram came down it caught his finger. At other times, the little finger was left under the bottom of the cup, and in this way, the little finger was taken off. To overcome this, we just built a slide and all the operator does now is to place his cup on the slide and push it ahead. This is so simple that one wonders why it has not been done a long time ago. It has increased production and made the work absolutely safe.

At another plant, a boy lost all of his fingers and part of the left hand, in taking a piece out of the die. This work was of such nature that it was necessary for him to use all of his fingers to take out the work. We overcame this by cutting out part of the lower and top die so that he could use his thumb and index finger in taking out the work. In the former method the operator used all of his fingers and there was a great deal of hand strain. Now he uses only his thumb and index finger, and it makes no difference if the press repeats for he cannot be injured. A gate which is on slides has been placed in front of the machine. When the iron is pushed into the press, it is straight, and passes under the gate; as it is formed he withdraws it and the gate rises and falls into position of its own accord. To make this change did not cost ten dollars, and the operation is now fool-proof. The young man who lost his fingers was the superintendent's son.

THE PRESS REPEATED

At another plant, a young man who operated a press lost three fingers of his right hand when the press repeated. The young man claimed that the press had repeated; the superintendent said it was not possible as it was a new press. He took the boy to the doctor, and when he returned, said he was going to run the press himself and prove that it could not repeat. After working one hour, the superintendent had the same kind of accident as the young man had. I went to investigate this accident and it looked to me as though it was not a difficult matter to remedy, and so stated to the superintendent. He asked me how it could be done. I said I did not know what to do at the time, but took two pieces home with me and that evening solved the problem of overcoming this hazardous operation. I went to him and said "I have got it figured out how it can be done safely". He asked me how. I found the die they used was closed on one side and the front, so that when the material was placed in, these two places acted as a gauge. As these pieces were not always

of the same width and four holes had to be punched into the piece, it was necessary to have the pieces fit exactly in a certain place. I told him to cut out the front and place in the other side so that the piece could be punched in. He said he had figured that out but it would have to be up against the one side on account of the different sizes. We put springs in on one side and that overcame that trouble. Then he said the piece would have to go in just so far. I said we would put in a gauge pin in the back. He said he had thought of that and could put in a disappearing pin but when he wanted to push out the finished piece with the unfinished pin coming up from the bottom always displaced the piece so it always would be necessary to reach in after it or pull it out with a hook. I said I will push it out just the same. You have been thinking of this gauge pin one way and I in another way. You are thinking of the pin coming up from the bottom and I am going to have my pin coming down from the top. As this piece has a depression through the center when finished my pin will release the finished piece and it can be pushed out by the unfinished. He just jumped up and down when he saw the idea and said "You got it—You got it".

The only thing that was changed was that instead of having a gauge pin at the bottom I placed it from the top down, which cleared the work, and it could be pushed out instead of taken out. All they have to do now is to push out the finished piece with the next piece.

At another plant a boy lost all of his second finger, all the third finger and half of the index finger, and crushed the little finger and thumb. This accident had been looked up and it was reported that the young man had tampered with the guard on the machine. This was given as the reason for the accident. If this had been true, in our State the boy would have been penalized fifteen per cent of his compensation; but as he was to receive only \$320 for this accident, the Industrial Commission felt that they wanted to be sure that the boy had really and deliberately placed the guard in such a position that it was of no use before penalizing him. I investigated this accident and found that the press had repeated and that the guard which was on it would not have prevented the accident. And yet for less than \$5 we changed the work on this press and made it fool-proof. All we did was to put the press on an incline, slide the work in and have it kicked out automatically. We closed the front of the press and left an opening through which the material could slide.

At another plant which used punch presses, one of our men called and ordered guards for the presses. This was followed by a letter to inquire what progress was being made in guarding these presses. Finally the Commission received a strong letter from the firm, stating that it was impossible to place the guards as ordered. Let me read the letter to you.

Industrial Commission,

Madison, Wis.

Gentlemen:

"In reply to your favor of May 16, we have had several expert people, including the superintendent of the company which manufactures this press, endeavoring to devise some safety device, and we have also taken

it up with several other expert people, and when they see the work we do with the press, they state that nothing can be made, so far as they can see, that will enable us to secure output to permit us to use the press and at the same time have a safety device on that would be anywhere adequate for the use in question.

"Of course, if the State of Wisconsin will not permit us to use this press without a device thereon which doubles the cost of the work in question, we will simply dump press in the scrap heap and have our work done outside the State of Wisconsin."

I went down to this plant and as soon as I came in, the superintendent started to tell me his troubles and what impossible things we asked him to do. And yet after thirty minutes I had convinced him how this work could be done in a safe way, and you can believe me that he felt embarrassed to think he had written such a letter. I can assure you that this man was a fine mechanic, because he showed me a machine he had worked out and which could not make a mistake; yet as simple a thing as building a tool for a punch press seemed impossible, due to the fact that everybody he asked had something else in mind—thinking of mechanical guards.

AN ENGINEERING PROPOSITION

So in building dies the thing to think of is how to get the material into the press without using the hands, and taking it out in a similar way. The work is simply an engineering proposition and demands mechanical thought and ingenuity, and a device which will fit one case will not help another. Every job is a little different, but every one must be worked out and can be made safe. Heretofore every man who had a new guard had a cure-all, just as the patent medicine man claimed that a bottle of his preparation cured all ills to which a man is heir from chilblains to whooping cough.

The trouble starts when you go into a plant and talk to the man, telling him to build safe dies. He has big things in mind and the one big thing is that he is always afraid that the production will be decreased. I will agree that the production must be kept up, today more than ever. Men must produce more today than ever before. We will never see wages down to where they were at one time, and the thing we must keep in mind is production for no business can exist when production is hampered. But if we keep up production at the expense of jeopardizing hands, eyes, even lives, we must go under. No business, no city, no country can exist when it ceases to have regard for the lives and welfare of its people. One country has just tried this and had to go under as it deserved. So will every business go when it once loses interest in its men. We have had too much stop-watch production. We found out how much a man could do in five minutes and then figured out how much he could do in an hour and in a day. I believe that theory is absolutely wrong. Let us take for illustration the boy who lost his fingers in the press on which the dies were so easily changed. I made these changes because I found that the boy was doing two-thirds of the work, and the press only one-third. The change I made was that the press now does

two-thirds of the work and the boy only one-third. Instead of having the boy place the work into the press and being compelled to take it out, leaving only the forming of the metal for the press, we made the press form the work and kick it out, and all the boy does is to slide the work into the press. You can see what this did to production immediately, beside making the work safe.

This idea of increasing the work of the machine and decreasing the effort of the operator, can well be compared to an automobile. Suppose you had only one set of gears in an automobile, and that of course would have to be a low gear. If you were in a bad place, you could start; and then if you came to a smooth road and wished to go faster you would have to race your engine, and the faster you wanted to go, the faster you would have to race your engine. If you wanted to pick up some of the speed the speed-demons have, you would have to burn up your engine; it would be impossible to keep it cool. But we have three sets of gears, and simply shifting the clutch increases the speed of the car without increasing the efforts of the engine. The engine represents the average workman and the gears the ordinary punch press. The only trouble is that we have not been shifting the clutch properly; we have been burning up the men rather than using the punch press to its fullest capacity. We have been burning men up at the job, and I want to say right now that men are working faster than we can safely work them, and a great many accidents are directly traced to that speed. For that reason tools must be built so that no matter what men may do, they cannot place their hands in danger zones. Let this great safety organization shift the clutch so that machines will do the maximum work and the human element the lesser amount and do it safely at the same time.

INCREASED PRODUCTION AND ELIMINATED ACCIDENTS

Let me take this plant in which thirty fingers were taken off in 1917 and which has gone on from January, 1918, up to the present time without an accident; this has been accomplished by building safe tools. When I first went into the plant in 1917 and presented the idea of building safe dies, their master mechanic told me that he had been in this work all his life time and the things I talked about were impossible. After every accident I called on him again to try to make him see it my way. When I found that I could not get him interested in this, I had to try another way so I went through the plant to find some jobs on which I could increase the production. I found such a job, which happened to be the cover for a coffee pot. This work was done in an unsafe way. It was blanked and formed out of a sheet and the operator had to reach in to take it out. He was making 6,000 pieces a day, and six thousand times a day he had to lay his hand underneath the die. If by accident he would have tripped the press, or the press repeated, he would surely have lost his hand. They had had several accidents on this press and when I took the master mechanic to this job and told him that I could increase the output, he asked me how. He was immediately interested because he thought I did not know anything about building dies, but

thought I might know something about production, and if it could help him, he wanted to know about it. Again I made use of my idea of the automobile. I found here also that the man was doing two-thirds of the work and the press the other one-third, and we changed this, putting the press on an incline, putting on a kick-out, and all the man then had to do was to move his material. We put a basket guard around the press, and it made the job fool-proof. The work was increased from 6,000 pieces a day to 13,000, an increase of 117 per cent, besides doing the work in a safe way. When this machine was put into operation properly guarded, I asked the master mechanic what he thought of the safe die, and he immediately said "Is this what you mean by building safe dies?" and I said "Yes, that is one of the ways; don't you think it is a good way?" He said, "Yes, there is nothing to this." I agreed that it was simple; just a little horse sense was needed.

Then we took the second bad job on which a man had lost four fingers. In the report, the firm stated that the man had been out fishing during the day time, and while working at night he became sleepy and through carelessness lost four fingers at this job. We made that fool-proof by building a new die for the machine and now it is arranged so the material is slid in and kicked out and the front of the press is closed. This job is fool-proof and we don't care whether a man goes to sleep or not, he cannot be injured. This, of course, increased the output 100 per cent immediately in spite of the carelessness or lack of alertness of the operator.

It took some persuading to get this superintendent to adopt my plan of building safe dies and he was not convinced until after I had demonstrated the feasibility of my plan. After I showed him how to increase production and eliminate accidents, he became an ardent advocate of safe dies. Let me read you a letter which he wrote sometime after giving my scheme a thorough trial:

March 18, 1918.

Dear Mr. Kaems:

About a year ago when you came to this plant looking up punch-press accidents, you advocated the plan of making dies in such a way that it would be impossible for the operator to be injured, or in other words, making fool-proof dies.

I did not think a great deal of this and could hardly see how it would be possible to make dies according to your suggestion. But after each accident you called again and I will be frank to state that I did hate to see you come as I knew beforehand what you were going to talk on.

I was finally convinced that such dies could be built and have several in use now that I know have prevented accidents.

A short time ago, I instructed one of the machinists to make a die which I had carefully planned with reference to safety. After he had given this some consideration, he thought of a plan by which this die could be made much safer than I had thought of, which goes to show that all of our men are now interested in this matter and are anxious to plan with us so as to avoid accidents.

I am also pleased to say that our foremen come to me with ideas about making safe dies, and in some cases they have been very good.

I believe that with proper thought and care, most dies can be made so that at least a great many accidents will be prevented. It has also proven that, in each case in which a die was made safe, the production was increased, which is an indication that a safe die is also an efficient die.

I hope to see you at the next meeting.

Yours very truly,

Master Mechanic.

At another time the same master mechanic became interested in another difficulty. I will show you a piece:

This is the bottom of a coffee pot percolator and was always made in three separate operations; First it was blanked out, and formed; the next operation was punching the holes and the third was trimming or sizing it, and each one was a hazardous one because the operator had to take the piece from under the die. A combination die was built for this and it is now all done in one operation; blanking, forming and trimming; throwing out the finished piece and separating the piece and trimming by having them fall into a V-shaped slide, which is open at the bottom slightly, letting the trimming fall through and the finished pieces fall into a basket. All this is done by simply feeding a strip through the press, and increasing the output 300 per cent. What chance would your stop-watch man have against this? He could place four presses in a row and work his men to the limit until they "burned up" and they could not produce as much as this one man easily, working alone. He is doing his work in a safe way and they are doing their's in an unsafe way. The first thing this firm thinks of now when they are building a die is "How can this work be done in a safe way?" I came into their plant not very long ago, and found the superintendent, the master mechanic and the foremen from the different departments in which punch presses are used, in the master mechanic's room and I wondered what the trouble was. When I inquired I was told that they were planning a safe die. When you think back only a short time ago, how the master mechanic had said to me that this could not be done, you can imagine how I felt when I found them planning such a die. Now nothing was said about production, but they talked of a safe die because it has been proven that every time they built a safe die production was increased. He told me that every time they built a safe die production was increased from 15 to 300 per cent and they are now enjoying a 100 per cent increase in business and all this without an accident in 21 months. Let us think again. Only a year ago, every time an accident occurred in this plant, there was an excuse for the accident. Every time the injured man was to blame, and yet for a year and nine months it has not been necessary for them to write a single excuse. Do you believe that their men were better in 1918 than they were in 1917? I believe you all will agree with me that the help in 1917 was as good as in 1918, and if anything, it was better. The excuse so often made that accidents were due to change of help had nothing to do with it as I have proved. So I believe it is not hard to see where the difficulty has been.

The trouble has not been with the men, but it has been with those in charge of the work by not providing men with safe tools with which to work. This must be done, or sooner or later we must reap what we have sown.

THE FOREMAN A BIG FACTOR

Another big factor in this work is the foreman. As long as we must work with the tools as we have them now, he is the big safety factor in every plant. I don't care what your safety committees may do, but until your foreman has become a safety man nothing can be accomplished for the reason that he is in contact with the men all the time, while your Safety Committee meets once a week or less frequently. The Safety Committee may plan ever so well but it is the foreman who must carry out these plans, and if he is not converted to the idea of safety the plans are never fully carried out. It is surprising when a foreman once becomes "safe" how many dangers he can find in the work. I find in plants where the foreman has become "safe" he can show me more dangers and things he thinks should be remedied than any one can imagine. I have in mind one plant at which a large number of accidents had occurred, and after having several meetings with the foremen where I had advised them to insist upon the men doing their work in a safe way, a foreman told me one day that he had lost the best punch press man he had. I said "Well, you are still running, but how did you lose him?" He said he had told the man to do his work in a different way, and the man had replied that he could not do the work that way and make any money. The foreman told the man if he was to stay there, he had to do the work in a safe way, and the man refused. The foreman then told the man that he was the best punch press man they had, but that sooner or later something would go wrong with the machine over which they had no control, and he would be injured. He said they would have to break in a new man anyway and might just as well start in now as later; if this man wanted to lose fingers he could not lose them there, that he would have to go to some other plant to lose them; and the man quit. If this had happened a year ago the foreman would have been scared to death to think he was going to lose the best punch press man in the plant, but he was not afraid of it now because he had a platform of safety to stand on. He was not afraid to break in a new man because he knew he was going to have a safe man. What effect did it have? The other men working there said: "Well if he lets the best man go, what will he do to us?" And the men saw the foreman meant to have the work done in a safe way, and realized that he was working for their interests. Again a year ago this foreman would have said: "Well, if he wants to lose his fingers, let him; they are not my fingers." But now he said: "If you want to lose fingers you will have to go somewhere else; you can't lose them here." This foreman had become a safetyman. There is no further worry over this foreman because we know he is on the job and where he stands. It is interesting to note here that the man who quit because he feared he could not make money and work in a safe manner is now back at this same plant. He has come to realize that

while he had to work, it was better for him and his family that he work in a safe plant than in an unsafe one.

In a meeting sometime ago, I asked the foremen how many of them had explained to the new men the dangers on a press, and to hold up their hands if they did. Not a hand went up, and I will be frank to state that at least 90 per cent of all our accidents on punch presses happened to new men. So you can see how necessary it is that the new men be fully instructed in their work. The average foreman cannot see much danger in the punch press. He thinks that if a man will keep his hands from under the die the man cannot be injured. Not long ago, I investigated an accident where a man had lost a thumb. They had taken the work from the press on which the accident occurred and put it on another which they thought was properly guarded and when I watched the new man work I could see that it would only be a matter of time when he would lose not only a thumb, but both thumbs because of the way he was doing the work.

When I called the foreman's attention to this he said "My, my! I showed him twice how to do the work right." So you can see that while he had shown the man the correct method of work when he started, he then let him alone and the operator had formed the habit of doing the work in an unsafe way. Of course, this foreman was not a safety man, and accidents are bound to occur in such places.

SAFETY BEGINS AT THE TOP

But the big factor in all this is that safe tools and devices cannot be built unless the head of the firm is interested. If he is not interested, we cannot expect the superintendent to be interested, and if the superintendent is not interested, we cannot expect the foreman and the men to be. So it all begins at the top, and it is surprising how little has been done to sell the idea of safety to plant executives; the men who must determine the policies of this safety movement.

I went into a large plant not long ago, in which thirteen fingers had been lost during the first six months of the year. When I told the General Superintendent that they had lost 13 fingers inside of six months, he said, "The Hell, we have!" Now that shows he did not know a thing about what occurred. The man who took care of the accidents saw that the injured man got proper medical attendance and when it was all over, the compensation was paid; if he was not able to work, on a punch press, other work was given to him. It was not thought necessary to burden the general superintendent with little things like this. Let us suppose that instead of 13 fingers taken off, material had been spoiled amounting in dollars and cents to compensation paid for these 13 fingers what would have happened? Would they have been able to get by with it? Why, no. Requisitions would have to be made out for new material and in the end it would have been necessary to come to the attention of the general superintendent that five or six thousand dollars worth of material had been wasted and I am sure he would have been interested in knowing the cause for this waste of material.

I have in mind a plant where three hands were lost in 1918, and when the first hand was lost, I went to the plant and showed them how this work could be done in a safe way. I am sure it would not have cost more than \$50. to have done this, but the superintendent in the department absolutely declared the man was to blame for the loss of his hand; that he would make this change, but the responsibility was on the man just the same. Only a short time later another report came in of a hand lost, and I went again. The superintendent again claimed the man was to blame for this second accident, for not attending to his work; that if he had, the accident would not have occurred. But they promised to change the work at once, and yet before it was done, the third hand was lost. It was then done, and the same accident cannot occur again. The superintendent also informed me that it had not decreased the output by a single piece.

Now let us stop and think. Suppose this man at one drop of the ram had spoiled two thousand dollars worth of material, and this had been brought to the attention of the general superintendent. When he called in his assistant and the foreman of the department, and they both told him that the man was careless and he had been warned several times but had not heeded the warning, and for that reason had spoiled two thousand dollars worth of material, would he have shrugged his shoulders and have said "That is too bad!" Why no. And if a few weeks later this same machine had spoiled \$2,500. worth of material and again the superintendent and the foreman of the department had been called in and again informed the general superintendent that the man on the job was careless; that he had been warned to take care and that the man next to him had warned him to be careful or he'd spoil the material; but he had been careless, would the general superintendent have shrugged his shoulders and said "That is too bad!" If he did, he would soon ruin the firm. If a few weeks later this same machine had spoiled \$3000. worth of material, would he again have said, "Too bad!" Why no; there would have been a housecleaning long before that. All this material could have been replaced, but hands cannot be replaced because they are God-given.

I will tell you why some firms are not interested in fingers, hands, and even lives. Hands and fingers are figured in the overhead expense and do not cost the firm anything. The consumer pays this overhead expense. But material cannot be figured that way and for that reason, they are interested in material and not in fingers. The public that is paying for this has not grumbled over what it has cost but some day it will awaken and demand that this work that they are paying for be done in a safe way. Several states have passed laws which authorize inspectors to go into the plants and seal dangerous machines so they cannot be used until they are made safe, and all will agree that punch presses should come in for their share of such sealing. Are we going to wait until that overtakes us in all states, or are we going ahead and do the things we should do? I say again that the heads of the firms must become interested and must begin to think how it must feel for one to be injured. Unless they can put themselves into that place, they cannot know. I am showing you the picture of a young boy sixteen years of age who has lost his hand due to

the fact that he was not properly instructed by the foreman, or to the fact that the machine was not properly guarded. How would you feel if that was your boy brought home? Let me show you a picture of a man who has lost his arm due to the fact that he was not properly instructed in his work, or that the machine was not properly guarded, and suppose it was yourself brought home to your family. Now, we men often think that we are the ones who are carrying the big load, but that is not true. It is the little woman at home who is taking care of the family all day, who sits up at night and nurses them when sick, that carries the big load, and then to have the breadwinner brought home crippled for life. How would you feel? That is exactly how these poor unfortunates feel when they are injured and their loss of limb or life may be directly charged to men higher up who have not yet become exponents of safety. I was in a hospital the other day when the nurse told me of a man who came in to have a finger dressed. When she saw his other hand she noticed that it was terribly crippled and she wondered how a man with such a hand could get in. I told her as I had told many a man before who had a crippled hand to keep his hand in his pocket while he looked for work, that this man kept his hand in his pocket while he looked for work knowing no one would hire him if it were seen. Not long ago I held a meeting in a small town at which a superintendent related how only a short time before he had hired a man and when the man came to work next morning, he noticed how badly crippled one of his hands were. The superintendent did not know what to do. He took a chance and allowed the man to work and found him to be a good mechanic and satisfactory in every respect. The superintendent stated, however, that if he had seen the man's hand, he positively would not have hired him.

Just think how you would feel if your hand was crippled through no fault of your own, and it would have to be hidden when you went to look for a job. How do you suppose such a man feels toward the society in which he lives?

SAFETY WORK LIKE RELIGION

Safety work is like religion. I do not care a snap for the man who goes to church regularly and then tries to get the best of his fellowmen; that is not religion; nor do I care a snap for the man who talks safety and does nothing; that is not safety. Safety must be within you. If you follow out the few simple things that I have suggested, punch presses can be made just as safe as any machine in the metal trades.

DISCUSSION

CHAIRMAN LYNCH: Gentlemen, it is in order to ask questions of Mr. Kaems if you have anything you'd like to straighten out.

MR. FRED HAZEL (O. J. McQuiston Co., Detroit): I'd like to ask Mr. Kaems on what press most of the accidents happen?

MR. KAEMS: It is on the quick action press. If you went through our records in Wisconsin you would find that not 10 per cent of the accidents occur on the larger presses; a much larger percentage occur on the small, quick action presses.

MR. A. W. GARDEN (National Cash Register Company, Dayton, Ohio): We can make our dies safe, but I believe we ought to get more to the root of the matter.

We have developed a system of tripping our presses by operating two air valves. There are many tripping devices on the market, but almost without exception a man can operate the press with one hand and have the other perfectly free. This is absolutely impossible with the device we are using. We have it so arranged that a man operating a press that runs 125 strokes to the minute can't feed it faster than that. We have had our experts try to beat that and only one man succeeded. He beat it when nobody was there to witness.

There is just one place a press can break that will cause it to repeat, and that is in the springs. If you have a flywheel press you have three little short springs any one of which breaking will cause that press to repeat.

Right now we are going over all of our presses and replacing those springs. We have about 200 presses, 95 per cent of which are the small, fast-action presses used for blanking, forming, and piercing work. It costs money to replace those springs but it doesn't cost as much as the cutting off of fingers.

We have reduced our accidents over 95 per cent in a force of 200 men. When a man loses a finger there, I tell you, Gentlemen, the Safety Committee is due for a calling.

On our work we first blank and then we shave off a great deal of the metal. We do that to get away from milling. It is faster and a cheaper operation. Sometimes we have only one-thousandth of an inch to shave off, and the stock must be put into a nest that is tight, otherwise we will shave all on one side and not on the other.

A man must put his hands underneath there, and it is entirely due to this air trip that we are able to cut down our accidents. We are working on a scheme now that may work and it may not, but up to the present time we haven't been able to solve this problem completely.

MR. G. H. McCLAIN (Cincinnati Local Council): I was connected with a concern, before my present connection, using a large number of punch presses, and we were convinced that the duplex trip was the final word in protection and safety. We were resting on our oars until one day a lad lost two fingers and a half because the press repeated, and since then that firm has learned that they can't put absolute trust in a press with the duplex trip because it is a mechanical device that involves a good many springs, and if any one of those springs failed to work it is likely to mean the loss of a finger or hand. I'd like to ask Mr. Kaems' opinion on that.

MR. KAEMS: Absolutely true! Anything that is mechanical makes it necessary to deal with certain springs and other things which are bound to go wrong at some time. If you could once get a press that was absolutely non-repeating, you would have the solution of the problem, but we can't get that, and so we have to deal with so many different things in the press.

This firm I mentioned that cut off 30 fingers in a year has gone 22 months without cutting off a finger, without an injury. We did it all by

building safe tools. We had one job there that gave lots of trouble; the making of the little piece that belongs in the bottom of a percolator. It took three operations to make that piece—first, to blank and form it; then to pierce it; and then to trim it. Now it is all done in one operation—formed, pierced, and trimmed—the trimming falls down into one receptacle and the finished article falls into another.

All the operator has to do it to take a sheet and run it underneath. We do not care whether the press repeats or not; the operator does not have to place his hand or fingers in the way of the die.

One report we received told of four fingers that were lost on a new die. The report said the man had gone to sleep; but now we do not care if he does go to sleep, just as long as he does not fall off of the chair and crack a leg, because he cannot put his hands underneath the die.

MR. FRANK ELWELL (Delco Company, Dayton, Ohio): In using air trips, if the air pressure goes down due to leaks or some other reason, the press will repeat. I was wondering if anything could happen to the supply of current on electric trips to cause the press to repeat.

MR. SHAW (Ford Motor Co., Detroit): If the current isn't there, of course it will not pull down the plunger. If there is no current your press will not trip. On the top of our machine we have a switch so arranged that every time the press goes down it breaks the current; there is then no chance of the current being continuous.

MR. E. J. CLARKE (General Motors Corp., Detroit): In commenting on punch presses I notice that no one has mentioned the automatic press, the type of press about which Mr. Case can inform you from his experience in the New Departure. In that plant there is a press which has the die operating horizontally and as the parts are blanked and formed they drop out automatically. The press operates continuously and is fed automatically.

MR. E. ROTH (Cleveland Metal Products Co.): There are three distinct features we have to contend with on punch presses. In the first place, the dog is apt to block. If there is a key on the shaft, the key is liable to break.

We have devised a safeguard for our presses so arranged that even if all the springs break the press can be controlled.

MR. SHAW: If the spring breaks, the press will repeat. If anything breaks and your hand is under there, it is going to come off.

MR. C. T. BANKS (Michigan Mutual Liability Co., Detroit): Am I to understand that someone has solved the problem of guarding the punch press and making it fool-proof, if something doesn't break?

MR. ROTH: Yes, sir.

MR. BANKS: Well, let's take, for instance, a punch press that is on jobbing work, where you put a die on in the morning and run it up to noon, and in the course of the afternoon change it several times more. And in the courses of those changes you have different thicknesses of material. What kind of a guard do you recommend to be adaptable to all of the different kinds of material that go through that press?

MR. ROTH: We have devised a guard that will meet all conditions.

When we run a blanking job we have a guard that has a glass front and wire mesh sides. We permit just enough room to get the stock underneath. If anything, it increases the output. Our guard is so designed that it will guard any kind of a die and any sort of operation.

CHAIRMAN LYNCH: The time is up on this discussion. The next order of business is a paper by Mr. L. C. Kahle, Chief Engineer of the Independent Lamp Wire Company, New York City.

ELECTRICAL EQUIPMENT, ITS INSTALLATION AND GUARDING

L. C. KAHLE, CHIEF ENGINEER, INDEPENDENT LAMP WIRE COMPANY, INC.,
NEW YORK CITY

The importance of properly guarding electrical equipment is beginning to be generally recognized, and it has progressed considerably from the time when some electricians, who were pioneer Safety First exponents, hung a piece of cardboard marked "Danger" on a piece of electrical apparatus.

We must protect all electrical apparatus so that when Bill carelessly leans up against a switch he may finish his yarn in comfort and not in the hospital. Then again there is the electrician who thinks "Oh, I have been working around electricity all my life, and I never got hurt yet." I think the problem of guarding to protect the latter man is the harder, and anything which can be done to make it hard for him to get hurt is a step in the right direction.

The chief operator of a large railway power house told me that his greatest accident hazard was the human element, that his best men sometimes take a chance. "Familiarity breeds contempt" and it will take much thought and ingenuity in the matter of guarding to help counteract this human failing.

The manufacturers of electrical apparatus and accessories are constantly devising new ways of insuring absolute safety and in every case when they advertise a new product, its safety features are prominently mentioned.

I once knew an old engineer who had made several crude guards for switches, and he was trying to convince a fellow engineer in another plant of the value of his guards. "Huh" (this engineer said) "the only way to guard that stuff is to lock it up and throw the key away and then somebody might find the key."

I am glad to say that that sort of an argument is giving way before modern ways of guarding against electrical accidents.

Much has been written and discussed about what voltage should be considered dangerous, and it seems to be the opinion that anything above 440 volts is dangerous. However, much depends on the conditions obtaining, and I, personally, have had a very severe burn from 6 volts. I had a ring on my finger and was oiling the motor in my car. I had the oil can in my hand and my ring made contact with the live side of the starter switch. Instantly the ring became red hot and I had difficulty in removing

it from my finger. The finger had a blister $\frac{1}{4}$ inch high all around it. Later, infection set in and I had a pretty sore finger for a while, so hereafter I will consider that the voltage of any line I come near is of high tension.

I consider that all electrical apparatus should be 100 per cent safe regardless of voltage, because the fact that the voltage is low and not dangerous, makes the average person more careless.

Safety apparatus is inherently more difficult to inspect than open apparatus, but the manufacturers have made the parts more rugged and therefore more reliable so that the necessity of extra work due to failure of apparatus is lessened to a large degree. Safety apparatus naturally is of higher first cost than previous standard apparatus, but the accident liability clause of various states makes the employer liable for accidents to employees. So there is a financial justification for the use of safety apparatus in addition to the main reason, which is a humanitarian one.

In considering safety as applied to any industrial plant, the source of current, either from sub-station or private power plant, should be first considered.

In one of our plants the power is obtained from a sub-station at 13,200 volts and enters the plant transformer house about 5 feet from the property line where it is transformed to 4,400 volts with the power company's transformers. From the transformer house it is conducted to the plant sub-station where it is again transformed to 440 volts and carried to the bus bars of the switchboard.

There are disconnection switches on the 13,200 volt line coming into the transformer house and oil switches between transformers in transformer house and those in private sub-station. There are also oil switches between transformers and bus bars on switchboard so that both sides of transformer may be killed, making it safe to work on same. By having an oil switch operated from switchboard connecting bus bars to feeder, this section may be killed so that it is safe.

The oil switches are against the wall and about 10 feet from the back of the switchboard. This is a good feature for nothing is more conducive to an accident in back of the switchboard than lack of room to work properly. A platform covers the connecting levers from the switchboard.

The transformer vault is locked and no one not authorized can enter. The openings at the ends of the switchboard are closed with heavy wire partition and the door locked so that only an authorized person can enter here.

SAFETY FEATURE IN CONNECTION WITH SWITCHBOARDS

The latest safety feature in connection with switchboards consists of an enclosed standard unit removable panel switchboard, which may be built up to form a complete switchboard, as the bus compartment is arranged so that bus bars can be continued from unit to unit through openings in the side wall. These panels are made in the form of a truck, and should a breakdown occur, the entire panel can be moved out, as it is mounted on wheels. As soon as the panel is removed, the connections are automatically broken so that workmen have no live parts to handle. Barriers

prevent accidental contact should any one enter the compartment when the panel has been removed. It has an interlocking device making it impossible to either remove or replace the panel with the breaker closed. A padlock may also be used so that no unauthorized person can remove the panel if the breaker is open. These units come complete with instruments, oil circuit breakers, instrument transformers and other appliances which may be desired, and should a breakdown occur, a spare unit can be immediately placed in service without taking the power off the main bus. It is stated by the manufacturers that this change can be made in less than a minute.

ELECTRICALLY-HEATED ENAMELING OVENS

The method of control for the electrically-heated enameling ovens is interesting and makes for safety.

The switches for these ovens were originally on an open-faced panel in the enameling room and naturally under the right condition a spark from a switch might cause an explosion and fire. These ovens are now controlled from a central point called the control room which is situated at a distance from the ovens. This room is of concrete construction and has a switchboard on which are mounted the thermostatic relays which control the temperature of the ovens. This eliminates a very dangerous fire hazard and centralizes the control in connection with these ovens.

I would like to mention the fire-fighting apparatus in the ovens. There is a pipe drilled with holes running each side the length of the oven and in case of fire the steam is automatically turned on and the fire is smothered by the blanket of steam. It is also possible to use Foamite to extinguish the fire. All lighting fixtures through the enameling department are fume proof, the receptacle being of a fume-proof composition. The lamp is screwed into this and then is covered with a glass globe which screws on to the receptacle in such a way that if a spark should in any way occur in the interior of the globe, it could not reach the outside.

All panel boards controlling the lighting throughout the plant are of the safety type with push-button switches mounted on a slate frame. These switches are covered by a steel door provided with a catch. The fuse holders are mounted outside the safety frame and are covered with a steel door provided with a lock preventing unauthorized persons from gaining access to the fuse compartment.

The motors driving the pumps for the clarifiers are direct geared to the pumps doing away with the fire hazard due to static from driving belts.

NEW TYPE OF MOTOR-STARTING SWITCH

A new type of motor-starting switch, which is low in first cost but provides complete protection to both the operator and the motor, has just been placed on the market. It is designed for connecting single or poly-phase alternating current motors of from 1 to 10 horsepower, 250 and 550 volts, directly to the line without the use of auto-transformers or resistance.

All of the mechanism with the exception of the opening handle is enclosed with a steel box. Parts needing regular inspection are easily accessible on opening a door in the cover; but this door cannot be opened except when the switch is in the "off" position (nor can the switch be closed when the door is open) and all parts reachable are then dead.

Therefore, it is impossible to receive injury from contact with live parts when either operating or inspecting the switch or making ordinary adjustments and renewals. The upper part of the cover is held in place by screws and so can be removed without difficulty by authorized persons, thus exposing the entire mechanism to inspection.

No voltage protection to the motor is provided by a magnetic release which opens the switch automatically on a failure of voltage. Overload protection is provided by means of relays, resembling cartridge fuses in appearance, each of which contains a contact connected in series with the release magnet. Harmless momentary overloads have no effect on the relays, but as soon as the load on the motor becomes dangerous, the contacts open the magnet circuit and the switch automatically flies open. The contacts then automatically reset themselves. The switch is so arranged that it cannot be kept closed on an overload or no-voltage even if the handle is held in the "off" position.

Enclosed switches may be used wherever the ordinary knife switches may be applied. The switch parts are so mounted inside of the box that the door over the fuses is automatically locked when the switch is in the closed position. When the switch contacts are open, the door can be opened after turning the handle to the "off" position. With the door open, in which position it is held by means of a catch, the switch cannot be closed. When the switch is in the open position it is impossible to reach the hand in far enough to touch the live contacts. The switches are made with the fuse holders in such a position that the fuseholders are always "dead" when the switch door is open and fuses can be replaced, therefore, in perfect safety. The door of the safety switch may be locked shut by a padlock thus making it possible to be operated by inexperienced persons and only persons who have access to the key can replace a fuse. A padlock may also be used to lock the switch in the "off" position so that safety is provided to the workman in case the switch were accidentally closed.

Automatic starters for both direct and alternating current motors may be had, to operate which you simply press a button and the motor accelerates with scientific exactness preventing excessive starting current making it possible for any inexperienced hand to start a motor without injury. The starters are totally enclosed in sheet-iron cases which may be locked shut and the line switch may be locked open by inserting a padlock. This is a good safety feature for then no one but the person holding the key may operate the starter.

Quick stopping may be obtained with the direct current starter by the use of a drum reverse switch which provides dynamic braking in the "off" position and speed adjustments may be obtained by the use of a master switch and field rheostat combined. With this arrangement the handle

My idea is to put polarized receptacles in all places where we use extension cords. One side of all those polarized receptacles is the grounded side of the circuit. That part of the plug cap which goes into the polarized side of the receptacle is connected to the screw side of the socket. I believe that is going to make it safer.

CHAIRMAN LYNCH: I think this must conclude our discussion on this topic. I am sure you have all been waiting to hear Mr. Shaw on "Our Method of Safety Education."

ABSTRACT OF PAPER ON OUR METHOD OF SAFETY EDUCATION

R. A. SHAW, DEPARTMENT OF SAFETY AND FACTORY HYGIENE, FORD MOTOR COMPANY, DETROIT, MICH.

INTRODUCTORY

Gentlemen, I will give merely a synopsis of our work. Our system of Safety Education has proved successful because the number of accidents, have not only been checked, but have decreased. This is strikingly shown by a comparison of the months of October 1916 and May 1919, when there were 194 and 40 accidents respectively; a reduction of nearly 80 per cent in three years, while the number of employees increased 18 per cent.

Our fiscal year ending August 1, 1919, shows only 1 death among 50,000 employees, and no deaths for 11 consecutive months.

GUARDING

The first thing we do is, keep all machines, conveyors, and other necessary equipment in a safe condition with efficient safety guards or devices. This convinces the employee that the Ford Motor Company is willing to do its share; and creates a desire on his part to do likewise.

EDUCATIONAL REQUIREMENTS

Safety Education should be something possessing power to cause inspirations and develop the individual along the lines of safety. It must be the thing to encourage men to respect the safety laws, and love humanity to such an extent, as to endeavor persistently to prevent suffering by reducing accidents.

A certain amount of humor is necessary in this work. It develops cheerfulness, which produces a fertile mind for the reception of seed (new methods) and causes it more readily to take root and become (as it were) a tree with many branches spreading in all directions, comforting those in need.

MOVING PICTURES

The Safety Moving Picture is a vital and important phase of our work. It shows the less intelligent workman the safe and unsafe ways of doing things. The pictures are acted by their fellow employees and conse-

quently produce personal interest and enthusiasm. There was a 27 per cent reduction in accidents during the period these pictures were shown.

In conjunction with them we had different foremen talk before the men, to bring out more specifically the hazards encountered by the men in their respective departments.

SAFETY RULES

Safe working rules are not all put in one large volume as is the general custom. Rules for punch presses, saws, milling machines, cranes, elevators, etc. are printed separately on a booklet cut pocket size with detachable section on the bottom which is signed by the operator and kept by his foreman.

We feel that in this way they are read and the results gratifying.

BULLETINS

Bulletins are changed each week in our 100 bulletin boards. This serves to acquaint the employees with the different hazards. When placing them in the boards, we watch to see whether the foreman is anxious to look at the new bulletin; if so, one-half of our desired accomplishment is attained, because the men will soon follow.

INSPECTORS

Our minute-men, or as some term them, safety inspectors, patrol the buildings, and are ever ready to cooperate with the men or their foremen in any safety requirements.

INTERCHANGING OF IDEAS

Safety Suggestion boxes are placed at each entrance. No prizes are given because we believe that all of our men are interested in safety to such an extent that they will gladly give their ideas to prevent suffering to themselves and fellow employees. We also have the use of the "Ford Man" to advance the interchanging of safety ideas.

MONTHLY SAFETY STANDING

A Monthly Safety Standing is compiled and distributed to the different departments, to stimulate a race between them. A letter from the Managers and President, to departments free from accidents, also creates a desire to be free from accidents.

LINING UP AT STREET CARS

A crusade, to line up the men at the street cars, has been successful. It matters not how many thousands of workmen are waiting for the cars, you will find them lined up one behind the other. Our exhibit at booths 5 and 6 contain pictures of this system in operation.

CONCLUSION

Gentlemen, I do not wish to burden you with a lot of ideas which you no doubt have had experience with, but I do feel that if you are to be successful in educating the workmen in Safety First, you first must have ideas that will seem reasonable and practical to them, and make them see that safety is to their advantage.

Universally, you will find that men are reasonable and will cooperate in any movement that is beneficial to them, if they only understand it to be such.

This is why Safety Education is absolutely necessary. You will succeed in the same degree as you are successful in presenting your ideas to the men in a way readily understood by them.

Before we give a rule book to a workman and allow him to put it in his pocket, the foreman first reads over all the rules to the man. If the man understands these rules, is willing to live up to them, he signs his name and badge number on a detachable section which is torn off and filed at the foreman's desk.

The foreman will cooperate in safety, but he must have absolutely a fair and square deal. The men who cooperate in safety must also have a fair and square deal. For instance, if you have an accident, it is a disgrace for the company to allow that man to say, "The foreman has never told me anything about my particular job." On the other hand, the foreman can say, "I talked these things over with you; read the rules to you and you said you thoroughly understood them. You signed your name here, which implied that you would practice and live up to these rules."

It doesn't mean that you have anything on the man in a legal way by which you can take his compensation away, because I wouldn't dream of such a thing. It is just a backing to the foreman.

I have heard so much about saws. We have a few rules on saws; not many, but just a few that a fellow will read. They do not tell the size of the shaft and saw, or a lot of stuff like that, but they tell about saw guards and a few other things of importance.

Our largest rule book is labeled, "Safety on Cranes and Elevators." We have put in here the safe load for manila rope and the safe load for steel cables, for an operator should know what his cables will stand.

Another rule book is, "Safety Rules and Suggestions for Shipbuilders." When those shipbuilders got started and had twenty boats under construction it was like a sham battle, only they weren't using bullets. After six months of education we had a reduction of 75 per cent in accidents.

We also have a few rules for the crane operators, which are placed up on the frame in the cab, so there is no question about their not having seen the rules.

On every crib in the plant we have three styles of goggles. If a man goes on a job where there is light dust, he picks out the light goggles. Where there are heavier particles flying around in any operation, of course they choose the heavier goggles.

The rule book we got out on punch presses tells how to put the hands on the machine. It also gives other details, and it certainly hits the nail on the head.

I think that moving pictures are very effective. The men will see themselves in the picture, and if you make it just a little bit humorous, so they will poke their neighbor in the ribs and have a good laugh, it will have a more lasting effect. They go home and tell their wives about being regular actors, and you know how that stuff goes. The wife will have to come and see the picture too, just in order to see her husband on the screen.

And then you can supplement the pictures with a short, snappy talk, telling the men it is part of their work to make the safety plan a success. At each meeting drive some one point home. Do not try to give a bunch of thoughts in your talk, but make one point conclusively and let your pictures do the rest. Then the next night make another point, and so on.

CHAIRMAN LYNCH: Gentlemen, it is necessary to appoint a Committee to nominate your officers for the ensuing year. I will appoint on the nominating committee, Mr. Michael Barratt, of the Michigan Bolt and Nut Works, Detroit; Mr. F. X. Wells, of the Packard Motor Company, Detroit; and Mr. J. H. Goldie, of the Cadillac Motor Company, Detroit.

Adjournment.

FRIDAY MORNING SESSION

THE meeting convened at 9:45 A. M., Mr. James J. Lynch, of the Chevrolet Motor Company, New York, presiding.

CHAIRMAN LYNCH: The first number on the program is a paper on "Employment and Safety," Mr. E. F. Blank.

EMPLOYMENT AND SAFETY

E. F. BLANK, MANAGER OF EMPLOYMENT AND SAFETY, BUICK MOTOR CAR COMPANY, FLINT, MICH.

The subject has a number of different angles, but I am going to deal more particularly with the relation of the Employment to the Safety Department. Few safety men realize the accident prevention work that can be done through the Employment Department.

Safety work should start with the new employee when he is selected and assigned to his job. The qualifier should consider carefully the type and size of men he is dealing with, and whether they are mentally and physically equipped for the position.

PHYSICAL EXAMINATION NECESSARY FOR PLACEMENT

The man should then be given a thorough physical examination, and should any defects or deformities show up that could disqualify him for the position to which he has been assigned, he should return to the

qualifier for better placement or rejection. For instance, if you should have an applicant who was subject to epileptic fits, you wouldn't want that man operating a crane or some power driven vehicle where his own life and that of others would be in danger. Or if it should be discovered that he had the sight of only one eye, you wouldn't place him on a job where he would be liable to lose the sight of the other eye, or where he would be liable to injure or cause others to be injured through his inability to judge distances accurately.

These are merely some examples of what we encounter in placing the new employee on the right job. The new employee seldom realizes how much has been done for his own safety before he has reached the job on which he is to work.

I have a few figures which might be interesting to you. Out of 20,000 men examined at our plant in 1918 there were 17,839 defects recorded. This in itself, I believe, is convincing evidence of the necessity of physical examination. There were 631 rejections during this period, and 712 applicants put to work under observation of the Medical Department. The percentage of rejections was very small but when you stop to consider the conditions in 1918, when we were short of men due to war work, when we were practically hiring the lame, the halt, and the blind, you will wonder why we rejected as many as 631. The physical examination is absolutely a safety measure, and should not be overlooked. It is one of the most absolutely worth-while propositions in connection with employment and accident prevention.

Most industrial concerns give out books of rules and instructions to their employees. These books should really be given out by the Employment Department right at the time the man is hired. A few signs or slogans on a bulletin board well appointed in the Employment Department will have a good result. The first impressions are the most lasting.

INSTRUCT NEW EMPLOYEE IN SAFETY

The new employee should be impressed with the fact that he is entering a factory in which everything possible is being done for the safety of the men, and that his help is needed to make this factory a safe and healthful place in which to work. Statistics show greater accident rates from new employees than from old men, therefore particular care should be taken in the training and instruction of the new men. The employment manager as well as the safety engineer is interested in this because a large percentage of the labor turnover comes from men of less than a month's service. A great deal of this can be traced to inadequate means of training, instruction, or supervision right at the start.

Some of you have training schools for instruction, but most of us rely on the foremen to instruct our new employees properly. The foreman's position is a very important one in any organization; he must be human and patient; he must understand human nature, and possess that personal touch that will win the friendship and confidence of his men.

If your new man is entrusted to a job, be sure that he is qualified to do that job. He must realize the importance of proper training and his

INDUSTRIAL RELATIONS DEPARTMENT

responsibility in that position. Some foremen are better fitted than others to do this training work, and to them this should be assigned. It is very desirable to make a good safety man out of your job setter or assistant foreman because he is closer to the men and they feel that he is one of them. No matter who the instructor is, the job of training is a mighty important one, and it should not be slighted. It is your best chance to make the new employee a safe and steady worker for your organization.

Most plants have well defined safety organizations. The safety engineer or the safety director is expected to work out means of reducing accidents, just as the employment manager is expected to reduce the labor turnover. The problems of the safety engineer and the employment manager are identical, inasmuch as their greatest problem, I believe, is the gaining of the cooperation of the foremen. This is purely a matter of education.

You must win the foreman's confidence, in order that he shall know that your recommendations for a change of operation or the installation of a guard or device is for the best. He must be with you heart and soul in order to make the operation successful. You must sell yourself and your recommendation or suggestion to the foreman on the job.

And so it is with the employment manager. He must have the utmost cooperation and confidence of the foremen in order to be successful in his work. He must be close enough to the foremen so that the latter will help the employment manager, through proper training and instruction and supervision, to hold the employees on the job.

INDUSTRIAL RELATIONS DEPARTMENT

The Industrial Relations Department is a department of service. The success of this department depends entirely upon cooperation. Each sub-department, whether employment, safety, welfare, or what not, has a distinctive service to sell, and your job and mine is to sell that service. The method of selling depends a great deal upon the make-up of your organization, and the policies of the management.

Good results can be obtained through foremen's and superintendents' meetings. By calling the foremen together periodically their interest in safety work can be stimulated. And if the different departments are properly coordinated one with the other, the employment manager or welfare director can take advantage of these meetings to drive home the important points concerning his work.

Shop publications are an excellent means of getting your message before the employee. A good deal can also be done by maintaining personal contact with the employees and the foremen. You must be sales engineer as well as safety engineer, and if you are part of a well organized industrial relations department with a well defined sales policy, you will find no trouble in selling the service which you have to offer.

DISCUSSION

MR. A. H. BISSMEYER (Cincinnati Milling Machine Co.): Mr. Blank spoke of employing defectives. I would like to know the practice of the

Buick Motor Car Company—do they employ an applicant who has epileptic fits?

MR. BLANK: We have some epileptics in the plant. We are not making it the policy to hire them, but there are certain jobs where you can place such men, on bench inspection, etc., where they won't be in danger of injuring themselves any more than they would be on a farm or anywhere else.

My statement was really an exaggeration to bring out a point. We hire epileptics only in exceptional cases where a man is especially qualified for some particular line of work. Of course, if his spells are frequent we do not hire him. There are certain places we have such men at the present time, but they have to be well placed.

CHAIRMAN LYNCH: Do you have any method of taking care of men who are defective?

MR. BLANK: We have some in the shop who give us some trouble once in a while. We have a man running a lathe who has thrown a fit a couple of times. Now, it seems to me in the larger shops the man is confined more than in smaller ones, and in the latter case he can get around and he is liable to get into some trouble more than in the former instance.

MR. R. A. SHAW (Ford Motor Co., Detroit): This brings up a topic that is very human, and it is a thing I think all industries must take part in. If every firm would take in one new man who is subject to epileptic fits, it would be a fine thing, but if several reject them, then, some firm that has a big heart has to make a special job for those men.

MR. E. B. CASE (New Departure Mfg. Co., Bristol, Conn.): I would like to inquire of Mr. Blank what the percentage of turnover is under his system.

MR. BLANK: Our percentage for 1918, of course, ran pretty high, due to war work, but at the present it will run around 100 per cent. We keep a weekly tabulation and a monthly summary.

MR. WM. POWELL (International Harvester Company, Chicago): I'd like to ask Mr. Blank to describe the manner of introducing the new employee—that is, after he has been hired, up to the time he reaches his place of employment.

INTRODUCING THE NEW EMPLOYEE

MR. BLANK: The new employee comes into a waiting room and is interviewed by an outside interviewer. This man turns away any one he knows is not qualified to fill any positions that are open, and either a record is made of his qualifications, or he is told to return at a certain time. If he is found to be a man we can use at that time, he is passed on to the qualifier inside who assigns the man to his work. He then goes to the physical examiner. Should he be found by the doctor to be, through physical reasons, disqualified to go on the job, he is returned to the qualifier. This brings the doctor and the selectors close together. If the qualifier explains to the doctor the nature of the work (the doctor isn't supposed to know everything about the shop, but of course

they know more than a lot of other fellows in the organization) and the doctor thinks the applicant can do the work, he will pass him.

Then the man, if he is hired, is passed on to the write-up, where he is assigned his work and a record is made for the pay roll, etc. In our plant he is then delivered by automobile to the factory to which he has been assigned. We have thirty-nine factories and they are scattered over a good deal of ground—all in one bunch, but spread out over a plot one and an eighth miles long and six blocks wide.

So he is delivered by automobile to the head time checker of the factory in which he begins work, and is there entered on the roll and signs his clock card, and is delivered to the foreman on the job. Then our man from the employment department gets a receipt from the foreman or the departmental clerk. So he is passed along out to the foreman who meets him personally, and the man either goes to work immediately or comes in the next morning.

CHAIRMAN LYNCH: Do you give these men any safety instructions before they go to work?

MR. BLANK: Only our Rules and Regulations book is given them there. We do not give any general safety instructions at the employment department on account of the varied work to which the different men would be assigned. It could be done to good effect in a general way, however, and when the man reaches the job have the foreman explain the specific dangers of the operation he is to go on.

MR. E. B. CASE: I believe it is an important safety measure that when a man is employed he should be taken by the runner, or whoever takes him to the foreman, to the gate by which he is to enter the plant. From there he should be conducted to his place of employment by the most direct and safe route, and the possible dangers explained to him on the way. Then he should be formally introduced to his foreman.

Mr. Blank lays particular stress on selecting men who are qualified for the position. I'd like to ask to what extent he is able to select men who are qualified for certain positions in the factory.

MR. BLANK: Ordinarily by trade questions, cross examination, etc., the qualifier can pretty well tell whether the man is telling the truth. In fact, that is what he is there for—to read personality—and if the man is telling something that is untrue, why, he can usually catch him in some way. But there are cases that get by. I imagine practically every employment department has had instances where the man, when he got out on the job, got cold feet and admitted that he was not qualified for that position.

MR. GLENN BYERS (Corn Products Refining Co., Granite City, Ill.): I would like to ask Mr. Blank how much time is consumed in placing the man on the job under his system.

MR. BLANK: From the time the man is called in it does not take much over fifteen minutes. We have a stripped examination, of course, and that takes a little time for disrobing and dressing again.

MR. A. C. CLARK (Delco Company, Dayton, Ohio): I'd like to ask Mr. Blank what action his company takes in regard to defects that are

detected after the man becomes an employee of the company. Suppose, for instance, he develops a venereal disease—what do you do in that case?

MR. BLANK: Once in a while it comes back, and, of course, that man is referred to proper medical care.

MR. CLARK: Suppose he gets a disease while an employee of your company?

MR. BLANK: In that case I imagine the doctor would request that we lay him off until he is properly able to go to work again. We don't have a re-examination except in case of transfer, and of course it would be disclosed at that time. If it were, he would be sent home until such time as he would be able to function properly on his operation.

MR. CLARK: After a man is employed is there any follow-up as to whether he is satisfied with the job? Does any one from your office pay him a visit to see that he is acquainted with his fellow workmen and is getting along well on the job? That is the method we pursue. We have a man who does that in addition to his transfer work. He gets a list of the new employees and makes a visit throughout the factory, and he makes it his business to grab the new man by the hand and see that he is acquainted with the man next to him. He asks him whether he is perfectly satisfied with the job, and so on, and we find it a good scheme because then the fellow doesn't think as soon as he lights on the job he is forgotten, and in a great many cases we find that the man working next to him is a fellow with his ears pinned back who doesn't pay any attention to the new man. And so when the man from the employment department goes up to him and grabs him by the hand and wants to know how he is getting along he feels there is a warm spot down there and that he hasn't been forgotten.

CHAIRMAN LYNCH: That's a fine idea.

MR. BLANK: How many do you hire a day?

MR. CLARK: We average about fifty to seventy-five, and possibly over that.

MR. BLANK: He has quite a job.

MR. CLARK: Yes, but he gets away with it.

MR. G. H. HAWES (O. J. McQuiston, Inc., Detroit): Mr. Blank, I'd like to ask if the book of rules and regulations which you hand your new men are printed in any foreign languages.

MR. BLANK: No, sir. There is only one language in the United States, according to us.

MR. GLENN BYERS (Corn Products Refining Co., Granite City, Ill.): If you want to reach the foreigners it would be a good idea to get text books and have them attend school, but your safety literature should be printed in English only. That is the way we are doing it.

MR. F. A. FREDRICKSON (Industrial Commission of Wisconsin, Madison, Wis.): I'd like to ask Mr. Blank if there is a discrimination as to wages when you find some of these physical defects on the employee.

MR. BLANK: Not according to our system of assignment. If a man is assigned to a certain job, he is able to do that job with a hundred per cent efficiency, as far as physical fitness is concerned. If he wasn't, he

wouldn't be assigned to that job. He'd be assigned to some other, or else rejected.

MR. FRED HAZEL (O. J. McQuiston, Inc., Detroit): I'd like to ask Mr. Blank what form of records the medical department keeps on applicants for employment, and to what extent they are used after the man is put to work, and are they used for any future reference with regard to his safety qualifications for the purpose of replacing that man or promoting him to any other position?

MR. BLANK: That medical record has nothing to do with promotion except in case he should ask for a transfer, we would refer to his card and find out what his physical examination showed up. If there was some defect which might prohibit his transfer to that specific operation his card would show it. Of course, he'd probably be given a re-examination, and if it was deemed advisable to put him on light duty or outside work, why, we would transfer the man on the physical record.

SECRETARY HOWE: When a man is introduced to the work do you have instructors there to break the man in to the job?

MR. BLANK: There are certain men assigned to that work in each department, and they do that along with the other productive work. Usually, the man who introduces the new men to the jobs is the assistant foreman or what we call the "job setter".

SECRETARY HOWE: Does that assistant foreman train the man along safety lines while he is working on the job, or into the job? Is that a part of his duty?

MR. BLANK: Yes. He points out the way to the new man. And we get in contact with the foremen doing this work through the foremen's meetings, and by the safety engineer talking with these foremen at these meetings he can get over any message he wants on instruction and training.

The line of instruction isn't exactly the same in every case, because your job is different, but the man who is breaking the new one in, points out the specific dangers of the particular operation, whether it is a lathe, drill press, or some other machine, or even if it is in handling stock.

CHAIRMAN LYNCH: Gentlemen, I'd like to close this matter and take up the next talk. We sent a letter to each member of the Automotive Section asking them to send in their opinion on the standardization proposition, and as a result a great many letters were sent to Mr. Goldie. In fact, he wrote me and said that he had too many letters. Everybody seemed to be interested in the matter.

I want you to pay particular attention to this, and this is the matter I had in mind when I suggested the resolutions and the committees for following out the work. A resolution at the end of this paper, if you gentlemen see fit, or a motion to appoint a committee for the purpose of putting through a resolution I think will be in order after you have heard Mr. Goldie. Gentlemen, I take pleasure in introducing Mr. Goldie.

STANDARDIZATION OF GUARDS (EXPERIENCE OF THE
AUTOMOTIVE GROUP)

J. H. GOLDIE, CADILLAC MOTOR COMPANY, DETROIT, MICH.

The thing that Mr. Lynch and I were interested in on this particular question was the movement, as you know, to standardize by either federal or state statutes the building of guards, and the applying of guards to machinery. I have come in contact a good deal with state boards and with courts in the matter of accidents, their settlement, causes, and compensation laws, and I have been inclined to think that on the whole it would be impossible to make any standard reasonably applicable.

REASONS FOR NOT STANDARDIZING

There are two or three reasons for that. I think the biggest reason (with all due respect to the gentlemen who are sitting here from the Wisconsin Industrial Commission, and I understand there are some other state men here) is that we have often placed upon our state boards for factory inspection service men who are not qualified, because they are placed there purely from political connection. Just a few days ago a factory inspector came into my office and wanted to talk to me about guards. The man had never been in a factory in his life; knew nothing about mechanics, and the only job the man had ever had in his life was that of a carpet salesman for a wholesale carpet house. That man was on the job because his brother-in-law happened to be at the head of the factory inspection service of the state.

That is one of the biggest objections, men, to standardization—the fact that it is so absolutely impossible, due to our political machinery, to get fully qualified men on the job to interpret these statutes with reference to standard guards.

I think the second big objection would be the attitude of the employer. I know that I have felt, and I believe that a lot of you men have felt, that the employer is beginning to see he must do safeguarding because his pocket-book has been hit by the Compensation Act. I will grant that is true in a lot of cases. I do know, however, in a lot of cases the employer has gone ahead with safeguarding and humanitarian methods because he wanted to keep his men from being hurt. But if it is true that men are being compelled to guard because of the necessity to save money on compensation, those men are going to look for every possible loophole to get out of putting a guard on a machine.

I believe that most of you men who come in practical contact with the guarding proposition will agree with me when I say the biggest loophole they find is that the guard is impractical, that it can't be put on, that it is going to tie up production, or the physical circumstances are such that it can't be done.

Now, I am here to say that if you have a standard specification made by a federal or state statute, you are going to have one fine time to get the man to put it on unless the state or federal officials are around to

jump on his neck. I think that is where the biggest objection is going to come.

Now, if that same manufacturer can have the service of a trained safety department with men of mechanical ability, with men who can work with him, and even adjust, if necessary, a different system of production in the department, so that a guard can be put on the machine to make it safe in the opinion of the trained safety man, then I think the real object of safety work has been accomplished. The men who must work around that particular guard are protected, and I don't believe that there is any necessity in this case for any specified guard.

Perhaps this discussion arose largely from the recommendations that have been made in numerous instances by insurance companies and state officials and some long-haired men in safety work, that a guard on a vertical belt should be six feet high, or six feet six inches, or something of that sort. Mr. Shaw says it is just as reasonable to say ten. I have seen in my limited experience in observing these things, guards four feet from the floor that I can't help but believe were perfectly safe from the standpoint of hazard from the moving belt.

There are other guards that have been suggested on pulley and horizontal belts. Some years ago I had an argument with a certain manager in our plant with reference to the guard on horizontal belts. He couldn't see any sense to it anyway; it was all foolishness! Just about the time we were having our argument a first class man in our millwright department walked down the passageway between a row of machines, when one of the metal fastenings on the belt came apart and gouged an eye out. From that time we didn't have to argue metal guards on horizontal belts.

If somebody sat down and attempted to standardize the proposition, there would be absolutely no limit upon the number of operations upon which standards might be set, and no limit upon specifications that might be made. It would be absolutely unworkable in the ordinary plant. We in our own company are looking forward with a lot of hope to the day when we shall be in a new factory where we will have everything done to the last word in factory machinery, belting, and working conditions, but if any of you men would come over to see us at the Cadillac factory now, the small number of accidents would seem unbelievable when you consider our working conditions. We have men working where machines are so crowded that you wonder how they ever get by at all. If we didn't keep on the job at all hours with safety inspection and with the installation of guards, and all this with the backing every single minute of the plant management, we wouldn't be able to keep from killing men every day in the week. But if you are to say to your management today that they have to put on a certain guard because the state law says so—well, I know what we'd be up against.

OPPOSED TO STANDARDIZATION UNDER FEDERAL OR STATE STATUTE

I believe this group could well go on record as being opposed to standardization under federal or state statute. I do think, however, that with the movement on foot in the National Safety Council at the present time for the establishment of an Engineering Section, it may be possible for

our group to work with this new Section, to have adopted by the Council, if you desire, a standardized guard system as recommendations of the Council or of this group, or both, but not as a must-be-done proposition by any state or federal board.

I find that the insurance companies, on the whole, are very glad to follow the recommendations of the National Safety Council on guarding. And I think the average insurance company is willing to follow the recommendations of a good, safe, sane bunch of engineers, although some of the insurance companies are not giving credits on ratings in some states where there is a standardized guard statute at the present time, if the particular employer or manufacturer does not live up to the standard set by the state.

Most of you men who come in contact with the new machine that comes into your plant have discovered that sometimes a lot of them come guarded to a reasonable extent, but in a lot of cases the guards applied by the manufacturer of the machine are not the guards that your own safety organization would recommend. For that reason I say if we have a standard of guards set by the Federal Bureau of Standards and by the state boards, you will have to make it so general and so absolutely applicable in the case of every manufacturer of machinery as well as every user of machinery, that it seems to me absolutely unworkable, because if the manufacturer goes ahead and puts on a lot of guarding on his machinery and charges it to the purchaser, the purchaser is going to be up in the air about it when the machinery is delivered to the plant and he finds that the machine with guards attached is not suitable to the particular operation for which it was bought.

Mr. Lynch was kind enough to remind me of a statement I made about getting too many letters. I didn't get too many, although I told him I was swamped with the number of replies I got to the letter which he sent out with reference to the opinion of the members of the Automotive Section on standard guarding.

I am not going to attempt to take up all your time with reading all these letters, but I want to read extracts from letters that came in from fellows on the firing-line. I say that the only way to get this thing ironed out is to get a real idea of how it should be handled from the fellow who not only has to put the guards in, but who has to fight the management all the time, or argue with the management as to the merits of the guard and whether or not such guards can be purchased or applied.

OPINIONS OF MEMBERS OF AUTOMOTIVE SECTION ON STANDARD GUARDING

Here is a letter from an automobile parts company. I am not going to mention these names because some of you might be embarrassed:

"It is our recommendation that a committee be named representing the tool builders of the country, who will assist with a practical outline for guards that will be effective and that will conform with the general design of machine tools, rather than put on some makeshift guard which is usually ordered by the state board."

I don't quite agree with the makeshift proposition, but I do think that

the recommendation that the matter be passed upon by tool builders falls in line with the recommendation or the thought in the back of the heads of most of the fellows who have been thinking on the subject that the matter ought to be recommended by some men who are really qualified to make the recommendation, and that it ought to be a recommendation and not an order.

Here is a company that uses a lot of gear machines:

"Many of our machines, the Gleason gear cutting machines in particular, have a cast iron guard which closes the pulley vent, with slots at the top for allowing the drive belt to run through. We have the type of guard necessary where a machine has to be adjusted by hand, but the commission (New York) would not accept the guard as standard."

Another member writes, with reference to the United States Government standard for these guards:

"We sincerely hope that it will not only work in conjunction with the National Safety Council, but give the matter serious consideration with the idea of standards that are practical, so they will not work a hardship on either the operator or the manufacturer."

That is the idea of every man who comes in contact with this particular subject—to have the thing made reasonable, so that it will be workable. That is the big trouble that is likely to result if we have to leave it to some highbrows on standards, rather than practical men on engineering problems.

The works' manager of another large company, after discussing a lot of the guards which are not practical, makes this remark:

"It has been rather a hobby with the writer to be a step ahead of the game, and we are very proud of some of the remarks and decisions made by the Safety and Health Inspection, and also the Compensation Board of our state in regard to the conditions in our factory. But it is the writer's belief that standard guards cannot be made except as adapted to particular types or sizes of machines for guarding in the proper manner; that is, that while a cylinder grinding machine is used only in the front, the feed and pump mechanism in the back is free, and consequently presented to the aisle as a source of danger to passing operators, but the makers while guarding the wheel do not feel it is necessary to guard the back part of the machine.

"You will certainly have our hearty cooperation in any steps taken along the line we have indicated. We believe that considerable could be done in the education of inspectors by placing them upon merit, rather than political preference or reward."

That didn't happen in Michigan; nor in Wisconsin, either.

"The state factory inspectors do not visit on the average oftener than once in one and a half years, and from my past experience with them they are very lenient. They have not as yet required any guards installed prior to the adoption of the trade regulations to be changed to conform with present regulations."

That is to their credit. A very good letter was received from one of our members who evidently made an exhaustive study of the subject of

standardization. I am sorry the gentleman is not present. I understand he is in another section.

"My first criticism of standard guards is of the term itself, or the promiscuous application of that term to various parts or to individual sets of specifications. Guard specifications in general are subject to such frequent alterations and revisions that even at the present time the term "standard" in this connection is used in anything but its accepted sense. In consequence of the revisions an undue hardship is imposed on the well meaning and honest industries to comply with the unusual rigidity, and it makes it necessary to rebuild a disproportionate number of apparently adequate guards.

"At the same time, the inflexibility with which these specifications are applied by those administering them leads to a great waste of material and labor in constructing guards of disproportionate dimensions, merely for the sake of compliance, rather than for the fundamental reason of protection."

Now, men, there is the whole argument in a nutshell against standardized guards. Guards will be built merely for the sake of compliance rather than for the fundamental reason of protection. I think that the experience of the Automotive Section, and the experience of the National Safety Council as a whole in the work done by the members of the Council on accident prevention, is that the spirit rather than the law has been working on the matter of guarding. I think it has been done from the humanitarian standpoint as much as, if not more than, from the standpoint of the saving of dollars and cents. That man goes on to say:

"It seems to the writer that the matter of standardizing guards without reference to standardizing the equipment is a proposition, to a great extent, like putting the cart before the horse. In that even in the individual plants great variations of construction exist in different places of equipment designed to perform the same operation."

That is true in a lot of our plants where even the physical conditions are different in the same plant. I know in our own plant we have crowded machines into such positions and driven them in such a way we wouldn't even think of doing if we were operating under different physical conditions in the plant. He continues:

"With this in mind, the idea of attempting to disregard not only individual difference of construction, but plant differences as well, seems rather far fetched. It would seem that the installation of inflexible specifications by the state or insurance carriers was an attempt to place not only the burden but the expense of adoption on the industry rather than on the state or insurance companies. It also seems it is an attempt to place the industry at a permanent disadvantage in respect to compensation for injury by unguarded machinery, in that the state or insurance carrier has constant recourse to the technicalities of standard construction as a defense."

Another: "Our experience has been that a guard necessarily must be constructed to fit the situation in hand. So far as is practical we have aimed to standardize all the guards used."

I believe that is the experience of every man in the Automotive Section

—make the matter practical, and get it as nearly the standard as possible. I might speak of just a little experience in our own company. We have been attempting to design and work out some system of standard guards on grinding wheels and buffing wheels, and through the assistance of our friend Mr. Shaw and some of the ideas that we have been able to steal from some of the other fellows, together with the ability of our good safety engineer, we have worked a standard guard, and while it does cost a lot of money to build the first few guards, the company works' manager was very heartily in favor of using them.

This extract comes from a letter from the superintendent of the plant of the Sterling Motor Truck Company:

"We have not been hampered very much in making our guards to certain standards, either by the state or the insurance company. They only give us a few fundamental rules which any one considers in making an efficient guard, and I personally believe they should be made to suit individual needs."

I think that is a mighty fine tribute to the gentlemen from Wisconsin who are here today.

The assistant general manager of the General Motors Truck Company has this remark to make:

"To sum up the guarding of machinery, we find in our case it is necessary for us to study our requirements and arrive at what we believe to be the best each time a guard is moved."

There is the point again by a man who has had to deal with it in a great many instances.

Here is a paragraph from a letter received from the Underwriters Laboratories:

"It naturally follows that standardization should have consideration in connection with the production and use of any mechanical appliance; that development is but the outcome of natural economic laws and possibly the application of Darwin's theory of the survival of the fittest. Nevertheless, authorities in enforcing the use of devices should refrain from pursuing the course of bringing about actual standardization as to form and character of appliances used.

"We attribute much of our success in the past to a policy rigidly adhered to of a standard of performance rather than specifications as to design, material employed, etc. To pursue any other course results in throttling development, and while on the surface standardization appears to have become necessary, it is a fact that standardization in results is the primary object of interest to the users and to regulatory bodies."

I have just given some of the points developed in the letters received in reply to Mr. Lynch's circular. The whole object of my taking this subject and the whole object of talking as I have and reading the excerpts from the letters received is to start a discussion from the members of the Automotive Section. If we are going to make this an experience meeting, the only way is to have everybody shoot questions just as fast as we can so that we may have some new ideas on the subject, or ideas perhaps opposed to some of these I have attempted to bring out.

CHAIRMAN LYNCH: Gentlemen, Mr. Goldie has been extremely inter-

esting. I am sure you will all agree. There is one point that hasn't been brought out I wish you gentlemen would discuss. If any of you are from New York state and know of this experience, kindly bring it out. Sometime ago the standard guard in New York was 5 ft. 6 in. That was passed on by the Bureau of Labor. The rating board accepted that as a standard and gave a credit for it.

A year or two later they passed a new standard guard of six feet. When the inspector got on the job he looked in his book of standards for the rating schedule to compare with the standard guard that had been applied a year or two before. He saw that the old standard guard was not six feet; it was six inches short—not standard, no credit.

Gentlemen, discussion is in order.

DISCUSSION

MR. J. A. DICKINSON (Bureau of Standards, Washington, D. C.): There is no intention on the part of the Bureau of Standards, nor has there ever been, to put through any codes by legislation. In the first place, we don't believe it is a government function. We don't believe that using the club is the proper idea.

The Boiler Code Committee has shown the proper way to handle standardization, and that is to make it so good that the states will be forced to it. The A. S. M. E. Boiler Code is today undoubtedly the best boiler code ever published, with the possible exception of the Ontario Boiler Code, which is copied very largely after the former with a few added requirements.

About four years ago the Bureau of Standards started in coöperation with the electrical engineers and the underwriters and a dozen different associations to produce an electrical safety code. That code today has been revised twice and is just about ready for publication. In spite of the fact that it has never been officially published there are in the United States today no less than eight states that have made that a law. By making your other codes equally good you will force their adoption by popular demand for them.

There is one thing on which I believe Mr. Goldie will agree with me, as a good attorney, and that is the fallacy of attacking a standardization code, or law because its administration is poor. The code should not be forced upon the people in an ironclad, stereotyped form, but with good common sense, and it takes men of experience to administer it and make the necessary waivers and exceptions where the demands arise. No inflexible code can be made. It is a physical impossibility. But you can make a code that will apply in eighty or ninety per cent of the cases that will save thousands of dollars.

There are a couple of points Mr. Goldie brought up that I am might glad to see. One was the question of the manufacturers not building standard guards. How can they build a standard when there is no national law to build on? The manufacturer will build a guard that will take care of the hazard in a large percentage of the cases. Guard machines are coming. We have to do something to meet the competition.

of the other fellow. And we will put on some sort of guard that perhaps won't pass, so we will have to tear it out.

Mr. Goldie has pointed out that guards should be fitted by experience, and yet he goes right back on his own assertion, stating that in their new factory everything is going to be the last word in guarding.

I am speaking from eight years' experience in the safety field, as a practical safety man, and you will find that most of the men in the Bureau of Standards are men of that type. My contention is that until you have covered your obvious hazards and shown your workmen that you are really trying to take care of the mechanical hazards, you cannot get your educational work started.

CHAIRMAN LYNCH: These things I hold here are a tentative program you are getting out; recommendations that haven't been adopted yet. I think you show 6 ft. 6 in. on the belt guard.

MR. DICKINSON: That is a tentative draft that was drawn up last June. There has been no real work done on that machine guarding code yet.

CHAIRMAN LYNCH: Then will your committee consult the Automotive Section regarding their wishes?

MR. DICKINSON: We certainly will be glad to cooperate in every way.

EXPERIENCE OF BUICK MOTOR CAR COMPANY

MR. R. F. THALNER (Buick Motor Car Co., Flint): Regarding education and safety work, I believe, myself, that machines must be guarded before we can carry on our educational work, but I'd like to cite the instance of the Buick Motor Company in Flint. Some years ago a recommendation was made to have six-foot guards installed throughout the plant where the man who recommended them thought they were necessary. The result was the guards were made up and installed.

The installation of those guards created more discontent among the men and hindered the safety movement in general in that plant more than anything else that could have been done, because guards were put up that were impracticable. As you were going through the factory the men would say to you that the guards were a joke. Now, a guard that is built so high, past the point where there is no danger, will naturally be taken as a joke by the men in a movement of this sort.

The quicker we can get the men out in the plant to use our appliances, our guards, the better it is for us, and that is the only way we can get something that is practical. The trouble with these high guards is that when machines are moved they will not suit the new condition. I have found that to be true especially during this period of movement since the war work is over and machines can be put back into their old positions, where the large guards which formerly suited the purpose do not conform to the new conditions of the machine when set up again.

In my estimation, the only way to protect against that is to make a guard that is adjustable on the machine and does not have to come up to an ungodly height. In my mind, I think the issue at hand this morning is whether guards should be built a standard height—not the standardization of guards, but the standardization of height. We might stand-

ardize guards, but to standardize guards with respect to height, I think is something that is out of the question.

MR. C. D. BANKS (Michigan Mutual Liability, Detroit): Mr. Goldie's remarks which he dug out of that voluminous correspondence reflect our opinion (speaking for the insurance company I represent) that standardization on most guards is impossible. That has been our experience.

Perhaps some of you remember yesterday that I got up here and questioned somebody about a punch press proposition. Somebody here said that if a punch press broke down four things had to happen to it, and if any of those four things didn't happen to it, why, they couldn't be injured. I took exception to that, and he told me that "Seeing was believing." So I went out yesterday, and it was proven to me beyond any doubt that standardization of punch presses, anyhow on guards, would be impossible.

In their plant that man has about three hundred punch presses of every kind; some of them they made themselves; and when I tell you they are a hundred per cent guarded and they are not all guarded alike, and every one of them are fixed so they are foolproof, you can see how standardization of guards, at least on punch presses, would be impossible.

MR. H. KNOLLMAN (Maxwell Motor Co., Newcastle, Ind.): Have any of the men in the room any records of any men or percentage of men being hurt from a vertical belt that is four inches or under? We have been keeping records for six months at our plant and we haven't had a case of a man being hurt either on his hands or any part of his body from a vertical belt that is four inches or under.

It seems to me as though the guards on the Gleason gear cutting machine answer the purpose fairly well. I won't say that belts over four inches should not be guarded, due to the possibility of the larger belt hurting somebody, but vertical belts under that size I don't think need to be guarded, except at the pulley where the belt comes on.

ANALYZE THE ACCIDENTS

MR. E. J. CLARKE (General Motors Corporation, Detroit): We should analyze the accidents and apply our guards and our remedies according to what those accidents represent.

A state factory inspector came into one of our plants with nine hundred employees, and said, "You have to put up high six-foot guards." Sixty per cent of the employees were women and forty per cent men. I said, "Let us analyze this thing. Let us first find the necessity for changing all of those guards and putting up six-foot guards. Let's go down to the hospital where they have the records."

So we went down there, and found that in one year and three months (as far as we traced the records back) not a single belt accident had occurred among nine hundred employees in that plant. He said, "I didn't think such a thing was possible; that isn't the general rule." "Well," I said, "let us go into this thing along sane and sensible lines." So I took him to another plant where four thousand men were employed. In two years—the period for which we were able to trace the records—we found two belt accidents, both on overhead belts, on the counter shaft.

You can't go to the hard-headed factory manager and say to him, "Here, we want a contribution for six-foot guards around this plant." Time and again I have gone into the back yards of plants and seen truck-loads and carloads of six-foot guards. Why? Simply because the managers are antagonistic to it, and also you can't place a man on a machine to do piece work and then say to him, "You have to waste your time fiddling with that guard." He will steal that guard out from under your nose with the most adequate supervision. I have been in a plant where they have done it. In the Studebaker plant I have seen guards where the arms attached had been sawed off with a hacksaw, and there a man had plenty of time to saw them off despite all of their supervision.

What are you going to do with that kind of a thing? Can't you see that the managers eventually say, "Boys, this safety business is all bosh! We can't go on with it. It is cheaper to pay the losses." That is what you are confronting. What we want to do is to make this thing constructive and not destructive. There is a limit to everything. The extremest has no position in this field.

What brought forward this idea originally was the tendency on the part of the different states to run into the proposition of six-foot guards irrespective of the actual necessity for a guard.

MR. A. L. KAEMS (Industrial Commission of Wisconsin, Madison, Wis.): I believe the thing we should know first is: Where are our accidents?

In our state we don't insist upon the six-foot guard. We don't care anything about a six-, six-and-a-half-, or a seven-foot guard, as long as it takes care of the hazards.

MR. D. R. LIVINGSTONE (Reo Motor Car Co., Lansing, Mich.): Regarding the six-foot proposition, I feel a good bit like Mr. Clarke, and have worked along that line.

MR. G. H. HAWES (O. J. McQuiston, Inc., Detroit): I have a specific instance in mind that Mr. Clarke failed to recall which I think should be brought up, of a plant where we have so-called six-foot guards or unreasonable guarding going on throughout the plant. These guards ultimately reached the scrap yard and have been displaced with guards that are more sensible and more adaptable to the individual hazards of the different operations, and the actual cost in accidents in that plant per man employed has been reduced from 47 per cent to close to 4 per cent per man per month for accidents.

We feel that the reduction came not only through changing the guards, but through a greater sympathy on the part of the individual working man, and a greater sympathy on the part of the management and support, on account of the sensible, reasonable engineering principles applied to the individual hazardous conditions.

MR. GOLDIE: I feel today somewhat in the position of a boy who sticks a stick into a hornets' nest when he knew about what would happen before poking it in. I knew exactly what was going to happen when I made the remarks I did.

My friend from the Bureau of Standards got me wrong on some ideas. I am not at all opposing standardization. I am in favor of standardiza-

tion as far as it is reasonable, and as far as it is made as recommendations rather than made compulsory.

I would make this recommendation, and I think he will agree with me: That some of us fellows down on the firing line ought to be kept in touch with the work of the committee when standards are being worked out. The committee can get some pretty good ideas from some of the men who are right up against the real thing with the human element and with the mechanical element in the factory.

To start the ball rolling, I move you, Mr. Chairman, that a Committee on Resolutions be appointed by the Chair, to consist of three men (and I will put in that motion that I won't be on the committee) to draw resolutions giving the attitude of the Automotive Section with reference to the matter of standards, with the recommendations of this group both for and against the movement on standardization.

MR. DICKINSON: I would suggest that in addition to that, a coöperative committee be appointed. It is all right to outline your position on this movement. We are mighty glad to have it, but the fact is we want the actual active coöperation, because work on the code will probably be taken up fairly soon. Whether that will be sponsored by the A. S. M. E. or Bureau of Standards, I do not know. We are waiting until the formation of the Standards Association is put through to decide on the bodies best fitted to handle that. I rather imagine it will be the A. S. M. E., but in any event the coöperative group will be called together from all fields of industry. If you appoint a Coöperative Committee at this time I believe it will be worth while. I would suggest five men.

CHAIRMAN LYNCH: It is moved that a Resolutions Committee be appointed, as outlined by Mr. Goldie, to consist of five men, as amended by Mr. Dickinson.

(The motion was unanimously carried.)

EXPERIENCE AT NITRO

W. E. WILLIAMS,¹ SAFETY ENGINEER IN CHARGE, U. S. EXPLOSIVE PLANT "C,"
NITRO, W. VA.

When our Government decided to enter the war against Germany the providing of explosives was a subject that received considerable discussion and a lot of legislative action. As a result of the findings of the War Board it was decided to build a number of plants for the sole purpose of manufacturing various gases and explosives that would be required by OUR BOYS when they arrived over seas. Smokeless powder being essential to the elimination of the Hun, was one of the most needed of these explosives. As a result of this need our Government decided to build United States Explosives Plant "C" at Nitro, West Virginia.

The plant is located on the Kanawha River about fifteen miles below the State Capital, which is Charleston, and is surrounded by hills that

¹Mr. Williams was not present at the Session, but sent in his paper for printing in advance.

lend beauty to an otherwise, to some people, undesirable establishment. This plant was designed by the Graham, Anderson, Probst, and White Company of New York and the actual construction of the project was entrusted to the Thompson-Starrett Company of New York. These two companies, when operating on the ground, coöperated in the safe designing and building of this plant to the extent that accidents were mostly of a minor nature. The actual construction of this plant was begun when the engineers arrived at the site in December 1917 and the first building that was erected was the barracks for the housing of the workmen, completed January 1, 1919.

The conditions for building were not of the best. The ground was not in a fit condition to do much excavating, being subjected to the frequent attentions of Jupiter Pluvius who reigned supreme; and you can imagine what the men were up against when I tell you that this ground was mostly red clay. This clay was of such a consistency that for sticking to anything and everything it would make a celebrated glue look and act like so much water. The workmen wrote maudlin verse upon their working conditions and, if you will pardon me, I will attempt to give you a sample:

There is mud in your eyebrows,
There is mud in your nose,
There is mud in your hair,
There is mud in your clothes.
There is mud in your coffee,
There is mud—Gee, how it grows!
Where isn't there mud?—Nobody knows.

Yet—in spite of these conditions the workmen stuck to the job like true Americans.

Mr. Milo S. Ketchum, a noted Engineer whose works have been adopted as a standard by the engineering profession, received the appointment of Director of this plant and to him is due considerable credit for the safe manner in which the actual construction work was carried to completion. I wish to call to your attention the fact that the Safety Department was under the direct supervision of Mr. Ketchum and as a result of this arrangement, safety suggestions and devices were given the necessary authorization that would insure of their being carried out or installed whenever conditions warranted.

SAFETY ORGANIZATION

The Safety Department was designated by the United States Employees' Compensation Commission to administer the Federal Compensation law as applied to civilian employees and as a result of this arrangement a fairly large staff was necessary to handle all details in an efficient manner. The personnel of this department of Safety and Compensation was as follows: Safety engineer in charge, assistant safety engineer, three safety inspectors, one general inspector, chief clerk, two stenographers, one typist, two clerks; in all, twelve employees.

Safety Inspectors were provided with horses to enable them to cover the territory assigned them, which was about *two hundred acres each*, but even with this added facility they were kept busy from morning until night.

Inspection blanks were furnished to all inspectors and at the end of each day their reports were turned over to the assistant engineer who checked them for their practicability and later checked their installation. One suggestion only was allowed on each sheet, this sheet forming a complete record of the entire transaction, being dated with the day of the report, the date of the beginning of the work, and the date of its completion.

Each week a meeting was held in the safety engineer's office at which all the inspectors, the chief clerk, and a stenographer were present. The meeting was called to discuss the conditions and practices that required attention and also to give the Inspectors an opportunity to discuss any peculiar condition that existed in their respective territories.

Standard details were arranged and stairs, pits, wells, machinery, etc., were guarded according to the detailed plans that were designed for each building, the guarding being done *before* the building was turned over as complete. The proper place and time for the safe-guarding of all classes of machinery and buildings is when the plans and drawings for said machinery and buildings *is still on the drawing board*.

The buildings were checked for unsafe conditions before being turned over by the construction foreman, all safety recommendations being taken care of while the construction work was under way. One point that was very carefully gone into and that had a very beneficial effect upon the foreman was, that *we never made a suggestion until absolutely sure* that it would be practical and a material benefit. As a result of this method more than *ninety per cent* of recommendations made were carried to a successful conclusion.

RESULTS OF THE YEAR'S WORK

The final results of the year's work can be summarized in a few words as follows: The average number of employees for the entire year was 9,596. Of this number there was an average of 182 admitted to the hospital for treatment weekly with injuries such as wood splinters, scratches, contusions, abrasions, etc., instructions having been issued to the foremen to send all men to the hospital for treatment no matter how small an injury they received. The result was that only 414 infection cases were treated during the entire year. In other words we had only *eight* infections per week for a working force of *nine thousand* men or an average of *one per thousand*, roughly speaking.

The actual lost time days were 1,440 or an average of one-sixth of a day per employee for a period of one year, these figures based on an eight hour day.

METHODS OF SAFETY WORK EMPLOYED

The work of our safety inspectors was of a varied nature, in fact it ranged from the inspecting of water and sewer excavations to the inspecting of the erection of *two hundred and fifty foot* power house smoke

stacks. When the water works system was about to be started the inspectors were on the job to see that there were no unnecessary risks taken and due to their good work we are able to say that only one minor accident occurred and it involved no lost time. When the water intake was being built and the excavation had reached the stage where it was necessary to build caissons, the assistant engineer went with one of the inspectors to take a look at conditions. When I entered the air lock the foreman in charge, a genial Irishman by the name of Murphy, turned to me and said, "Hould yez nose and brathe tr-oo yez ears for if yez don't ye will be in the divil of a fix win yez get tr-oo." This was Murphy's way of saying "Safety first" and with his men he stood ace high and always got results.

The greatest contributor to the accident list was our old and familiar enemy *Nails Plus Carelessness*. In fact I might conservatively estimate that about 60 per cent of all accidents were nail injuries and our inspectors were ever on the job preaching the seriousness of the nail hazard.

Handling materials naturally was one of the contributing factors when you consider that there were more than four hundred buildings erected for the manufacture of smokeless powder. There were also erected 29 store buildings, 43 hospital buildings, and more than 1,250 bungalows for the workmen, in addition to which there were 90 residences erected for the executive officers making in all more than 1,800 buildings constructed in a period of nine months. This would average over six buildings a day.

Naturally you would expect to have a great number of deaths in an enterprise of this magnitude, and you will no doubt be surprised when you are told that there were only eleven deaths due to accidents during the entire year ending December, 1918. One method employed to educate the men in the safe way of doing their work was the use of some good bulletins. We had scattered around the plant some forty bulletin boards that were equipped with removable fillers, these fillers being made removable so that they could be prepared in the office and then the inspectors could take them to the bulletin board to which they were assigned. The system we used required the bulletins to be changed daily. We would start a bulletin in box No. 1 and the next day transfer it to box No. 2. From box No. 2 we would then transfer the same bulletin to box No. 3, and so on until that filler was returned to the office. We used National Safety Council bulletins and also others that we designed ourselves. The latter usually pertained to accidents which occurred on the plant, or to conditions which existed here, and these seemed to make a hit with the men as they were often personally familiar with the topic.

I had opportunities to speak to the men on several occasions, and during the summer of 1918 had the good fortune to be able to take a hand in getting a band together that could play fairly well. We would start for a certain point and play a march or two; when a goodly crowd had gathered I gave a heart to heart safety talk that never lasted more than ten minutes. Immediately after the talk a singer or an instrumentalist would entertain them after which I made it a point never to let the men get away before the question of making things safe had been put up to them in such a way that results would be forthcoming, and the record

that was made shows clearly that the workmen kept their promises.

Two deaths occurred when an ambulance that was out on a night run got mixed up in the signals of a train crew switching loaded cars of material in the plant about midnight. The ambulance driver and the doctor who accompanied him were killed almost instantly, and the automobile was made into the finest lot of junk that I have ever seen.

One of the most remarkable things from the accident prevention standpoint happened during the building of the power plant. This power plant covers an area of 240,000 square feet. This includes boiler room, power house proper, and coal bunkers. The coal bunkers have a capacity of 50,000 tons and the daily consumption is 2,500 tons every 24 hours. Coal is handled by traveling cranes using clam shell buckets. There are 34 horizontal boilers generating 1034 horse power each or a total of 35,156 horse power per day of 24 hours. When running full capacity there are pumped each 24 hours 40,000,000 gallons of water, this amount being necessary to supply all needs of manufacturing purposes as well as the supplying of all employees' bungalows. To safeguard the health of the workmen this water is tested daily for colon bacteria. Not a single case of typhoid fever has occurred since the filtration plant was put into operation so you can readily see the water supply is of the best. *Not a single death or permanent disability accident occurred while this project was under way.*

The electrical hazard was also a very serious one, the plant being wired with high voltage cables, the trunk lines carrying 6,600 volts. This voltage is then stepped down to 4,400 and then down to 220, this being the average voltage used throughout the reservation.

There are 11 miles of narrow gauge track and 46 miles of standard gauge, the narrow gauge track being used for the electric storage battery motors and powder cars, and the standard gauge track for the moving of all standard rolling stock handling materials to and from the plant. Railroads were responsible for the deaths of four men and the permanent disability of one.

When the actual manufacturing of powder was under way there was need for the men to exercise more precaution than during the construction period and the one thing that the inspectors preached was carefulness. A clean house reduces the fire hazard and as a fire would have disastrous results every precaution was taken to insure the safety of all employees. Rules were put into effect with very gratifying results as there is on record only one person that received severe burns, this accident being to a powder operator who turned off the water that is necessary to keep the revolving knives from heating up when they are cutting the lengths of powder to standard size. This woman was so severely burned that she was not expected to live when admitted to the hospital. The surgeon at the hospital did a good piece of work and the woman finally recovered.

In the manufacturing of powder, sulphuric and also nitric acids play a very important part. If you will allow me I shall give you a brief sketch of the manufacturing process as applied to the making of smokeless powder.

PROCESS OF MANUFACTURING SMOKELESS POWDER

Raw sulphur when taken from the railroad cars is dumped into a series of bins that are located directly behind the burner houses. This sulphur is then placed into a slowly-revolving drum where it is ignited and the fumes are then carried through a series of lead pipes. Oxygen is then added and the fumes pass through platinized asbestos. The mixture is then conducted through glass wool filters to insure that it is purified and at the conclusion of this treatment we have what is known as 60 per cent sulphuric acid, this acid later being concentrated to 99 per cent.

All dirty cotton is placed in the huge kettles that are known as digestors and from there it is conveyed by vacuum to the bleaching house where all foreign matter is removed. When the cotton reaches a certain stage of cleanliness it is put through a continuous drying process that finally delivers the cotton in a clean dry condition. This cotton is then blown by the fan through a conduit and finally delivered to the nitrating house storage room. The cotton is then placed in the mixing tubs and a certain percentage of prepared acid is added. After it has been mixed thoroughly a flood valve is opened and the mixture is dropped into the wringing machines where the excess acid is removed by centrifugal force. Any foreign matter getting into the wringers at this period or the shutting down of any individual wringer would cause the mixture to fire, and should this occur it would mean the closing down of that particular wringer for one-half hour to allow it sufficient time to cool. Airplane fans, thoroughly guarded are used to disperse the nitric fumes when a pot fire occurs. After the necessary time has elapsed the wringer is shut down and the contents are removed through the bottom of the wringer by the operator who forks the cotton down with an especially prepared fork. The fork has the tines capped with brass balls, this being necessary to eliminate the hazard of causing a spark when the fork hits the side of the cast iron pot; while the operator is forking the treated cotton into the opening it is flushed down into the drowning sump where it is kept in constant motion. This treated mixture is then pumped into long flumes where it can be deflected into any one of a hundred tubs where it goes through a boiling process, after which it is passed to a large tank and subjected to a considerable beating necessary to break up the cotton into very fine particles. From this point it passes through screens and finally brings up at the blending house where it is thoroughly mixed with other batches to insure a mixture that will be as nearly uniform as possible. It next goes to the final wringers where the excess water is extracted from it and it is then placed in an almost dry state into what are known as pyro cars and shipped in these cars to the clearing house. At this stage the mixture is known as gun cotton.

The gun cotton is now placed in tanks where a revolving spindle keeps it in motion and ether is added to the mass which emerges in jelly form. This is removed and pressed into blocks and placed into cans for transmissions to what are known as the press houses. These presses have a die placed in the lower end which is equipped with a number of holes the necessary diameter of the powder. Inside each hole there are placed

projections to cut the longitudinal holes which are necessary for the rapid combustion of the powder. The colloidal, as the powder is known in this state, is then raised by means of small elevators to the floor above the cutting machine floor and is placed in the mouth of the ram guide and the ram, in descending, forces the colloidal through the die holes and forms a continuous string that is fed to the cutting machines where it is cut up. The powder is then stored in houses where the ether is driven from the soft or green powder, and, after a certain period, it is removed to what are known as water dry or the natural air dry houses where it is allowed to reach the required seasoning necessary.

The final process before it is packed for shipment is blending. To accomplish this the powder is hoisted to the top of a tower and is then allowed to drop upon a large spreading plate from whose sides it falls into another hopper. From this hopper it then falls upon another spreading plate, and finally rests in a large hopper equipped with a gate which will allow a certain amount to pass through into weigh scales where it is automatically placed in boxes for shipment. All metal work that comes into contact with the powder is grounded so that static electricity, that may be generated, will not throw a spark and cause an explosion or a fire. Although thousands of pounds of acids were used we had very few bad burns. Our safety inspectors made it a point to spend a considerable amount of their time around the places where the greatest danger existed, cautioning the workmen at these points to pay strict attention to business and formulating among these workmen certain safe working habits that they readily adopted. Their success in keeping down acid burns exceeded our expectations.

CREDIT DUE TO WORKMEN

In summing up the entire situation in my experiences on a Government explosives plant I wish to give due credit for the excellent safety record made to the men who were in a large measure really responsible, and I may state that the finest number of real men that it has ever been my pleasure to work with were employed by the engineering and construction companies. Their accepted motto was, "SAFETY FIRST, LAST, AND ALL THE TIME," and safety coöperation could be had at all times.

CHAIRMAN LYNCH: I am going to call for the report of the Nominating Committee, and then we will ask the members to give their names to the chairman—either to me or to the new chairman—regarding those who wish to serve on the committee. Then later we will appoint the committee to take up the matters of standards.

Mr. Barratt, will you kindly report?

REPORT OF NOMINATING COMMITTEE

MR. MICHAEL BARRATT (Michigan Bolt and Nut Works, Detroit): It is the unanimous report of the committee that James J. Lynch be re-elected as chairman of this section, and R. A. Shaw as vice-chairman; and that R. F. Thalner be elected as secretary of this section.

The report of the committee was unanimously adopted. The meeting then adjourned.

Cement Section

October 2 and 3, 1919

H. G. JACOBSEN, Chairman

Manager. Accident Prevention and Insurance Bureau. Portland Cement Association, Chicago

THURSDAY MORNING SESSION

CHAIRMAN JACOBSEN: This is the fourth cement sectional meeting we have held in connection with the National Safety Council's Congress. The meetings we have previously held have been very successful and interesting and instructive talks have been given. I hope this year we will have more discussion of the various subjects. We have some very important subjects on our program; they should be of great interest to all cement men.

The first paper is by Dr. C. E. Coleman.

PHYSICAL EXAMINATION, FIRST AID AND CARE OF THE INJURED AT CEMENT PLANTS

DR. CHARLES E. COLEMAN, PLANT PHYSICIAN, MARQUETTE CEMENT MANUFACTURING COMPANY AND LEHIGH PORTLAND CEMENT COMPANY,
OGLESBY, ILL.

ORGANIZATION

At the two plants I represent we have committees of which the company physician is the chairman. There is a slight difference in the organization at the two plants. I like some features of both. At the Marquette plant we have a man from each department at the safety meeting and an alternate from each department automatically becomes a member of the committee when the regular member's term expires. They change every six months. Then we have a man from each department whom we try to train as first-aid man.

EQUIPMENT

We have a centrally located first-aid room with all necessary equipment for treating injuries and making physical examination of employees. In

the various departments we have first-aid cabinets, not the ordinary stock affairs, but cabinets we have fixed up ourselves. In these cabinets we have bandages of several sizes, tourniquets, hemostats, iodine, boric acid solution, applicators, cotton, 1 to 2000 bichloride of mercury solution, bicarbonate of sodium solution for burns, and aromatic spirits of ammonia. We also have blankets and litters at conveniently located parts of the plant.

PHYSICAL EXAMINATION

Every man hired is examined. When a man comes to me for examination I size him up as he comes in—his gait, height, approximate weight and general contour. I can tell by that to a fair degree whether he is physically fit or not. Then I go on with the examination.

The first thing I do is to weigh the man. Then I measure his height, look at his nose, throat, teeth, listen to his heart and lungs. Close examination is made for hernia and varicosities and particular stress is laid on examination of the eyes. It is surprising that some men are blind or almost blind in one eye and don't know it. That sounds funny to some of you, I expect, but it is true.

As an illustration we have a victim right in front of us. Mr. Jacobsen came in one day and said, "Why do you make such a close examination of the eyes"? I said, "Sit down and I'll show you." When I got through with him, I told him not to go to an ordinary oculist but to an eye specialist. Mr. Jacobsen's left eye I found to be in poor condition and 80 per cent of our men have some defect in their eyes. When I have finished with the examination of a man's eyes our examination blank is so complete that the man can take it to any oculist and have glasses fitted if necessary. It is just the same as if he had had an examination that he would have to pay for.

Next I have the man remove his clothing in order to make a thorough examination of his body. The teeth are also examined and a chart taken of them. Although we have not done anything in respect to dentistry work we give the man good advice as to the use of a toothbrush, etc. This examination is not made to find perfect specimens but to find the right man for the work. I think we have examined about 700 men at the Marquette plant during the last eight months and have had about ten rejections. One had hernia. The man was given good advice and told if he had his hernia fixed, he could come to work. Others had venereal diseases. A man with syphilis if in an infective stage is not put to work.

If a man has bad eyesight, we are not going to put him on a motor car—he might run over some one. If he has a bad heart we don't want him shoveling coal, or doing some manual labor like that. We give him an easy job. We have found positions for those men. In the past, if a man was deformed, had a leg off, or something like that, he would be a watchman. Three years ago there were two watchmen at the Lehigh plant each without a limb. Now one is second engineer and the other is running the coal house engine. Both are making more money and doing better work than they did before.

CARE OF THE INJURED

If men have small cuts or bruises they come in to see me during the clinic hour. I give them the necessary treatment and see them every day as long as necessary. I believe we are saving money by having these men lose that time each day to come in and see me. We have found that only a few piece-workers are hard to get in but that is all. The other men are willing to come and all are satisfied. The more serious cases, of course, we take to the hospital. We have no hospital at either plant.

A good treatment to prevent infection of wounds I have found is chloramine-T. That is a new chlorine preparation generally called Dakin solution. I use one tablet to a four-ounce bottle of sterile water. By bandaging the bruise and keeping it wet all the time with this solution the wound generally heals readily. There is another preparation we use—di-chloramine-T. It is an oily preparation and we use it in strengths of from one to five per cent. By using this solution on a rather bad burn a short time ago perfect healing was obtained.

We have a good many scalp wounds, but I believe we have not lost more than one day this year on that account, although in one of the cases four stitches had to be taken.

We have had several fractures at both plants this year, all foot or hand fractures. I take X-ray pictures of all fractures. A man often gets a bump and just a little splint is cut off a bone in a finger and this makes one of the most troublesome cases. The finger swells and a stiff joint is likely to result. For that reason I take an X-ray picture of everything that looks like a fracture. Of fifty or sixty X-ray pictures I have made this year, all but four or five proved to be fractures. In compound fractures, where the bone comes through the flesh, never pull the bone into the flesh, the thing to do is to put iodine on, because, as we all know, iodine cleans and infection will be prevented even if the bone should happen to slip back. We have a metal splint which can be adjusted to any angle to fit the limb and good results have been had in using it.

We have had one case of cement suffocation this year, the only case in two years. A boy had gone into a bin and someone piled the cement down, covering him. I got there almost immediately. The boy was taken home and did not seem to be in very bad condition. He carried a little temperature and spit quite a bit of cement for several days after I had given him ammonium chloride to bring up the secretions. The boy has fully recovered.

Shock is something we must be very careful with. Almost any severe injury may cause shock. There is only a slight degree of difference between fainting and shock. Fainting is caused by blood leaving the brain. Shock is the same thing, only to a greater extent. What must be done first is to get the head low. The symptoms of shock are pallor, rapid pulse, clammy, moist skin, and the temperature is usually sub-normal. Sometimes the finger nails and lips get blue. External heat must be applied as quickly as possible. I also use morphine atropin hy-

podermically. At the Marquette plant we have two hypodermoclysis outfits. In case of severe shock they will come in handy. We have not used them yet, but they are there in case we should need them.

An electric shock is usually not fatal at once. The heart beats for some little time after. It is necessary to get bodily heat and respiration almost immediately. The center of respiration in the brain is stunned and breathing ceases, although the heart is still beating. Remember that prompt and continued artificial respiration is of the greatest importance in these cases. First find out if the man has anything in his mouth. Then you can begin to apply the resuscitation method with which you are familiar. Personally I believe in the insufflation method. I use that method on a good many newborn children. The first aid schools say that by that method you are blowing carbon dioxide into the man and doing him no good, but I think by this method he gets more respiration than by any other I know. Lay the man down, put a piece of gauze over his mouth, blow into his mouth, fill up his lungs with air and then press that out, working about 18 times a minute. I do not believe in lung-motors at all at the plant.

METHOD OF TREATING BURNS

In treating burns our method is to use a saturated solution of bicarbonate of soda at the first-aid station. Then the doctor is called and if the burn is bad I use parresine, which is a wax. You can get ambrine, parresine, liquidine; they are all about the same. In treatment of burns you should carefully clean the part by douching it with a comfortably hot one per cent Dakin solution. Clean the part as well as you can; if there is any loose burned skin clip it off. If we have a third degree burn we use a waxed gauze which is rather open, somewhat like a fly screen. We spray this with the wax, then put on cotton and spray again and repeat this until we get like a little splint over the wound. A sprayer can be used in applying the wax; I use the DeVilbliss atomizer. When the atomizer is not available, a fine, soft camel's hair brush may be used. The brush is dipped into the melted wax and applied with the utmost gentleness not only to avoid unnecessary pain but to cover all parts definitely and smoothly.

To prevent infections we try to see every injury, no matter what kind it is. If a man has an infection—it may be a swollen hand—he generally comes in and says, "I didn't sleep last night." That is the reason he came to see the doctor.

We wrap the hand in a towel saturated with a 1 to 2,000 solution of bi-chloride. It does not have to be bi-chloride, you can use plain water; the reason I use bi-chloride is because if the man is infected I do not want to infect any other part. Wrap the hand completely with the towel. If there is a spot left open a blister will break out on that spot. After covering the hand we put it into the electric light cabinet from 15 to 30 minutes. I refer to the electric light cabinet illustrated and fully described in the July-August 1919 number of the Accident Prevention Bulletin issued by the Bureau of Accident Prevention and Insurance of the Portland Cement Association. After the first electric cabinet treat-

ment, patients say the pain is gone. This treatment is equally good in cases of sprains.

I have removed some very large pieces of cement from the nasal cavities of the workmen. The best procedure is to break the mass, so there will be no laceration, as this would be the outcome if the piece was removed *en masse*. The after-treatment is to keep the nostrils clean for a day or two. I usually use equal parts of iodine and glycerine.

CEMENT IN THE EYES

We also have a good deal of trouble with cement in the eyes. The thing to do is to stop the burning as quickly as possible. We get the man to the first-aid room immediately and by placing him on the operating table we have him in such position that we may make a pool of his eye. We never use eye cups, as it is never certain that the man will open his eye with an eye cup over it. We use a solution of boric acid; this neutralizes the lime in the cement and in a minute or two the burn has stopped. Then we use a few drops of cocaine. If you have no physician at the plant, use holocaine; you need no license for that. Holocaine will do the same work as cocaine, but is a little slower. The patient after this treatment is at ease; you have his confidence and can work on him readily. After having made the eye insensible, to remove any substance a good loupe is necessary. I use the B. B. loupe which is something every plant should have. As an after-treatment I use argyrol or a two per cent holocaine ointment. It keeps the pain down. If after an eyeburn a man's eyelids stick together the next morning, he has a little infection, and then we have to use 25 per cent argyrol. This spring we had a great deal of what is commonly called "pink-eye". A workman will say the cement is burning his eye. We find it is only one eye, and it is a case of catarrhal conjunctivitis. In those cases we use 25 per cent argyrol.

If a man gets a foreign body sticking to his eye, I make the eye insensible, pick the piece off with an eye spud and put argyrol on for two or three days. We have no trouble when we pursue that method, if the man comes in immediately. It is the man who lets it go for two or three days with whom we have trouble. We had a case recently. The man came to me and said, "Three days ago I hurt my eye; I think it is burned." I told him to go to an eye specialist immediately. That man by this time has lost complete use of the eye. The specialist could do nothing for him.

I think a very good feature is the daily clinic. All cases of minor injuries are seen and treated. We also carry a small line of medicines at both plants. I do not know what you gentlemen have to contend with but we have a large number of foreigners and they are all "bad sick" here, there, or other places. In such cases our small supply of medicine is a great help to us. It is given to the men gratis. It has taken a year to educate them to come to me, but they are coming every day now. It is not only the men from the plant, we have a number of calls from the people in the office.

In respect to general sanitation our plants are continually making improvements, by installing wash and bathhouses, lockers, improving our drinking water, etc. We find it is rather difficult to keep the plants clean, I do not know why. Because there is dust around is no reason why there should also be a lot of rubbish. I believe a cement plant can be just as clean as any other plant. I do not mean free from dust, but free from rubbish. Your workmen can do much in helping you in this respect if the right methods are used.

DISCUSSION

CHAIRMAN JACOBSEN: Have you any questions you want to ask Dr. Coleman? You had one, Mr. Josse, which I asked you to defer until the discussion of this paper.

MR. J. C. JOSSE (Continental): The doctor answered the question about the length of time the arm or the infected part was to be left in those cabinets.

DR. COLEMAN (Lehigh and Marquette): As I said, that all depends on the individual: some men can stand it longer than others. But the thing to do is to have the part thoroughly covered. That is, the wet towel, or whatever is used, has to cover the whole part entirely. Wherever it isn't covered, the man will become blistered, almost invariably.

MR. JOSSE: I have another question on this parresine treatment. You say that you build up this with gauze, cotton, etc., and the parresine. How long will that treatment stay on?

DR. COLEMAN: If it is a recent burn, you can leave it on for about three days.

MR. JOSSE: We have had burns recently, and they had to be treated every day.

DR. COLEMAN: Some of them do.

MR. JOSSE: The water got in beneath this treatment.

DR. COLEMAN: Did you use parresine wax?

MR. JOSSE: No.

DR. COLEMAN: That allows the serum to run out. That is why you can leave it on three days when you use that method. The cotton will absorb the effusion and you can leave it on longer. There are some men who, we say, are "pussy." The pus doesn't come from the inside, it comes from the outside, but we have to watch to prevent its getting on the inside.

MR. JOSSE: We had a case recently where a man was being treated and died of toxin poisoning.

DAKIN SOLUTION

DR. COLEMAN: Dakin solution is very effective. You can get tablets, and one tablet makes a quarter of one per cent solution. I use it as a gargle for all throat troubles, as a mouth wash for all conditions of the mouth, and for all kinds of infections, or wounds that we think will become infectious. I had a man whose skin was cut to such an extent that

every time he bent it opened. I didn't give it a chance to become infectious, although it was awfully dirty. I splintered it, cleaned it as well as I could, and had the chloramine on it, that is, the water solution, for three days. Then I took the bandage off. I didn't take it off in the three days, because I felt sure that I would get into trouble if I did. Then I took it off, and the wound healed by first intention. The tendon was exposed in that case, but there was no trouble, although I looked for it, as those men are not at all clean.

We sometimes have hobbies. The Dakin solution is mine, because I am getting results from it, and that is what we are after. We have had results with our electric cabinets, and we believe in them. And I don't feel that it is out of the way at all to say that his chloramine-T is the best thing we ever had for industrial work. It is cheap—we get 100 tablets for 65 cents. It is very easy to apply them. Put one tablet in a four-ounce bottle of sterile water. Don't use any but sterile water, because if you do it will precipitate the chlorine and you will have nothing.

Results were obtained during the war from this solution that could not have been achieved in any other manner. Men who had badly-infected wounds were cured by this method. The peculiar feature of it is that it irritates the outside of the wound, the good, live flesh, but it does away with the necrotic tissue; it seems to eat it up, and the healthy tissue builds up right under it. I think all plants could profit by using it. Of course, I suppose the physician would have to authorize it, but in the places where a physician does not come to the plant every day, if you will try chloramine-T in a watery solution and di-chloramine-T in an oily solution, you will eliminate many of the cases that are causing you a lot of annoyance now.

MR. SCHLICHER (Lehigh): In your ambrine treatment, what success have you had?

DR. COLEMAN: That depends a great deal on the size and character of the burn. Mr. Josse said they had a man who died from toxin. I presume he had an infected burn.

MR. JOSSE: Yes, although at first this man did not seem to be very seriously burned. The accident happened about 11 o'clock at night, and he was taken to the hospital immediately. The parresine treatment was given him at once, but the man got gradually worse.

DR. COLEMAN: When the analysis was made, wasn't there any sign of kidney trouble?

MR. JOSSE: No kidney trouble at all. He was only a 19-year-old boy. He had the most expert treatment we could give him, but he died just the same.

DR. COLEMAN: We had a man last year who was burned badly. He was like a human torch. I suggested at the time this happened that all men who work where they can easily catch fire should be provided with woolen clothing. This man had on cotton clothing, and he threw some coal dust into a place where it exploded, and it set him afire immediately. He had no pain at all. I knew he was going to die. We just used vaseline on him, but that was only because we wanted to do something. He had no pain, he was burned beyond pain. His essential nerves were

all gone, and he died the next day. His was a fatal case right from the start.

MR. JOSSE: We had a fatal case like the one you mentioned. The man's clothes caught fire from some coal dust which had exploded, and he started running. Before they could get to him, his clothes were burned off him, and of course he died. But the other case I mentioned happened because of the curiosity of the young fellow. He wanted to see just how things looked "in there", so he crawled in through some hot ashes.

DR. COLEMAN: How long did he live after it happened?

MR. JOSSE: He lived three weeks.

DR. COLEMAN: That sounds unreasonable, but it could have been pneumonia, and other things. The parresine treatment is good, if it is given properly. The whole idea of keeping the burn covered is to keep the air away from it, whether we use soda, vaseline, or some other method of covering it. I don't bother putting wax on the smaller burns; I just cover them well with vaseline, a sterile vaseline, and bandage them; but the more extensive burns—and we don't have very many of them—we treat with parresine wax.

MR. SCHLICHER (Lehigh): The reason I asked that question is because the ambrine people have put a case on the market, and I wondered whether you use that case.

DR. COLEMAN: No, we bought the parresine, which is practically the same thing. We bought it from the Abbott Alkaloidal Company, of Chicago. They call it parresine, but ambrine would do the same thing. It is a wax method.

MAJOR RENINGER (Lehigh): I saw them use ambrine in France.

MR. FORTUIN (Pennsylvania): Do you make a physical examination compulsory at the plants you are connected with?

DR. COLEMAN: Yes.

MR. FORTUIN: Do you ever have any objections on the part of the men?

DR. COLEMAN: Never, unless they know there is something the matter with them.

MR. FORTUIN: How long has that system been in force?

DR. COLEMAN: It has been in force for two years, and we have never had any difficulty, except in one case where a man had poor eyes, and he knew it. I happened to know this man's brother, who also had bad eyes, in fact the whole family had bad eyes. This man is likely to go blind any day, so I was only too glad when he quit.

MR. FORTUIN: I thought you said you had 10 rejections out of 700 men, or something like that. What was the cause of the other rejections?

DR. COLEMAN: Bad hearts, hernia, and venereal diseases. We don't always reject them, but we put them to work where they can work without injury. For example, there was a man who was injured while working for the city last year, who had a very bad hand. He came to our plant, after he got so he could use his hand for work, and as they needed men very badly at the time, they employed him. I told the employment manager at the time that this man could not do any hard work.

He went to work marking cars and I told him at the time not to do any hard work, because we couldn't hire him for that. After a while, they wanted to get cement out, and they put him on trucking. It was his fault, of course, and a few days later he came down to me with his hand swollen. If we have men who have hernias, we tell them not to do heavy work.

MR. FORTUIN: Instead of telling the man that he should not do certain classes of work, wouldn't it be more proper to tell the foreman who is directly over him what kind of work he can and should do?

DR. COLEMAN: Of course the foreman should be informed. We had a man not long ago whom we found in the coal house with a bad, leaky heart. He went to work in the morning, and in the afternoon he was examined. He had a very bad leak, and wouldn't have lasted a year in the coal house. We put him to work as a belt tender, and he is getting along very nicely now. He is making a living for his family, and will probably live for years.

MR. FORTUIN: It seems to me, under those circumstances, that a physical examination isn't of very much value if you take men, whether they are physically fit or not, and attempt to put them on special work, and then they are put on other work.

DR. COLEMAN: We have tried to fit the men for the work that is best suited for them, but it is a very difficult thing to do. The past summer, for instance, it was hard enough to get men at all. We have taken men who were nearly in their seventies. You have to allow for the fact that the labor market is very scarce where we are, and we had to take men whom we felt we didn't want—that is they weren't physically fit—and take chances on them.

MR. FORTUIN: That is what I wanted to bring out. Is that due to shortage of labor, or is it your usual custom? What practice would you use now?

DR. COLEMAN: We are still short, although we are getting a little better pick of men, but the labor market is still close.

MR. HALPIN (Marquette): It isn't as bad as it has been.

MR. JONES (Atlas): Have you any method of following up people who are absent from work because of sickness or accident in your plant?

DR. COLEMAN: We haven't gotten that far yet, but I think that is coming. I think that a little later on the physician will look after every man in his plant. If men are sent home, and we have men who live in different places around the plant—some in La Salle and Jonesville—I go to them. If they are at the hospital, I go to them there. We are keeping track of them pretty well. If we have a man with his finger off,—he is able to walk, but he isn't able to work—I have him report to me every third day in order to keep him in line, and as soon as he is able to work, we send him to report to the insurance company, and then he comes back to work.

CHAIRMAN JACOBSEN: Have you any other questions to ask the Doctor about this proposition? I have seen this work out from the very beginning, the method of physical examination and keeping close watch on

the men in case of injuries, and there is no doubt as to the benefit that can be derived, if it is done right and done conscientiously. I know of plants where certain accidents have occurred, and less than half the time that usually is lost by such accidents was lost in these plants. In some places, they eliminate about 75 per cent of their time loss on this account. It stands to reason that if a man comes in with a small scratch on his hand, and gets it treated, he is going to go back to work as soon as he can.

MR. FORTUIN: Has that been during the war period?

CHAIRMAN JACOBSEN: Yes. What is the difference after you have the men in the plant?

MR. FORTUIN: They don't want to stay.

CHAIRMAN JACOBSEN: You can't expect your men to follow out your instructions, if they are not looked after. You have to have somebody to handle that work. That is the basis of the whole proposition. If you have nobody to handle the work, it is not done.

MR. FORTUIN: I know of lots of large plants that have always, prior to the war, made physical examinations of their men, but they had to abandon that idea during the war period, because they had to take anything they could get.

CHAIRMAN JACOBSEN: I am not talking about the physical examination as much as the daily check-up on the men.

DR. COLEMAN: If we know our men, we know just about what to expect from them, no matter whether they are incompetent or not. I believe it is a check. Another thing that I want to mention is the thorough understanding between the employment manager and the doctor. We try to have that as much as we can.

CHAIRMAN JACOBSEN: Are there any other points that any of you wish to bring up on this matter? This is a very interesting question, of course, and it is something we ought to look into. We still have far to go on it.

MR. LAWNICZEK (La Salle): We have a scheme of checking up our men at our plant. We have our foreman report every man who does not report for work. Then, we find out what the cause of the absence is. In regard to fitting a man for a certain job, if a foreman should get a man who is not fit for a certain place, he turns him over to the employment man, and he is put into another department. During the war period, if the foreman couldn't get along with a certain man, we would turn that man over to the employment department, to be put into another department. In that way, we cut our labor turnover considerably. Lots of times it was the foreman's fault that the man couldn't work for him, and lots of times we have had to change a man from four to five different departments before we discharged him.

CHAIRMAN JACOBSEN: How long have you had that physical examination in force in your plant?

MR. LAWNICZEK: About three years, and it is working out very nicely. We had a case of strangulation in a rock-bed one time, and after the doctor examined the man, he found he had locomotor ataxia. If we had

known that was the condition of the man at the time we employed him, we wouldn't have used him in that bed.

CHAIRMAN JACOBSEN: The physical examination is a very difficult and delicate proposition, but because it is difficult, I don't believe there is any reason why we should not give it careful consideration. We will have to go on the next subject on our program now, which is "Sanitation in Cement Plants." Mr. B. L. McKay, of the Buffington Plant of the Universal Portland Cement Company, has been prevented from coming so Mr. G. C. Huth, of the Duluth plant of the Universal Company, will read that paper.

SANITATION IN CEMENT PLANTS

B. L. MCKAY, EMPLOYMENT AND SAFETY INSPECTOR,
UNIVERSAL PORTLAND CEMENT COMPANY'S BUFFINGTON PLANT,
BUFFINGTON, IND.

Sanitary conditions are great factors in the successful operation of every industrial enterprise and give to that industry character, which is the foundation of every success in life.

I fear the subject of sanitation has been sorely neglected in a great many of our industries and should be given more thought.

One of the greater problems in operating any industry is the shifting of men from one place to another.

Results accomplished by the safety and welfare movements have demonstrated that there can be no stability of labor unless working conditions are sanitary, agreeable and safe. One of the great secrets in handling men, if not the greatest, is to keep them contented, and in order to do this physical surroundings must not only be safe but healthful.

Plant sanitation equipment is a part of these surroundings and plays an important part not only in the happiness of the employee but also in the health and happiness of his family.

From my experience in employing men, I have found our sanitary conditions a great asset, as they appeal to the better class of men, for he who is clean physically is clean morally.

The tremendous attention bestowed upon the work of sanitation, the increasing large sums spent annually to preserve the health of the employees and their families are two of the outstanding features in the work of the United States Steel Corporation's Bureau of Safety, Sanitation, and Welfare. Already the annual expenditures run into millions.

DRINKING WATER

One of the first things I would like to mention is drinking water. Contaminated drinking water has unquestionably been one of the most potent agents in spreading disease in industrial plants, and it is only within the last few years that the importance of furnishing germ-free water has been recognized and acted upon. Therefore, one of the first steps in sanitation is good drinking water.

There isn't anything I know of more refreshing and healthful than a glass of pure, clear water.

The most sanitary and convenient method of furnishing drinking water to large numbers of people, such as work in industrial plants, is the bubbling fountain. It is all important that the design and operation of the bubbling fountain is such that the germs of disease from an infected person who has used it cannot come in contact with the subsequent users, and that they become entirely removed from all parts of the fountain coming in contact with the users.

These fountains are being used in our plants and give perfect satisfaction. Our drinking water is furnished from the Gary Water Works and is the same that is used in hundreds of homes in that city. I would like to recommend that these fountains be installed in every department and department building, just as near to the workmen as conditions will permit. Convenience should be the object in all sanitary installations.

LOCKERS

The next thing I want to mention is lockers. Upon entering employment one of the first requirements of an employee, is a place to keep his or her clothes, so that it is possible for them to make a complete change before starting and upon the completion of the day's work.

It is my experience that the individual locker system is most satisfactory to the employee, and by using a sensible locking system the lockers are always accessible for inspection. Employees are expected to keep their lockers clean, but inspection is necessary.

The lockers should be made of metal, substantially constructed, and connected in units to the best advantage of the space available and should be closely connected with both lavatories and bathrooms. Each unit of lockers should be set in a double row, back to back, on a concrete platform about 18 inches from the floor. This platform should extend about 12 inches on each side of the lockers. This makes a very suitable seat and is also convenient in flushing out the locker rooms as the platform keeps the lockers from any dampness that would result from the flushing.

Lockers should be of a sufficient height to take care of the average length coat. They should be set on a base of four legs about 8 inches from the floor or platform. They should be about 64 inches in height—width 15 inches and depth 18 inches. There should be a shelf at the bottom of the locker, for the shoes. This shelf should not be on a level but slant toward the back with a screened opening for ventilation. A shelf should also be installed at the top of the locker about 54 inches from the floor, and extending about 10 inches from the back. At least three hooks should be installed under the shelf, also, if possible, grooves for a cross bar for the purpose of hanging coat hangers if desired. Here also should be openings for ventilation, which, with the openings at the bottom of the lockers will allow a free circulation of air at all times. The top of the lockers should not be flat, as it has been the custom to build them, but they should be built with a slanting top, the pitch being toward the front, thus preventing the gathering of dust and rubbish.

A good locking system is that operated by the handle pulling down latch bars which fit in grooves at either end, this making it impossible to pry open the ends.

The system of locking that we are using is a metal bar fitted through the latch on lockers. Each bar has a hole at either end large enough to admit almost any lock. The two holes are for the purpose of putting two locks on each locker, one to be furnished by the man and the other by the company. This system of locking has been found very satisfactory and also very convenient as it has been the means of saving many an employee's lock from being broken, when he left his keys at home. Whenever this happens the key for the company lock is obtained from the foreman and the locker opened without any damage. This system has also been found very convenient for inspection.

LAVATORIES

Some of our lavatory equipment consists of white enamel steel ware, but the greater part is of cement and of a design to suit the purpose. Those of cement have been acid-proof treated, and have been found efficient.

Hot and cold water is always available and connected to mixing valve where it can be made the desired temperature. The lavatory units have no stoppage at waste openings, in order to assure each user that he may wash in clean running water, which has not been used nor can be used by any one else. Liquid soap dispensers are installed in all lavatories.

SHOWER BATHS

Shower baths should be equipped with shower heads, each shower contained in an enclosure for the purpose of privacy, and thorough floor drainage. The baths should be contained in well-lighted and well-ventilated rooms free from all draught, in order to prevent discomfort to the users. Shower baths should be closely connected with locker rooms.

TOILETS

Toilets should be located conveniently to and easily accessible from, all places where persons are employed, and with outside exposure for light and ventilation. This is very important.

Our standard consists of full porcelain and cement urinals equipped with pipes for constantly running water and separated by slabs for privacy. Solid porcelain closets with open front type of seats, automatically flushed by seat action. Each closet in a cabinet with a door. In every case lavatories, toilets, and wash rooms should be installed in each department and be for the use of that department.

A janitor should be placed in charge of every wash room lavatory, and toilet. All lavatories and toilets should be equipped with a faucet and hose for flushing purposes.

WASTE CANS

Waste cans should be furnished every department in order that refuse can be properly disposed of. This is a great problem and every effort

should be made to curb the fly nuisance that causes so much sickness. Signs should be posted in conspicuous places ever to remind the employee to help keep the plant clean.

WALKS AND ROADS

Good walks and roads throughout the plant is another step in plant sanitation. It permits thorough cleansing. There is a complete network of concrete roads and walks around our entire plant leading to and from every department. The roads and walks are washed and cleaned regularly. Another thing is the settling of dust on windy days, for dust is a carrier of disease. We have a system of fire plugs throughout the plant where hose can be connected and yards sprinkled as required.

It is a habit to take more or less pride in looking and feeling well dressed and clean, for Cleanliness is truly next to Godliness. I believe the better dressed and cleaner an employee is the greater asset he is to the business.

The concern then, which has all the sanitary conveniences will attract and hold a better class of workmen as well as educate the negligent, for the workman is not worth while who would not prefer employment in a place where he can wear a good suit of clothes to work, change when he gets there, put on working clothes, and when he has completed his day's work, bathe, and don his street attire, feeling like a new man.

A Bulletin issued by the Pennsylvania Department of Labor and Industry declares that the chief aim of education is to train the individual to do the right thing at the appropriate time without having to think. From habit the varied activities of our daily life become automatic, leaving the higher powers of the mind free for the performance of their own peculiar work. In order to make the nervous system our ally and not our enemy in relation to habits of health it is necessary to make automatic as early as possible as many acts as we can which will promote our physical well being. The employee and his trade, the employer and his profit, the product and the national output, are either helped or injured by the method of living of each individual. It is generally recognized that the chronic habits of unhealthy living produce industrial inefficiency, and is strikingly illustrated by alcoholism, but such losses among employees are easily controlled because they are apparent. On the other hand losses from faulty personal habits or bad housing conditions are more difficult to anticipate and remove. For this reason it is harder to convince a worker that habits of health and cleanliness will increase his earning capacity as surely as intemperance will decrease it. Factory, shops, and tenement supervision, restriction of hours of labor, prohibition of child labor—all these welfare movements inculcate in the people of the community, where they operate, habits of health which promote efficiency.

CHAIRMAN JACOBSEN: This question of sanitation in cement plants is probably bigger than we sometimes think it is. Years ago, I believe few industrial plants gave much attention to the question. It is a thing that has to develop slowly. It will probably take a year or two before you get the system working.

The idea of putting in a bathhouse, change room, and things like that, is a very good one, but if you build those houses and don't take care of them, the men will have them looking like shacks within a month. If you don't want to keep up the house you build, I would advise you not to build it, because you will do more harm than good. Where it has been done in the right way, it is very easy to see the results.

In the last two years I have visited 50 or more cement plants, and I have found probably 20 bathhouses among them, and most of them are in fairly good condition. The companies have come to realize that if they want to keep that equipment, they must keep it clean. Are there any gentlemen here who wish to discuss any part of this paper?

DISCUSSION

MR. FORTUIN: I don't think there is very much to discuss in that paper, but I presume that when Mr. McKay refers to bathrooms, he really means shower rooms, because you don't have bathrooms. In the past, there is no question but that nearly every cement plant considered its workmen; but the price of cement, as you all know, didn't permit spending much money. I think nearly every cement plant, as long as it is in prosperous condition, is only too willing to do everything possible for its employees, and will spend as much money as necessary to better their conditions. There is no question about that.

MR. JOSSE (Continental): And another thing, Mr. Fortuin, you will find that most of the cement plants are old plants. We can't take Universal as a criterion, because they have plenty of space. Take our plant, for example: we are set down on a small piece of ground, with a railroad on one side and a creek on the other, and we couldn't expand until we cut out enough quarry to expand. At present we are using Keokuk power. The engine and boiler rooms are being converted. We are moving the engines out, and they will probably be removed by the first of the year. That will give us room for a nice looking locker room and nice shower baths. We improvised a shower bath a couple of years ago, but it was a dusty and dark place, and the only persons who used it at all were the office men. I think it is just as Dr. Tucker says, the cement workers are the cleanest fellows in the world, if they can bathe on the company's time. And I suppose that is what it will all come to when we get our shower baths up; the men will have to bathe on the company's time if we want them to keep clean.

MR. FORTUIN: At our plant we now have locker rooms, showers, and toilets. It is a beautiful place and kept very clean, in fact we have a man who has nothing to do but keep it clean. We employ women in the bag department, and we have a separate place for the women. It is fine, and they appreciate it. We allow them to change on the company's time.

DR. COLEMAN: In the Lehigh plant, we formerly have had a man janitor. For the past four months, we have had a woman doing that work, and now we have a good, clean locker room; it is rather incon-

venient, because when the men come in she has to go out, but that is the only inconvenient part of it.

CHAIRMAN JACOBSEN: Major Reninger, wouldn't you like to speak a few words to us on your installation? You have probably had more experience on that than any of us.

MAJOR RENINGER (Lehigh): The installation that we have out at Oglesby is the installation we have at all of our 15 plants. We have tried to divide up our washrooms and locker rooms so that they would be scattered around the plant; instead of having one central locker room, we thought it would be better to have two or three. The foundry men, the carpenters, the locomotive men, the belt men, and all the others each have their own place. We have arranged our toilet rooms and locker rooms with the washstands in the center of the room. The washbasins are made of steel, white enameled.

MR. FORTUIN: Are the showers there, too?

MAJOR RENINGER: Yes. We built this locker room with the washbasins in the center.

MR. FORTUIN: Would you consider this advisable in a small plant?

MAJOR RENINGER: Yes. I would, because it avoids congestion. We originally had one big locker room, but we divided it up into a number of smaller ones. At one end, we have the foreman's locker room. That is separate from the workmen's locker room, and it is for the use of all the foremen. They come together there, and they have desks on which they can do their writing. Chairs are placed there so that they can sit down and have a conference.

Each man has his own locker, and at each end of the room we have shower baths; there are four shower baths in each washroom. There is an attendant, who keeps the place absolutely clean at all times. We try to keep the tops of the lockers free from any material whatever, waste or packages, or old shoes, or clothing. If a man leaves his stuff on the top of his locker, when he comes for it at noon, it is gone. They all know they are not supposed to leave rubbish around, and if they do, the janitor cleans it out. That is one thing we are very strict about. We have the open-type locker, so that we can see just what every man has in his locker. They can have their change of clothing in there, but they dare not keep any rubbish or any old clothes that they can't use. If they have any in the lockers, the janitor finds out whether or not they want to use it, and if they don't, he destroys it.

MR. FORTUIN: How about the dust?

MAJOR RENINGER: We have tried to keep the washrooms away from the plant as much as possible, that is, away from the dusty parts. They are well built, have windows and ventilation above the tops of the lockers. Of course, you can't prevent some dust coming in, but the place is washed twice a day, and we have walks leading into the washroom. We are now trying to have lawns around every washroom, so far as possible.

MR. FRAME (Alpha): Major Reninger, how do you obtain the hot water at the different washrooms that are scattered around your plant?

MAJOR RENINGER: That comes from the boiler. We pipe it from the boiler room to the shower bath.

MR. JOSSE: Did you every try the scheme of turning the steam into the cold water?

MR. MACFETRIDGE (Lehigh): Invariably you will have a man scalded, if you use that method.

MR. FRAME: Major Reninger, do your men do all their washing up on the company's time?

MAJOR RENINGER: Yes.

MR. HALPIN (Marquette): What percentage of the men do not use these lockers?

MAJOR RENINGER: I am sorry to say I can't answer that. I have been in the service for three years, and I do not know what has gone on during that time.

MR. KLECKNER (Lehigh): At our Newcastle plants they are used 100 per cent.

MR. HALPIN: It seems to me that the greatest difficulty with this bathroom question is that all the men will not use them. A large percentage of them would rather go home and wash there. How do you let the men wash, on company time? How do you arrange it? I believe you said you did that.

MR. FORTUIN: When the shift changes, the night shift comes on a little earlier so as to give them a chance to wash.

MR. HALPIN: I mean your day men, your men who work eight or ten hours a day.

MR. FORTUIN: The 10-hour men are allowed to quit 15 minutes early. They are also allowed 10 or 15 minutes when going for luncheon.

CHAIRMAN JACOBSEN: Mr. Huth, what is the system out at your plant at Duluth? Do the men wash on the company's time or on their own time?

MR. HUTH (Universal): They do it on their own time, and practically every man goes away from the plant clean. We haven't had any difficulty at all.

MR. SCHLICHER (Lehigh): Have you had any trouble with respect to foreigners and Americans washing in the same room?

MR. FORTUIN: In our plant in New York State, there is only one place where we have washstands installed, and there is no difficulty in that respect at all. We keep the lockers for the foreigners on one side of the room, and for the Americans on the opposite side. We try to keep the lockers separated, but there is no difficulty as to the washing. They get along splendidly.

MR. JOSSE: I believe the feeling of antagonism between foreigners and Americans is very rapidly diminishing. We have experienced a lot of trouble with Americans working with foreigners in different capacities, but I think that condition is diminishing very rapidly. The war and the Americanization movement the Government has started have helped a great deal toward that end. I think it is a very good movement, too.

CHAIRMAN JACOBSEN: I would like to know how you could teach the

cleaned the thing out when the night men started, and they were given the same instructions. They also had four men working on it.

They had it all cleaned out, as they thought. One man crawled in and said there weren't any more hot ashes in it. The mill, of course, was shut down and we were grinding clinker. That was all we could do. One young man came over from the clinker pile, and while the other four men were talking this young fellow crawled in under the drier. There must have been some hot ashes still hanging up above the drier in some way, because they came flowing down right in front of the manhole. The boy crawled right through the hot ashes to get out of the manhole, although there were three manholes he could have gotten out of. That is the man we thought wasn't burned very badly, but after lingering along for three weeks he died. The man was only in our employ about two weeks. The first man who was killed was a foreigner. How are you going to educate these men to have self control? That is all that was required. This foreigner, if he had stopped and brushed his leg, or jerked his trousers off, would never have been even blistered. These are very important things to know, and they are pretty hard to teach to the foreigners.

There are other dangers that you can get away from. For instance, there are burns. We never before have had burns at our plant, except small ones. We recently had a young man in the electric shop who had been shellacking a motor, and he got some shellac on his hand. After finishing the job, he went over to the gasoline can, poured out some on his hands to wash them, then reached into his pocket for a cigarette, lit a match, and both hands were on fire in an instant. He wasn't burned dangerously but he was burned so that it hurt him. That incident went all over the plant and it did a wonderful lot of good. I don't think there will ever be another man there who will light a match with gasoline on his hands. That kind of an accident is really a help, if it doesn't hurt the man seriously. He was only out one day, but it hurt enough so that he isn't going to do it again, nor any of the other men. It happened there was a safety man standing about three feet away from him at the time, but he didn't know what this man was doing, and could not prevent the accident. Everybody to this day "kids" this man about lighting a match with his hands full of gasoline.

The difference between the foreigner and the American is like the difference between a broncho and a thoroughbred horse. When a broncho gets scared, you can't do anything with him, but you can stop a thoroughbred. In that first accident, if he had been an American, very likely he would have arisen to the occasion and put the fire out, whereas the man being a foreigner his wits left him. He could have gone 10 feet to three or four men who were nearby, and they would have had the fire out for him in a few seconds, but he went the other way, just out of reach of everybody, and he had on only a pair of trousers and a thin undershirt, which burned off.

That accident made me feel bad, because I had begun to think we were just about "it" on accidents. It just shows you how quickly you can

"stump your toe"; of course it makes you feel pretty bad, but after you get away from the shock of the first few days, it is an incentive to work harder. I think the majority of our men now realize that everything we are trying to do is really for their benefit. While I admit that these accidents put the figures on the wrong side of the ledger, that isn't the first consideration with us.

SAFETY WORK GROWING

Our first consideration has been the conserving of man, his life and limb. But by doing that we are also cutting down our insurance rates and putting money where it belongs, because you are not going to make any money by selling your cement and making a profit on it, and then giving it to somebody who was hurt or killed while making the cement. That is a waste of energy and a waste of money, and those conditions have to be met and overcome. Of course, we are just scratching the surface safety work now. It is growing very rapidly and it is going to be easier for us later. The longer this safety movement works, the easier it is going to be for all of us. As you know, a great many of the workmen travel from one plant to another, and if they get safety instruction at one plant, and go to the next plant, that instruction will come in handy. While this pioneer work is very slow and very discouraging sometimes, I am sure we are getting results from it all over the country.

The only place where I know positively we are getting results is in the St. Louis district. I have a chart which I got from the coroner up in my room and I intended to bring it down here. The reduction in deaths in the industrial plants in 1918 over 1917 was 57 per cent. During the first eight months of this year, the reduction over that of 1918 has been 29 per cent. So you see this intensified work of the industries in and around St. Louis is telling.

Of course, the work is a little further along in St. Louis than it is in a great many other cities. We have had two years of intensified industrial safety work. For instance, we have foremen's and superintendents' meetings once a month. We start the latter part of this month and continue meeting all through the winter and early spring. These meetings are attended by from 1,500 to 2,000 foremen and superintendents, and we always have the best authorities on the subject under discussion that the United States affords, so that the St. Louis district is not a criterion for the rest of the country. But the same thing, you will find, is taking hold here in Cleveland very effectively, and you will find it going all over the country.

MEDICAL EXAMINATION NECESSARY

Missouri is about to have her compensation law go into effect, and the doctors' medical examination will then be necessary because we have records in the Safety Council from various states where this examination is not in effect in the different plants, and we have found that a man will come to the plant with an injury or a defect that is not ap-

parent, unless a physical examination has been made, and after working for a while, he will develop some condition which the compensation law allows him a certain amount for. Some of these cases have been traced, and we found that the same man had done the same thing in three or four different places, and got the same compensation in all of them. So it becomes almost a necessity, where the compensation laws are in effect, to really have some kind of medical examination. Even if you can't place the men where they should be placed, you have that record, so that you are protected when they sue for compensation. That, I think, is one of the reasons why we will all be compelled, especially in Missouri, to give our men the "once-over" at least, before we hire them.

ACCIDENTS SERVE TO CORRECT HAZARDS

The best time you can find out what your hazards are is when you have an accident. We analyze an accident when it occurs, and try in every case to eliminate the reason, or the cause, or the chance for that same accident to happen again. Mr. Jacobsen knows that we did that until this burn case; and never before had we had a case of that kind. Where this puff of fire came from we don't know, but it is our opinion that the fine coal dust was on top of the grating which these two men were walking over. We have latticed grating. The coal that is mined near St. Louis carries a very large amount of sulphur, from 4½ to 5 per cent, and burns very readily after being pulverized and dropping on anything that will catch it. We have to clean our coal room twice a day in order to keep this coal from burning. When we were able to get coal from southern Illinois, Franklin County and that part of the country, we weren't bothered that way. But since the war, that coal has all been diverted to Chicago, and we don't get any of it. So we have to have our coal room floors swept constantly; we have one man there who does nothing else. Twice a day, the millers shut down the mills and sweep all the coal off anything that is likely to burn. It is our opinion that some of this coal was hot, and they couldn't see it—it doesn't blaze, of course—and the man walking across the grating knocked some down. There was enough air and coal dust to cause a little flame to come up his leg. The man right next to him said there wasn't a puff big enough even to burn the hand. He didn't know this man was burning until he screamed. He said he wasn't two feet from him, but he managed to get away. He tried to grab him, but the man was so terribly excited that he couldn't hold him.

FIREPROOF CLOTHING

The solution, I think, to this burn case is fireproof clothing. That can be obtained very cheaply. The Commonwealth Steel Company furnishes suits of clothing to their men who operate acetylene burners and electric welders. They buy an ordinary suit of overalls, and the solution they use I think is magnesium chloride. It is very cheap. They buy the overalls and jumpers and soak them in this solution, and sell them to the men at just what the overalls cost them. When the men wash

the overalls, if they want to use them again, they bring them back and the company soaks them again in this solution.

That is what I am going to do in our coal room, and after this I am going to make a dustless coal room if I possibly can. We have analyzed the causes of our accidents, and we have eliminated 95 per cent of them by eliminating the causes. The only reason we hadn't eliminated the cause of this accident is because we never had one like it before and we didn't know there was any danger of one. Of course, we feel that we are responsible for this man who was burned, because he was burned while doing his daily work, and it is really up to us to compensate his family. But I don't think we can be blamed for the accident that occurred to the young man who crawled in under the drier to see how it was constructed, although, of course his family naturally think that we should pay for it.

EDUCATION OF MEN DIFFICULT

I don't know of anything else I can say in regard to educating the men, except that it is a continual grind and no fun. It is a hard job; you have something to do all the time. You can't let up on it for a minute.

Since we have started this safety work, and since Mr. Jacobsen has had this Bureau, we have given him a report of every scratch. In 90 per cent of the cases there is no time lost at all and no injury except a scratch, but they are brought into the laboratory and are dressed, and we make out a report regardless of how slight an injury it is. Mr. Jacobsen is receiving a great many reports, but with the exception of these cases very few of them are of a serious nature.

We had one other serious one that I think I had better tell about, because I think it will do us all good. We had a man who used to run a "dinky" for us, who was taken in the first draft. He was in the front line trenches for three or four months, was gassed, and got back after the armistice was signed. He came to us for his old job. That was about the first of the year and he got his old job of running a "dinky" on our stripping field. In March or early in April, we had a very long siege of rain. It lasted for about three weeks and the field got in such condition that we couldn't use him there; he wanted to work for us and we wanted to keep him on the job. We were constructing a little conveyor to try our pulverized coal in rock driers, and had it all up, and were just putting the screws in.

EFFICIENCY OF PRONE PRESSURE METHOD

The assistant superintendent and the draftsman took two men—one had been working on this job for some time and the other was this "dinky" engineer—along to put the hangers in the casings and put the screws in. About three feet away there are three wires running to an electric light transformer, carrying 440 volts. After they got everything ready to go to work, the young man who had been working on this job for about two weeks said to the "dinky" engineer, "John, those wires

over against the wall are wet; they are perfectly insulated, but they are wet and we had better not touch them, we might get a shock." John wanted to see whether that was really a fact, so he put his hand over on one of the wires, and both men were knocked off the conveyor. When we got to them one man was breathing but the other apparently was dead. We were taught the prone pressure method in a safety school at St. Louis last winter, and three of the men whom I had sent to this school started to work on this man. He seemed to have no pulse, no heart beat, and no breath at all; he was all blue. These boys rolled him over on his stomach and started to work on him. I telephoned the chemical company in our part of the town to bring their pulmotor. I think it was about 40 minutes before the pulmotor arrived, but in the meantime they had started artificial respiration. A doctor came with the pulmotor, and our plant physician was there. They decided not to use the pulmotor at all, but just give the man oxygen. He was out about an hour and ten minutes all told, before he started natural respiration.

The general opinion of all of the electric companies in St. Louis—I happen to attend a meeting with them every week—is that a man is easily resuscitated from an electric shock if he is reached within 10 minutes, but that after a lapse of from 10 to 12 minutes, there is no hope for an electric shock victim. This man is all right now, so far as the electric shock is concerned. He was unconscious for four days. When he started his natural respiration, it took six men to hold him.

There was a condition that we could have eliminated, and we did eliminate it inside of 30 minutes after the accident happened. Those wires were placed in conduit. They were underneath the eaves of the roof and we had no idea that anybody could ever touch them, but they were touched.

When you have an accident, if you analyze it you can eliminate the chance of the same accident happening again, so if we have accidents they are going to be new accidents. The old accidents, and the old causes, can be eliminated to a very large extent.

DISCUSSION

CHAIRMAN JACOBSEN: I believe that is a remarkable thing they did down there. If they hadn't known about this Schaefer method that man would certainly have died. Had they had a pulmotor, the man may have died just as surely, because perhaps no one at the plant would have known how to operate it, or the motor would have failed to operate. That shows what it means to be prepared for something that may happen five years from now. They may never use it—let us hope they will never again have a chance to use that method there or at any other mill—but let them be prepared when the emergency does arise.

I heard of a case, through a report I received from one of our member companies. It happened on the ground floor, so that the man had no occasion to fall any place except on the floor. There was a door leading outside; it was raining very hard that day and the wind blew the rain

in on the floor. One of the men volunteered to close the door, but the mill operator ordered him to leave it open. Immediately afterward he went over to start the motor, and that was the last of him. The rain had soaked the electrical equipment. The man died.

Those are the most important things in our work, I believe; those are the things we must know about. That method is so simple that a child could do the work. One person could do it alone, or at least he doesn't have to have a big crew with him. The main thing is, as Mr. Josse said, to get it done immediately.

MR. JOSSE: I was over at the safety exhibit yesterday afternoon. They have a small oxygen tank there with the pulmotor exhibit that has been perfected, I believe, on account of the gassing over on the other side. All there is to this is a small oxygen tank, and you can use the oxygen from any tank that you have at your plant for oxygen welding; just fill it any time you need it. It has a reducing valve so that the pressure is very slightly above the atmospheric pressure. It can be used in connection with the Schaefer method. The mouthpiece is strapped around the mouth; the man is laid on his stomach; then you turn on the oxygen and start working on him. Every time he exhales nothing comes into his lungs, but when he inhales, a little oxygen goes in. I think that process is going to be the real thing. There is no good done, of course, if the pulmotor is used by somebody who is not an experienced operator.

CHAIRMAN JACOBSEN: The Schaefer method is now considered by all authorities on that matter to be the most efficient method, and I believe everybody ought to train himself in it. In the last issue of the Accident Prevention Bulletin I had occasion to give a full description of it, and I believe all that is necessary will be found there in the chart. Get your men in the plant to experiment with it a little bit.

St. Louis, as Mr. Josse says, is one of the shining stars in accident prevention work in general, public as well as industrial. We have another man from that location and I think we ought to hear a little bit from him. His plant has started some novel methods of educating the men and getting them to see the dangers connected with their work. Mr. Ross, of the Missouri Portland Cement Company, will you tell us a little of your experiences?

MR. ROSS (Missouri): We have our committees—the foremen's committee thought it had done everything it could do in the way of suggestions, so we organized the workmen's committee. For the most part this committee is composed of foreigners. They were bashful at first and wouldn't say anything. We had a stenographer at the meetings to take the minutes down and we made a round-table of it; we brought in cigars and they got to joking; then they became very efficient and everybody was anxious to offer his suggestions.

One of the things we have done is to teach the Schaefer method to the men and to make an inspection of the mill. I suppose over 90 per cent of the men in the mill know how to resuscitate a man from shock. In line with accidents, we have worked out the scheme of taking a photo-

graph of how the accident happened and the manner in which it could have been avoided. We post that photograph up just as soon as we can finish it, which usually is the next day. I do that myself in our mill, and I think that is a better scheme than using some of the bulletins we receive. Those bulletins don't apply to cement plants, while the actual photographs of cement plant accidents do apply. The picture is put up in the morning, say at 8 o'clock, and about half an hour later if you go around, there will be a half dozen to a dozen men talking about it, past members of the safety committee and people who have not been on committees.

CHAIRMAN JACOBSEN: What size are the pictures, Mr. Ross?

MR. ROSS: They are about post-card size.

CHAIRMAN JACOBSEN: I wanted to bring this matter to your attention. As a matter of fact, I have slides here of all the photographs Mr. Ross has taken, and as soon as the management of this hotel will permit us to get our material, we will show them, which I think will be tomorrow. I have several other slides which I will show here, that I think you will be very much interested in seeing.

DR. COLEMAN (Lehigh and Marquette): We had a cement sectional safety meeting at La Salle this year, and there was lots of good stuff suggested. I have spoken to Mr. Jacobsen about having a kind of query column in his bulletin. What would help a whole lot is a description of this man being hurt by electric shock. If that had been printed a good many of us would probably have looked around and found some of those places in our own plants. I believe if we could bring up and discuss our views in the Accident Prevention Bulletin, it would be helpful.

MR. RICHARDSON (Marquette): I would like to ask Mr. Josse a question. When you have the workmen's meeting, that is the safety meetings, who presides?

MR. JOSSE: The workmen appoint their own chairman.

MR. RICHARDSON: And how often do you change?

MR. JOSSE: Every three months we change one man from each department, and those men elect their own chairman. We don't have a thing to do with it. I don't go near them at all; nobody does. They bring in their own recommendations in an envelope and put them in a box.

MR. RICHARDSON: And how do you eliminate some of those recommendations?

MR. JOSSE: We write to the men saying that a certain recommendation is good and will be complied with as soon as possible. We have three men who do practically nothing else but put up guards and do other work that the safety committee recommends. We say this recommendation is good and will be complied with as soon as our men can get to it, or that another is impossible for us to comply with at the present time. We may say, "If the conditions change so that we can do it, we will be glad to take care of it," or in another case, "If we comply with this recommendation, the hazard in another way will be greater than it is at present."

We let the men know that we examine their recommendations and give them considerable thought. It is surprising how few bad recom-

mendations they bring in. The men who are working right where the accidents occur can bring in some of the best recommendations you ever heard, and most of them are simple. We don't have any more scalp wounds. They have all been eliminated by screens at the points where the rock would drop off the elevator or conveyor. We haven't had a scalp wound for a long time, just because of these committees' recommendations. And it doesn't cost much money to comply with them.

CHAIRMAN JACOBSEN: I think Mr. Josse brought up a very good point in the talk he has given us—that is, to let the man know what is being done with his recommendation, and to recognize him as one of your organization. He is really an official you might say, when he is on the committee. It may be a good or it may be a bad recommendation. I don't believe the man will care much whether it is turned down or taken up, as long as he knows that action has been taken on the proposition. If a man turns in a suggestion and you let him wait a couple of weeks for an answer he gets "lukewarm"; then if he doesn't hear anything for a month he drops the whole proposition and you will never hear from that man again.

I believe there should be more efficiency in connection with the handling of that kind of work at cement plants, and not only cement, but any other industrial plant. It is the handling of human nature, that is the whole proposition. Good, common sense is going to put the thing over much more quickly than anything else.

MR. FORRUIN: Under the Pennsylvania state law, if you want to get credit for all they will give you under the Compensation Act, it is necessary to have a safety engineer in conjunction with the safety committee. But you can appoint any one, and call him a safety engineer.

MR. JOSSE: In St. Louis we discovered that there was no such person as a safety engineer. So last winter we had a Safety Supervisors' School, comprised of 15 lessons. And as I said in speaking about the Schaefer system, if we never got another thing out of that school we will have at least saved that man's life, and isn't that worth while?

Three of our men and I attended that school for the 15 lessons. Mr. Ross was also one of the members and several from his plant. He can also tell you of the wonderful benefits we derived. Of course, we were all new, we didn't know anything and we don't know very much yet, but all of that education helps and there is where we learned the Schaefer system and saw it worked out. They put a man up on the stage and showed how it was done, and it is very simple.

One day last week there was a storm in St. Louis and a wire of the Union Electric Company was broken so that it hung down on the street. A man passed this wire and put his hand on it to push it away and of course down he went. As it happened, there were a couple of boys passing at that instant who knew the Schaefer method. They turned this fellow down on his face and started working on him, and they had artificial respiration started when a doctor came along. The doctor stopped them. He said, "That man should not be on his face," and he turned him over, and started working on him. That man is dead today,

and the fellow who has to pay for that man's death is down here at a meeting today. He has now given instructions to all of the men in all of the departments not to pay any attention to what anybody says, but to keep the Schaefer method going.

CHAIRMAN JACOBSEN: That gives me another idea, and that is the doctor at the plant. I think the doctor is one of the greatest helps that you can have at your plants. If you have the right doctor, who knows the men, or at least knows their way of thinking, that doctor can help you more than you realize. Why don't you get your minor accidents reported? Why do the men sometimes go for a week before they come in with an infected hand which then is far beyond the doctor's help? Probably some of them don't like doctors; they think the doctor is always ready with the knife, and they have a general dislike for doctors' treatments. If the doctor can get all of that nonsense out of their heads you will get along far better than you do now.

How is your plant situated with respect to a doctor? How quickly can you get a doctor? That is another very important point. Sometimes you want a doctor quickly—you may have a man tangled up in a gear or something like that, and have an arm or a leg torn off. That man will surely die before the doctor gets there if it takes an hour or so before he arrives. I received a report the other day of a man who was smothered in a cement bin. I asked them how long it took to get doctor. It took them an hour. Of course the man was dead.

How are you equipped for taking care of your men at the plant when an accident occurs? Have you a room set aside for that particular purpose? It is not enough to say that the chemist—and that is the explanation I generally get—handles all that work in the laboratory. He can do that in case of minor injuries, a scratch of a finger, or something like that. But just let us take the case of a coal dust explosion in a coal house, or a premature explosion in the quarry, where you probably have half a dozen men injured at the same time—where are you going to take them until the doctor comes?

It is very easy to rig up a little room with a couple of cots and things like that in it, and keep it clean, and have that room used for nothing else. It may be years before you have to use the room, and I admit it is difficult to keep that in mind, but you must have it. In many cases it becomes dirty and is neglected. It is necessary to keep that room in good condition so that if an accident should happen you can take care of the victims, and the doctor will have a place to work when he comes to the plant.

DR. COLEMAN: With reference to being prepared, last summer soon as the hot weather came on I gave specific instructions that should any man be overcome with heat, either by heat stroke or exhaustion we should know about it immediately. A man in the boiler room became sick, as he thought. He was getting heat exhaustion. He went out and crawled between two buildings to take a rest. Luckily, a man came along investigated, and found the man unconscious, or almost. Suppose nobody there had known what to do—that man might have died before I could have gotten to him. But instead of that, he was carried

into the first-aid room. We have an electric fan there, and that was turned on him, alcohol was rubbed on his arms, a blanket was thrown over him, and he was kept warm. That is all that saved his life. How long he was lying there before found we do not know.

Another case: They were doing a lot of rebuilding this summer, and a man was overcome by the heat. The foreman said, "Throw water on him." He thought he had fainted. Fortunately, I was right at the plant when this happened, and in 10 minutes I was at the man's side. I gave him hypodermic injections and took him to the hospital, and in three days he was back at work.

Mr. Ross (Missouri): We recently had a lecture by our physician, who laid a great deal of stress on heat stroke and recommended that we post minutes of his lecture in our first-aid room, which we will do as soon as they are completed. About 40 former committee members heard this lecture, and every one of them will be given copies to digest thoroughly.

CHAIRMAN JACOBSEN: If you will let us have those minutes we will reprint them and have them sent out.

MAJOR RENINGER (Lehigh): There is one thing that we sent around to all of our plants, I think that was Circular No. 8, issued by the Bureau of Mines, describing their method of first aid. We sent about 25 or 30 copies to each plant. It was very complete. This circular can be had for about five cents a copy from the Government printing office.

CHAIRMAN JACOBSEN: While that circular is very good, Major Reninger, I think the more personal contact and local flavor you have to the thing, the better it will work. Now if your own doctor would give the men those instructions and have them printed probably on the company's letterheads, or something like that, it would take better than if it came from the Bureau of Mines. Of course, that is only my personal opinion.

Mr. Ross: This physician has been our doctor for 14 or 15 years; everybody knows him and they will pay more attention to what he has to say than they would to any Government bulletin, I think.

MAJOR RENINGER: Of course, I realize that there is nothing like advice from the physician, but what I meant was that by having those books around your plant, in a second a man could pick one of them up and look at it and know just exactly what to do. It illustrates the Schaefer method and all those other things.

CHAIRMAN JACOBSEN: As a matter of fact, all of our plants should make it their business to get all the Government bulletins describing any kind of work relating to our industry, and I think we should see that the men get those bulletins. There have been some very valuable bulletins issued on explosives, and things like that.

Dr. Coleman: Could I ask Mr. Halpin to tell you what he told me about our meetings that lagged this summer and what happened at the plant?

Mr. Halpin (Marquette): What the doctor refers to is this: During the summer, we were shut down for some time because of our construction work, repair work, and other things. We let the meetings go and

we lagged on safety work, and our accidents increased I believe, about 60 per cent during that time in comparison to previous months in that year. That is a little evidence of what will happen when you let a thing go, which is a very easy thing to do, unless you are at it all the time.

MR. FORTUIN: Do you think those accidents were due to your laxity in regard to safety work, or due to the fact that you had men employed on work they were not accustomed to?

MR. HALPIN: I don't believe it is on account of change in work, because the same men do the same work they do every day, even during the construction period.

MR. FORTUIN: Nevertheless, when a plant is down, the men are on repair work, and they don't work with the same efficiency that they do when the plant is operating.

MR. HALPIN: You may attribute part of it to that. I suppose. I won't say we were down all the time. We were down for three weeks, and then we ran, but still the construction work went on, on the outside. But I know that the cause of the accidents was that we just let everything lag; nobody tried to do anything. We let the meetings go for about three months, whereas before that we had had a meeting every two weeks. The men got so they didn't care. The first meeting I called, we had about 10 men where we should have had 20. They didn't care to come; they were "too busy."

MR. JOSSE: I believe the only way to get full attendance is to have your meetings on the company's time.

MR. ROSS: We have a meeting every week, even if we have to shut down some department of the mill in order to hold it.

MR. HALPIN: Of course, the foremost idea in all plants is "cement first," and that is the way we went at it. Everything was thrown aside to load cement. Sometimes you have to teach the management a great deal, or you won't get anything out of the men. The battle is with them more than with the men.

MAJOR RENINGER: I might say that we had the same thing. But we were pretty fortunate in the East. We have five plants where safety work has fallen off during the war, and we didn't know just what to do to reestablish it and to get the men interested in the safety committee. So we got the plants at Ormrod, West Coplay, and Fogelsville together, and we have a meeting once a month now. The month the meeting is at West Coplay. All the safety committees from the three plants get out of their particular plants in the morning, leave at about half-past ten, and get over to West Coplay at about half-past eleven. We have our own boarding house at each plant for the office men and the foremen. We give the men a good dinner, then make an inspection of the plants and quarries, then come back and have discussions. You would be surprised to see how clean that West Coplay plant is, because there are safety men coming from all the other plants, with their eyes wide open. Those men find the smallest defect that can be found. What one man doesn't catch, somebody else will, and you won't

be surprised to see what a great difference that has made in the last four months in all three of those plants.

CHAIRMAN JACOBSEN: That is always the case when a new man comes into a place—he generally sees twice as much as the old man. It is a good thing, if a company has more than one plant, to have a little friendly rivalry between them.

MAJOR RENINGER: We try to get the Vice-President, Mr. Ritter, out there, or Mr. Bear, the chief engineer, or Mr. Woodward, in case the men have any questions to ask, and you would be surprised to see how easily they go at it.

CHAIRMAN JACOBSEN: When I go into a cement plant I find a whole lot of things to talk about, but I have to be very careful because I am just there by tolerance. I recently made a visit to a plant in Oklahoma. They hadn't had any bad accidents at this plant for a long time. I said to the plant manager, "You are running along rather smoothly now; I think you are doing fairly good work." "Yes, we are," he said, "although the other day we had a surprising accident. We had a line-shaft about eight feet from the floor, with a collar and set screw. Eight feet from the floor that shaft was running 20 revolutions per minute. Next to it was a platform with a stairway. A man wanted to get up there, and instead of using the stairway, he crawled up there in some manner—we don't know how—and got caught in that setscrew and was killed." What would this manager have said if anybody had come in and said that setscrew was dangerous? A person would have been a little in doubt as to whether that point should be brought to his attention or not, because he could hardly see the setscrew. This shows that small things can cause big accidents.

Are there any other points you would like to bring up? If not, a motion to adjourn is in order.

(Motion made and carried to adjourn.)

FRIDAY MORNING SESSION

CHAIRMAN JACOBSEN: The first paper we have this morning is "Hazards in Cement Stockhouses. Packing and Shipping Departments." I think you will all agree with me that in these departments we have some peculiar hazards which very often are difficult to take care of, and a little deliberation on that subject will be of advantage to us all. Mr. Russell Frame, of the Alpha Portland Cement Company, will read a paper on this subject.

HAZARDS IN CEMENT STOCKHOUSES, PACKING AND SHIPPING DEPARTMENTS

R. FRAME, SECRETARY, CENTRAL SAFETY COMMITTEE, ALPHA PORTLAND CEMENT COMPANY, EASTON, PA.

A study of the causes of personal injuries in connection with cement manufacturing will disclose that the screw conveyor and sliding materials

are always among the leading hazards. The Stock House and Packing Departments, having such a large proportion of these risks together with other dangers, are worthy of careful consideration.

Taking the experience of the Alpha Company at eight stock houses and six packing rooms, during a period from January 1, 1918, through July 31, 1919, they furnished about 8 per cent of the total injured, the same percentage as to total days lost, and the only fatality on our records during the years of 1917 and 1918. Half of the men injured were compelled to go off duty. This runs close to the general average from the studies of the Association.

BINMAN'S FATAL ACCIDENT

With reference to the fatal accident, the employee (a foreigner) had been in our service over two years and was following his regular occupation as binman in a small stock house in which the cement was stored on the bin plan. The employee was directed to do his work in Bins No. 5 and No. 6, each one having a capacity of 4800 barrels. This certain afternoon there remained 400 barrels in each bin which had to be hoed in feeding the cement to the screw conveyor. After loading one car of cement the foreman failed to receive an answer to his signal and upon investigation found that the deceased instead of working in Bins No. 5 and No. 6, had gone over to Bin No. 3, where he could secure the required cement with far less real work on his part as compared with the hoeing he would have to do in the former bins. His portable light he left hanging in Bin No. 5. Working on a contract basis we think caused him to change from an almost empty bin to a full bin where he could have less wearisome working conditions, and his further neglect to afford himself ample light contributed to the recklessness resulting in his death.

HAZARDS OF STOCK HOUSES

Cement stored in bins presents greater danger to the workmen during the course of its removal than is usually found in the Open House.

At Martins Creek we have two types of stock houses. No. 1 has been partitioned off into bins where a known quantity of cement can be stored for special orders, tested and sealed, and drawn during the presence of the inspector who is sent to the plant to see that the cement in his shipment comes from this particular bin. The capacity of the bins is as follows:

- 1 bin 10,000 barrels
- 1 bin 6,000 barrels
- 2 bins 5,400 barrels (each)
- 1 bin 4,000 barrels
- 1 bin 2,300 barrels

and the remainder of the bins each holding 2,600 barrels.

No. 2 Stock House is 270 feet long, 73 feet wide, and the walls are 39 feet 6 inches high. The capacity is 185,000 barrels. There are no bins such as described in Stock House No. 1, the cement being discharged at different points from the overhead screw conveyor and left to follow its natural course as it strikes below. This has been termed an "Open Stock House".

The storage bin has a limited capacity and while being emptied the cement tends to cling to the surface of the partitions and therefore gives the working face a steep pitch. When the cement is being disturbed to cause a flow, the workman must be on his guard in event of abrupt and heavy slides of material, which very often occur. The space in which the man can safely do this work is limited, the bin may not have adequate natural or artificial lighting, the flow of cement creates a continuous dust and the man will have his entire lower limbs wrapped up with cement sacks that retard quick movements—all of which increase the chances of injury. In case a man is covered up by cement it takes only a few moments for him to smother to death.

In an open stock house having tunnels the conveyors in which are fed by spouts and arranged at short distances apart, the cement that does not flow to the opening freely will remain in small low piles in the stock house. Men have plenty of room, more light, and better ventilation during the course of hoeing the cement.

When walking over the top of cement in an open stock house during the course of taking an inventory, care must be exercised against starting a slide. At one of our plants a Finishing Mill foreman, appreciating this danger, has been known to follow the chemist in the course of this inventory without the knowledge of the latter, so that he might be close at hand in case of accident.

Sometimes we find a small leak in the stock house roof or sidewalls, through which moisture will penetrate and reach the cement when the storage is well filled. In cleaning the last cement from the stock house, there is a danger from any cement which has hardened sufficiently to hold fast to roof supports, to other overhead construction, and to the sidewalls. At Plant No. 6 a formation which was clinging to the eave of the roof fell and struck the binman across the back, causing a disability of 70 days duration. Another man was injured in removing hard cement from the stock house sidewall.

In 1914 the Association received a report of a man being killed by a slide of cement caused by jar from the railroad. This brings to mind another source—the deep-well blast in the quarry. Every man should be ordered from the stock house during such blasting. Our experience shows that slides are induced by the accompanying jar. Particular care should be observed when working in freshly-ground cement, as it is known to move quickly and in heavy slides upon disturbance.

During the course of the removal of cement, the safe practice is to work not less than two men at any one time; to furnish a long rod and long handled hoe to start the cement, ropes where conditions permit their use, and careful instruction to men as to the danger should they undercut the cement to induce slides, together with a rule that hoeing should be begun from the top of the pile and the cement worked on the terrace plan. Compressed air is a good agency to start a flow of cement from a bin. The floor of the stock house between the tunnels, when constructed on an angle, will induce a greater free flow of cement. The "Association Bulletin," of February, 1917, contained an interesting account.

of the man in the bin being furnished with an extension carrying a push button to signal persons on the outside when in danger.

Drawing cement in tunnels by reason of the limited ventilation is a dusty occupation and there are numerous cases of cement getting into the eyes. A good design for tunnel construction is that described in the August, 1918, number of the "Association Bulletin." We have the conveyors in the tunnels of one stock house set in a concrete trough which is built up from the floor and on one side of the tunnel so that the attendant cannot walk over the conveyor gratings. This gives room for thorough inspection, and is convenient in case of repairs. Where artificial light is required, due care should be given to keeping the system in good service.

All bins need strong iron ladders. These should be guarded, and connected with the ladder at different heights in the bin there should be working platforms protected by guard rails and toe board. This construction will give the workman a chance to go about his work more freely, and affords better safety. We had an employee who lost 49 days when, to avoid a slide, he jumped on a wooden ladder with such force that he broke the wooden rungs and fell into the cement. Last year a report was furnished the Association of a fatality due to the bin collapsing. In this connection the construction of bins must allow for a liberal factor of safety. At one of our stock houses, iron columns in between which were inserted wooden planks were found inadequate, as the columns buckled and broke loose at the top fastening. An all-steel bin designed by the construction company's own engineer proved a failure in a near-by plant. When wooden partitions are used a liberal use of iron supports and a frequent inspection is advisable. Reinforced concrete makes very strong bin partitions. Since 1910 we have had them in one of our stock houses, built of 8-inch walls, 17 feet by 30 feet. for a bin of 3000 barrel capacity.

Recent storage construction shows the silo method of reinforced concrete to be in favor. Single containers, built high and narrow so as to promote self emptying, with port holes through which to reach from the outside to disturb any cement that clings to the side walls, would remove many of our present hazards. In addition the tunnels connecting these single containers would permit all necessary openings direct to the outer air to secure good ventilation, better light, easy access, and a general improvement in present working places.

The dangers of a screw conveyor are too well known to require a lengthy review. They are like poison gas in effect, causing death or permanent injury. Long ago the screw conveyor was indicted, found guilty, and sentenced for life behind strong iron bars, made up in form of a heavy grating $\frac{3}{4}$ inch rods spaced at $2\frac{1}{4}$ in. centers, secured to angles—3 in. by $2\frac{1}{2}$ in. by $\frac{1}{4}$ in.—placed legs down, in sections 11 ft. 9 in. long and bolted securely in place. This guard is your gas mask, and we must insist on the same recognition of its value by keeping it in place, as all soldiers who were compelled to have their masks on their chests ready for instant use. Many casualties in the late war were due to soldiers not having gas masks for immediate protection, and the cement industry can poin

to a long list of amputated limbs and fatalities caused by the lack of appreciation of the awful dangers of screw conveyors and the necessity for the best guards and inspection service to overcome this menace in every department and in every location in the Plant.

To eliminate further danger and dust, a ¼-inch thick plate, the full width of the conveyor and covering the entire length, excepting such places where material is inserted, is added. The plate is fastened with bolts to the grating angles.

HAZARDS OF PACKING AND LOADING

In the packing room, the Bates Machines need guards on the main drive belt, the gears, the pulleys on the bin feeder drive, and the eccentrics in back of machine. Our records show one man lost two fingers in the gears and another had a close call from fatal injuries by having his clothing caught on small feeder drive pulley which had a piece broken from flange. Twenty per cent of our accidents in the packing room and stock house are due to cement spurting into the face and eyes of the operator on Bates Machines, due to a bag bursting or a small hole in same. Only a small percentage of our employees will wear goggles.

I have been advised that a member company follows a practice of having a small equipment at the stock house for giving immediate treatment—only an eye wash—as soon as a man gets cement in his eye, claiming that if the chemical action of the cement is neutralized immediately, the usual burn will be prevented. They have now followed this method about eight months and during that time have not lost one single day from a cement in the eye accident.

On hot days in packing freshly-ground cement, the men often experience chafing of the arms and fingers. Our experience has been that there is a good deal of lost time on this account and the extent of this disability may escape attention because the ailment is not classed as an accident, and therefore the same complete reports of the full facts are not received and kept on file. The decisions under Compensation Laws have been so liberal to the claimants that we may expect to be required to pay compensation for a serious infection or death resulting from this cause. We hope the medical department of some member company can offer an ointment that is quick healing and antiseptic, to be kept on hand for immediate use in case of chafing and the men educated to obtain prompt treatment, as a means to reduce this lost time.

The question of dust control in the packing room is in the mind of every manufacturer. State factory inspectors have registered a criticism on working conditions, and who knows how much longer the workman will tolerate them.

The Security Lime and Cement Company is reported as having secured good results with an installation of the Bates Valve Bag Company which produces a draft and collects the dust so successfully that the air in this department of the Security's plant is practically free from cement dust. The Alpha Company is about ready to try out a collecting system, recently designed.

Trucking has its hazards in men striking their hands, slipping on the

floor, and upsets when passing over the runway. New men need instruction as to proper methods in handling a truck.

The shifting of cars at packing rooms has its dangers. Failure to give the workmen proper notice before the shift is started, neglect of the men to heed the warnings, cars breaking loose, men crossing in front of and jumping on cars, are responsible for accidents. At one plant where the tracks to packing room are on a grade, we have derailleurs and the crew must give the packing room full notice of a shift about to be made before the cars can pass the derailer.

The stock bins and overhead walks require the standard guard rails with toe boards. A fatal injury on our record shows that while engaged in conveyor repairs over the bin a bar slipped and caused the man to fall from the platform on top of bin. The same standard guards that are generally used in other departments of the plant will afford necessary protection to belts, pulleys, gears, sprockets, chains, clutches, and electric apparatus which make up the general machinery hazards. Care should be exercised to see that machinery, particularly that in tunnels and elevators, is equipped with locks to prevent starting up without notice while men are working in positions where they can be caught.

Education of the workmen in safe practices has a large field in the stock house and packing rooms as it takes time to train new men and because of the importance of having an efficient crew on duty each day to load your cement promptly, and therefore have it arrive at its destination in shape satisfactory to your customer.

DISCUSSION

DR. COLEMAN (Lehigh and Marquette): At our plant we recently had a cement-burn case. I never saw a man so badly burned. If he had been in fire he couldn't have been burned more badly. He lost two days. His arms were burned from the wrists up to the back and he was burned around his waist. We used a zincochinol ointment, and I really believe if we could get the men to put that on before they go to work in the hot weather, it would prevent that burning.

CHAIRMAN JACOBSEN: That question of cement burns is a very important one. We all have trouble with it in the summer time. I don't know that it should really be called a burn. It is really an irritation of the skin I suppose, caused by the dampness of the skin and the cement dust coming in contact with it, and the effect of the clothing rubbing on the skin.

DR. COLEMAN: Yes that is right, but it is a burn.

MR. FRAME: It has been our experience that often our regular packers will want to take time off because of chafing on their fingers, hands or arms. Of course, we don't class it as an accident, but we may get caught some day.

MR. MACFETRIDGE (Lehigh): It may become a compensation case.

CHAIRMAN JACOBSEN: I don't think there is any question about that; it is caused during work at the plant.

MR. FRAME: Mr. Chairman, do you get many reports of disability from that cause?

CHAIRMAN JACOBSEN: Not a great deal of time lost. They are mostly just doctors' treatment cases.

MR. FORTUIN (Pennsylvania): The old-time packers use lard for that and when the new packers come on, they are instructed also to use lard. It takes all that chafing away, and also takes the cement out of the pores. The only trouble they have is when their fingers get sore, which is in the summer time.

MAJOR RENINGER (Lehigh): Do they apply the lard before they start work?

MR. FORTUIN: No, when they get through.

CHAIRMAN JACOBSEN: Dr. Coleman, what effect do you think bathing facilities would have on it?

DR. COLEMAN: No effect at all; the man is burned when he comes in.

CHAIRMAN JACOBSEN: Do you remember when we had Dr. Turner at our cement safety meeting at Bethlehem? He holds a different viewpoint on that. He claims it can be eliminated to a great extent if the men will keep thoroughly clean.

DR. COLEMAN: At the Lehigh plant, I believe 85 per cent of the men bathe freely, and we have just as many cement burns there as we do at Marquette, where they don't bathe quite so freely.

MR. FORTUIN: If you want the cement off your hands, or your neck, or wherever it may be, you either have to take it off with a dry towel or use cold cream; water won't take it off. Cold cream is really the best. That is what I have used; it takes it all off.

DR. SNELLING (Trojan Powder Co.): I would like to make a suggestion along that line. I believe the primary cause is really a preventable one. I am not acquainted with this particular phase of the matter, but I have had experience with a somewhat similar matter, in which irritation was brought about by working with a dusty chemical. In that particular case, I found that the trouble was confined to men who perspired freely, and occurred on those parts of the body where the chemical could touch the skin, and where the man perspired freely. It was a rather serious problem at the time it came up, and I investigated the matter. I decided I would prevent it from the beginning by preventing perspiration.

It happened that at this time a proprietary medicine was coming on the market for the use of ladies who didn't want to perspire under the arms, particularly. We analyzed that material and found it was perfectly harmless; it was made up of aluminum chloride. It costs only a few cents a gallon, and it completely eliminated our trouble. I can't see why, at the beginning of the hot weather, you couldn't let the men try a wash of this with a piece of absorbent cotton. It closes the pores, and prevents excessive perspiration. I don't know whether that will solve your problem.

MR. FORTUIN: I don't think Dr. Snelling understands the method of packing cement. Have you ever been in a cement house where cement was being packed, Dr. Snelling?

DR. SNELLING: No.

MR. FORTUIN: The men get sores on the neck, as well as the hands, and they perspire all over their bodies. They become saturated.

DR. SNELLING: Really, though, it would be where there was an excessive amount of dust and an excessive amount of perspiration. If it weren't confined to those particular parts of the body, you would have this difficulty all the time.

DR. COLEMAN: I tried a 3 per cent solution of formaldehyde on the feet, and it worked there. I have never tried it on the body. I think though, that if we use some grease it probably will eliminate a great deal of trouble.

MR. FORTUIN: I would like to ask Mr. Frame, when he refers in his paper to a man working in a bin and the foreman not receiving an answer to his signal, what that signal is.

MR. FRAME: Electric lights. By pressing a button the light is turned on and off in the bin where the man is working.

MR. FORTUIN: Is there a light in each bin?

MR. FRAME: Yes.

MR. FORTUIN: Isn't it a fact that when no cement comes to the bin they try to locate where the man is, rather than go to the signal?

MR. FRAME: Yes, but this foreman gave the signal on account of a car being finished. They loaded the car and he wanted the man out there for some purpose or other. He gave the signal and the man didn't answer.

MR. FORTUIN: But at other times they don't try to locate a man as long as the cement is coming into the bin?

MR. FRAME: No. Of course they would signal him in case of a breakdown in the packing room.

MR. FORTUIN: When you referred to the chemist taking inventory of your bins, you said that the foreman followed him up for fear he might be covered up in a slide. Haven't you a walk over your bins?

MR. FRAME: In this particular case it was an open stockhouse and not a bin stockhouse, and there was no walkway on the side at all, but only overhead where the screws come close to the roof.

MR. FORTUIN: Can't he see down into the stockhouse that far?

MR. FRAME: He can, but he won't trust his judgment that far. He would rather walk over the stock piles.

MR. FORTUIN: You also referred to ladders in bins. Couldn't you get your men inside the bins by having an opening in each bin from the outside, through the stockhouse wall?

MR. FRAME: Possibly we could, but we never have had that arrangement.

MR. FORTUIN: Wouldn't that be better than having a ladder going into each bin?

MR. FRAME: Hardly. Suppose your opening would have to be on the far side of the bin. If your bin were full you would draw from the front side, and a man couldn't get into the bin unless it was a very high door.

MR. FORTUIN: If the bin were low you wouldn't have occasion to use a ladder.

MR. FRAME: After the first big tap you have to use a ladder to go into the bin.

MR. FORTUIN: We don't have ladders and seldom have occasion to go into the bins. If we do, we have a manhole on the outside that can be taken off.

MR. FRAME: How large a bin is that?

MR. FORTUIN: Four thousand barrels capacity.

MR. FRAME: How much of it will flow freely?

MR. FORTUIN: It will leave three or four hundred barrels.

MR. FRAME: We don't have a bin that will empty out that much.

MAJOR RENINGER (Lehigh): Do you put toe-boards on your screw-conveyor platform?

MR. FRAME: Yes.

MAJOR RENINGER: We had them in most of our places, but the Pennsylvania law at the present time has eliminated that. We take them away, so that we can clean up our top runways.

MR. FRAME: Our standard is open walkways.

MAJOR RENINGER: That is our standard but we don't have them in all of our plants.

MR. FORTUIN: There is one other question I would like to bring out. Mr. Frame refers to the packers invariably getting dust in their eyes. That is a point we raised at a local council meeting in Allentown, at which I had the pleasure of presiding. The matter was brought up for the reason that there was a law being formed to compel the wearing of goggles in cement plants. We attempted to find out from the members present as to whether their eye accidents were mostly due to cement in the eyes. The majority of them said they didn't have any.

This matter brings up that same subject. Apparently they have lots of trouble, and I would like to find out from the representatives of other cement companies, out West, whether they have the same troubles. We have them, as I explained at that time, but we have compelled our men to wear goggles. We get special glasses for them. Our safety committee compels them to wear the glasses, and if they don't wear them they can't work in our plant. We enforce that rigidly.

MR. MACFETRIDGE (Lehigh): What do you do during the labor shortage, even "fire" them then?

MR. FORTUIN: Our men do wear them, although we did have some trouble at first in getting them to do it.

CHAIRMAN JACOBSEN: I remember once I had the pleasure of visiting the Alpha Cement plant at Cementon. I noticed all the packers wore glasses there. I asked them whether they had any trouble and they said, "No, we prefer to wear the glasses and take no chances on having our eyes burned." I don't know whether they maintain that practice any more.

MR. FRAME: Possibly we had a different crew of men at that time.

MR. FORTUIN: I would like to find out whether there are mills not in our district that are having this same experience.

MAJOR RENINGER: I can speak for our Western plants. Take for in-

stance our Mitchell plants—49 accidents reported, 19 of them eye cases from cement dust. They don't wear glasses. We have tried to install that system but they absolutely refuse. We have the same trouble at Mason City, Iowa.

MR. FORTUIN: The reason I bring that out is that at the meeting the majority of the representatives claimed they had no eye accidents due to cement getting in the eyes when packing cement.

MR. MACFETRIDGE: The condition existed but I don't suppose they thought it serious enough to give it any attention.

DR. COLEMAN: Could you enlighten me as to what kind of glass that is? And do the men have trouble with the moisture on the glass?

MR. FORTUIN: I think they do sometimes. I really don't know, Dr. Coleman. The glass is made by Wilson, of Reading. It is a light-weight glass. We use two kinds, the heavy ones for chipping, and the light ones in packing.

DR. COLEMAN: I tried wearing glasses myself. I tried regular automobile glasses; they fit very tightly and kept out the dust, but I perspire rather freely and my trouble was that there was a steam on the glasses most of the time, and I couldn't see. We have had a lot of trouble from a stream of cement getting out of bags at the packing machine. I think the week before last we had a lot of bad bags, and we had seven cement burns in one day. One man lost one day but that was all the time lost.

MR. LAWNICZEK (La Salle): We don't have very much trouble with cement in the eyes, unless we get new packers. At this time of the year, when we get new packers, they forget to turn off the valve. The bursting of bags doesn't bother us any because our men sit above the machine.

MR. JOSSE: To eliminate the danger from old bags we tack some sacks underneath the man's seat, so that the sack hangs down below the bag. When the bag comes down, the sack tacked to the seat being pliable, it is not in any way impeded.

MR. MACFETRIDGE: We don't trip our bags; we lift them off.

MR. FORTUIN: When the bag is placed on the valve it gets right on the seam and becomes all wrinkled—this will happen to new bags sometimes—then when it straightens out under pressure a hole gets into the bag and the cement shoots right out toward the man's face.

MR. MACFETRIDGE: Our packers sit higher and don't catch that, but it catches the men down below.

MR. JOSSE: That is why we have the sacks nailed down on the bench behind the man sitting up on top. I don't think you have so much trouble getting the men on the machines to wear goggles as you do the men on the trucks.

MR. MACFETRIDGE: The man on the truck is the man who needs the glasses, but he won't wear them on account of perspiration and dust.

MR. JOSSE: I saw a goggle over at the exhibit which they claim eliminates that trouble. It has a very fine gauze right up close to the glass, which keeps the dust out, but the air can get in.

CHAIRMAN JACOBSEN: It seems to me that if Mr. Fortuin has been able

to get his men to wear the glasses, there is a possibility that all the plants might do the same thing. There is no question about their being a safeguard, and glasses should be used as much as possible. In regard to eye accidents though, I wish to tell you that if we had only the time lost on eye accidents in packing houses to contend with, we would have very few days lost. Most of the eye accidents that we get are usually caused in the machine shop, and there are other places that cause really bad eye accidents, so it would pay you to give a little more attention to wearing glasses in those places particularly. I never saw anybody wearing goggles around the crusher and we have a number of bad accidents there. And in the quarry and various other places, we have many eye accidents.

Are there any other things you would like to take up in regard to Mr. Frame's paper? What about the screw conveyor? I think we ought to consider that a little bit.

Mr. MacFETTER: Everybody is guilty, there is no argument.

Mr. FORTUIN: If we keep them covered the men take the covers off.

Mr. MacFETTER: And if you "fire" the men the plant can't run.

Mr. HALPIN (Marquette): We have a watchman at our stockhouse who visits the alley once every hour. He has a station there and he has to go in once an hour to see that the conveyors are covered.

Mr. FORTUIN: Are they loose covers?

Mr. HALPIN: They are wooden conveyors and the covers are nailed down.

CHAIRMAN JACOBSEN: There is no question about the danger. We all know that, but how to eliminate the hazard is another proposition. I think it is mostly a matter of education.

Mr. JOSSE: It is a matter of education, just as I said yesterday. It is a slow and hard process, but it has to be gone through, and if all of us work toward the same goal we will get the men educated some time.

CHAIRMAN JACOBSEN: I think you ought to put up to the men in actual figures what has happened on screw conveyors, and get them to see it in that light. A man may work around a plant for years without appreciating the danger, he may walk along on screw conveyors until the day that some one has left off a cover, and then he is hurt. If they could see in plain figures what happens every year, in the way of accidents on screw conveyors, they would probably look at it in a different light. What do you think of that concrete screw conveyor cover I had in the Bulletin some time ago?

Mr. JOSSE: It would be all right if it were not too heavy to lift. I feel this way about it: I think that we have disciplined our men, or the safety committees have disciplined them so that very rarely do they leave the covers off any more, whereas the covers used to be off all the time. I would say it is a matter of education among the men themselves, and the safety committees in your mills can have more effect on the men who take these covers off than the bosses can.

Mr. LAWNICZEK (La Salle): Do you bolt your cover?

MR. JOSSE: We bolt some of them. We use a C-bolt. The others are just laid on. Those that are taken up frequently are just laid on.

MR. LAWNICZEK: We used to have a triangle on each side; we didn't use any clamps; that holds the cover down, and also prevents the dust from coming out.

MR. JOSSE: That is good.

CHAIRMAN JACOBSEN: What about the question of the cars at your pack house, the box cars, or whatever you ship your cement in? We have had a number of accidents at the packhouses by men being caught between cars, run over by cars, caught between the car and the platform, or even between the car and the roof of the platform. There is a hazard there that is worthy of consideration.

MR. MACFETRIDGE (Lehigh): Whose hazard is it in case the railroad company sets in several empties, and the brake fails and your men don't know it?

CHAIRMAN JACOBSEN: I think you will be held responsible.

MR. JOSSE: About a month ago three of our negroes were hiding between a string of cars, which were five or six feet apart. They were in the yard gang, and were taking a rest. The switching crew hitched to this string of cars four cars of coal ahead, and of course pushed the cars together. Two of the men got out but one was caught. It gave him a terrible wound. It took about 200 stitches to sew him up. But to come to the point of who is to blame for this accident, it is a mighty close question in Missouri. It is going to be a hard job to decide. The Missouri Pacific Railroad representatives, of course, have investigated it, and they got all the details from the other men. We are taking care of the injured man and are waiting to see whether the Missouri Pacific is going to pay for this or not. We are going to have a pretty close fight on it, I believe.

CHAIRMAN JACOBSEN: They were not hurt during their course of employment, they were just fooling around when they were hurt.

MR. JOSSE: Of course, the industrial contract these railroads have with all industrial plants that have switch tracks has the clause that if any of your men are hurt by their crews, you are responsible, but I believe the court holds that they can't make you responsible, because there is no comeback the other way. It is not a two-way contract, and therefore we are not responsible. So we are going to have a fight.

MR. MACFETRIDGE: Would you naturally think, then, that it is up to us to inspect all the equipment that comes in there, to find out if there is a defective brake?

CHAIRMAN JACOBSEN: There is no question about it so far as the compensation law goes. If a man is hurt at your plant, you will be held responsible for him.

Is there anything else on this paper? If not, we will go on to the next one, which I know you will all find very interesting. The title of the paper is "Safety Factors in the Use of Explosives in Cement Rock Quarrying," and it has been prepared by Dr. Walter O. Snelling, Director of Research, Pennsylvania Trojan Powder Company.

SAFETY FACTORS IN THE USE OF EXPLOSIVES IN CEMENT ROCK QUARRYING

DR. WALTER O. SNELLING, DIRECTOR OF RESEARCH, TROJAN POWDER COMPANY, ALLENTOWN, PA.

A cartridge of explosive may be thought of as a small bundle in which a very large amount of energy is bound up in latent form. Just as a knife owes both its usefulness and its danger to its sharp cutting edge, so it is the ability to explode which gives an explosive its utility and its hazard.

By a better knowledge of the characteristics of explosives, and a more complete understanding of the proper methods for their handling, the number of accidents arising from their use is constantly decreasing. Accidents do not "just happen"; behind every accident there must be a chain of circumstances which lead, step by step, up to the final result, and the more complete our information is in regard to the influences of all the factors entering into any given operation or procedure, the simpler it will be finally to bring that operation or procedure to a basis in which the chance of accidents will be reduced to a minimum.

It is always helpful to bear in mind that explosives form no exception to the general rules of cause and effect. In order to liberate the energy that lies latent in a cartridge of explosive it is necessary to apply to the explosive material a sufficient impulse of some sort to commence the chemical changes which we call detonation. Friction, or a heavy blow, or even a very tiny spark, may be sufficient to start the cycle of chemical and physical changes which lead to explosion, but without such primary impulse the explosive will remain inert, and its bound energy will be dormant for months or even for years. Accordingly it becomes quite important for every one whose work has to do with explosives to become as familiar as possible with their characteristics, and to acquire a thorough knowledge of the principal conditions which may lead to accidents in connection with their use.

UNLOADING THE CAR

The first point at which the quarry superintendent is likely to be concerned with the handling of high explosives, is in unloading the car which brings the material from the manufacturer's plant or magazine. The manner in which the cases are packed in the car is prescribed by the rules of the Interstate Commerce Commission, the method having been carefully worked out with the thought in mind of reducing transportation risks to a minimum, and insuring the consignment of explosives reaching its destination in good condition.

It is quite uncommon to have a car of explosives arrive in damaged condition, but where the contents are found to be damaged, and cases are broken or otherwise in improper condition the matter should be reported to the transportation company, and the condition of the damaged cases should be carefully determined. If there is evidence that the roof of a car has leaked it is always advisable to examine the condition of the

cases of explosives under the leak quite carefully. Nitrostarch explosives when very wet become insensitive and difficult to explode, while nitroglycerin explosives under the same conditions tend to "leak" nitroglycerin, and this free nitroglycerin is of course far more dangerous than is the nitroglycerin in absorbed condition in the original explosive. Cases of explosives which show exudation of nitroglycerin should be handled with the most extreme care, and every precaution should be used to avoid any friction, or any jar or blow that might be sufficient to cause an initial explosion which would undoubtedly communicate at once to the entire lot of explosives.

In unloading a car of explosives, just as in handling the cases of explosives in all subsequent operations, care should be taken to avoid unnecessary rough handling. It is true that cases are on record where boxes of dynamite have fallen in quarries for a vertical distance of 100 feet or more without explosion, and it is also true that railroad accidents have occurred in which cars loaded with explosives have been literally torn to pieces without explosion resulting. It is just such facts as these that make it so difficult for the average user of explosives to hold a proper mental conception of the degree of care which should be used in handling explosives, and to draw a clear distinction between that over-cautiousness which leads to a general fear of explosives on the one hand, and such careless handling on the other hand as amounts to true foolhardiness.

A case of high explosives need not be handled with quite the same care that would be given to a crate of eggs, nor can it be handled with quite the same roughness that would be used with a block of stone. Between the two extremes lies that safe ground which leads to the handling of a case of explosives with that degree of care which its nature warrants, and yet with the absolute assurance that when handled in this careful way the case of explosives is practically as safe to handle as any other box of like weight would be.

It is needless to say that the throwing of cases of explosives from a car to a man on the ground is to be condemned, as is also the too rapid passing of cases of explosives through a chute. I have often seen explosives loaded through a chute of considerable length, and once during the unloading of explosives from a boat I saw a case of explosives broken open by striking another case of explosives which had become stuck at the bottom of the chute. I do not doubt that this sort of handling could be repeated many times without explosion, but nevertheless I feel confident that the operation involves some risk and is therefore to be condemned. The handling of the cases, a few at a time by means of a small truck is decidedly preferable to the use of a chute unless it is quite a short one, and the passing of a case of explosives from one man to another is a great deal better than the throwing of the case, with the possibility of the man failing to make a good catch and dropping the case.

MAGAZINES FOR STORAGE OF EXPLOSIVES

A good deal might be said as to magazines for the storage of explosives. It is most desirable that a magazine should be water-tight and well ven-

tilated, and in addition should be located sufficiently far from surrounding buildings to offer proper safety. As to the actual type of construction for a magazine opinions differ widely. The Bureau of Mines advocates magazines made of cement-mortar, and Tech. Paper 18 gives a rather full description with bill of materials for a magazine with a capacity of 20,000 to 30,000 lbs. of explosive. At the time Tech. Paper 18 was published the cost of a magazine of this kind was \$400.00, but the price would of course be materially higher at the present time. The walls of the Bureau of Mines magazine are 6 inches thick, and the roof and door, both of which are also of cement-mortar, are 3 inches thick.

The principal advantage of cement mortar of the composition suggested by the Bureau of Mines is that the material is substantially bullet-proof, and yet crumbles so readily under a blow such as would be produced by an explosion as to greatly reduce the danger from large flying pieces of material.

MAIN AND AUXILIARY MAGAZINES

Where it is desirable to carry a large stock of high explosives at a quarry, it is preferable to provide a main magazine located at a safe distance from the quarry, and an auxiliary magazine close to the quarry for the day's supply of explosives. The magazine for high explosives should always be located a proper distance from the detonator magazine or storehouse, and it is very important always to bear in mind that detonators and high explosives should never be stored together. In spite of the fact that the storing of detonators with high explosives has been most strongly condemned by government and state bureaus, and by practically all investigators who have studied the matter, one occasionally sees rather clear violations of this simple rule of safety.

MAGAZINE SITE

The selection of a magazine site, particularly for the main magazine, is a matter to which some thought can profitably be given. It is well recognized that an outcropping rock ledge forms a less desirable location for a magazine than alluvial earth or sand, since in the event of an explosion the earth waves are transmitted to a considerably greater extent through rock, and destructive effects are thus more extended than when a magazine is on a compressible and less rigid foundation.

METHODS OF THAWING EXPLOSIVES

Where nitroglycerin explosives are being used during cold weather it is necessary to provide a thaw house in order to insure the explosives reaching the work in proper condition. It is interesting to note that frozen explosives appear less sensitive to a detonator, and more sensitive to ordinary shocks or blows than the explosive in its normal condition. This subject has been under investigation for a number of years, and a large amount of information as to the cause of this peculiar phenomenon has been accumulated. At the present time the belief seems to be that although frozen nitroglycerin is relatively much less sensitive

than liquid nitroglycerin, yet frozen explosives, in part because of their rigid condition and in part because of the presence within them of crystals of nitroglycerin, are in unfavorable condition to resist friction and forces which tend to distort the form of the cartridges.

The thawing of frozen explosives should always be carried out at a relatively low temperature, and any effort to quicken the thawing action is to be condemned. When only small amounts of explosives have to be thawed, a double jacketed vessel may be used, in which the heating agent is water at a temperature of about 50 degrees C. (122 degrees F.) The temperature should never exceed 55 degrees C. (130 degrees F.)

While explosives are being thawed their sensitiveness seems to be increased somewhat, and accordingly both during the thawing operation and while the explosive is still warm after thawing, exceptional care in handling should be exercised.

Where a considerable amount of explosive has to be thawed, it is best to make provision for thawing at one time the entire amount of explosive used in a day, and for this purpose a special thawing house is necessary. The thawing house should be located at a safe distance from all quarry buildings, and should be provided with some means of indirect heating. Technical Paper 18 of the Bureau of Mines describes a type of thaw house which is recommended by the Bureau, and in which exhaust steam or hot water is utilized as a means of supplying heat, the heating coils being placed in a small shed adjacent to the thaw house proper.

"Make-shift" methods of thawing have led to frequent accidents, and it should always be borne in mind that the thawing of frozen explosives is an operation which should be given careful thought. Where electric current is available it has been the custom in some quarries to place resistance coils or resistance bars in a magazine for the purpose of maintaining a temperature above that at which the explosives freeze, but accidents have been directly traced to this arrangement, and indirect heating, with the heating element placed in an auxiliary fire-proof box connected with the thaw house by a flue or by some other like means, is much to be preferred.

In thawing explosives the use of a high temperature for a short time is much less desirable than a considerably lower temperature for a longer period. Although temperatures as high as 50 degrees C. (122 degrees F.) are sometimes used a temperature of 40 degrees C. (104 degrees F.) is much to be preferred. The long-continued exposure of explosives in a thaw house should be avoided, and the Bureau of Mines has called attention to the fact that some explosives, such as gelatin dynamites, have been known to decompose and explode after only a few days when continuously heated.

PRIMARY AND SECONDARY BLASTING

The characteristics of different types of explosives is really the subject for a paper in itself, and I feel that this matter, and a study of the factors on which the selection of explosives for any particular type of blasting depends, would require more time than can be properly given to them in this paper. With proper explosives from 3½ to 4½ tons of

rock can usually be obtained per pound of explosive used, but this also is a factor which is dependent upon many conditions in the quarry, so that a direct comparison between blasting in one district and in another district is often impossible, and sometimes leads to conclusions which are unfair to really good practice in a district in which unfavorable conditions such as clay parting seams exist. I have known of districts in which the "lay" of the rock and its toughness have caused $2\frac{1}{2}$ tons per pound of powder to represent really excellent blasting, and I have also seen districts in which 4 tons of rock per pound of powder was being produced by blasting methods which by improvement could easily have been raised to at least $4\frac{1}{2}$ tons per pound of powder and possibly some little higher.

It should be remembered that the cost of the powder in the blast is far from being the sole factor to be considered in blasting costs. Many a quarry superintendent has found to his cost that a primary blast in which too little powder was used may lead to an increase in the cost of shovel work and of secondary blasting entirely out of line with the small difference between the cost of the powder originally used, and that which would have been required for a well-balanced shot.

It is the cost of the rock at the crusher which the quarry superintendent should regard as his standard of comparison, rather than the cost per ton of the rock immediately after a shot. Frequently it will be found that adding one or two cents per ton to the cost of the primary blasting will result in a reduction of three or four cents in the cost of secondary blasting and steam shovel operation, and the wisest economy is that which looks beyond the first cost, and gives careful consideration to the ultimate cost.

Secondary blasting is at best to be regarded as a necessary evil. Modern practice tends to reduce secondary blasting to a minimum by the following methods:

- a. Improvements in primary blasting, for the purpose of reducing to a minimum the amount of rock which must be block-holed or bulldozed.
- b. Increase in the size of shovels and cars, and increase in the opening of the crusher to take rock in larger sized pieces.

These two methods of procedure should in fact go hand in hand, and as manufacturers are today building crushing machinery of greater strength and with increased size of inlet, and increased skill on the part of the superintendents and foremen is leading to constant improvements in blasting methods, we can confidently look forward to a steady improvement in regard to secondary blasting operations.

METHODS OF FIRING

Two methods of simultaneously firing a number of shots in quarrying are available, one method being by the use of electric detonators, and the other by the use of detonating fuse or cordeau.

Cordeau, frequently known as "Cordeau Detonant, or Cordeau Bickford" is lead tubing filled with T. N. T. Experiments have shown that such cordeau explodes at the rate of approximately 5,300 meters per second,

and accordingly where a number of holes are connected together by means of lines of cordeau the holes become in effect one single hole.

Electric detonators are copper capsules which contain a detonating charge of fulminate of mercury or equivalent material, and a small loop or "bridge" of very fine wire, which can be heated red hot by the passage of a very small electric current. As the rate at which an electric current travels is stated to be 300,000 kilometers per second (186,000 miles per second), it is evident that where a number of electric detonators are connected to a single source of electric current, their detonation is absolutely simultaneous for all practical purposes.

Both cordeau and electric detonators have their advantages and disadvantages for the simultaneous firing of large blasts. Where a number of widely separate charges are to be simultaneously fired electric detonators have some advantage over the use of cordeau, while on the other hand cordeau has some advantage in wet holes, and particularly in holes where the explosive charge is interrupted by lengths of stemming for the purpose of "raising" the average height of the charge.

One of the advantages possessed by cordeau is that as the line of cordeau extends the entire length of each hole, the entire column of explosive is brought into detonation at a speed which is determined by the rate of detonation of the cordeau itself. If, for example, a hole 100 feet deep were to be filled with an explosive having a rate of detonation of 3,000 meters per second, and the explosion of its charge to be brought about by an electric detonator placed in the bottom of the hole, the detonating wave would pass through the column of explosive at this rate of 3,000 meters per second. If instead of this arrangement a line of cordeau extended from the top to the bottom of the hole it is evident that this would communicate detonation to all parts of the explosive in contact with the cordeau at the rate of detonation of the cordeau itself, instead of at the normal rate of detonation of the explosive. The explosive would still probably detonate at its normal rate, but the cordeau would increase the rate at which the column of explosive would appear to detonate through its length. Opinions differ as to the advantages which are gained from this simultaneous detonation of the entire length of a column of relatively slow explosive. For certain special purposes there can be little doubt that it helps bring about a desired "timing" of the explosion of several different types of explosive used in a single blast, and possessing different normal rates of detonation. The use of cordeau as a convenient and safe means of simultaneously firing a number of holes is increasing, and many quarries have replaced the use of electric detonators by this method of firing holes.

When electric detonators are used in blasting in well-drill holes, the best practice is thought to be the use of at least two detonators in each hole. The detonators should be so spaced that the uppermost detonator is about equally far from the top of the column of the powder and from the center of the charge, and the lower-most detonator is similarly equally far from the bottom of the charge and from the middle of the charge. By this arrangement the detonator occupies the center of the column of explosive of which it is to bring about the detonation. In a

well-drill hole having 60 feet of powder the lower detonator would be 15 feet from the bottom of the hole, and the upper detonator would be 15 feet from the top of the column of explosive, the two detonators being 30 feet apart. Whenever electric detonators are used, care should be taken that several feet of powder are above the detonator, before tamping the powder, since the fulminate contained in detonating caps is much more sensitive than any high explosive used for blasting purposes, and the striking of a detonator by the tamping bar, and particularly the grinding of a detonator between the tamping bar and the side of a hole, would be practically certain to lead to an accident.

In lowering electric detonators into the hole the best practice is to attach the detonator properly to a cartridge of explosive so that the cartridge will hang perfectly plumb when suspended from the wire. The cartridge is then lowered by means of the wires to its proper position in the hole. If sufficient care is not taken to have the cartridge of explosive hang plumb from the wire it is very apt to strike against the side of the hole while being lowered, and to cause a "jam." On account of the detonator being in the cartridge, a cartridge so caught should of course be dislodged with considerable caution, and it is better to take a little more care in arranging this priming cartridge, so as to avoid the difficulty and danger of attempting to dislodge it when caught.

When cordeau is used in the hole, it is also best to use a cartridge as a "weight" to carry the cordeau to the bottom of the hole. The advantage of having a cartridge on the end of the line of cordeau, in addition to keeping the cordeau straight, is that it enables the blasting foreman to tell by the "feel" as soon as the line of cordeau has reached the bottom of the hole.

No advantage is gained by having more than one line of cordeau in a hole, and accordingly this is never done. If there is reason to believe that a line of cordeau has been broken off in the hole it is sometimes good practice to lower another line of cordeau into the hole to the depth at which the break of the first line is known to have occurred.

In using cordeau, it is well to remember that in spite of the remarkable rate at which the explosive wave passes through the material, it does not have the ability to jump a gap. Even so small a space as two or three millimeters (one-eighth of an inch) acts as an efficient barrier against the transmission of the detonating wave, and for successful results it is imperative that there should be no break whatever in the continuity of the line of cordeau.

SAFETY IN LOADING WELL-DRILL HOLES

In primary blasting the use of well-drill holes has now largely supplanted earlier methods of bench work, and although I will discuss safety precautions mainly from the standpoint of well-drill methods, the same principles will generally hold good wherever open cut blasting work is being done.

In the loading of holes particular watchfulness should be given to insure the complete absence of sparks or hot cinders from the steam shovel,

from locomotives, or from the steam well-driller. Those who have watched a steam shovel at work at night will probably have a better appreciation of the menace that sparks represent, than those who have only seen the work going on by daylight, and it should be remembered that it is not only those sparks which are visibly red which are capable of igniting explosives, but that hot cinders which appear quite black may be at a sufficiently high temperature to bring about an ignition. I am inclined to believe that rather more accidents during loading are caused by hot cinders than are usually attributed to that cause, and the only safe practice is to keep all sources of sparks away from the vicinity of the holes during the time that loading is going on. Some quarries have small tents which are placed over the holes while they are being loaded, and while this is better than no protection whatever, yet it is not so satisfactory as the complete removal of sources of sparks during the time of loading.

Of course lighted pipes, cigarettes, or cigars should be rigidly excluded from the vicinity of loading operations. It is even best that men engaged in loading should have no matches in their possession, since a hole in a man's pocket or some other accidental condition hard to anticipate may lead to a match dropping down in the hole, or falling on the rock near the hole where it may be stepped on by the men loading the hole. Even gasoline engines are to be considered as a potential source of sparks. It is true that a gasoline engine only occasionally throws out sparks, but the carbon which accumulates on the piston head and at the end of the cylinder is ejected from time to time in glowing condition, and this, together with an occasional backfire makes a gasoline engine a possible source of accident if too near a hole during loading.

In loading the hole with explosive, it has been proposed from time to time to use holders or clamps of various sorts, in order to avoid dropping the explosive to the depth of the hole. These are not commonly used however, and experience seems to show that the hazard in dropping a cartridge of explosive through a hole 100 or even 150 feet deep, is very small indeed. The first cartridge would naturally seem to be the one most likely to explode if detonation from the shock of dropping were really a considerable factor, since the later cartridges drop on the cushion formed by the cartridges already in the hole.

PREVENTING "BANGERS"

The experienced blaster is able to learn a good deal about the condition of the hole from the sound made by the first cartridge as it drops down, and the sound of the cartridge striking the bottom of the hole, or striking the surface of the water if the hole is wet, is used to determine the fact that the cartridge has gone completely to the bottom. It is excellent practice to "follow-up" the hole by measurements after each case of powder has been loaded, a case of powder ordinarily giving a "rise" of about 4 feet. There is always the chance of cartridges "banging" on the side of the holes, and thus leaving an air gap between the powder beneath which has been loaded properly and the point at which the first cartridge thus becomes crossed in the hole. If the "rise" in the hole is carefully followed by frequent measurements such a "block" in the hole will be

promptly noticed, and the condition can be readily corrected, but if a considerable amount of powder is loaded over the crossed cartridge before it is discovered that a "choke" exists, the matter is naturally more difficult to correct. An experienced loader can usually tell from the sound made by each cartridge as it drops that it has landed properly on the powder already in the hole, but occasionally a cartridge will hang on the sides of the hole even with good loading practice. A single cartridge can be dislodged safely by the careful use of a tamping stick, but if the "hanging" of the cartridge has not been noticed, and more powder has been loaded on top of this cartridge, so as to leave a column of two or three feet of powder above the choke, the dislodging of the material becomes more difficult. Efforts to dislodge such a choke by the vigorous use of the tamping bar are decidedly dangerous, and this procedure should never be followed. The best practice is of course to prevent any column of powder from building up on a "choke," by using the measuring line sufficiently frequently to keep in close touch with the level of the powder in the hole, and by paying proper attention to the sound made by the dropping cartridges as they land on the powder beneath. If a "choke" should occur however and more than a foot or so of powder should be built up over the crossed cartridge, the safest procedure is usually believed to be the cautious driving of a sharpened stick about 2 inches in diameter through the "choke," followed by the flushing out of the powder above the "choke" by means of water. Unless a quite excessive amount of water is used, this procedure will not cause the loss of the hole, as the powder will detonate in spite of a rather considerable amount of water which may be present after this treatment.

The size of the cartridges used in loading the hole is not a matter of indifference. For the standard 5½-inch well-drill hole the 4½-inch by 10-inch cartridges are commonly used, unless the hole is quite rough and ragged, in which case 4-inch by 8-inch or 4-inch by 10-inch cartridges are used. Using cartridges which are too small is a disadvantage, because the proper density in the hole is then more difficult to attain, while using too large cartridges is a disadvantage, because the chance of such cartridges catching on the side of the hole is materially increased. As a matter of fact the chance of a cartridge catching a hole is increased by the use of cartridges which are either too small or too large, and for well-drill holes the cartridges should preferably be one inch smaller than the diameter of the hole.

In measuring the hole a special tape given the best results, although in many quarries the tamping stick may be used instead. Whatever may be the method adopted to keep track of the bottom of the powder in the hole, the point which should be remembered is the accuracy of the measurements being made so frequently as to enable the loader always to know the height of the powder in the hole.

DISCUSSION OF CARTRIDGE TAMPING

The extent to which powder should be tamped during loading really depends upon the type of explosive which is being loaded, and therefore should more properly be considered in connection with a discussion of the

selection of powder for various types of blasting. Tamping of the explosive during loading is quite desirable in the case of the more plastic nitroglycerin explosives, but increasing use is being made in cement rock quarrying of explosives which require little tamping, and indeed in many quarries the explosive is not tamped during the loading, the tamping bar being only used at the end of the loading operation in compacting the stemming in the hole.

I have seen some rather surprising tamping bars at various times, ranging all the way from solid iron bars to iron tipped wooden rods. Once, in investigating a "mysterious" accident which had occurred on a piece of railroad work on which a nitroglycerin explosive of low nitroglycerin content was being used, I found that although suitable wooden tamping bars were supplied to the powder men by the contractor, a powder foreman had "shoes" made of lengths of iron pipe fastened to the end of each of the bars, "to keep them from fraying out so quick," and naturally the inevitable happened, and several men lost their lives in the resulting explosion.

Even wooden tamping bars can be unsafe if too heavy or if carelessly handled. It is not infrequent for sharp pieces of rock to become imbedded in the bottom or sides of a wooden tamping bar, and no one needs to be told that such a tamping bar will strike a spark under favorable conditions by rubbing against the side of a rough hole. The tamping bar should not be too large, in order to avoid excessive friction against the side of a hole, this precaution being particularly important in connection with piston drill holes.

A suitable layer of powder should always overlie each priming cartridge containing a detonator. Detonators are always to be treated with great respect, and having two or three feet of powder above the detonator before allowing any tamping to be done is an excellent rule.

TAMPING THE STEMMING

The energy that might otherwise be spent in tamping the powder can be utilized to advantage at the top of the hole in thoroughly tamping down the stemming which is applied over the powder. The first two or three feet of stemming should not be tamped, but after this the stemming can be tamped down quite hard, and indeed, if care is taken not to damage the line of cordeau or the electric feed wires, it may almost be said that the harder the tamping of the stemming material, the more efficient the shot will be. Experiments have demonstrated this point rather thoroughly, and a shot which is well confined does perceptibly more work per pound of powder used than can be obtained from a shot in which poorer confinement has been provided.

If explosives are to be tamped, however, it is most important that too much force should not be used. A rather considerable number of accidents have been due to improper use of the tamping bar, and to the use of unsuitable materials as tamping bars. It should be evident from what has already been said that the presence of any iron surfaces on the tamping bar is a potential source of danger, and that the use of too heavy a tamping bar also involves a rather heavy risk. I have sometimes been told

that a heavy tamping bar has advantages when it is properly used, and there may be some truth in this, but the fact remains that when improperly used such a bar becomes a source of danger, and the chance of the bar being improperly used is always present. I have been told of one case in which a type of tamping bar which has been used for some years with perfect safety by a powder foreman was used in his absence by a less experienced man, and in the course of the loading operation a choke developed and an effort was made to drive it out with the tamping bar, and an accident resulted. A lighter tamping bar would have been safer in this case, just because of the possibility of the misuse of a heavier bar by an inexperienced or careless man.

It is usually unnecessary for workmen to stand on the rock lying in front of the line of holes after the loading begins, and this is a safety precaution which may accordingly be given consideration. Should a premature explosion occur from any cause during the loading operation, the chance of men being injured is naturally less if the workmen are on the far side of the line of holes, instead of between them and the quarry face.

CONNECTING WIRES FOR FIRING SHOTS

It is of course evident that the final connecting up of the electric detonator wires, or the cordeau connections, should not be made until shortly before the blast is ready to be fired. When electric detonators are used, the method of wiring or connecting up a shot is a matter to which thought should be given. Where only a few shots are to be fired the detonators are often arranged in series, and fired by a blasting machine of the usual type, but in quarries where a good deal of blasting is being done, and where quite a number of holes are to be fired at one time, the parallel method of wiring is often preferred, the electric current being furnished from the power circuit. The connections should always be in parallel when current from a live wire is used in firing the blast.

As electric detonators are sensitive to relatively small currents, and may be fired by "stray" currents the existence of which may not have previously been known, the wiring should always be in the hands of competent and trustworthy men, and the holes should not be connected up until the shot is practically ready to be fired. Several cases are known where electric detonators have exploded apparently without cause, and investigation has shown that the wires were abraded at certain points, so that direct contact was established with moist earth or with some conducting metal. In coal mining several accidents have occurred through stray currents from a passing electric locomotive finding passage through an abraded wire to a charge which was not yet ready to be fired, and at least one accident in a cement quarry has been found to be due to a quite similar cause. These accidents only emphasize the point already brought out, that the lead wires connecting up the separate holes should only be attached when the tamping of the holes has been completed, and when the blast is ready to be fired. In addition, the lead wires should always be kept in good condition, and should be taped if any abraded spots are found.

One of the points which is to be avoided in the connecting up of a blast is too great haste in making the electrical connections. Wires loosely twisted together do not form a good electrical connection, and more than one quarry superintendent has no doubt criticized his powder foreman and his blasting men for a poor blast that has in fact been due to the failure of some of the holes to be fired by the electric current, the detonation of these holes coming through the shock from adjacent holes, and too late to enable the explosive to do its proper share of work in the blast.

The lead wires should not be brought near the exploder wires while loading is going on, and all the connections of the blast should be completed before connecting the battery to the lead wires. The custom of having shots connected up to the lead wires and firing battery before work around the holes has been completed is strongly to be condemned, and there is always the possibility that some one will unintentionally fire the blast under these conditions, in the effort to "test out" the battery or the connections without realizing that electric detonators are in the circuit. Probably the safest method that I have seen for preventing accidents from the unintentional applying of current before the blast is ready, is the placing in the circuit of a special block, which leaves the circuit open unless a special form of key is placed in it. The key is retained by the man responsible for the blast until the time that the current is to be applied, and is then inserted. Where firing is done from a power circuit a modification of the same principle may be applied, or the switch connecting the lead wires may be locked in position in some suitable way. The one point which I consider quite important is that one man should be responsible for the circuit, and that this man alone should have the key controlling the switch or the safety block.

In firing with cordeau the electrical circuit should be made before the exploder is placed in the special union which connects the detonator with the main strand of cordeau. The manufacturers of cordeau provide special attachments which may be used either with electric detonators or with detonating caps, and in addition special tools are provided for slitting cordeau in the making of connections and joints.

SAFETY IN SECONDARY BLASTING

The rules for safety and efficiency in the handling of explosives in connection with secondary blasting operations are of course not dissimilar from those rules which should be followed in primary blasting operations. In block-holing one pound of explosive will represent fully the execution that ten pounds of the same explosive will even in a well placed "dobie" or mud cap shot, while a poorly placed mud cap shot is notoriously wasteful of explosive. It is frequently economical to use the larger quantity of explosive required by the mud cap shot, because of the cost of the drilling of the holes in the block-holing method. A few years ago the situation was much more difficult than it is at present, but recent improvements in light air hammers have materially cut down the cost of secondary drilling, so that the alert quarry superintendent will bear con-

stantly in mind the advantages for and against the block-holing method. Where mud capping is done, it is well to remember that earth and clay are much cheaper than explosive, and that a somewhat larger pile of dirt will be equivalent to a noticeable amount of explosive in the charge that is necessary to break the rock.

Proper protection for workmen in the quarry from fragments thrown by the blast should of course be provided. The usual cylindrical safety shanties of boiler plate provide rather satisfactory protection if located at a suitable distance, and if the doors or openings are turned away from the direction of the blast. In firing a large blast no one should be permitted to remain on the quarry floor in front of the blast even though the distance may seem safe, for small pieces of stone are frequently projected with exceptionally high velocity and are capable of causing serious or even fatal injuries at a distance considerably in excess of what would appear normally to be a safe distance.

PERCENTAGE OF ACCIDENTS DUE TO EXPLOSIVES

I do not believe it is best to end this discussion of safety factors in connection with the handling of explosives, without calling to your attention the rather small percentage which accidents due directly or indirectly to explosives bear to all accidents which occur in connection with cement rock quarrying. Some years ago I had occasion to investigate and classify the accidents which occurred in coal mining over a period of years. I had read, as all you have, of those terrible accidents due to the explosion of coal dust which at times sweep through the entire extent of the mine. One such accident, at the Couriere mines in France, led to the loss of more than a thousand lives, while in our own country two such accidents led to the loss of 350 and of 250 lives respectively. On taking up the matter of tabulating all accidents which had occurred in coal mines however, and of classifying them according to their cause, I was rather surprised to find that accidents due to explosives and explosions together were really rather a small fraction of the total number of accidents which occurred. The Bureau of Mines has recently reported that for the year 1918 there was a total of 2,579 fatalities in connection with coal mining in this country, and of this total 135 deaths were due to explosives, and 129 deaths were due to gas of coal-dust explosions. Accordingly only about one-tenth of all fatalities were due to either explosives or explosions, and only about one-twentieth of all the fatalities which occurred were directly due to accidents from explosives.

Government statistics in connection with quarry accidents show rather similar results. In Tech. Paper 165 of the U. S. Bureau of Mines accidents classified by cause are shown for the year 1915, and of 149 fatalities in quarries or at rock dressing plants and mills the number killed by explosives was but 28, this figure including not only all fatalities due directly to explosives, but also all fatalities due to flying pieces from blasts and other indirect causes.

ACCIDENTS FROM EXPLOSIVES IN CEMENT ROCK QUARRIES

Mr. Jacobsen has very kindly given me figures in regard to accidents from explosives reported to him during the year 1918 by members of your association, and from these figures I note that of all fatal accidents of which he has record which occurred during the year 1918 somewhat less than 8 per cent were due to explosives, and somewhat more than 92 per cent were due to other causes than explosives. Of all accidents, including fatal and non-fatal accidents, those due to explosives constituted somewhat less than 2 per cent of the total and those due to other causes than explosives constituted more than 98 per cent of the total.

This is a rather satisfactory record, and shows quite clearly that explosives, far from being one of the most dangerous factors that you have to contend with, are really less dangerous than many other factors to which much less attention is usually given. Falls and slides of rock cause many more fatalities than do explosives, both in coal mining and in rock quarrying.

The ratio which the number of fatalities due to explosives bears to the number of fatalities from all causes is considerably higher in quarrying operations than in either coal mining or in metal mining. It is interesting to note however, that the number of accidents due to explosives in the quarries of the members of your association, compared to the number of accidents from all causes, represents a materially lower ratio than that which exists in the quarry industry as a whole. The last available figures from the Bureau of Mines show that 19 per cent of all fatalities in and around quarries and including crushers, rock dressing plants and mills were due to explosives, while the figures which Mr. Jacobsen has collected covering the operations of the members of your association show that the percentage of fatal accidents due to explosives was only 7.9 per cent of all fatalities, or less than half of the ratio which exists when all quarrying operations of the U. S. are considered.

It should be our aim to improve still further the good record from a safety standpoint which explosives now have in quarrying operations, and I feel sure that this result will be obtained by that spirit of cooperation and mutual helpfulness for which your association so truly stands.

DISCUSSION

CHAIRMAN JACOBSEN: As Dr. Snelling said, there are very few accidents happening from explosives in the cement rock quarries. We ought to be proud of that. Still we ought to remember that we have a condition there where the carelessness of one man can do an enormous amount of damage, and we ought to keep that in mind all the time. I know there are several people here who want to ask Dr. Snelling questions, and I also know there are several who have had experiences lately which will be of considerable interest in connection with this subject.

MR. LAWNICZEK (La Salle): I would like to relate an incident that happened at our plant the day before I left. We occasionally fire "dobies" ahead of the shovel. We have a signal, and also a shelter

house for the men to go into before the shot is fired. One of our men was carrying a fuse, along with the dynamite he had to use for the "doby." As he was passing the shovel, it was fired, and a cinder fell down and the dynamite became ignited. He had the fuse in his hand, and that caught fire, but he had presence of mind enough to throw the dynamite away. As it exploded it tore two of the doors off the shovel and blew all the windows out of a locomotive that was standing close to it. Fortunately no one was hurt, although the force of the explosion blew the hat off the engineer who was in the cab.

CHAIRMAN JACOBSEN: Dr. Snelling has a paragraph in his paper, which he did not read. He recommends that you look at your steam shovel at night in order to get a good idea of what the actual condition is, and particularly on a dark night; then you will probably get a little better idea of what comes out of the smoke stack. During the daytime, nobody notices that, of course, nor ever thinks of it. From this case you can see that there were sparks that nobody would think of ordinarily. I have often seen powder stored in big quantities without protection, and there is no reason in the world why an accident couldn't happen in a case like that.

Mr. Josse (Continental): I have a few questions I would like to ask Dr. Snelling. I want Dr. Snelling to understand that I don't mean anything personal in this. This is for the benefit of the Cement Association—that is what we are here for, and if we can get anything out of this discussion we want to get it. While this one question I am going to ask you refers to your own powder, I don't wish you to take this as a personal matter at all.

Three years ago we were loading a large shot, 22 holes. We had used a lot of Trojan powder, and we thought we knew how to handle it. We loaded 21 holes, and were on the 22d hole. We had about 150 pounds of powder in it. The "powder monkey" was sitting on the side of the hole, and the men were handing him the sticks, and he was listening to hear them hit. He dropped a cartridge in, and the next thing we knew his head was blown off and six or seven others were injured.

We have asked six or seven different powder experts of their opinion in this case and none of them has been able to tell us anything. So we are still in the same frame of mind that we were in at that time. I would like to have you explain if you can what happened to fire that cartridge. There wasn't a pipe or a match on the job, nobody was smoking, no fire from a "dinky," or anything; we were a quarter of a mile away from a "dinky." I had personally left the hole about 20 minutes before it happened.

DR. SNELLING: For a number of years past my work has been primarily in connection with research, and I have learned to have very great confidence in the uniformity of natural laws. I do not believe that any accident ever happens without an adequate cause, and accordingly I feel that in investigating any accident it is desirable to look at the situation from this point of view. We have all seen cartridges of explosives dropped into much deeper holes than in the case mentioned by Mr. Josse,

and I know that day after day many holes are being so loaded in different parts of the country without accidents. I have perfect confidence that under normal conditions powder can be dropped into holes day after day without accident, and accordingly it is necessary that we should consider this particular affair as quite an exceptional matter, for which we are justified in looking for some most exceptional cause.

Conditions could not have been quite the same at the time this hole was being loaded as prevail in the many other holes which are loaded each day in the same manner without accidents occurring, since otherwise we would hardly have justification for our belief in the uniformity of the working of the laws of nature. Some condition must have been different, and accordingly our problem narrows down to a search to determine what possible factor could have been present in this particular case, to cause a result so wholly different from normal conditions. There are cases on record where holes being loaded with high explosive have been known to detonate during the loading operation, and in at least one of these cases it is known that a piece of stone from the side of the hole dropped down the bore the instant before the explosion occurred.

DUPRÉ'S "SENSITIVENESS TEST"

It is well recognized that a thin layer of an explosive caught between two sliding surfaces may under certain conditions be caused to explode. A chemist by the name of Dupré, connected with the British Service, gave this matter some little study some years ago, and developed a "sensitiveness test" which furnished quite a surprise to explosives men in general. Mr. Dupré found that by spreading almost any type of explosive in a thin layer upon a wooden floor, and striking it a sharp but glancing blow with the handle of a broom, he could produce the ignition or explosion of the sample. Many explosives which have proved to be very safe in commercial use were found to ignite or explode when subjected to this test, and accordingly it is necessary for us to believe that under quite exceptional conditions of friction, and particularly under the influence of a glancing blow from a hard and sharp object, almost any explosive can be caused to ignite. A piece of stone dislodged from the collar of a hole might furnish, in some exceptional case, the particular combination of sliding friction and glancing blow that has proven to be the most effective in causing an ignition. Unfortunately it is not a wholly impossible thing for pieces of stone from the edge of a hole to loosen and drop down, and in the light of Dupré's "Broomstick Test" it seems rather clear that a piece of stone of the proper size and shape might produce under rare conditions just the conditions of friction that would bring about an ignition. Fortunately, the dislodging of a piece of stone from the collar of a hole is far from being a common occurrence, and in addition the size and shape of the stone would have to be just right, in order to be effective. If the stone were too large, or if it were too small, the conditions necessary to produce the glancing blow might be absent. In addition the stone would have to have sharp edges of the right type, in order to provide a surface capable of limiting

the friction to a narrow edge. Provided all of the factors were within the necessary limits however, a stone could undoubtedly cause an explosion, and I might add that this result would occur without reference to the particular type of explosive which was being used. I have recently installed at our research laboratory a pendulum friction machine of the type designed by the Bureau of Mines for the purpose of testing the sensitiveness of explosives to sliding friction, and I believe it is only fair to state that no nitroglycerin explosives which we have tested have shown as great resistance to sliding friction in this test as nitro-starch explosives have shown.

It is my desire always to be perfectly fair in any discussion of accidents, and so I think it is only proper for me to say that any explosive may occasionally be involved in an accident, no particular type or class of explosives being free from this danger. If a material is an explosive, it necessarily is capable of exploding when certain conditions are present, and such conditions sometimes arise through wholly unanticipated causes. In investigating accidents you will occasionally find however, that some of the conditions are very hard to determine and even when you think you have fully determined all of the possible factors in the case, there may still be other factors which are hidden.

Now you say that there were no steam shovels around, no matches, nothing which could cause sparks. My experience in powder plants has shown me that matches will sometimes be carried in spite of the most careful instructions, and even detonator caps are sometimes carried loose. A tiny hole in a man's pocket may lead to either a match or a detonator cap falling to the ground, under conditions quite favorable to the causing of trouble. For several years past I have devoted some attention to a study of the many possible causes of accidents in the handling of explosives, and I can assure you that these causes are of the most diverse nature. In the particular case which you have mentioned however, I am inclined to believe that a piece of rock falling down the hole represents the most reasonable explanation of the matter.

I do not know whether this fully answers your question or not.

Mr. Josse: I think it does. You have brought out a point that has been the only question in my mind, after making a most thorough investigation covering a period of six months. You mention friction. In my opinion that is the only thing that could have caused our accident.

When we first bought Trojan, it was supposed to be less sensitive than the gelatin and nitro-dynamites, so when we got our first small batch to try—there were only about 5,000 pounds—we took several cartridges up on top of the quarry, and threw them as hard as we could over into the middle of the quarry, to see if they would explode. They did not. Another test we made was to set up a 5 by 10 cartridge about 50 yards away, and shoot it full of holes with a rifle, and it didn't explode. Finally, we were using No. 6 detonators on our "doby" work, and very frequently a No. 6 didn't explode a stick of Trojan, so we felt quite confident that it was not as sensitive as the other dynamites.

In the accident I referred to we were using 5 by 10 sticks, dropping

them 80 feet, and we had dropped about 150 pounds. Before dropping the cartridge, we had men on each side of the "powder monkey" rip the paper with a knife, so that when we tamped, it would fill the hole.

My opinion is that some of the dynamite from the cuts on the side of the cartridge probably adhered to the side of the hole, and in dropping the stick, it received the proper amount of friction to explode it. I think that is very likely the only way the powder was exploded. It had dropped about 70 feet, and it had been dropped long enough so that the other man was handing another stick to the "monkey." It almost got to the bottom of the hole before it exploded and it shot off the 150 pounds that was in there. The next hole, 10 or 12 feet away, was not disturbed.

MR. MACFETRIDGE (Lehigh): Isn't there also a possibility that in drilling the hole, there might have been a jagged rock sticking out of it, and when the dynamite went past that projecting piece of stone, it would create sufficient friction?

DR. SNELLING: One particular point has been brought out which I believe could be given a little further discussion. Most quarries slit their cartridges, and if it were not that many holes are loaded with slit cartridges every day, and as such an accident as has been mentioned is extremely rare, we might possibly attach importance to this factor. As a matter of fact however, the mere slitting of a cartridge probably has no particular significance as a factor in the producing of friction, although I will not say that under exceptional conditions this might not be true. In this connection I will relate a little incident which happened in Washington a few days after the sinking of the Titanic. There was a little gathering of prominent scientists, and one of them said "Did you know that the sinking of the Titanic was caused by striking a rock?" As we all knew that the Titanic had sunk in mid-ocean by coming in contact with an iceberg, there were of course general protests from the others in the group, but the scientist who had brought up the subject held his ground, and said that he would undertake to prove to all of us that the Titanic struck a rock, and that it was this fact which had led to the loss of the vessel.

He then took up the matter step by step, showing that icebergs are merely floating parts of ice sheets or glaciers, and that the lower part of every glacier contains rocks which it picks up during its formation, and which it holds rigidly. This man was a noted authority on the Alaskan glaciers and his statement of the manner in which the lower portion of the glacier picks up and holds jagged pieces of rock was most convincing. He then took up the matter of the physical characteristics of ice, and showed us that ice is entirely too brittle a material to be in any way capable of making a slit through the heavy steel of a vessel's hull, except by head on impact. But the Titanic did not strike the iceberg head on, but instead sidwiped the iceberg, the shock of impact being so slight that some people on the boat did not know that anything unusual had happened. He then showed how utterly impossible it was for any projection of ice alone to be capable of cutting the steel hull of a boat by a sliding impact, since in such a case the projecting

piece of ice would have been ground off by sliding against the boat's hull, and under no conditions whatever could the very heavy plates of steel have been cut by the fragile ice. But if a piece of rock were held rigidly in the side of the iceberg, it would provide just such a cutting edge as would be necessary to explain the peculiar rip through the steel plates which extended almost the whole length of the vessel. The mass of the iceberg would have furnished the necessary rigidity, and the sharp edge of the rock would have provided the necessary cutting edge, and the whole incident became explainable. I left the gathering fully convinced that the explanation was the correct one, and that except for some firmly held piece of stone in the side of the iceberg the Titanic would have gone on its way quite uninjured from its brush against the side of the iceberg.

In an unusual accident, we are fully justified in looking for an unusual cause. Is it not possible that a small stone, or still more likely a small splint or flat stone might catch in the slit of a cartridge and form a sharp cutting edge as the cartridge went down the hole? If a cartridge of explosive alone could produce sufficient friction by sliding down a hole to produce an explosion, then we would expect to have accidents every morning and every afternoon, since cartridges of explosive, both slit and unslit are dropped every day down many holes in many different kinds of rock, sometimes through smooth bore holes and sometimes through rough ones. We have all heard the "pound" of the cartridge as it strikes the bottom of the hole, and we know that it must be moving very fast to make such a thud, and that the friction against the side of the hole must be considerable. Yet such an accident as you have described is not only uncommon, but indeed is exceptionally rare. You have yourself brought out the point that you threw cartridges of Trojan powder to the bottom of your quarry, and that you shot through cartridges with a rifle, which is not very gentle treatment by any means.

My own belief is that the mere friction of a cartridge cannot under any conditions cause an ignition. There must surely have been some other condition present. A sharp fragment of rock catching in the slit, or a small piece of stone being dislodged by the cartridge, and following it down the hole, seems to be a much more logical explanation. Perhaps some of you have had the experience of getting a bad cut on your finger from turning the pages of a book. It seems unreasonable, because your skin is tougher than the paper, but if you get the edge against your skin in just the right position, you will bring blood. So a small piece of stone, falling down a hole and exerting friction from a narrow cutting edge against the side of a hole could undoubtedly produce sufficient friction to cause an accident and I might add that this would occur without particular reference to the type of explosive against which the sharp cutting edge should exert its friction. Fortunately, however, such a condition is extremely uncommon.

MR. MACFETRIDGE: Had that hole been sprung a short time before the accident occurred?

MR. JOSSE: No.

MR. MACFETRIDGE: We had an accident happen once, where we had sprung a deep hole. Twenty or thirty minutes afterwards they were working on that hole, and there was an explosion which killed two men.

MR. JOSSE: Another point was brought up, namely that perhaps we had just drilled the hole, but the hole hadn't been touched for 14 or 16 hours. It had been drilled the day before, the evening of the day before.

DR. SNELLING: While we are on the matter of unusual causes of accidents, I would like to bring to your attention a matter which came up during the building of the Panama Canal. They had several accidents in springing holes, the exact cause of which was at the time unknown. They would drill a hole, and sometimes on getting ready for the first spring, the powder would go off. I was asked to look into the matter, and found the situation to be very perplexing. The explosive which was being used was nitroglycerin dynamite made under government specifications and carefully inspected before it went down to the Isthmus. The examination of the explosive did not disclose anything which would give us a clue, but later the accidents were considered to be due to the production of heat from chemical action in the hole resulting from certain minerals coming in contact with air and water during the drilling of the holes. I myself had an interesting experience along this line, in connection with a specimen of a mineral called marcasite, which is a sulfide of iron quite similar to ordinary pyrite, but of slightly different chemical constitution. I obtained a very fine specimen of this mineral and put it away in a case, quite proud of the excellent purchase I had made, but after only a few days the specimen was reduced to a pile of oxidation products, quite different from the original material. The specimen had been dug up only a few days before I received it, and although it had been perfectly permanent for thousands of years while buried in the earth, it commenced to go to pieces almost as soon as it came in contact with the air. The chemical changes which go on under these conditions can produce heat, in just the same way that lime will produce heat when it comes in contact with water, and the accidents in the Panama work to which I referred were finally concluded to be due to this particular factor. Of course such a condition as this is most unusual, and I do not remember of any other case in which sufficient heat to produce ignition of powder has ever been found to be due to the oxidation in the hole of minerals, although of course you are all familiar with the fact that piles of coal containing certain sulfur minerals are very apt to catch fire simply from the heat developed within the pile by chemical changes produced by the oxidation of the sulfur minerals.

Fortunately minerals of this type do not have to be considered as factors in the quarrying of cement rock, and accordingly I brought the matter up only because of its interest as a most exceptional cause for the ignition of an explosive.

CHAIRMAN JACOBSEN: I have jotted down a few things which I just took from our accident reports that we receive from the various companies, to show you how we have accidents, due to handling explosives. The first one says, "Touched lighted match to blasting cap, to see if it

would explode." It did, and the man knows, he is short three fingers. Another is a defective, or delayed fuse, which caused delayed explosion, and the man was hit by a stone and killed immediately. Then we have a number of accidents, due to flying stones from shots. The men have been out in the quarry so many times, probably during shooting, that they think they are perfectly safe. They do that once too often, perhaps, and I believe we ought to pay more attention to that point. Mr. Fortuin, you had an accident at your quarry at the beginning of last year: you had a number of men hit by flying stones at the same time, or something like that. It was nothing very serious, but it might have been.

MAJOR RENINGER (Lehigh): Do you have a shelter house?

MR. FORTUIN (Pennsylvania): Yes, but they didn't get in them.

MAJOR RENINGER: Do you have enough of them?

MR. FORTUIN: Yes. You bring one thing to my mind now. We blow a whistle from the time we are ready to blast until the blast is over, and then we give the double signal, to show that the blast is over. On the blowing of the whistles, all the men are supposed to seek shelter. On this occasion you refer to they didn't, that is they didn't get far enough away, and this shot spread out farther than they had expected it to.

QUICK THINKING SAVES LIFE

MR. FRAME (Alpha): We recently had an incident that might have resulted seriously in our No. 4 quarry. The blasting gang was lighting a number of "dobies", probably ten or twelve, and about half of them had been lighted, when the man caught his foot between two large stones, and couldn't release himself. Of course, he was very much frightened, he knew the fuses were burning behind him, so he yelled as hard as he could, and some of the men nearby quickly ran in and pulled the lighted fuses from the dynamite. It took quite a little effort to extricate the man from his position. It shows that quick thinking on the part of his fellow men saved that man's life.

MR. SCHLICHER (Lehigh): I would like to know whether Doctor Snelling ever had any caps explode while they were being handled?

DR. SNELLING: I never have. I have always wondered at the freedom from accidents with caps, due to the fact that occasionally you would expect, fulminate would get loose, and would get between the metal surfaces of the box. I have several times made the same inquiry and so far I have never heard of a case where a box of caps has exploded while being opened, although it has been reported that a coal miner met with an accident while opening a box of caps in the mine, a drop of blazing oil from the miner's lamp dropping into the box while he was opening it.

MR. SCHLICHER: We had an accident in our quarry last May, where a box of caps, containing about 40 or 50, exploded and the man who was opening the box had two hands blown off and the side of his face blown off. He died that night. Nothing was near them to have caused the explosion. One of the other men had put off a shot, and a small stone

hit this box. The man walked over to it, took the lid off, and off they went right in his hand.

DR. SNELLING: I think the stone hitting the box is very likely the explanation of the accident. In the manufacture of caps care is taken to get rid of loose fulminate, by putting the caps in a drum with sawdust which is then agitated. The caps are then sieved to separate them from the loose fulminate and sawdust, the object being to get rid of any particles of fulminate which might be free.

Now, in this particular case, the stone which hit the box undoubtedly damaged the caps. It probably loosened the fulminate in some of the caps, so that this could get between the tin lid and the sides of the box. Any quick movement in opening the box would undoubtedly be sufficient to set it off.

MR. SCHLICHER: According to that, don't you think it would be better to keep them in a paper container?

DR. SNELLING: That is a matter that has been considered, but I believe that accidents have been too infrequent to make the cap manufacturers feel that any advance would be gained by changing their present practice.

MR. SCHLICHER: I took this matter up with one of the Du Pont men, and he told me that this was only the second accident they knew of that had happened in that way.

CHAIRMAN JACOBSEN: There is just one thing more I would like to have you hear. This is in connection with explosives, and it is a matter that Mr. Josse will bring up, and ask Dr. Snelling's opinion about.

MR. JOSSE: This matter is not a new one to several of the gentlemen in the room, they have heard me ask this question before, but for the benefit of those who have not heard it I want to mention a peculiar accident of thawing we had last February. We had a small shot ready, the holes ready, and were waiting for the dynamite. The car came during the afternoon. The quarry foreman told me all the dynamite was hard. The weather at that time was mild, although it had been freezing before. The foreman suggested that we unload the dynamite and haul it up on the hill and thaw it near the holes, which we decided to do. All the dynamite was taken up on the hill, and we had a thawing house that we pulled around with a team wherever we needed it. It had double walls and there was no floor in it. We pulled this thawing house down near the shot, and we unpacked about 5,000 pounds and laid it on the shelves inside. The floor was the earth, but we threw dirt around the edge to keep the air out. There was a four-inch square hole for each steam line to go into the radiator. This radiator was a large pipe, laid on a couple of stones off the ground. We had an exhaust line of a quarter-inch pipe. The "dinky" engine was 135 feet away, and we connected the steam line. The quarry foreman had given instructions to the watchman that in case the dynamite was soft about midnight, or getting soft, to shut off a little steam, and if it wasn't soft, to turn on a little more steam, but not to carry the steam above 70 pounds.

At midnight the watchman went in and felt the dynamite and it was getting soft, so he shut off a little steam. Shortly afterward he said he heard a cracking noise, and looked over, and the entire house was burn-

ing from the inside; the flames were licking the outside. He didn't know what to do. He shut off the steam immediately and notified the second quarry foreman. The rest of the dynamite was piled up about 30 or 35 feet away. The entire house burned up, the heat from this ignited the other pile, and that entire 14,000 pounds of dynamite burned up and didn't explode.

I presume this was covered at a cement safety meeting we had in St. Louis, where it was said that ignition can happen, even though your dynamite is being thawed perfectly, that it can happen from the internal heat of the dynamite itself. But in my opinion, or at least from the knowledge I have of other cases, there are very few cases where so large an amount of dynamite burns up and does not explode; we certainly were very fortunate that it didn't explode. It would have killed 75 people if it had exploded, because the boarding houses—not over 500 yards away—had 50 men sleeping in them, and those houses would have crumbled like shells. There are 20 small three or four-room houses up there besides, and I presume about 75 people were sleeping in them.

The weather report showed that the wind was blowing away from the "dinky," and it was blowing the smoke and the sparks, if there were any, away from the dynamite, and that is the only thing, in my opinion, that kept the dynamite from exploding. That is another case of unusual things happening, I think. Did you ever hear of a large amount of dynamite burning up without exploding?

DR. SNELLING: Yes, I have on several occasions known of large amounts of dynamite burning without exploding, and I have also made burning tests myself, using considerable amounts of material.

The cause of the original ignition of the powder is a matter of some interest in this case, and I believe must be laid to the self generation of heat in thawing. This is a factor about which comparatively little is known, and I believe a few years ago the whole subject was practically a mystery. In the course of some work which was being done at the Bureau of Mines we tried to see what would happen when nitroglycerin was heated, and a box was constructed of heavy plates of steel, and provided with a small window of very heavy plate glass so that occurrences in the inside of the box could be observed. The purpose of the work was to find out what we could about the cause of the "unexplained" accidents which occur in thawing nitroglycerin explosives. Accidents during the thawing of dynamite had frequently occurred under circumstances which were very hard to explain, the explosive sometimes catching fire, and sometimes detonating, and in either case the causative factor being very hard to determine.

We put a small tube containing nitroglycerin in the apparatus, which was so arranged that we could heat the tube by means of a small electric heater, and could control the temperature from the outside of the box.

After a few experiments, we noted that the nitroglycerin appeared to be hotter than the heater was. To explain this I will tell you how we made the experiment. We had a glass vessel filled with paraffin oil, this glass vessel resting on an electric hot plate. The test tube containing the nitroglycerin was surrounded by the bath of paraffin oil, and we

had thermometers, or rather electric thermocouples for measuring the temperature, placed in both the paraffin bath and in the nitroglycerin in the tube. As we assumed that the nitroglycerin could only be heated by taking up heat from the paraffin bath, we naturally assumed that the nitroglycerin in the tube would always be slightly colder than the paraffin bath, in proportion to the heat "lag," but we never thought that there would be any chance of the nitroglycerin becoming hotter than the oil. In making the experiment, however, we found that although at the beginning the thermocouple in the nitroglycerin indicated a lower temperature than the thermocouple in the paraffin bath, yet after a short time the thermocouples registered the same temperature. This was a most unusual matter, because if you are heating a thing, the thing which you are heating should not become hotter than the source of heating. So I had the heat cut off, but even after the current was cut off from the electric heater and the paraffin bath began to drop in temperature, the temperature of the nitroglycerin kept right on rising, and a few minutes later the tube exploded.

This was a most interesting and unexpected result, and we continued the experiments for some time. The results have been published in Technical Paper 12 of the Bureau of Mines. We found that there was a certain temperature beyond which any particular sample of nitroglycerin could not be heated without starting internal changes which themselves produced heat. Accordingly if you raise the temperature of the nitroglycerin to the temperature at which it begins to give out heat from internal changes, it will keep on getting hotter, even if you take away the original source of heat. Just how rapidly it will heat up will depend on the mass of the sample, and most nitroglycerin explosives are good heat insulators, so that the heat that is evolved is stored up and this increases the rate at which further decomposition goes on.

This gave us another line to work on and we made some tests to see what would happen if nitroglycerin were heated to the point where decomposition with evolution of heat commenced, and were then rapidly cooled so as to withdraw heat as fast as it was being generated. We surrounded a tube of nitroglycerin with a jacket through which we could pass very cold water, and under these conditions we succeeded in distilling nitroglycerin, the decomposition going on at a temperature between that at which the internal changes commenced and that at which detonation occurs.

It seems probable to me that in the case which you describe some portion of a box of the explosive must have been placed where it received heat sufficient to commence internal changes, and where it received heat more rapidly than it could give the heat off from the free side of the box. If you had a wall made of boxes of dynamite three boxes deep, you could only apply heat very gradually to the innermost box, without danger of supplying heat faster than it would be transmitted through the other two boxes, which would tend to act as heat insulation. Just as your winter overcoat is effective in keeping the internal heat of your body from radiating outwards, so the two outside boxes would serve to hold in the heat applied to the innermost box. In the case which you

have described a box probably got heated, not to its explosion temperature, but to the temperature at which it commenced to evolve heat from internal changes. The outer boxes still served to hold in this heat and accordingly the temperature kept right on rising, until finally the temperature became sufficient to cause some of the explosive to ignite.

There are many cases on record of large quantities of dynamite and other high explosives burning up completely without explosion, although there is of course always some risk that the burning will pass over to an explosion. If your boxes had been long exposed to radiant heat, this fire would not have lasted a great length of time before it would have set the other boxes on fire.

MR. JOSSE: In 10 minutes everything was all burned up.

DR. SNELLING: I am inclined to believe that the fact that the dynamite in the second pile caught fire in the case which you described, was a fortunate occurrence. In other words, I believe that dynamite which is on fire is safer than dynamite which is being baked by radiant heat, but which is not on fire. When a stick of dynamite is burning the material burns away faster than the heat penetrates the cartridge, and under these circumstances explosion is much less likely than when the cartridge is penetrated by heat without the heated portion being continually removed. As you all no doubt know, miners sometimes place cartridges of dynamite in the oven of their stoves at home to thaw, and then forget and leave the material there until someone starts the fire up again. Under these circumstances the dynamite seldom catches fire, but nearly always explodes, thus proving that it is safer to let a large quantity of dynamite burn away than it is to heat it up gradually without letting it catch fire.

So, taking all things into consideration, it seems to me that the whole set of circumstances that you have described were all rather favorable to you, and the fact that the two piles were close enough together to allow the second pile to catch fire from the first probably prevented an explosion, which might have occurred had the distance between the two piles been such as to permit the second pile to heat up more slowly from the radiated heat from the thaw house.

CHAIRMAN JACOBSEN: Does that answer your question, Mr. Josse?

MR. JOSSE: Yes.

CHAIRMAN JACOBSEN: We have one more paper on our program, which is on "Platforms, Walkways, Stairs, Ladders, and Floors in Cement Mills." This is a very important point in our accident prevention work. The paper has been prepared by Mr. E. R. Abbott, Safety Engineer of the Canada Cement Company.

PLATFORMS, WALKWAYS, STAIRS, LADDERS, AND FLOORS IN CEMENT MILLS

E. R. ABBOTT, SAFETY ENGINEER, PLANT NO. 1, CANADA CEMENT COMPANY,
LTD., MONTREAL, CANADA

The above subjects have been taken up so thoroughly with regard to construction and safe practices, in bulletins issued by the Association

(Nos. 2 and 18), the *Safe Practices* pamphlets issued by the National Safety Council (Nos. 2 and 11) and in Hansen's *Universal Safety Standards*, that very little can be added. This paper will be in the nature of personal experiences we have had at Canada Cement Company's Plant No. 1 and I will endeavor to show good and bad points that we have found.

Cement plants that are being designed today take into consideration accessibility to bearings, overhead drives, etc.; but in many of the plants built several years ago this was not done and it is difficult to make these places safe for workmen.

About five years ago we took up seriously a Safety-First Campaign, and it was early realized that good housekeeping and a clean mill were necessary if we were going to make any progress with the campaign. It became apparent to us that in order to keep our mill clean it was necessary that we should replace the wooden platforms and walkways with platforms made of material that would not allow the dust to sift through when being swept and cleaned up.

PLATFORMS

In our grinding departments the ball mills, pulverizers, and tube mills are driven by motors placed on elevated platforms, or galleries, about 10 feet above the floor of the mill building proper. The pulley of the motors overhangs the edge of the platform, the center of the motor pulley being about 5 or 6 feet above the center of the mill pulley. When these platforms were originally installed they were built of timber covered with a 3-inch wooden floor. These platforms were never very satisfactory, owing to the fact that there was more or less vibration to the motors, which caused serious trouble with the bearings and coils. Another objection was the fact that whenever the floor was cleaned a shower of dust was precipitated on the floor beneath, through the cracks caused by the drying out of the flooring boards. It was also difficult to keep railings in proper repair, due to the vibration. Eventually we replaced these wooden structures with solid reinforced concrete platforms, with standard pipe hand rails along the edge, and steel and concrete stairs leading from the main floor to the platforms. These platforms have been highly satisfactory in every respect.

A more difficult problem was presented in the replacing of wooden platforms around elevators, along line shafting and other necessary overhead walkways and platforms, as well as floors in bridges, connecting different buildings and carrying conveying machinery. Owing to the fact that our mill had to be kept in operation while these replacements were being made it was necessary for us to use different types of construction. Wherever possible we put in forms and cast concrete slabs reinforced with wire mesh. This we consider the most desirable type of platform floor. In some cases we used what is known as "Ferro Dovetail" sheeting, covered with 2 inches of concrete on the upper side. This makes a very satisfactory floor, provided the lower surface is kept painted, or is covered with cement plaster. Another method was the use of perforated

steel plates, but we only used this material where it was impossible to make use of concrete as these perforated plates had the same objection from the standpoint of cleanliness as the wooden platforms.

Pulverized coal is conveyed from the coal house through an overhead bridge to the kiln room. To eliminate dust collection on the floor of this bridge and thus lessen the liability of an explosion, a floor was constructed of flat iron bars on edge, spaced about one inch apart.

We have under contemplation plans to erect in our coal house, a system of walkways leading from all elevated platforms to a stairway built outside the building, so that employees will have a quick and easy exit in case of fire or an explosion.

STAIRWAYS

Stairways have been the cause of a great many accidents. Beyer states that out of approximately 90,000 accidents reported in one State during one year, from all causes, about 1 per cent came from falls on stairs. In addition to minor accidents these falls caused fractures and other serious injuries in many cases and one death.

The most satisfactory type of stairway for mill buildings, that we have used, are those made from 7-inch channel stringers with treads of 9-inch channels filled with concrete and finished rough with a wooden float. Standard specifications call for risers on all stairways where the distance to the floor is over 5 feet. If sheet metal be fastened to the underside of the stairs, thus preventing any material from falling through, risers are not required.

We also use stairs of solid concrete and those that have been erected inside the mill building have proved very satisfactory, but we have not had the same success with the outside ones. This is principally due to the fact that in removing snow and ice in the winter time the concrete becomes chipped and damaged to such an extent that it is dangerous and is exceedingly difficult to repair. The most serviceable and durable type of stairs that we have found for outside use is made of channel stringers, with $\frac{3}{8}$ -inch plate tread covered with 2-inch planks which are bolted to the plate.

ALLEYWAYS AND TUNNELS

All our conveyor tunnels under storages at this plant are of solid concrete construction. Where single conveyors are used the conveyor is placed against the wall at one side with a walkway along the other side. These tunnels are constructed 7 feet wide and 7 feet high. Where double conveyors are used the tunnels are constructed 11 feet wide and one conveyor is placed against each wall with a walkway in the center.

In the tunnels under the cement storages we had trouble with cement gradually building up on the floor, owing to dampness, in spite of the fact that care was exercised to keep the floors clean. To overcome this we laid over the concrete, a matched wooden floor, which has proved very satisfactory and is easily kept clean.

FLOORS

We do not know of a better material for floors in a cement plant than concrete. Reasonable care must be taken in the moving of heavy material on concrete to prevent pitting. One point in connection with concrete floors in a cement plant, that may be used to advantage in order to facilitate keeping the mill clean, is to eliminate the right angle between the wall and the floor. This is easily done by making what might be called a concave baseboard around the walls.

The following is a summarized specification for stairs, and guarding of platforms, which has been taken from the Association's Bulletins (Nos. 2 and 18). We have adhered to these specifications whenever possible.

"Greatest pitch of stairs allowable 50 degrees. Most desirable practice is riser is to tread as 8 is to 9. Steepest allowable is riser is to tread as $9\frac{1}{2}$ is to 9. Landings should be provided so that rise in one flight is not more than 12 feet. Direction of travel should change at least 90 degrees at each landing. Minimum width of tread 9 inches inclusive of nosing. Maximum rise allowed $9\frac{1}{2}$ inches. Risers should be provided where the distance to the floor is over 5 feet, or where material may fall into moving machinery. Standard double pipe railings shall be provided on all open sides of stairs. Hand rails 36 inches above the center line of treads should be provided on all enclosed sides of stairways."

Platforms should be guarded as follows: Toe boards shall be provided and shall be 6 inches or more in height and shall fit tightly to the floor. Railings shall be provided. Height of top rail above platform to be 42 inches or more. Distance from floor or top of toe board to center of lower rail, to be not more than 18 inches. Posts to be not more than 12 feet apart. In general where we have passageways between belts, pulleys, etc., pulleys and belts are enclosed by screens and angle iron bars.

WALKWAYS

Under the heading of walkways might be mentioned the advantages to be derived from concrete walks around a cement plant. A few years ago we had no walks connecting our buildings and consequently the yard levels were always changing, especially near the doors, and it looked as if in a few years the floors of many of our buildings would be below the ground level. In wet weather the yard was a morass and much good lumber and material was destroyed by being used as temporary walkways. It was decided to establish permanent yard levels and construct concrete gutters around all buildings, close to the wall, to catch the cave water, and beyond the gutters concrete walks. The original program was carried out and extensively enlarged. This expenditure has been a good investment. We are able to keep the yard clean, which we never did before and we spend less money in doing it. Many other advantages might be mentioned, such as saving time of employees, in moving about the plant or trucking materials from department to department, where it was formerly necessary to use a horse and cart.

We consider the liability of men being caught in conveyors one of our worst hazards. Screw conveyors are covered so that there should be no

danger of men breaking through and we have taken an extra precaution by providing a walkway where men are likely to cross over.

Bucket conveyors, travelling at a low rate of speed of about 30 to 50 feet per minute, do not seem hazardous, yet we had a fatal accident caused by a man stepping on one of the conveyors when crossing over. The only way to guard against accidents of this kind is to provide liberally proper walkways across conveyors to obviate the tendency of a workman taking a short cut. In the construction of walkways over conveyors we have used light angle iron frame with sheet iron floor and steps covered with fabric belting to prevent slipping. In several cases where we have two bucket conveyors running side by side we combine a gear covering with a walkway.

CHAIRMAN JACOBSEN: The question of stairways and walkways in cement plants, I think is probably one of the most important we have. I suppose none of you gentlemen have been around to as many cement plants as I have. I have seen some awful conditions in regard to walkways and platforms, stairways, and so forth. We have some slides here which show the various conditions.

(The chairman showed slides.)

Mr. Josse then demonstrated an electric switch box with a quick make and break attachment invented by one of the workmen at his plant.

CHAIRMAN JACOBSEN: If there is nothing else to bring up we will close. Our Cement Section I believe has been very successful, and I hope that we can meet again in far larger numbers next year. Let's have at least 200 at our next meeting. If you have nothing else to bring up now, a motion to adjourn is in order.

Adjournment.

Chemical Section

October 2 and 3, 1919

E. H. FIESINGER, Chairman

Safety Engineer, Solvay Process Company, Syracuse, N. Y.

H. C. SLADE, Vice Chairman

Safety Engineer, Hooker Electro-Chemical Company, Niagara Falls, N. Y.

S. M. SCHOTT, Secretary

Morgan & Wright, Detroit, Mich.

THURSDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M., Chairman Fiesinger presiding.

CHAIRMAN FIESINGER: On the nominating committee I will appoint Mr. S. H. Kershaw of the Hercules Powder Company, Mr. Ira V. Kepner of the Pennsylvania Salt Manufacturing Company, and Mr. H. F. Doepke of the National Aniline and Chemical Company.

The first paper on the program is by Dr. Alice Hamilton, of the United States Bureau of Labor Statistics.

DR. ALICE HAMILTON: I am familiar with only one branch of the chemical industry and that is the dye industry—the making of dyes and dye intermediates—and I will confine myself entirely to that.

It is quite impossible for me to talk about the protection of the workmen in the dye industry without going into the chemistry of it. I will ask your indulgence if I make glaring blunders. I shall do my very best in handling that frightfully complicated subject.

During the war I had an opportunity to learn about the dye industry. Then, after the armistice, I took up this industry in earnest. It is so complicated and difficult to understand, and I haven't as yet, a clear understanding of it—I am still groping around in a mass of chemical formulæ.

It seems best to confine myself in this paper to what I saw in France, Switzerland, England, and Germany, during this last summer.

A STUDY OF FACTORY SANITATION IN FOREIGN DYE WORKS

ALICE HAMILTON, M. D., UNITED STATES BUREAU OF LABOR STATISTICS,
WASHINGTON, D. C.

While I was engaged in investigating the explosives industry for the Bureau of Labor Statistics, from the spring of 1916 up to the day of the armistice, I had an opportunity to learn something of the dye industry, especially the making of intermediates, so closely connected with the making of explosives. Then after the armistice I took up the dye industry in earnest, but I have found it so complicated, so infinitely more difficult than any other industry I ever studied, that I often despair of ever getting a real understanding of it. Certainly I have not yet anything like a real understanding, only a very superficial one, and I must ask your indulgence if I venture to discuss the protection of workers in the strange and complicated processes of dye manufacture. It is impossible to do so without going somewhat into the chemistry of these processes, but I realize to the full my hardihood in attempting to do it before an audience such as this.

In this paper it seems best to confine myself strictly to what I saw in the dye works in France, Switzerland, England, and Germany, my visits being of course made only for the sake of discovering what methods were used for the protection of the workers against industrial poisoning. The experience of the Germans is so much longer than ours that we should expect them to be able to teach us a good deal, and even the English and the Swiss have been in this industry many more years than we. I succeeded in gaining admission to a plant in Basel, Switzerland; one in St. Denis near Paris; one near Frankfurt-am-Main, several in Manchester, and one each in Huddersfield and Liverpool.

DANGEROUS COMPOUNDS USED IN THE INDUSTRY

It may be well to take up first the experiences of those countries with actual cases of poisoning from the substances made or used, for in some ways this was to me surprising, both with regard to the compounds which they have found to be dangerous and those which appear, in their experience, to be fairly harmless. Of course, the dangers from nitrobenzene and aniline are recognized everywhere, taken for granted, the former being considered there as here the more dangerous of the two. The French have had some severe cases of industrial poisoning from mononitrobenzene, and not a few fatalities. The factory I visited is of very open construction, amply ventilated, but they believe that ventilation is not enough, for more important than fumes is skin contact. There is still some controversy over this question in England. For instance, in one plant the manager, who has had 28 years' experience in this industry, is sure that aniline and nitrobenzene are absorbed through the skin, while the doctor, whose experience extends over 11 years, is sure that poisoning is always caused by fumes. The experts of the British Factory Inspection

hold to the skin theory and so do the Germans, though they will take no risks with fumes. The elaborate precautions which the Germans have taken to eliminate poisoning by these two compounds will be described later. I saw them in one plant and they were described to me by a chemist who was employed more than 20 years in a factory now inside the French zone of occupation.

I was interested to find out how far the occurrence of bladder tumors in old aniline workers was known to men in the industry and so I asked every one about this, but the only men I met who had been long enough in the trade to know much about this very slowly developing form of chronic poisoning, were the Germans and the one British firm. Both told me that whatever the substance is that reaches the bladder and sets up an irritative process eventuating in cancer, it is derived from an amide not a nitro compound. Nitrobenzene workers do not have more than their share of bladder carcinoma, aniline workers do. It is of course rare. The oldest British plant has had only two or three known cases in 20 years, although their physician has heard of several more and believes that cases could be discovered in any one of the older plants.

Aniline salt was said not to give trouble, though in two plants where this was said, it did not seem to me that poisoning would be impossible, and aniline salt can be used to produce in animals all the typical symptoms and blood changes of aniline poisoning. In one English plant which I did not visit, there had been trouble in the aniline salt department and this had led to local regulations of the process in the Manchester district; all tanks must be covered, provided with fume pipes and exhaust ventilation. The general opinion is that what cases do arise in the aniline salt department are caused by the aniline itself. For instance, I was told of a severe case of hematuria, blood in the urine, but the man had spilled aniline on the floor and undertook to sweep it up, walking into it as he did so. Before leaving aniline, I want to mention the occurrence of jaundice, which may follow poisoning by aniline, or one of its derivatives.

DINITROBENZENE HAZARDS

Dinitrobenzene is dreaded in the British factories, both because of the dermatitis and because of systemic poisoning. They had a great deal of experience with it as an explosive before and during the war and say it is much worse than trinitrotoluene (TNT). The French have had distressing cases of chronic poisoning but no fatality from dinitrobenzene (DNB). In Germany the barrels of DNB and of nitrochlorbenzene were stored for shipping in an open-walled building, because they had found that during warm weather a perceptible amount of fumes might arise from them. One English physician told of a symptom he had noticed in two DNB men, attacks of staggering gait, coming on at intervals for about a week. The men walked as if they were drunk. Women are said in England not to stand DNB as well as men.

Dinitrochlorbenzene is said to be more dermatitis-provoking than DNB, but not so likely to set up grave systemic poisoning. In one plant they said that even the shippers who loaded the barrels of dinitrochlorbenzene on the cars got dermatitis. The chlorbenzenes are not considered

as toxic as the non-chlorinated bodies, although I heard of one fatal case, a boy who spilled mononitrochlorbenzene on his clothes and died the same day. Other cases were spoken of, not fatal, the men usually not showing any symptoms while at work, going home and growing more and more drowsy, becoming cyanosed and then collapsing. Of course, that history is characteristic of all this group of poisons.

With regard to other nitro and amido compounds opinions differed, suggesting to me that in one plant a certain powder or fluid was more carelessly handled than were others and therefore was regarded as more dangerous because it gave rise to more poisoning. Thus, in one English factory I was told that paranitranilin was about the worst substance of all, in another they had had no trouble with it but were bitterly prejudiced against the nitrochlorbenzenes. Metaphenylandiamine was a fruitful source of dermatitis in one plant, never gave any trouble in a second. Of course, dermatitis is the great problem. Not that it is as serious as systemic poisoning but it is so much more common and then it really does cause more disability. At least, it is my experience that men will endure fairly serious symptoms of general poisoning without quitting their job, but they will not endure an itching, burning eruption, and the latter is much slower to clear up than the general poisoning, as a rule. All nitro and chlor compounds may give rise to dermatitis, according to foreign experience, and also the amido compounds though not so markedly.

Dinitrophenol seems not to have given much trouble in England or Germany but in France it was the worst of all the munition poisons and during the war caused more than forty deaths among munition workers. So far as I know the particular isomer which has this rapidly toxic effect on men is the one used in dye manufacture, and although I know of no cases of poisoning in American dye works, I speak of it in this connection because it is a peculiar poison, different in its action from any known nitro or amido compound, and we should know what effects it may be expected to produce.

The isomer formed in the course of manufacturing picric by the French method is the 1-2-4 grouping with OH occupying the 1 position. In man and in animals the effects are about the same, a rapid rise of temperature, profound sweating, rapid, panting respiration, great agitation and fear, temperature increasing, great thirst, constriction in chest. Often the symptoms preceding the attack are very slight and several times the men were overcome on their way home far from any help. When death occurs it is usually only a short time after the onset of the attack. Absolutely nothing characteristic is found in the organs at autopsy. Animal experiments carried on with the other isomers of this compound do not bring on this train of symptoms. I may mention the fact that this was also one of our war poisons. Three men who were engaged in handling dry dinitrophenol for French picric acid were severely poisoned and all died after only a few hours.

According to experiments reported by the French, the dangers from nitro and chlor compounds are about as follows: At the head of the list

come this 1-2-4 dinitrophenol and dinitranisol. Next come trinitrophenol or picric acid, trinitranisol and dinitrotoluene—the 1-2-6 isomer, the others being less toxic—and in the third class come mono and dinitrochlorbenzene and paradichloronitrobenzene. The last place is taken by chlorbenzene.

DIMETHYL SULPHATE

Dimethyl sulphate has for some time had a bad reputation in the dye industry and this is borne out by the evidence given in some of the German and English plants, but not in all. Those that still use it to methylate aniline or to methylate nitrophenol to nitranisol for dianisidine, say that it is quite safe, with a little care, while those that do not use it say it is bad stuff and they would not have it around. I never know in such cases which is cause and which effect. There are two English plants in which the men handle dimethyl sulphate with less caution than they do caustic soda.

I was told that inflamed eyes or burns on the skin were the worst results to be expected, that only one man had been badly blistered, that the burns were not so bad as those from caustic soda, and that systemic symptoms were unknown. On the other hand, certain English factories will not use it, the Swiss one does not and neither does one of the German factories, while in the other it is claimed that if handled with care there need be no fear of accident. The famous case of fatal dimethyl sulphate poisoning which seems to have fastened the stigma on this compound occurred in the Mannheim factory. As I remember it, a chemist spilled dimethyl sulphate on his person, sustained severe burns, and also developed a pneumonia which was rapidly fatal. No other such case has appeared in the literature, so far as I have been able to discover, and yet we know that dimethyl sulphate was one of the war gases and that experiments on animals show it to be capable of causing death through the production of pulmonary edema, or dropsy of the lungs.

The occurrence of chrome ulcers on hands, lips, nostrils, eyelids, and even on the feet, from getting shoes soaked in chromate solution, is recognized as a danger and a very troublesome one in alizarin dye works where the anthracene is oxidized to anthraquinone by means of this agent. Very strict cleanliness of person and premises is necessary to avoid such accidents. Phosgene has long been known to the Germans and they have learned to treat this very poisonous gas without risk, but the British have had some accidents with it, none fatal, they say. There were a good many in connection with the manufacture of gas bombs, as one would expect.

Benzidin fumes are complained of in one English factory; in all other places I was assured that benzidin itself is harmless, though its manufacture may be one of the most dangerous of all processes. Pyrogalllic acid is said by the Germans to be one of the worst poisons in the dye industry, setting up symptoms almost exactly like those of arsenic. Sulphuretted hydrogen seems not to give rise to as much apprehension over there as in this country, yet the French factory makes its sulphur dyes in an open-walled building and in one of the English factories the

making of sulphur dyes was pronounced by far the most troublesome branch. This was, however, more because of the intermediates used than the sulphuretted hydrogen. In the plant near Frankfurt the work is done in an enclosed room but the draft inside the apparatus is so strong that there can be an opening in the top of the kettle 8 by 10 inches and yet no gas escape. In several places I was told that the danger from this gas was obviated by burning the fumes after the reaction, and I would like to learn if that is done in any of our plants.

ARSENIURETTED HYDROGEN

I have saved till the last the poison about which I heard the most, arseniuretted hydrogen, evolved in the course of several processes where acid and metal come together and one or the other is contaminated with arsenic. In Germany this danger in the dye works has long been known and some of the elaborate precautions taken in German plants are based on the fear that such fumes may be formed and escape. In England they have recently had a series of cases of arsenical poisoning and have ordered precautions against such accidents. In this country we have not, so far as I know, recognized the danger, although I believe that five cases of this have occurred in one plant in New Jersey and three in another.

In English factories these accidents have taken place in the course of several processes. One fatal case was in a plumber who went into an empty sulphuric acid tank to repair it. That is, it was technically empty, it had been washed out and there was only one bucketful of fluid left at the bottom, but the acid contained arsenic and the man died two days after with hemorrhagic nephritis. A very similar instance occurred in New Jersey recently, three men being overcome by fumes of hydrogen arsenide in an iron tank which had contained chamber acid but was supposedly empty and clean. Two died, the third recovered. Here the acid carried arsenic.

The other sources of poisoning from AsH_3 are in reduction processes. In reducing nitrobenzene to aniline these fumes may be formed and for that reason it is dangerous to send men into a reducer for repair work, aside from the danger of the aniline or nitrobenzene. The arsenic may be in the iron but is more likely to be in the acid. One English manager told me he had had four men invalidated at one time by an accident of just this kind. In reducing nitro to amidonaphthosulphonic acid the same risk must be thought of, but it is especially in the making of benzidin that precautions against arseniuretted hydrogen are necessary. The British Home Office will soon be publishing reports of a number of cases of arsenical poisoning that occurred in connection with alkaline reduction processes followed by acidification in making benzidin.

As I understand it, benzidin is made in these English plants as follows: nitrobenzene is first reduced by means of zinc dust and caustic soda. The English expert from the Factory Inspection Department believes that AsH_3 can be evolved at this stage, the plant chemists are sceptical. There is no doubt, however, as to the danger in the next

stage, when hydrochloric acid is used to dissolve out the zinc dust and leave hydrazobenzene. The process must go on in the cold, for otherwise some of the hydrazobenzene might be converted to benzidin and go into solution and be lost, so chunks of ice are added at the same time as the acid, necessitating an opening up of the acidifying kettle. This is where the serious accidents have arisen, for there may be a sudden evolution of AsH_3 , a "boiling up" as the men call it, when the acid and ice go in. The arsenic is usually in the zinc in these cases, and zinc is likely to contain a larger amount than the acid ever does. Since the zinc is finely powdered, the conditions are ideal for the production of AsH_3 . The next step is also attended with some danger, the filtering out of the hydrazobenzene, for if AsH_3 is present the filter water may give off fumes of it. In one English plant especially it was evident that poisoning from this source had taken place, for my guide, the chemist, was very insistent on the necessity for good drains under the filter press so that the fluid would be carried off at once, and for thoroughly flushing the floor as soon as the filter press was opened. The use of compressed air to blow out the presses was, he said, of advantage as it served also to blow away all traces of arsenic. Finally, in the last stage, when the hydrazobenzene is heated with hydrochloric acid to form benzidin, it is still possible to have fumes of arseniuretted hydrogen, but it is not as dangerous a point as is the acidifying stage.

Other departments in which accidental evolution of fumes of hydrogen arsenide should be looked for are the making of the homologue of benzidin, tolidin, by the reduction of orthonitrotoluene, and the making of dianisidine by reduction of orthonitranisol, both being alkaline reduction processes followed by acidification.

PRECAUTIONS FOR REMOVING FUMES

The seriousness of this menace is shown by the precautions taken in English and German factories to guard against it. While going over the German plant I remarked on the universal practice of providing a fume pipe with exhaust on all kettles and autoclaves, regardless of the harmlessness of the compounds in them. My guide told me that experience had taught them that accidental contamination of acids and metals with arsenic could not be guarded against and that the only way to be sure of preventing arsenical poisoning was to treat all fumes, gases, steam, as potentially dangerous and see to it that they were carried off. The rule is to turn on the exhaust before the receptacle is opened. The English plants were in the course of installing fumes pipes at all points which they had learned could possibly be dangerous. In one, they have built a long slide or chute for the ice to run down, so that though the kettle must be opened to admit it, the man in charge may stand at the far end of the chute and not get the whiffs of fume that may be given off when the ice falls in. The acid also goes in through a long pipe which he can control at the same point. A valve is placed over the manhole which drops back as soon as the ice has passed through. This was the place that had the notorious cases of poisoning and till they could get in the

necessary changes in equipment they were obliged to use chemically pure acid and zinc. In another plant they had trouble in acid reduction of nitro to amidonaphthosulphonic acid and since then they have used contact acid only in this process, but even so the iron may contain As and so they test the fumes for it from time to time with mercuric chloride paper.

This crude way of chilling with chunks of ice dropped into the acidifying tub is not usual in this country as it seems to be in England. In our plants chilling may be provided for by brine coils or it may not be needed, for there are other ways of getting rid of the zinc dust. But in one New Jersey plant in which the ice method was used five cases of poisoning occurred on one night shift and one of the men died. I came on the histories of two of these men in a hospital record while I was studying munition poisons. One of them was at first supposed to be a case of typhoid fever, later diagnosed as aniline poisoning, the other was said to be caused by alpha-naphthylamine. Both men had been employed in a plant making benzidin base and sulphate, and naphthionic acid. I visited this plant and found that they were making benzidin by the usual process from nitrobenzene, and naphthionic acid from alphanaphthylamine and sulphuric acid. The Company had installed a fume pipe system with a fan but had never completed it. From the meagre account to be obtained in the hospital—no account at all could be obtained from the company—it appeared that the men had been overcome by fumes evolved accidentally while they were working on the night shift. One of them had been there some months, the other had gone to work that night for the first time.

A SERIOUS CASE

Luckily it was possible to run down one of the men and I sent an investigator to interview him. This is his story. He worked on benzidin in a process which involved watching the color of the compound formed and when it changed from red to white the process was completed and acid was added. I believe that means that he was told to see when the reddish oxyazobenzene was converted to the deep red azobenzene and then to the white hydrazobenzene. Then, he said, acid had to be added. He had had attacks of illness quite often and attributed them to the fumes which were so bad that few men would work there for any length of time. He, being foreman, was not obliged to stay in the fumes as the men did, but they affected him nevertheless, giving him kidney trouble as shown by dark colored urine and pains in the lumbar region. He suffered also from a band-like feeling around the body and from severe pains in the back of his neck, his appetite was poor and he often vomited, he was depressed, sometimes almost melancholic. On the night the accident happened, this man whom I will call "C", and the two men whose histories appear in the hospital records, "D" and "E", and two more were at work. The chemist was not there and they had to guess at the amount of acid and when it was added the mixture suddenly boiled up and all five were "knocked out." C went home and lay on the floor feeling sick but no more so than he had at other times. When, however, he

saw that his urine was apparently pure blood he realized that his condition was more serious. As a matter of fact he was ill for three months and his wife said that he looked like a yellow corpse. Apparently he suffered from anemia and jaundice.

D was treated at home for about two weeks for supposed typhoid fever showing that abdominal symptoms were prominent. The history I obtained begins on the fifteenth day after the accident when the man was received at the hospital unconscious. There were ulcers on his tongue, and throat, muscular tremors, weakness, diarrhea and vomiting of greenish fluid. The typhoid test was negative, there was albumen in the urine but no blood, there was a very profound anemia, the red blood corpuscles being reduced to 1,780,000, the hemoglobin to 40 per cent. Both spleen and liver were enlarged. There was difficulty in urination and pain. The man's condition grew worse, especially the retention of urine, the nausea and delirium, and he died on the third day.

E went to the hospital forty-eight hours after the accident. He was then deeply jaundiced, in great pain, vomiting greenish fluid, voiding blood-red urine. The pain was in the lower chest and in the bladder region, especially on urination. These symptoms persisted for two days, then slowly improved and he was discharged on the sixth day. "cured" according to the record, but according to C's story—the men are cousins—he has never regained his health nor been able to do a real day's work since. No blood examination was made in this case but hemoglobin was found in the urine.

Now the fact that the men were rapidly overcome by a sudden pouring out of fumes in the course of some process in which various amido derivatives of benzene were used or formed, would lead one to assume that the fumes were those of aniline or some similar body, but although this might explain the early symptoms, it would not be possible to attribute the later ones to poisoning by aniline or an allied substance. On the other hand, typical arseniuretted hydrogen poisoning brings about just this train of symptoms, headache, prostration, nausea, profound destruction of red corpuscles as shown by hemoglobin in the urine, vomiting, diarrhoea and later jaundice and extreme anemia. The English authorities told me that a case of supposed nitro or amido poisoning which does not clear up but progresses to pronounced anemia will probably, though not certainly, prove on examination to be one of arsenical poisoning. In these American cases no search was made in the urine for arsenic. In England such a procedure has become usual, indeed it is resorted to in all dubious cases which arise among the process men. I saw the records of one plant physician who had recently examined sixteen men for arsenical poisoning, including a quantitative estimation of arsenic in the urine. Traces of arsenic were found in almost all, but in only five was the amount great enough to be significant. These five men were with one exception employed in the benzidin department. The fifth was said by the physician to be working in the diamidodiphenylamine department at a reduction process which required sodium bichromate, hydrochloric acid, zinc dust and iron filings. The symptoms in these cases might have

passed for aniline poisoning; dark urine, headache and abdominal pain, jaundiced skin or simply a sort of lividity, or in two cases, no subjective symptoms at all, only the dark urine and livid color.

I think you will agree with me that, in the light of this English experience, it behooves us here in America to revise our views of the dangers that may be encountered in different departments of dye and dye intermediate manufacture and also our views as to what is adequate protection against industrial poisoning in this industry.

METHODS OF PROTECTION

As for the methods of protection used in Germany and England—I did not see anything really new in France and Switzerland—part of this has already been spoken of but there are still some details deserving of mention. For instance in one English plant they have had a bad time with DNB. Consequently they do as little work with it in warm weather as possible. Every new man who is put on DNB is watched carefully for the least sign of dermatitis or blueness and when it appears he is taken off and put to other work, but that other work must never bring him in contact with other nitro or amido compounds. Their theory is that some men may acquire gradually an immunity to DNB if they are exposed to it with caution, though others will never be able to stand exposure and must be taken off.

In the German plant there is no contact with DNB. It is melted and blown from tank to kettle. In the case of benzol an English chemist told me that they never let a pipe-fitter or repairer enter a benzol tank or still, even after it is thoroughly cleaned, till at least two days have passed, because they believe that the benzene actually soaks into the metal and must be allowed to evaporate first. Of course I need not refer to the many cases of distressing poisoning in this country in stills or tanks that were supposedly empty and free from any benzene fumes. Melting caustic soda and blowing it through pipes is not unknown in this country, but I wish it were the usual procedure, as it is in England and Germany.¹

To generalize about the precautions used in those two countries, I should say that in Germany every stage of the process has been looked upon as potentially dangerous and safeguarded, in England every stage at which any trouble has ever occurred is safeguarded. The German plant was a surprise to me even though I was fully prepared to find it good. The standard of cleanliness is so high that I can only say that the passages between buildings are as scrupulously clean as are our clean plants.

¹One interesting little detail that I might pick out from many is the method of filling the reducer for phenylenediamin and toluylendiamin in an English plant. The covered truck containing DNB or DNT has an opening in the side that is level with the lip of the man-hole of the reducer and the lid of this opening drops down so as to form a bridge from truck to reducer, along which the man pushes the DNB. Over it is a fume pipe with fan.

Inside the buildings it would be hard to guess what process was being carried on nor would the appearance of the workmen help much, for very few of them carry stains of color on their blue overalls. It is very remarkable to see the clean suits of men in the sulphur black department and in barrel packing. Perhaps one single instance will be enough to give you an idea of their attention to detail. In one room I commented on the condition of the floor and on the total absence of any odor. My guide, the chief chemist, explained that the men are not allowed to lay anything on the floor and showed me an iron shelf near the autoclave, where any piece of apparatus must be laid. It is for the chemist in charge to see that these shelves are kept clean and in his daily inspection of the room he sees to it that they are wiped off if any fluid or powder has fallen on the surface. Nothing is ever permitted to fall or drip on the floor, there is a great commotion at once if such an accident takes place. You see, compensation for occupational poisoning is paid, not by the individual plant, but by the association of all German establishments doing this sort of work, the "Berufgenossenschaft." In case of sickness from poisoning a committee visits the plant in question and the chemist responsible for that department has to appear before it and explain how it happened. Of course if it was caused by such a thing as a leak or spill, he has a decidedly uncomfortable time.

BRITISH PLANTS PROVIDE WARM FOOD

The standard of cleanliness in British plants is somewhat higher than in ours. I saw plants as clean as our cleanest and as fairly clean as our fairly clean ones, but none that were as bad as our worst. Where the British excel us, however, is in the intelligent placing of their exhaust ventilation, the attention to detail and the personal care of the men, especially of their food. I believe it is true in general of English industry that far more attention is paid to the feeding of the force than over here. They look on the dinner pail, with its cold, soggy sandwiches and cold soggy buns or pie, as distinctly bad because such food leads to indigestion and indigestion encourages poisoning. In all these dye works I saw kitchens equipped simply and inexpensively but with plenty of boiling water for the eternally necessary tea—I do wish our workers had the habit of stopping in the morning and afternoon for a hot drink with sugar and milk—and with a warming oven for the food the men bring with them. Opening this oven you see numbers of bowls of meat and vegetable stew or meat pie, being heated for lunch. A hot midday meal is considered a necessity. These Englishmen also believe that it is a matter of great importance to see that men and women do not start work in a poisonous process without a proper breakfast and as the only way to secure it they give each one a pint of milk as he comes to work. One manager has great faith in hot milk as a treatment for aniline poisoning and told me how he had brought it to a workman overcome by aniline. The doctor could not be got, so the manager had the man stripped and put in a bath and then he poured down hot milk and porridge till the man could hold no more.

The German plant furnishes hot coffee the first thing in the morning and soup at noon, charging the men one-tenth of the cost.

Washing facilities in English plants are much like ours, except that you always find at least one bath-tub in addition to the showers. This is partly because some workmen dislike showers, but also in case of accident. A foreman told me that he had once tried to hold under a shower a man who was unconscious from the effects of aniline spilled on his clothes. He insisted after that on having a tub installed. In the German factory the bathing provisions are more numerous than in any other place; I saw no less than 1,200 showers for less than 3,000 men. The provision of soap is general in Europe, but the English have not yet lost the roller towel habit. The Swiss lavatories were exquisitely clean and perfectly equipped. In the French factory, which also had a good equipment, they told me of an amusing device they had resorted to during the war to make the dinitro-phenol and picric men bathe. They were made to strip off their working clothes on one side of the room and between them and their street clothes was a wide gutter with running warm water. They simply had to get into it to reach their clothes.

One detail in connection with bathing facilities is worth mentioning. You know we have rather prided ourselves of late on giving women employees shower baths with the nozzle placed low so that they may bathe without getting their hair wet. The English are even cleverer. They attach to the hot and cold water faucets a two-branched rubber hose with an ordinary bath tub spray. Then the woman may direct the stream just as she wishes and a very short or a very tall woman is not at a disadvantage as she is with a fixed spray.

Working suits are furnished in the French factory and in the Swiss and German and some of the English. They were surprised when I said that some of our largest companies had refused to pay more than fifty per cent of the cost of overalls for their TNT and picric men during the war. Europeans all suppose that American industry is characterized by a lavish liberality in matters of that sort, whereas, with some striking exceptions, our plants as I have seen them in the dye industry are not quite so liberal as are the European. The clothes provided, laundered and repaired by the German company are of good blue jeans and are renewed after three months or six months according to the process. Then the old suit is given to the man, and since he knows it is to be his, he takes good care of it. They are quite a remarkable lot, the men in that German dye works. When I went into the locker room I saw clothes hanging in open compartments. My guide explained that they dried and aired so much more completely if they were not shut up. "But does nobody steal them?" I asked. "Certainly not," he said. "our men do not rob each other." Also in one of the Manchester factories the men's clothes are hung on the walls with no fear of their being stolen.

MEDICAL CARE IS EMPHASIZED

Medical care is much more emphasized in England than in the other countries, though everywhere a physical examination is made before em-

ployment and an effort made to exclude alcoholics and those of poor resisting powers. But in Germany there is no regular examination of process men, once they have been employed, so long as they make no complaint of illness or are not absent from work. In England, in the best managed plants, not only do the physicians see every process man once in a fortnight, but they try to see him at work, they make regular trips through all the process departments. They say it is absolutely essential for the physician to know just what the man is exposed to and under what conditions he is working and how much heat and physical strain there is in his work, and also that you can judge better of a man's appearance if you come on him suddenly in his workroom than if he comes to the office prepared to see you and either to make you think he is ill or to make you think there is nothing the matter with him. They make more of a case of poisoning than we do. One of the plant doctors and I were accosted as we were making our trip over the plant by a man who had been home for four days with aniline poisoning. His lips were pale but not blue and he felt pretty well, he said. The doctor looked at his gums and finding them still bluish, told him to go off and visit his father on the farm for ten days and then report back for examination.

CHAIRMAN FIESINGER: We will now take up the discussion of Dr. Hamilton's questions.

DISCUSSION

MR. C. P. TOLMAN (National Lead Company): It occurred to me that it would be a simple matter to put the ice in the chamber safely if an "air-lock" were used. The "charging" chamber would have two openings, one to receive the ice and the other to let the ice pass on into the main chamber. These openings should be interlocked so that only one could be opened at a time. A rotating drum could be used, the drum having one opening and being mounted in a cylindrical casing. The cylindrical casing would have two holes; for example, one at the top to admit the ice, another in the bottom so that when the drum is rotated the ice will fall out of it and into the chamber where it is needed.

Nothing was said about providing an air inlet for the ventilating system. It seems to me in dealing with the question of safety from gases that in addition to maintaining a suction on the apparatus it is desirable that an actual flow of air should be provided to keep down the proportion of the dangerous gas mixed with the air in the suction system. My thought is this: In a closed suction system the air is not changing and will take up gas to the point of saturation, whereas if there is a constant inlet of air there will be a corresponding movement, thus limiting the strength of the mixture.

With reference to the "absorption" of gas by the metal, the surface condensation on the metal is an important item to consider. This condition can be overcome by heating the metal (if that is permissible), and the metal can be better heated by a steam jacket than by blowing live steam into the tank. The steam jacket is more efficient and is free from danger of scalding the worker—a danger that is present always when a steam hose is used.

MR. A. H. MASSEY (E. I. du Pont de Nemours & Co.): I would like to ask Dr. Hamilton with reference to fatal cases of toxic poisoning: Did you have access to the physical record of the man beforehand? Was he subject to cyanosis right along, or was he a man that was practically immune? What was his physical condition?

DR. HAMILTON: All the men are examined before employment by a physician and rejections are made about on the same basis as we make them here. A man is rejected who has any evident lesion in the lungs, or in the kidneys, or is markedly anemic—bloodless—and they lay more stress over there on the presence of gout; in England they wouldn't take a gouty man. They try not to take an alcoholic. They do not like to take fat men, since they are more liable to get dermatitis, perhaps because they perspire so freely. Every man employed in one of these dye works passes the physician's examination and the physician sees the process men every two weeks. If he had never seen the workman with blue lips before and then an attack of cyanosis came on, it would be perfectly fair to conclude that the work was responsible for it.

MR. S. W. EVANS (Goodyear Rubber Company): What is your treatment for aniline poisoning?

DR. HAMILTON: I do not go into the matter of treatments because I am not a practicing physician. For aniline poisoning the physician in charge of the plants in Manchester uses a mixture of stimulants.

MR. D. F. CONKLIN (Ocean Accident and Indemnity Corporation): I want to ask the Doctor what she thinks is the best preventive for aniline poisoning in its manufacture. Would ventilation cure the ills?

DR. HAMILTON: No! decidedly not. The ventilation is not nearly so important as cleanliness. There are a few cases, but I do not think there are any very serious cases, of fume poisoning, so far as I know. The absorption through the skin is the important factor in poisoning.

CHAIRMAN FIESINGER: The next paper is "Lead Poisoning and its Prevention." In the chemical industry we have heard about lead poisoning, but we have never heard anything about its prevention. This morning we have one of the pioneers to discuss that paper for you—Mr. C. P. Tolman.

LEAD POISONING AND ITS PREVENTION

C. P. TOLMAN, CHAIRMAN, MANUFACTURING COMMITTEE, NATIONAL LEAD COMPANY, NEW YORK CITY

The chairman has said, "you have heard a lot about lead poisoning but nothing about its prevention"; that was exactly my point of view in preparing this paper. I felt it useless to spend time over the statistics and symptoms of lead poisoning. We recognize it among industrial hazards, and our particular interest is in preventive measures.

Unusual exposure to the fumes and dust from lead compounds is quickly followed by well defined symptoms and consequently the hazard was recognized as early as 1656.

The peculiar situation about lead poisoning is that unlike other hazards

which develop with the development of mechanisms, and with the mechanizing of hand operations, the development of machinery has been the direct measure of decreasing lead poisoning.

Certain manifestations of lead poisoning have a special appeal to the sympathies and, as a result of the incidental publicity, there has been a vast improvement in working conditions, beginning years ago, as compared with other dust hazards, such as stone cutting, cement manufacture, and abrasive operations generally. These dust hazards are free from the idea of poison and we hear little about them, but the results industrially are probably more serious, measured by the number of sufferers. Exposure to these abrasive dusts results in extreme susceptibility to lung troubles. There is generally a considerable lapse of time between exposure and disease and on that account the cause is not properly recognized. I mention this because the principles utilized in handling lead compounds apply equally to dust hazards in general.

MUST KEEP DUST OUT OF NOSE AND MOUTH

Industrial experience and medical experiments have demonstrated that in lead poisoning, lead compounds, as dust, or fumes, enter the human system through the nose and mouth. Experience does not support the theory of absorption through the skin. Our problem is to keep lead compounds away from the workman's nose and mouth—a dust problem plus a problem of personal cleanliness.

The labor in lead factories is largely unskilled and for the most part foreign born. Cleanliness is hard to teach. Special stress is laid on the necessity of washing the hands before eating and in all factories one wash-stand with hot and cold water, soap, hand brush, and towels is provided for each two employees. In most factories there is one shower-bath to each five men employed. In the other factories the ratio is one to four. Ample paid time is allowed at noon and at night for washing, and experiments have been tried of rewarding the men for each bath taken. Two locker rooms are used, one for working clothes and the other for street clothes.

Medical supervision is one of the most effective preventive measures. Under this system each man is examined within a few days of his employment and a record made. Thereafter he is examined at regular intervals. Our regular physicians naturally become expert in the recognition of early symptoms, and prompt measures are taken. This system also eliminates alcoholics and others especially susceptible to lead.

The success in dealing with the human factor depends entirely upon the local factory organization. Everything that has been said about the importance of the foreman in safety work applies several times over in this connection. He must not only instruct the men, but he must continuously be an example to them, and we have different degrees of success in the personal side of the problem in proportion to the natural ability and training of our foremen.

Among Safety men it is agreed that of one hundred preventable accidents, not more than forty can be prevented by mechanical devices or

improvements. This proportion does not apply to dust hazards. Most dust hazards can either be eliminated or substantially reduced by adequate special machinery, in which I mean to include dust systems.

The lead industry is fortunate in that the value of the dust collected often pays a substantial profit. The portable dust collector, described below, annually saves dust which in value amounts to over 20 per cent on the investment.

PORTABLE DUST COLLECTOR PAYS A PROFIT

In the Dutch Process of manufacture of white lead, the metallic lead is converted to white lead in small earthenware pots which, when the

lead is finished, must be emptied into the box in which it is taken to the mill. Naturally emptying these pots was a dusty operation, and because of the large area of corroding yard where the work was done no simple solution was evident. The process requires from three to four months and is carried on in bins, there being some twenty-four alternate layers of tanbark and pots in each bin of an approximate average depth of two feet to each pair of bark and pots so that there is a range of something like twenty-four feet between the bottom and the top layer. A solution was finally found by making a portable dust collector which is handled by an electric crane from tier to tier as needed.

This portable dust collector weighs slightly over 400 pounds, is a self-contained unit consisting of an electric motor driven suction fan and the necessary tubular cloth filter; the whole being enclosed in steel. A flexible canvas pipe, provided with internal wooden rings to prevent collapsing, connects to a cover, which cover is placed on top of the carbonate box. The cover has suitable openings through which the carbonate of

EXHAUST HOOD AT DUMP

lead is emptied from the earthenware pots. The action of the fan maintains a strong indraft of air through these openings, successfully keeping the dust within the system and recovering it by means of the cloth filter—the fan discharging clean air.

The white lead, when it comes from the corroding yards, is brought in boxes by electric cranes and dumped into hoppers, discharging into the

separating machinery of the mill. This dumping operation was formerly one of the serious dust hazards. This hazard was eliminated by designing a carbonate box with an automatic bottom dump. The bottom of the box is made up of two hinged doors connected by pivoted links to a rod, the top of the rod being formed into a ring to receive the crane hook. When the crane lowers this box into position on the mouth of the dump, the weight of the box is supported by the top of the dump. A further lowering of the crane hook allows the bottom to open downward completely discharging the contents of the box into the dump. A dump

METHOD OF REMOVING WHITE LEAD FROM DRYING PANS

was designed to cooperate with this box. A swinging suction hood is brought into position over the box, after it is lowered into position and before dumping, and in addition there is a perforated plate entirely around the margin of the top of the dump, covering an air duct which also surrounds the dump. The hood takes off all dust coming out of the top of the box and such dust as escapes from the bottom is carried away through the perforations leading into the marginal suction duct.

As you probably know, white lead in the mill is handled wet in a water floating system, so that in the milling operation there is no dust hazard. When the lead is finished, however, it is necessary to remove

the water, and this is usually done by evaporating the water on drying pans. The lead was removed from the drying pans by shoveling or hoeing, conveyed to a storage bin and then as needed taken from the bin, batches being weighed on scales. These batches were then transferred to "chasers" where the white lead was mixed with oil and again became free from the dust hazard. The problem of eliminating dust from these series of operations for a while appeared insuperable. The solution finally came about through the cooperation of several individuals, and we now have an equipment which practically eliminates the dust hazard.

The drying pans are completely enclosed in sheet steel and the enclosure connected to a suction fan. On the operating side the enclosure is made double with a space of about twenty inches between the inner and the outer casings. Both inner and outer casings are made up almost entirely of doors of convenient size, and the doors are arranged to operate in pairs. That is to say, an outer and an inner door both being opened affords access to a convenient section of the drying pans. Between the inner and the outer enclosures, at the bottom, is a screw conveyor, so that when the workman hoes the lead out of the pan it falls down between the inner and outer enclosures into the screw conveyor and is carried to the storage hopper. Meantime the powerful suction on the enclosed pans is drawing air through the opening, protecting the workman from the incidental dust. The storage hopper itself is entirely enclosed and is connected to a weigh hopper, also enclosed, making it possible to weigh out any desired quantity without handling the lead at all in the open. A screw conveyor from the bottom of the weigh hopper carries the weighed charge to the chasers and delivers it within the enclosure of the chaser. At that point linseed oil is added and the white lead in oil reduced to a paste in which form it is discharged from the chaser.

These examples are fairly typical of dust prevention apparatus and give some idea of the range of operation possible under dust control; the operation of filling a weigh hopper to an exact weight and then discharging under dust tight conditions is particularly interesting.

When dust prevention is not complete, and that is particularly the case during repair work, respirators must be worn. Respirators to be effective must fit the face, and must be kept in proper order. Each man must be given a respirator for his individual use. Ordinarily, the man takes care of his own respirator, except for repairs. In one factory the respirators are turned in each night. They are thoroughly cleansed and put in order by one man, who is held responsible. In the morning each man claims his own respirator by his number check.

DUST HOODS SHOULD BE CAREFULLY DESIGNED

Dust hoods should be more carefully designed than is generally the case. It would appear that they are usually left to the sheet metal worker. It is impossible to lay down standards, for different conditions require different treatments. A heavy coarse dust requires stronger suction than a light, fine dust. The angle of the hood, for efficiency, must

be different for a strong draft and for a weaker one. It is often possible, where furnaces or kettles are concerned, to develop the necessary suction from radiated heat, or by using the hot gases directly. The suction from such a source is of low intensity, but of relatively large volume and for efficient use requires that the hood be provided with an uptake pipe of generous size, both in diameter and height. Inasmuch as this method, when available, saves the operating and maintenance cost of a fan, it is well worth while to spend time and money on the design, experimenting, if necessary, to get the best results.

The best result is not always obtained with an overhead hood. It is sometimes better to draw the dust downwards, as in protecting the operation of heading barrels. Conditions may require hoods at one side

BAG SHAKING DEVICE

Through door at center (closed during operation) the rows of bags may be seen.

of an operating space, or a combination of two or more hoods. Hoods of suitable design and location will not only give vastly better results, but will effect a substantial saving in fan power.

Usually it is neither desirable nor feasible to discharge a dust system into the air. A collector of some kind must be used. Electrical perception of dust is limited in application to large units and is too familiar to the technical men interested to warrant discussion here.

Dust separators of the cyclone type are effective for the heavier and the coarser dust, and will remove the bulk of such dust from the air or gas. For the removal of fine dust, although a cyclone may be used for roughing out, cloth bag filters are used for the last stage of the opera-

tion. The design of the filter depends upon the character of the dust present. The air, or gas, must be fairly dry; if too moist, the filter will clog and the suction decrease correspondingly.

As ordinarily built, a bag filter comprises an air chamber into which the fan discharges the dust-laden air. Evenly spaced openings in the bottom of the chamber are provided with collars for attaching dust bags. These bags, which are really tubes, extend downward and are fastened to similar collars on the top of the receiving hopper. The air from the fan divides among several bags, and filtering through the fabric, leaves the dust inside the tube. Most of this dust drops into the hopper below but there is some accumulation and it is necessary to shake the bags once or twice a day.

The arrangement of the bags is such as to leave an aisle between each

WET SEPARATOR

double row. Formerly, it was the practice to shake the bags by hand; a man, wearing a respirator, entered the bag house for the purpose. For some years past, however, we have used a device operated from the outside of the bag house, which does the work more effectively and without exposing the man.

The bag-shaking device is a wooden grill work, suspended horizontally from the ceiling of the bag room. There is a slat of the grill between each row of bags. A rod extends from the frame of the grillage through the wall of the room and connects to a lever on the outside. When the lever is worked back and forth, the slats of the grillage shake the rows of bags with which they are severally in contact.

There is another method in which the result is obtained by momentar-

ily reversing the fan action and collapsing the bags. To describe this method, in detail, would take more time than we have. Obviously the bag filter system cannot be used when the air, or gas, is moist, or when it carries chemicals destructive to cotton or woolen fabrics.

For many reasons a wet separator, if capable of removing practically one hundred per cent of the dust, would be ideal. The possibility of making a wet separator, which would answer the exacting requirements, came about through researches in an allied line, and I am very glad to say that for the past two months we have been operating a filter of this type with complete success. It handles the capacity of a thirty inch multivane fan and requires only four gallons of water per minute. The construction is simple and is less costly than a bag system. Wet or dry gas can be treated, and it is not affected by corrosive fumes, whether acid or alkali. If any of you are interested, it will be a pleasure to hear from you and to supply the details.

Thus far, we have been considering current practice in the manufacture of lead products. Lead and its compounds are probably more widely used in industry than any other metal. The comparative cost of lead is such that there has been constant pressure to find substitutes, in spite of which, the uses of lead are increasing rather than diminishing. It is therefore desirable that the sanitary conditions under which these products are used, be made as perfect as possible.

A large proportion of white lead and a steadily increasing proportion of red lead, are finished with linseed oil as a paste. In this form it is, of course, dustless and therefore entirely free from hazard. The one exception arises when painters sandpaper a painted surface. This is a hazard which can be entirely avoided, as Dr. Alice Hamilton pointed out in a paper before the Master Painters' convention in Denver. The remedy, in brief, is to moisten the sandpaper in a light mineral oil. This practice is not only safe but effects a substantial economy in time and does a better job; an illustration that safety pays.

Red lead, until a few years ago, was necessarily used in dry form by painters who mixed it on the job. The red lead of this character, if mixed in advance, would harden in the pail almost over night. Some two years of development in laboratory and factory produced commercially a red lead so free from the litharge which caused hardening that red lead and linseed oil paste is now being widely used. It does a better job and there are certain advantages which makes this safe form of red lead from ten to fifteen per cent cheaper to use.

Among the large users of white lead in the dry form are manufacturers of ready mixed paints. To avoid the need of handling this product dry, a steel package was designed of a size suited to the requirements of the mixed paint industry. Two large concerns have been taking their whole white lead requirements in this paste form for some years past. There is a substantial economy to them and to us, apart from the satisfaction of delivering the goods free from hazard.

In the nature of the case, dust control is a large factor with us, whereas with a user of lead products it is a small part of his factory

problem. We have had occasion to go into the subject extensively and have naturally accumulated experience. Mr. E. J. Cornish, President of the National Lead Company, authorizes me to say that the technical staff of the Company will, at all times, be free to confer with the representatives of any users of lead products for the purpose of bettering working conditions.

DISCUSSION

DR. S. DANA HUBBARD (Division of Industrial Hygiene): We have had considerable trouble with our batteries. You speak of a container; is that of a sufficiently small size for the small battery manufacturer to make use of?

MR. C. P. TOLMAN: Yes, that container holds five hundred pounds of dry white lead. It is perfectly straight on the inside so that it may be easily and completely emptied. The cover is held in position by a central bolt. The package can be sealed, and so goods of any character can be shipped in it, under guarantee.

That package can be easily rolled, and a pair of tongs is supplied for use with an overhead trolley. The package is opened on the floor, overhead trolley using the tongs takes it where wanted, and it is conveniently emptied by tilting.

DR. ALICE HAMILTON: I should like to say, in bearing out my testimony of the great changes which have taken place in the white lead industry, Mr. Tolman is an insider and I am an outsider. When I think of it as I knew it in 1909 and now, it doesn't seem like the same industry.

He spoke of dumps, but he has not spoken of dry pans and clearing those, as it used to be. I have seen men shoveling from a dry pan, climbing into it, where they couldn't stand upright. I have seen them in the dust collecting room shaking and beating the cotton bags to make the dust fall down. That was less than ten years ago. In some places there has been an enormous change in this industry; I do not believe any industry has changed so much.

With reference to the changes in hospital records: When I went into cities where white lead was manufactured, the white lead cases headed the lists. In Philadelphia they didn't call them lead cases—they were simply such and such. If you go into those cities now, you will find the white lead men have disappeared and you get cases like "soldering" and "can-sealers." There shouldn't be much poisoning from those occupations because they are not necessarily dangerous, but nobody has paid any attention to them and the danger is still there.

I want to approve strongly the attitude of the National Lead Company in emphasizing dust. Mr. Tolman has won my gratitude by not saying anything about the men's finger-nails. I have heard physicians and employers talking about the worker's finger-nails. I cannot see how his finger-nails do him any harm, unless he sucks his fingers all day long. I don't think he does that.

In Salt Lake City I was talking to a lead smelter, a very intelligent man, and he said, "You know, those men are very careless—I am telling

them they ought to scrub their nails." I saw them dumping a pot: it was inverted, the smoking red hot ore falling into a grate, and as the dust and fumes lifted a little, I could see the men shoveling and breaking up the bigger fragments—those were the men who were to protect themselves by scrubbing their nails. The poisoning from fingers is still in the minds of physicians and manufacturers. Remember that a man eats only three times a day. He doesn't put his fingers in his mouth and soak his fingers in his coffee or soup. It is the dust, as the National Lead Company has found, which is the principal obstacle to be overcome.

MR. C. P. TOLMAN: I should be glad to hear from anybody. I really am quite serious in my desire to have the representatives of some of the industries that use lead products get together. For example, we furnish white lead to potteries in the dry form in many cases. The first operation at the pottery is to mix it with water. We could more easily ship the lead as a wet paste which would be free from the dust hazard. There are, I believe, similar possibilities. Lead products are used in the rubber industry. I have never been in a rubber factory, but I have an idea that improvement would follow interchange of experiences.

CHAIRMAN FIESINGER: The next paper is the "Dangers in the Manufacture of Dyes," and I am sorry to state that Dr. L. C. Cone of the National Aniline and Chemical Company has been detained. He has, however, sent on an able substitute, Mr. F. W. Barker, Jr.

(Mr. F. W. Barker, Jr., read Dr. Cone's paper.)

DANGERS IN THE DYESTUFF INDUSTRY

DR. L. C. CONE, NATIONAL ANILINE AND CHEMICAL COMPANY, BUFFALO, N. Y.

The amount of danger in any industry is in inverse ratio to the knowledge and experience of the organization operating that industry. If a green crew, under the control of an inexperienced foreman, is employed in even so simple an operation as ice-cutting, there are bound to be accidents. The dyestuff industry of this country has been, in comparison with our older established industries, in the class of the above ice-cutting experiment. As a further complication added to inexperience has come the insistent demand for a large tonnage production of new products. These conditions have accentuated the dangers to such an extent that many serious accidents have resulted. Statistics gathered from our dyestuff and intermediates factories during the past five years would give a rather alarming picture of the risks of the business. There has been, however, on the part of the more stable companies engaged in the industry, no lack of appreciation of the nature of the risks involved. As a result of this appreciation of the dangers, constant progress is now being made in reducing the number and severity of accidents.

WAR-TIME CHEMICAL DEVELOPMENT

Before we forget the hectic experience of the past five years some chemical genius, with a power of description and a keen sense of humor,

should write the story of the war-time chemical development of this country. Many events in this development have the elements of sublimely ridiculous humor in them. One instance I have in mind where two college boys, without industrial experience, rented an old, abandoned, windowless brewery, with broken wooden floors, and a couple of rusty boilers. In this building they installed a makeshift aniline plant, and in spite of every handicap, made aniline and sold it at a profit. It took American ingenuity and grit to make this plant go, and perhaps it also required American inexperience. An experienced aniline operator would have foreseen too many dangers to have ever started the project. Statistics of accidents from that and similar plants could hardly be considered the normal risk of our business. The proprietors themselves were always blue about the lips, and many a night they were just able to struggle home, get into a tub of warm water, drink a glass of milk, take a dose of salts, and go to bed. Is it not a wonder that, with the large number of such plants scattered all over the country, built by inexperience, and operated in spite of all hygienic laws, that the list of fatal accidents has not been greater? Gradually however, we have been learning, partly by experience and partly by study, more about the risks of our business until today the hazards of the well-regulated dyestuff factory are little greater than the hazards of any mechanical plant containing a large and varied assortment of moving machinery.

The chemical risks of the industry are largely centered about the manufacture of intermediates. The dangers of aniline, nitro benzol, binitrobenzol, binitrotoluol, etc., have been so frequently discussed, and the methods used by companies like our own for minimizing the risks of these manufacturers so thoroughly described, that there is no need to go into this matter at this time.

Our company has never suffered a fatality from any of these poisons although we have had some very sick men. Under the conscientious watchfulness of Dr. Kessler, of our Marcus Hook plant, the number of such cases has become relatively small. I am certain that if any safety man desires further detailed information in regard to our methods of handling these cases, Dr. Kessler in response to an inquiry would be more than willing to acquaint him with our experience.

The experience of our Buffalo works is the most illuminating experience of any of our plants, because in that factory is concentrated practically every risk of the dyestuff industry. While we do not make aniline there we handle enormous quantities of the product under a very wide variety of conditions. We make and use large quantities of binitrobenzol, binitro chlorbenzol, and other poisonous products. In the first six months of 1918, as shown by the table given on page 460, our serious chemical accidents were 21 in number against 59 of a mechanical nature, or 26.2 per cent. The first six months of 1919 there were 13 severe chemical accidents against 36 severe mechanical accidents, or 26.5 per cent. These figures, taken from a report by Mr. Doepke, our safety engineer, show that even under the rather strenuous conditions of high production pre-

vailing during these periods, and during the very unsatisfactory labor conditions of 1918, the mechanical accidents far surpassed the chemical accidents. A closer analysis of the preceding accident chart would show that the majority of these accidents are of the preventable type. Acid burns, alkali burns, fume poisoning and eye accidents can, by education and constant watchfulness, be reduced to a very low point. As trained safety men you are more familiar than I with the methods which are in use for bringing about these results.

Omitting further discussion in regard to these ordinary causes of chemical accidents I wish to call attention to what I consider to be the greatest hazard of the dyestuff industry today, at least from the stand-

THE EXPLOSION RISK

point of severity of results. This is the explosion risk. From this cause alone we suffered three fatalities in 1918. These fatalities occurred in one instance where a considerable quantity of explosive dye ignited and killed three men. Records of the dyestuff industry during the last two or three years especially, have been full of reports of similar accidents at other plants. The disastrous fire at the plant of the Atlantic Dyestuff Company in Nyack, N. Y., was caused by an explosion. According to the September 1 issue of the *Journal of Industrial and Engineering Chemistry* (page 893), there was recently another serious dyestuff explosion in Boston, Mass. Practically every dyestuff company in the country has had more or less experience along the same lines. This is a hazard which chemists and safety men must inform themselves about and which they must guard against more carefully. The greatest risks of explosions about dyestuff plants are three in number: Explosions of dyes and intermediates, explosions of pressure kettles, and explosions of vapors mixed with air.

The type of explosion which has caused our greatest loss is the explosion of dyes themselves. We have been prone to forget that dyes are organic compounds, some of them closely related to explosives. We have not accustomed ourselves to consider each new dye as a possible explosive but have gone ahead, powdering and grinding our products in blissful ignorance until an accident has called our attention to the dan-

ger. A dye widely used for khaki shades on wool during the war, was known as chrome yellow. This was made in very large quantities, dried, ground, packed, and shipped. It is doubtful if a single producer of this dye tested this material for its explosive properties before they began to produce it on a commercial scale, yet as I could quickly demonstrate to you by igniting a small portion of the dye, its quick burning properties render it more dangerous than many of our violent explosives. It is further doubtful if a single producer of this dye escaped the penalties of his failure to test the product. One large producer informed me that the total profits from his company's manufacture of this dye had been lost through disastrous fires and accidents. The same thing is true of another widely-used chrome dye, which is frequently known as metachrome brown. This product has been the cause of at least three disastrous explosions in different companies to my own knowledge. With these experiences in mind we shall be very remiss in our duties if we do not examine every new dye for its explosive properties. A general rule, well known to chemists who have dealt with explosives, indicates what classes of dyes are apt to develop explosive characteristics. This rule may be summed up very roughly as follows: "Be extremely critical toward dyes which are to be handled in the form of dry powders unless they are well supplied with sulphonic acid groups."

Even after the dye is given a clean bill of health by the chemist because of its composition, it would not be remiss to have the dye tested before drying and powdering. This is a service which the dye producers owe to their consumers as well as to their employees, for many dyes are mixed in mills and exposed to conditions which might, in a sensitive product, produce explosions.

With this danger of dye explosion eliminated, the next explosion risk which the chemical industry faces, is that of pressure kettles. Chemistry at high pressure has only begun its development in this country. Processes which have normally been considered impossible are gradually being carried out under conditions of high pressure. The best illustration of this is the Haber synthesis of ammonia from nitrogen and hydrogen. This reaction will not take place between the two gases under atmospheric pressure but when the two gases are brought together at very high pressure in the presence of a catalyst at elevated temperature, the two unite to a certain extent to form ammonia. With the growth of our American chemical industry, reactions of this type will be more and more largely introduced into our manufacturing plants. As they are introduced, the explosion hazard will become greater and greater, and the safety men must cooperate closely with the technical engineers to see that every possible precaution is taken against disastrous results to our workmen and to our plants. It has been rumored that the very important intermediate, paranitraniline, has been made commercially by only one process in this country because another process, which offers many advantages, has a great explosion risk connected with it owing to very high pressure. If the American dyestuff industry is to be permanently successful, it must not permit itself to be restrained because of high pressure explosion

risks. The control of this risk is primarily of course a technical engineering problem, but after the engineering lay-out is complete the safety man will find his opportunity to provide such appliances and such conditions as will give minimum destruction to life and property in case the engineering equipment ever fails.

The risks of explosion due to the ignition of mixtures and combustible vapors with air are already thoroughly appreciated by the technical and safety men. I only wish to call attention to the fundamental principles which must be followed in safety precautions to avoid explosions of this kind. While every effort to keep flames away from inflammable mixtures is commendable, these precautions alone will never entirely prevent ignition of explosive mixtures. Every effort must be concentrated on preventing the formation of such mixtures. Many disastrous explosions have occurred where every precaution has been taken to avoid the presence of all sources of fire. It is never possible entirely to do away with the chance formation of either frictional or electrical sparks. These are apt to be formed at most unexpected times, and at these times, if an explosive mixture of air and vapor is present, an unexplained disaster results. One of the most disastrous explosions I have ever witnessed, in which a large and well equipped plant was completely destroyed, was due to a chance frictional spark. In this particular case, every effort had been taken to avoid the proximity of flames to the combustible material, but a few simple precautions to prevent the formation of explosive mixtures had been overlooked.

As an illustration of the extreme difficulty of preventing ignition by chance sparks I will cite a case of my own observation where a large amount of toluene was stored in a glass enamelled steel tank. It never occurred to the operators that a glass enamelled steel tank is an ideal electrical condenser. The contents of the tank were not grounded in any way. A leak of toluene from the bottom valve soaked the floor under the tank; the workman in attempting to repair this leak, made connection between the contents of the tank and the floor through a wire in his hand; the toluene on the floor immediately became ignited. Quick-witted workmen threw a few shovels of snow, which happened to be convenient, over the burning toluene and succeeded in smothering the flame before it ignited the tank. All of the conditions for a disaster were there present. An examination of the conditions surrounding this flare caused us immediately to ground the contents of each storage tank through a large sized copper wire.

For handling problems of this kind the safety engineer must have a very clear appreciation of the fundamental principles of both physics and chemistry, and must further work in close touch with the technical men of his own organization. By such close cooperation and the careful study of each accident that occurs it will be gradually possible to eliminate the explosion risks of our industry.

CHAIRMAN FIESINGER; We are ready for the discussion of Dr. Cone's paper.

DISCUSSION

MR. L. A. DEBLOIS (E. I. du Pont de Nemours & Co.): I should like to ask the speaker whether it is his idea that in that accident he mentioned, the charge of static electricity on the contents of the tank came from the liquid in the tank or from outside?

MR. BARKER: We know that an anhydrous liquid in jet form is capable of producing static electricity—there have been fires from that cause. We know from our personal experience and experiments that the motion of any known conducting, dry material—wood-pulp, sawdust, flour, nitrate of soda, sulphur—will generate static electricity.

MR. D. F. CONKLIN: I should like to ask him how the company takes care of the reaction of the chemical—by personal control, or automatic means, or safety valves, or how?

MR. BARKER: It is done mostly by personal means. On all of our nitrifications we have duplicate thermometers—one recording thermometer and one indicating thermometer—and these thermometers are watched by the operators.

MR. CONKLIN: How many operators do you use?

MR. BARKER: That depends—perhaps three for each kettle. I think that is the safest way to do. One moment's inattention would prove fatal.

MR. DEBLOIS: It might be of interest to know that in the nitrating houses, where you have the worst possibilities, due to rapid rise of temperature of reaction, the nitration is hand controlled by a man who never leaves the stool and he has to be replaced by a helper. The shut-off cock on the glycerin is automatic. In other words, as soon as the man's hand is taken off the cock, the flow of glycerin stops.

MR. F. W. BARKER, JR.: The gentleman from the Goodyear Company asked about the treatment of aniline cases. Our medical department has had surprisingly good results with the treatment of aniline cases. The plugging tests have shown surprisingly good results in the course of five or six weeks after the man had been taken out of the process and taken away from the fumes.

MR. EDWARD M. COFFIN (Associated Industries of Massachusetts). I should like to ask for a bit of information regarding static electricity: What has been the best method of reducing that from belts?

MR. C. P. TOLMAN: The best method is to get rid of the belts.

MR. COFFIN: It was suggested to me that a chrome belt offered less hazard.

MR. TOLMAN: Don't use it. A cotton belt may be better.

DR. S. DANA HUBBARD: In the printing press work, particularly, in making color work, we have had trouble with spoiling paper. In the press of the "New York World" they have demagnetized, by a process of chroming—a secret process of chemical treatment—and they are printing at maximum speed. You can see these colored articles, one on top of another, and they do not smear.

MR. COFFIN: We met the same problem and got around it by grounding the shaft and treating the belt with a mixture of glycerin and water, which may be applied once a month—it doesn't have any deteriorating effect on the belt.

I have noted, with interest, in the dry cleansing establishment there is a serious hazard in the cleansing of silk gowns, particularly where there is metallic trimming, and I found one concern was overcoming that difficulty in grounding the contents by introducing a damp piece of linen.

CHAIRMAN FIESINGER: In connection with Dr. Cone's paper, Mr. Barker stated, I think, these statistics will be of interest.

MR. H. F. DOEPKE (National Aniline and Chemical Company): I shall read some figures from this chart and shall be pleased to answer any questions.

(Mr. Doepke read chart. See page 460.)

MR. L. A. DEBLOIS: I should like to ask whether the occupational diseases are included.

MR. DOEPKE: It does not include dermatitis. We had thirty-seven cases in 1918, as compared with twenty-two in 1919, and the average loss to benzoin dermatitis is two days. That is due to few men who have been negligent to the doctor's orders.

MR. DEBLOIS: That paper is extremely interesting because it shows how low the rate can be brought in the chemical plant. I should like to cite one instance in my own mind: With a group of one hundred and sixty men in aniline manufacture at our works, up till night before last they had gone within two days of a year without a major accident. I mean by a major accident, an accident that involves more than the day or shift on which the man is working. That shows how low you can go.

MR. DOEPKE: I have tried to take out an accident policy and in stating my profession I was refused a policy. I quoted this incident to the management and this is what they said:

"From our knowledge of the aniline by-product game as it is now played, we are inclined to look with disfavor upon any liability, or accident, or health risk in connection therewith. We have made a deep study of the chemical trades and we are well up-to-date on all the latest methods and products."

While the average American citizen may not boast of having indulged in deep studies of the chemical trades, we will share the views of the insurance company, just quoted, to the effect that our industry has an ill reputation, not only locally, but wherever man meets man. Focus your attention upon the graphic chart at the bottom of the experience sheet, and you will know why this reputation is as unfortunate as it is unfounded.

To substantiate Mr. DeBlois' statement, in 1918 we had two severe cases, resulting in fifteen days' loss and two minor cases, which totals 0.89 per cent in frequency and 0.7 per cent in severity.

As far as benzol dermatitis is concerned, our physician has made up a solution of grain alcohol, bi-chloride of mercury and epsom salts, and when applied to the workman, who was suffering with benzol dermatitis, and kept there, it guaranteed a cure in two days.

MR. F. W. BARKER, JR.: I might say the greatest stride we made at our plant was the installation of an efficient medical department. We have a physician on all the time during the day and he has as his assistant,

a technologist, who makes a business of taking blood counts and making urinalysis tests, and besides that he has a first-aid on, both day and night.

I want to emphasize the benefits derived from this technologist. We are able to make an examination once a month of every man connected with nitrol work and make a study of his blood and find out whether he is going backwards or forwards.

Adjournment.

FRIDAY MORNING SESSION

THE meeting was called to order at 9:40 A. M., Chairman Fiesinger presiding.

CHAIRMAN FIESINGER: No doubt some of you people know the Chemical Section sent a letter to each one of its members last year for suggested subjects for our program. This year we got so few replies, we thought this would be a very good time to pass slips around, and if you have any suggestions and would like to submit them for next year's program, they will be of great assistance to the program committee.

The first order of business this morning is the report of the Nominating Committee. Mr. S. H. Kershaw, the Chairman, will report.

REPORT OF NOMINATING COMMITTEE

MR. S. H. KERSHAW (Hercules Powder Company): Your Nominating Committee wishes to report the following nominations for the next term of office:

Mr. I. V. Kepner, Pennsylvania Salt Mfg. Co., Chairman.

Mr. S. H. Kershaw, Hercules Powder Co., Vice Chairman.

Mr. Henry F. Doepke, National Aniline & Chemical Co., Secretary.

(These men were elected.)

CHAIRMAN FIESINGER: The first paper on the program this morning is one which I know we are all very much interested in. We have heard so much about gas masks—I believe we are all at sea—we do not know what can be had, so this morning we have a man who has put a great deal of study on this subject. He has been doing research work for the gas defense of the Bureau of Mines, during the war, and also for the Chemical Warfare Service of the War Department. He was not in the production end but in research work, and since the close of the war he has taken up his duties again in the Massachusetts Institute of Technology. We are fortunate in having him with us this morning; I have great pleasure in introducing Dr. W. K. Lewis.

CONTROLLING FACTORS IN GAS MASK DESIGN

DR. W. K. LEWIS, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, CAMBRIDGE

The introduction of the use of toxic gases during the war made necessary the development of suitable masks for protection against them.

In connection with this development, a large amount of research work was carried on and the research results were put into practice in the manufacture of millions of military masks. Furthermore, these masks were continually in process of improvement, so that by the end of the war extremely effective types had been evolved. From all of this work a large amount of information is available, which should be of the greatest value in solving the problems of protection against toxic gases encountered in the industries.

During the war toxic gases were encountered only when admixed with air. This article will therefore, be restricted to the discussion of masks designed to absorb toxic gases from air, i. e., masks functioning essentially as air filters or purifiers, leaving out of consideration oxygen helmets and similar devices intended to furnish an artificial air supply. It is, however, probable that the majority of problems arising in industrial practice require air purification alone, so that the military experience of the war should be immediately available for industrial use.

REQUIREMENTS FOR PROTECTION

A suitable mask for protection against toxic gases must meet the following requirements:

- (1) The chemical protection must be adequate, i. e., the toxic gas must be removed from the air so completely that any remaining traces are physiologically harmless.
- (2) The mask must be throughout mechanically tight so that all inhaled air is forced to pass through the absorbing medium.
- (3) The mask must be capable of easy, quick, and safe adjustment; if possible, adjustment should require little or no training of the wearer.
- (4) The mask should be comfortable in fit and operation.
- (5) The mask should be as small in size and weight as is compatible with other requirements.
- (6) Ruggedness in construction and perfection in mechanical details are of the utmost importance to insure satisfactory service.
- (7) The life of the mask should be as long as possible.

From the military point of view, the size and weight of the mask and the ruggedness of its construction are of extreme importance, and, furthermore, the chemical protection of the mask must be universal, i. e., the mask must absorb any toxic gas which it is possible for the enemy to utilize, including the lachrymatory gases. From the industrial point of view, size and weight are less important than in military use, so that the industrial mask will probably introduce improvements at the expense of increase in size. The industrial mask does not have to give universal protection and in this regard possesses a great advantage over the military mask. The industrial mask can be designed to give the maximum possible protection for the one gas against which it is to be employed.

CHEMICAL PROTECTION

Two types of chemical absorbents were developed during the war, namely, impregnated cloth and solid, granular absorbents contained in a suitable canister. The cloth masks were simple in construction and relatively comfortable to wear, but they lacked the advantage of universality in protection. On this account they were ultimately discarded for military use. For industrial use against gases which can be suitably absorbed in this way, they will probably offer the cheapest and most satisfactory protection.

The most important solid absorbents developed were soda lime and absorbent charcoal. Mixtures of these were employed in the military masks, and together these two absorbents, when properly manufactured and used, offer protection against all toxic gases except carbon monoxide. In the military mask it was necessary to use a mixture which would furnish the best average protection against all gases that might be encountered. In commercial practice, the granular filling would be chosen for the particular gas in question. For most acid gases soda lime is essential, but it often functions best when mixed with varying amounts of charcoal. Properly prepared charcoal absorbs gases very quickly, and acid gases are frequently taken up first by the charcoal and gradually released, then being transferred to the soda lime by which they are permanently absorbed.

Many of the more inert gases are not absorbed by soda lime and for such gases the canister should be filled with charcoal alone. Charcoal offers perfect protection against such gases as gasoline, benzol, aniline, carbon bisulphide, and the like. Since these gases are encountered almost always in mixture with air, there no longer remains an excuse for industrial poisoning from these gases when the individual exposed to them is aware of their presence in advance. For such gases, however, relatively large masks are desirable because the absorptive power of the charcoal for them is limited. The charcoal which has accomplished these remarkable results was developed by the Research Laboratories of the National Carbon Company and at Nela Park in this city, and is now being manufactured for industrial use.

MECHANICAL TIGHTNESS

The mechanism of gas leaks through the canister or other absorbing element is too complicated for discussion here. Protection against this type of leak must depend upon the proper design of the mask. The point of major importance to the user is the question of the fit of the mask to the individual wearer.

During the war three types of fit were developed. The first involved a seal around the neck and chest. This mask is necessarily restricted to one of impregnated cloth, the mask consisting of a sack fitted with goggles and preferably also with an exhalation tube, the sack being tucked down under the coat around the neck and shoulders. Such a mask is cheap, simple in construction, relatively comfortable, and well worth consideration for use in those industries where such an absorbent

is satisfactory. The second type of fit employed a face piece fitted over the forehead, down across the cheeks, and under the chin. Both the French and German masks were of this type, the French mask being constructed of absorbent cloth, and the German mask employing a canister. Toward the end of the war this country also developed a mask of this type. The impregnated cloth mask of this type is even more satisfactory than the sack type of mask wherever its use is allowable. The third fit developed involved the use of a mouthpiece in connection with a nose clip to insure breathing through the mouth only. In order to protect against lachrymatories, the military mask of necessity utilized this fit in connection with the second type, thus securing double protection against mechanical leaks. In many industries this second protection might be unnecessary.

Wherever a canister mask is necessary, one or both of the last two types of fit are essential.

ADJUSTMENT OF MASK TO WEARER

For safety and "fool-proof-ness," it is believed that the mouthpiece-nose clip type of fit is the best. Even this mask requires a certain amount of instruction of the wearer. The mouthpiece must be inserted and the nose must be closed in order to make the mask safe. The forehead-cheek fit requires some experience in adjustment but is safe when properly used.

COMFORT

The forehead-cheek fit is by far the most comfortable. Even in this type, to insure comfort in use requires great care in manufacture. The writer is convinced that for emergency use by operatives who are only occasionally exposed to danger, the mouthpiece-nose clip mask should be employed, for although exceedingly uncomfortable, the operative would not object to using it during an emergency. For long continued use at regular periods, this mask should not be considered. The forehead-cheek type of fit is so much more comfortable that an operative who is to wear a mask for any length of time should be trained in the use of this type.

Ease of breathing is a great factor in comfort. To get low resistance, the canister should be as large as possible, and of large section, but in the design of the canister these points must be balanced against weight and a proper ratio of length to section in order to insure protection.

SIZE AND WEIGHT

The military mask was small in order to keep from over-burdening the soldier. Even at that the military mask offered excessive protection because in the open air of the battlefield gas concentrations were extremely low. In buildings gas concentrations are likely to be very much higher and much larger masks will become necessary. It would seem that in the industries the mask size can be increased without undue disadvantage.

CONSTRUCTION

Ruggedness of construction should never be sacrificed to decrease in weight or size. Mechanical perfection in construction is of the greatest importance and can be guaranteed only by rigid inspection during manufacture. Low cost of the mask should never be secured by lessening the protection. The testing of the mask under service conditions is of the utmost importance to guarantee its satisfactory performance in emergency. This testing should be carried out by the industries themselves, because they alone are familiar with the actual conditions under which the mask must be employed.

DURABILITY

A mask should have a life exceeding the period of any emergency for which it can possibly be employed. This requires a relatively large mask. In this connection, one must keep in mind the point already made, that under industrial conditions gas concentration will be much higher than in military service.

The proper design of a gas mask is an extremely complicated problem, requiring the attention of experts trained at this work. Such experts, however, must work in close cooperation with the organizations using the mask, since otherwise the mask will not be properly correlated to the requirements. It is, fortunately, possible to secure expert advice in mask construction from the Bureau of Mines, since this organization has had years of experience in mask development and still retains on its staff many of those men most active in the development of the military mask during the war. No industry should choose a mask for protection against toxic gases without securing first the cooperation and advice of the staff of the Bureau of Mines.

DISCUSSION

MR. WALTER GREENWOOD (Carnegie Steel Company): We have to contend with carbon monoxide, but in some branches we have large quantities of dust, and in the allied industries, of the iron and steel industries, I see large quantities of dust that must be analogous to the substance which gave the nailers consumption.

In cleaning out a blast furnace, to get it ready for relighting, we have large quantities of dust; also in our slag plants. We found, at least in my experience, that all of these filtering masks which are put on the market are not suitable or satisfactory.

I would inquire if this French mask and other specimens that are exhibited here would be suitable for our industry to filter the dust? I do not think it is necessary to protect the eyes, but to take care to filter the air they inhale.

DR. W. K. LEWIS: With regard to the two questions: first, carbon monoxide, the Navy developed that during the war, but it is my understanding that the information with regard to that is "military information." I am sure the military department will release that and I am

sure carbon monoxide protection will be available very shortly. Second, with regard to dust protection against smoke; this was one of the important developments of the war. You noted these pads they were to remove smoke, practically dust particles. The particles which this mask faced were extremely fine. Coarser particles have also been removed. This filter has the disadvantage of having a high resistance. The French mask will take care of almost any dust conditions. When the dust gets serious, it will be necessary to find finer filtering media.

Mr. L. A. DeBlois: In the industries we are faced today with a great number of commercial firms that have put on the market army gas masks, or modifications of the army type of gas masks; otherwise, we have no real source of information as to what masks to use in our works, how long they may be used, or really any solution for the specific working problems.

Some of you have gases with which you are not familiar. You may have a fire and lose two or three men from inhalation of the fume. This brings on edema of the lungs—it is an acid fume poisoning proposition. There are no immediate ill effects of any serious nature, but a delayed attack of a serious nature, causing the men finally to succumb. Perhaps that problem put in writing to the manufacturer of gas masks might lead to an erroneous assumption of what took place.

It seems to me, and I think it is Dr. Lewis' opinion, we ought to have some agency of government, or perhaps a body of the National Safety Council, some agency in the country which could furnish more definite advice on gas mask protection in the industries.

Dr. W. K. Lewis: With regard to this suggestion of Mr. DeBlois, I feel very strongly that there should be some unprejudiced central organization to function in the choice of gas masks for the industries. The manufacturer of the mask, however good his intentions, is, of necessity, a somewhat prejudiced party. There is no manufacturer of gas masks in this country today who has the whole story, who turns out all types of masks, who has a staff adequate to meet the many problems that come up.

The testing of gas masks is of the utmost importance. It is worse to give a man a defective mask than it is to give him no mask at all, because that defective mask inspires in him a feeling of confidence which will lead him to go into places where, without a mask, he would never dream of going.

The testing of such masks, however, should be carried out not by the manufacturer, because, as I say, he is a prejudiced party, nor by the user, because he is not a gas mask expert. He has entirely too many other problems to solve to take the time to master the technique of gas mask production and testing. This testing should be carried out by some unprejudiced organization, who could be implicitly relied upon.

Mr. EDWARD M. COFFIN (Associated Industries of Massachusetts): Possibly the Underwriters Laboratories in Chicago, that have recently gone into safety work, in addition to the standardization of fire apparatus, would be interested.

MR. A. H. MASSEY (E. I. du Pont de Nemours & Co.): Recently I visited a small paint plant which our Company took over. They had a home-made facepiece, similar to the Tissot facepiece, with possibly three hundred feet of one-inch rubber hose, using a small hand pump for air. I was talking to the repair men who used that apparatus and they were very much pleased with it.

MR. H. F. DOEPKE: I should like to ask Mr. James whether he encountered the hazard of the rubber hose becoming twisted, cutting out the air supply?

MR. J. D. JAMES: We have never had a particle of trouble with our hose connection. The check valve that is connected with the canister there for filtering purposes, at the off end where we are receiving the fresh air, maintains a steady flow.

MR. IRA V. KEPNER: I would like to ask the size of the hose and kind you use.

MR. J. D. JAMES: Three-quarter inch rubber garden hose.

MR. A. H. MASSEY: The hose I spoke of was one inch wire wrapped. You cannot twist that hose.

MR. J. D. JAMES: I feared something of that sort would happen and had a man there in charge of that hose, because we did not want to smother the man. He saw that there is no twist in the hose.

MR. A. L. THOMPSON (E. I. du Pont de Nemours & Co.): I should like to ask if you have come in contact with two hundred and fifty foot hose, hasn't the man a pretty hard time with that weight? You will find that in many cases the operator is going to object to that lift and that helmet.

MR. J. D. JAMES: We have a belt around the man's waist and the hose is fastened on this belt with a rubber belt, and he has no weight whatever.

MR. C. E. RICE (The Dow Chemical Company): Twenty years ago we were interested in the bleach manufacture of lime. We designed a mask or hood to put on, something on the order of a bonnet, with a wire frame and inlets for air around the crown of head. Air was furnished under pressure. I should be glad to furnish you with any information you want on that.

MR. N. S. NOBLE (B. F. Goodrich Company): Relative to the hose to be used, I would suggest they use a large wire inserted, instead of wire wound, similar to a vacuum cleaner.

MR. J. H. BARNHOLT (E. I. du Pont de Nemours & Co.): Just two weeks ago I tried Mr. James' idea out personally in our naphthalene subliming chambers and camphor subliming chambers, and while we only had a half-inch, three-ply hose the fact remains it did not work. We finally compressed the line and supplied the employee with one pound air pressure and that has been perfectly satisfactory.

Do you think, Mr. James, the half-inch hose would cut off any noticeably adequate air supply, as compared with your three-quarter hose?

MR. J. D. JAMES: Yes, there is a great difference in friction. We haven't suffered any inconvenience whatever from the air.

DR. A. D. RISTEEN (The Travelers Insurance Company): Mr. Chairman,

Mr. James seems to be the text for this discussion and I would like to make the suggestion that the success or failure of his plan appears to me to depend upon the question of leakage around the face mask. He has evidently been very successful in preventing such leaks and when you can protect that leakage you have a fine mask: but some day may it not happen that there will be a leak around the mask and the man suffer from a dose of monoxide? The point I have in mind is, even though it does call for some additional apparatus, isn't it a good thing to have the man draw his air supply into his lungs from what I might call a plenum rather than a vacuum? Any leakage will be from the inside out and therefore the man will not be harmed, whereas if the friction in the intake pipe causes a slight vacuum, then if there is any leakage, it is bound to introduce carbon monoxide. I only make that suggestion to emphasize the extreme importance, as it seems to me, of being sure that the mask is tight to the face.

Dr. W. K. Lewis: There are two points that have been brought up upon which I think I can give you some information. During the war we did a large amount of experimental work, as we literally had millions of men exposed to gas, and a great many of those were gassed and we know the conditions under which they were gassed. We carried on thousands of experiments.

In the first place, I wish to reiterate my statement that for use against carbon monoxide under conditions where it is applicable, this extended hose method appeals to me as the best thing available. Why? Because, as I said before, when carbon monoxide is present, oxygen is likely to be absent. On the other hand, if you are drawing your air outside you are sure of no monoxide and you are sure of good air. However, if a man has to go up and down ladders, or travel around too much with this hose tied to his waist, he cannot do it. There are going to be some places where the carbon monoxide mask is going to be necessary.

Let us take naphthalene or camphor, both of which have been mentioned; I wouldn't think of using a hose if I was going to use the mask. What I would use is a canister mask equipped with proper charcoal, but the choice of that charcoal is the whole story and I would test that charcoal before I went into the atmosphere—I wouldn't accept charcoal from anybody.

This absorbent charcoal will absolutely, quantitatively, remove camphor, benzol, carbon bi-sulphide, any of these gases.

I wouldn't go into a tank car with a three-quarter inch wire hose tied to me, and I don't think you would, but I would be willing to go into a tank car with a mask which I knew would absorb all the benzol in the atmosphere.

Suppose that there is so much benzol that there is only five per cent of oxygen—a man cannot live on that. On the other hand, that oxygen is air when he sucks that in the benzol and his oxygen goes up to twenty-one per cent. The point is, each problem must be analyzed for itself and solved for itself.

With regard to hose resistance, you cannot have it too small, but a

properly designed Tissot facepiece will never leak enough, with any suction that a man can pull, to gas that man in a CO atmosphere, with the combustion of carbon with the oxygen in the air. Why, this Tissot mask will never leak one per cent of the air when it is properly fitted. If you have any doubts about that, employ the mouthpiece and nose-piece mask—he is safe, but uncomfortable. In a chlorin atmosphere, or a phosgene atmosphere, a Tissot mask always gives safety, if the mask is properly adjusted.

The necessity for expert advice as to the type of mask to be used in each individual case, after a careful study of the conditions under which it is to be employed, is the prime necessity for us to recognize.

On the western front we put gas masks into use, the leakage of one part of fifty millionths of which would have killed the soldier. The percentage of the gas leakage around the facepiece is negligible and yet there was a gas one part of fifty millionths of which was toxic, so you see that was much more dangerous. I don't wish you to misunderstand me; I know the danger of carbon monoxide, but it is only when the concentration is high. I would not want to wear an absorbent mask with fifteen per cent carbon monoxide because I wouldn't have enough oxygen left.

MR. I. A. PALMER (Mine Safety Appliances Company): We are working on the carbon monoxide mask; it would be of help to us if we could get an idea of the average percentages of monoxide that the various plants contend with.

MR. MCCARTHY: The average is fifteen per cent; it will vary according to the conditions that surround the furnace plant.

MR. PAUL F. WILLIAMS (E. I. du Pont de Nemours & Co.): I should like to ask Dr. Lewis how you would take care of the proposition where you have a phosgene cylinder and the bottom blows out, and you go in and stop up the leak?

DR. W. K. LEWIS: There would be no trouble in going into a phosgene concentration, provided there is any air in the room, a good absorber, and a large enough canister. In the face of such a risk as that, you ought to have a canister ten times the size of this. I will go into that room if you will give me a large enough canister with the present type of mask.

The Chairman asked me how I would protect myself against ammonia. Any acid solvent is effective against that; there are canisters offering such protection. The skin cannot stand the irritation of more than four per cent of ammonia. Any man going into four per cent of ammonia is driven out by the irritation of skin—it is impossible to send a man into that room.

With regard to dimming, that is a large question. There were two years of active research on that problem and a number of solutions of the dimming difficulty were found. Unfortunately, they were rather complicated, from a military point of view. I don't think I ought to go into those in detail. The solution employed by the army, up to the end of the war, was the use of a special soap mixture smeared on the inside of the glass to form an absorbed layer of water, causing the condensed water to run in a clean sheet. You know the mixture on a windshield

on an automobile which causes the rain to run down in a clean sheet and does not form in droplets—that was employed with the gas masks and it is satisfactory. From a military point of view, the protection ultimately breaks down and in order to renew the protection the mask must be removed and a fresh supply of soap supplied. From a military point of view, where a man used it twenty-four hours, that was serious; from an industrial point of view, you don't expect them to wear it over an hour and the best emulsifying agencies on the market will give protection for that length of time. Some of the mechanical appliances are very complicated. You will notice in this Tissot mask the inhaled air is brought up and directed over the eyepiece, so the eyepieces are always swept with air and kept clean. In a cold storage house that will dim, but not completely. In a cold storage house you will freeze over the outside rim, but we have never frozen over that hole in the center about the size of half a dime. Those are drastic conditions which you wouldn't find everywhere. Dimming is one of the most serious problems in gas mask construction.

MR. H. H. PORTER (Newport Chemical Works): Speaking of the dimming of the army gas mask: We have been using those masks with just the standard army filling for the last four or five months. We have been fortunate in that we have had no spills where we have had a heavy concentration. We have gas masks posted around in cabinets outside the buildings. We have a place to keep them and the men take care of them themselves. If a man wants to get a mask, he breaks the glass in the cabinet. We have a man who makes the rounds and if there has been a mask used, he goes over it and smears the lenses with this non-dimming compound and puts it back. We use the ordinary canister, and have had ammonia spills and sulphuric acid, benzol, and dinitrol trouble, all of which were moderate, but a man could not have gone under without proper protection and we have been very fortunate.

MR. C. M. FINCH (Aetna Life Insurance Company): I want to substantiate what Dr. Lewis said. I had the opportunity to sleep with a mask on the front for five hours. I can swear by it because it saves life. As far as the dimming effect is concerned, the eyepieces are made of celluloid: We used to make watch crystals out of them.

MR. D. F. HEATH (Goodyear Rubber Co., Akron, Ohio): In the Goodyear Company, for some time we had trouble from hydrogen sulphide fumes and when we made our masks we experimented in the chemical department and to this day we are using the standard army mask and we keep a duplicate canister for each mask. They are used two or three hours each day in the morning and afternoon, and at the end of each week the canisters are taken over and the duplicates are placed in and the canisters reloaded. We have never had a sickness and they have been very successful.

CHAIRMAN FIESINGER: The next paper is "Some Experience in Accident Prevention in the Dye Industry," by A. H. Massey.

SOME ACCIDENT EXPERIENCE IN THE DYE INDUSTRY

A. H. MASSEY, E. I. DU PONT DE NEMOURS AND COMPANY, WILMINGTON, DEL.

The dye industry is so extremely varied that the work of the safety man in one plant is very different in detail from that of the man in another or from the man in a general chemical plant. The dye industry and the general chemical industry overlap in so many points that to differentiate between them would be impossible. The fundamental problem; however, is the same—that of the prevention of accidents and the preservation of health. These subjects are so closely allied that they should be considered as one and the same. In many instances the health problem is a more serious one than that which we commonly term "accident prevention."

The hazards are as varied as the industry; to those common to moving machinery and the handling of materials are added hazards pertaining to explosive mixtures and compounds; vapors and dusts which may be deleterious, or actively poisonous; and the hazards of open containers, fragile containers, and especially containers under pressure in which are hot, corrosive or poisonous materials.

Let us consider first some of the more important matters relating to the prevention of accidents and the preservation of health through mechanical arrangement and equipment, by which is meant the elimination of unsafe conditions in manufacturing buildings and apparatus, by changes in their construction, or by the addition of special appliances, etc.

PROPER DESIGN OF FLOORS AND PLATFORMS

This is of special importance where hot, corrosive, or poisonous liquids are handled as there is always the possibility of a spill. In buildings with several stories, special attention should be paid to both the tightness and the drainage of the floors, otherwise a spill of this material on a floor with openings, or with holes or cracks in it is apt to run through upon men below. If the floor is tight but does not have drains provided and the liquid is allowed to lie on it, there is always the possibility of someone walking or even falling into it, which might result seriously in either case.

For example, dinitrobenzol was being handled in a wooden filter on the second floor of a building and there were operations on the ground floor which required a number of men to pass under the section occupied by the filter.

The filter became leaky and the floor under it, being of rough 2-inch plank, full of cracks, there was considerable trouble from cyanosis among the men in the other operations due to dinitrobenzol water dropping on them, until a tight floor with the proper arrangements for drainage was installed under the filter.

Another example: A dissolving tank about 4 feet deep and 6 feet in diameter into which solid caustic was dumped and filtered water added and heated by means of steam coils to obtain a very strong and pure

solution, was located on the second floor of a building about 5 feet from the elevator shaft. To obtain the desired solution the tank was filled to within approximately 15 inches of the top. Prior to the accident, caustic and water were in the tank and the operator turned steam into the heating coils and went to another part of the building.

A mechanic had lowered the elevator to the first floor and was on top of the elevator cage repairing the counterweights on one of the gates when the caustic solution boiled over. The floor was tight but a gutter or drain had not been provided around the dissolving tank. Consequently, the strong boiling caustic solution drained into the elevator shaft upon the mechanic. He was penned there with serious consequences.

The importance of all control equipment, such as main line valves, valve clusters, etc., which are not within reach of the floor, being provided with operating platforms, cannot be emphasized too strongly, as the accidents resulting from their absence are numerous and usually serious. These platforms should be properly protected with hand-rails and toe-boards, and special attention should be paid to the location of ladders or stairs leading to them. The details of this matter will be covered in the next paragraph.

PROPER ARRANGEMENT OF THE APPARATUS, LADDERS, STAIRWAYS, AND EMERGENCY EXITS IN MANUFACTURING BUILDINGS

Apparatus should be installed in the manufacturing building in such a way as to permit the most efficient method of operation with the least congestion. We too frequently find the chemical manufacturing building badly congested with boxes, barrels, and bags of the intermediates which go into the operations, or even with the finished or semi-finished products. This is the result of the building having been originally designed with insufficient floor space or of changes which have taken place in the operation. The crowding of chemical operations and apparatus into a building invariably results in unsafe and inefficient operating practices, also excessive handling of material by hand.

It is very necessary to study the natural and artificial lighting conditions in order to procure the best light at the operating stations and to eliminate dark corners and pockets. Where the light is poor it is impossible to make accurate readings of thermometers, hydrometers, and pressure gauges. Inaccurate readings tend toward non-uniformity in the product. In some operations this may give abnormal reactions resulting in foaming, excessive heat being generated, or gases being given off in excessive volume, any of which conditions might lead to very dangerous results. Moreover, there being a large amount of material handled in the building, good light tends toward proper storage and good housekeeping conditions.

Stairways and ladders should be located so as to afford the most convenient access to that part of the apparatus or building for which they are intended. This is especially true as regards routine attendance and oiling. If we are to expect the operators and oilers not to take short cuts, we must provide them with as direct routes as possible.

Permanent ladders should not be installed over floor openings, open

tanks, vats, or containers in which hot, corrosive, or poisonous material is handled. They should not be used in the immediate proximity of machinery, the moving parts of which, due to their nature or location, cannot be totally enclosed. Special attention should be given to the termination point of stairways and ladders to see that they do not abutt on blind railroad tracks or lead into tanks, pits, drains, or sumps, which can be left open, or against moving machinery into which men may walk or fall. Reaction vessels or containers in which hot, corrosive, or poisonous materials are handled or the overflow pipes and vent lines from same which may be expected or are known to boil over or overflow are often located over or alongside permanent ladders or stairways. This makes a very dangerous condition.

In a building or room where there is a possibility of a condition developing which would be a menace to the lives of the occupants, special attention should be given to the provision of emergency exits. These exits should be installed so as to give the most efficient exit from the building at a point where the menace will be least, but should, however, not only be accessible to operating stations but be, as far as possible, in location somewhat removed from the immediate danger. Such exits should be placed so as to be subject to the least possible danger of obstruction either inside or outside the building from normal or abnormal operating conditions.

PROPER PROTECTION OF PROCESS OR REACTION VESSELS AGAINST EXCESSIVE OR ABNORMAL PRESSURE

This subject is very broad and can be covered only in a general way.

By reaction or pressure vessels is meant vessels such as sulphonators, nitrators, thionators, autoclaves, hydrolizers, acidifying and neutralizing tubs, tanks, stills, reducers, evaporators and condensers, etc.. These vessels either operate at atmospheric pressure or above or below atmospheric pressure. Materials may be used in them which are either slightly or extremely corrosive, and which sublime or freeze at or above the normal atmospheric temperature. In this case the containers and lines connected with same should be heated artificially.

Reaction Vessels Which Operate at Atmospheric Pressure: Where the vessel is open to the atmosphere or has a loose cover over it, there are no precautions to be taken against excessive pressure.

Where the vessel has a tight cover but is vented through a pipe line which does not have a valve in it, it is necessary to have the vent line sufficiently large to take care of any gases that might be given off.

Where materials are used in the operation which sublime or freeze above normal atmospheric temperature, precautions should be taken to eliminate the possibility of the vent pipe becoming frozen up or plugged.

Where the vessel has a tight cover and is vented through a pipe line but has a valve in the line the same precautions should be taken as in the case just cited. Also there is the possibility of the valve being left closed while the reaction is carried on. This would defeat the purpose of the vent, and to overcome it a pressure relief system or safety valves should be installed or the operation should be given special supervision.

Where the vessel has a tight cover and is vented through a pipe line into a condenser or into a series of condensers and thence to the atmosphere, the same precautions should be taken as in the cases previously mentioned.

Vessels Operating Above Atmospheric Pressure: Where the pressure of the reaction is controlled by heating or cooling it with some medium such as steam, water, or oil, circulated through coils or a jacket on the reaction vessels, if the medium would give a violent reaction in case it should come in accidental contact with the material in process, then coils inside of the reaction vessel or a jacket on the vessel should never be used. The temperature should be controlled by coils on the outside of the vessel.

Where the reaction vessel is heated by direct gas, coal, or oil fire, and the material in process is inflammable or gives off inflammable vapors, careful inspections of the vessel should be made before charging to see that there are no leaks which would allow the inflammable material or gases to get into the fire box. Fire box explosions are quite frequent around gas- and oil-fired stills. A leak will develop in the bottom of the still or process vessel and vapor or gas will collect in the fire box. When the fire is lighted this accumulation ignites, sometimes with such violence as to blow the vessel off its setting and partly or completely wreck the furnace. A precaution against this is to have a steam jet installed in the furnace and blow the furnace out thoroughly with steam before lighting a fire.

Where the reaction is carried on under pressure the bottom of the vessel should not be exposed to heat sufficient to cause the metal to run, due to pressure inside, thus causing a breakdown of the walls and resulting in what might be termed an explosion.

Where the pressure is controlled by the reaction itself, and governed by the rate at which the ingredients are added, and by cooling or heating with coils, the same precautions as previously outlined should be taken. In this case, if the control is by the gradual addition of a liquid, which if introduced in quantity would greatly accelerate the reaction, double valve controls should be used rather than a single valve.

Safety Valves or Pressure Relief Systems: All pressure vessels should be equipped with relief systems. The rapidity of the reaction within the vessel and the size of the vessel of course should govern the size of the system. For example, a steam boiler or water system under pressure would not require the same size relief system as a chemical reaction of the same capacity and under the same pressure. A one-inch safety valve installed on a 1000 gallon reaction vessel used as sulphonator where the reaction is being carried around a 100 lb. pressure is ridiculous. Should the reaction get beyond control in such a case it is questionable whether a 3-inch or 4-inch system would take care of the gases given off.

No hard and fast rules can be given for the size or type of relief valves or systems that should be installed on reaction vessels. Each case should be given careful consideration and a system installed in accordance with the dictates of engineering principles and common sense.

After deciding the size of relief valve to be installed the next question is to determine the type to be used. It is very hard, in fact almost impossible, to get a pop valve to stand up where acid or caustic is used. There is always the question whether the valve should be lead, brass, or copper-lined, or of cast iron.

Tin discs bolted between flanges make a very satisfactory relief system in some cases. Then again where the pressure is quite low and the life of a valve is short, seals are sometimes used with good results.

The location of the relief valve should also be given consideration. If the material in process gives off vapors which sublime or freeze above the atmospheric temperature there is always the possibility of the valve leaking and vapors passing into the vent line, freezing, and causing the line to become plugged. The line may also become plugged between the reaction vessel and the valve from the same cause.

PROPER DESIGN, ARRANGEMENT AND LOCATION OF STORAGE HOUSES AND VESSELS

The details pertaining to this subject are so numerous and varied that time will permit but a brief survey of the subject and in a very general way, which will be done by citing a few examples and precautionary methods in connection with the storage of strong acid and caustic solutions, cyanides, metallic sodium, chlorates, picramates, and general explosives.

Where strong acid and caustic solutions are stored in carboys or drums the containers should be in good condition. They should not be piled and they should be isolated where possible. Where large tanks are used, whether on the ground level or elevated, they should be fenced off and proper warning signs posted.

Where cyanides are stored every precaution should be taken to keep acids away, for a spill of acid into sodium or potassium cyanide develops a very ugly condition, hydrocyanic gas being liberated.

In storing metallic sodium special care should be exercised to keep water away. Both the containers and the building should be dry and water-tight; signs should be posted warning of the dangers to be expected from water coming in contact with the sodium.

Chlorates, picramates, and general explosives are all very much in the same class. Isolation of the storage building in accordance with the standard codes, elimination of foreign matter, and careful handling of the materials themselves while in transportation are the most essential points to be considered. A few common sense precautionary methods and careful supervision are the best safety devices.

ACCIDENT PREVENTION BY EDUCATION AND SUPERVISION

Let us next consider some of the more important matters relating to the prevention of accidents and preservation of health by education and supervision.

I do not mean the dictionary term for supervision or superintending—which is care and oversight for the purpose of directing—but direction with a view to instructing or educating for the purpose of increasing at one and the same time quality, production, and efficiency.

Supervision of the Handling and Storage of Material: By handling material is meant the carrying by hand, trucking, and rolling of material in boxes, barrels, crates, carboys, etc. By the storage of material is meant the proper piling segregation, and housing. It is from this class of work that a large number of accidents occur and they can be prevented only by careful supervision.

Maintaining General Equipment and Safety Devices in Proper Operative Condition: Equipment and safety devices and appliances that are perfectly safe when in good repair may present very serious hazards when allowed to get in bad repair. A safety device that is not safe or not in operative condition is worse than no safety device. They can be kept in good repair only by supervision.

Pursuance of Safe Practices While Repairs Are Being Made: Details of repair work are as numerous and varied as the industry itself and repair men are subjected to conditions which are in no way comparable to normal operating conditions. Frequently very hazardous conditions develop which could in no way have been foreseen and many very serious accidents occur while repairs are being made. There are general precautions which if taken at all times would prevent a large number of the too frequent accidents to repair men.

Men working in tanks should always be provided with life lines and have one or more attendants on the outside of the tank.

Men working on pipe lines or in tanks or boilers where there are acid, hot water, or steam connections, should take the necessary precautions to prevent acid, caustic, hot water, or steam being blown through the line. This can be accomplished by the proper locking devices and by signs, or tags, or, if necessary by disconnecting or blanking off the line.

Men working on machinery should take the proper precautions against having the machinery started up unexpectedly. This also can be accomplished by the proper locking device and signs or tags.

There are also jobs where it is absolutely necessary that the repair man wear the approved type of gloves, goggles, and at times special clothing and masks or helmets.

The accident frequency of repair men is governed by the precautions taken which revert right back to proper supervision.

Enforcement of the Use of Protective Equipment: The superintendent or safety man may provide every known safety device but their usefulness and efficiency is only proportional to their use. It is the tendency of the workman to ignore and in some instances practically refuse to use practical safety appliances. This can only be overcome by patient education and by "lining up" the foremen.

Supervision of Employment: In all chemical plants there is a certain amount of heavy material to be handled. There are operations where the floors are wet or there is excessive humidity at times and some of the operations involve toxic or poisonous material.

The man who is naturally weak and has a tendency toward hernia should never be employed where he is required to do heavy lifting or handle heavy material.

The man who suffers from rheumatism should never be placed where there is excessive humidity nor should the man with kidney, heart, or lung trouble be placed where he will be subjected to poisons. These matters can be controlled only through supervision of employment which in chemical industry is a very important factor.

Developing Practical Operating Rules and the Proper Enforcement of Same: There are correct and incorrect methods of performing every operation, likewise a safe and an unsafe method. Therefore, it is essential that the correct methods should be set forth in the form of operating rules. These operating rules should include operating, safety, fire protection, sanitation, and maintenance practices, and should be made ironclad. Their value will be in proportion to their enforcement.

Educational Work: Though much could be said on this subject, it will be touched upon very briefly.

It is first necessary to have the man or men at the head of the organization thoroughly familiar, in sympathy with, and actively back of the safety work that is to be done. They should then definitely establish the motto that "the safe way is the only way" and through them should come the instruction, rules, and propaganda for the education of the men down the line.

Assuming that a large percentage of the accidents in industry are preventable, let us ask to what can we attribute them. In most cases they can be attributed to indifference, carelessness, oversight, ignorance or neglect on the part of someone. The responsibility for the accident in nearly every case can be placed upon the employer or the employee. Those for which the employer is responsible and a large percentage of those for which the employee is responsible could have been prevented by better mechanical arrangement and equipment or by education and supervision, as previously outlined. Here it might be interesting to compare the relative importance of these two branches of the work. A careful analysis of the two years' accident records of one of our large chemical plants, where very active educational accident prevention work was carried on but which was rather temporary in construction and not particularly well-guarded, showed that 12 per cent of the accidents could be charged to lack of guards, defective equipment, etc.—or prevented by mechanical arrangement and equipment. Twenty per cent was chargeable to lack of proper supervision and 53 per cent to negligence or lack of skill on the part of the injured for which the employer was really responsible, making a total of 73 per cent which could be reached through education and supervision. The remaining 15 per cent was chargeable to risk of employment.

CHAIRMAN FIESINGER: At nine o'clock this morning I received a telegram from Mr. Rippel, stating that due to the steel strike he would be unable to be with us.

Adjournment.

Construction Section

October 2 and 3, 1919

L. D. WOEDTKE, Chairman

Director of Safety, Fred T. Ley and Company, Springfield, Mass.

W. J. LYNCH, Vice-Chairman

Assistant to Vice-President, Thompson-Starrett Company, Chicago

EDWARD W. BUSH, Secretary

Civil Engineer, Aetna Casualty and Surety Company, Hartford, Conn.

THURSDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M., Mr. L. D. Woedtke, presiding.

CHAIRMAN WOEDTKE: My report as chairman of the Construction Section is as follows:

REPORT OF CHAIRMAN

The Construction Section, as you are aware, was organized one year ago at the 1918 St. Louis Congress, and like all other sections its first year of existence has been accompanied with many problems involving membership, service to members, bulletins, publicity, program, etc.

In the coming year we shall be better equipped to continue and extend the work of our section through additional officers provided in our by-laws to be submitted to you later, as well as standing committees which will be appointed to undertake definite portions of the section's work which has hitherto fallen entirely upon your present three officers, the chairman, vice-chairman, and secretary, and the staff of the National Safety Council.

However, considerable progress has been made during the past year which you will note from the following data:

MEMBERSHIP

<i>Membership Oct. 1, 1918</i>	<i>Present Membership Oct. 1, 1919</i>
Construction Companies.....18	Construction Companies..... 29
Bridge Companies.....13	Bridge Companies..... 14
Structural Iron and Steel.....20	Structural Iron and Steel..... 24
Shipbuilding Companies.....38	Shipbuilding Companies..... 57
89	124
485	

You will note from these figures that we have secured thirty-five additional company members during the past year and that our present membership includes a total of 124 company members. This showing for a new section after but one year of existence speaks highly for itself, but this membership should be at least tripled during the coming year and it behooves all of us to interest our competitors and friends engaged in the construction industry of various lines, toward taking membership in the National Safety Council and in our section. You of course, appreciate that the greater our membership, the larger volume of income will be at our disposal for additional service to our members. Our goal should be to make our section so strong in members and financially that we may eventually be able to engage a permanent secretary for the personal service and benefit of our own section's members only.

BULLETINS

Bulletin service is of course a large factor in accident prevention work and education of our employees, and while many of the bulletins published by the National Safety Council are applicable because of their general nature for use of our members, we need continually to edit special Construction Section bulletins. The securing of material for these special bulletins has been left almost entirely to your three officers during the past year, with the assistance of the National Safety Council staff.

The Twenty-fourth Construction Section bulletin was distributed September 22. We have only one new bulletin left on hand and no more in sight at present: therefore, if we are to continue editing special Construction Section bulletins during the coming year, our members will have to send us some more material. Undoubtedly every one of you has some good bulletin material such as photographs or some specific experience in your work which could be illustrated and edited into bulletin form. If you will send us such material, we will do the work of putting it in shape.

Many of our special Construction Section bulletins during the past year were sent to members of the National Safety Council who are not allied with our section, and these special requests indicate value and approval of our work in this direction.

One of the most popular bulletins we have edited during the past year was Cn-11, "How Not to Build Scaffolds." Nearly a thousand extra copies of this bulletin have been sold in addition to the regular distribution. Other very popular bulletins were Cn-2, showing the incorrect piling of bricks; No. 14 quoting "Rules for Superintendents and Foremen"; and No. 15, "Don't Take Chances Needlessly." All of these bulletins sold over three hundred extra copies and there were seven others which sold over 150 copies outside of the regular distribution. This record extends only to August 1. and since that time there have been increased demands for many of our special bulletins.

Let me impress upon you once more the need of each and every mem-

ber sending us as much material and data as possible from which to edit and distribute special bulletins for our section.

PUBLICITY

We have striven continually during the past year to obtain as much good publicity as possible and several leading technical magazines of the construction world have given us space on various occasions, including "Engineering News Record," "Engineering and Contracting," and "Contracting." Our Secretary, Mr. Bush, will no doubt give you more specific information in this regard.

The National Safety Council staff now includes a director of publicity, Mr. Resnick, who is preparing some very good data for publication throughout the country in connection with the work of our section, and this will undoubtedly do us much good in the securing of new members and creating a keener interest in safety work in the construction field.

It is our intention to write and distribute an occasional news letter for our members during the coming year but to do this we will need material, experiences, data with regard to statistics and results obtained, from our members as well as the methods used, etc. Unless you forward us such information, we cannot, of course, create a News Letter from our imagination, as what we want to talk about in such letters is the experiences, methods, and results being obtained. Therefore, make it a point to send us promptly and as often as possible, such data as is at your command.

ADVANCE COPIES OF PAPERS

We had hoped to be able to distribute to our members in good season, advance copies of papers to be delivered at this year's Congress, but as we were able to secure only two papers in time for printing, we decided it would be better to let this matter go for this year; we will make every effort to provide for this need next year.

GENERAL

Your officers have undertaken to answer many inquiries and render special services to many of our members during the past year, with considerable success. There are, however, two or three problems yet unsolved which are being worked on and on which a special report will be made in a News Letter as soon as a definite result has been reached. For instance, the protecting of manilla ropes against the action of muriatic acid has engaged the writer continually during the past year and after locating compositions or products proposed by different concerns, arrangements have been made with the U. S. Bureau of Standards through the kindness of its director, Dr. Stratton, to make extensive tests in this connection.

The Bureau has been furnished with required lengths of various sizes of both new and used rope as well as an ample supply of the proposed composition and after tests have been made of both new and used rope, before and after being treated with the composition and before and after

being subjected to the acid and its fumes, the bureau will submit to us a complete report of its findings.

There has been considerable discussion and difference of opinion among our members as to the correct and most adequate method of recording accident statistics and data, and your chairman intends to provide twenty minutes to a half hour for a discussion of this matter at either today's or tomorrow's session when the subjects on our program have been disposed of.

It is our intention to keep the members of our section together as much as possible during this Congress and to that end the committee will provide the necessary space en-bloc for all of our members who intend to take in the Annual Banquet as well as the Frolic at the Winton Hotel.

Through the courtesy of the Builders Exchange, our members will at the conclusion of tomorrow's session adjourn in a body to the Cleveland Builders' Exchange, where a luncheon will be served and a suitable speaker for a brief address provided, followed with an inspection trip of some large construction jobs in operation, at which time demonstrations or illustrations of points or methods discussed today and tomorrow can be carried out.

Following this inspection trip, our members in a body will be conducted on a sight seeing tour of Cleveland and vicinity.

(A motion was made, seconded, and carried, to accept the report as read.)

CHAIRMAN WOEDTKE: With your permission I am going to introduce Mr. Edward A. Roberts, Secretary of the Builders' Exchange of Cleveland, to you and have him announce the program for tomorrow afternoon.

(Mr. Roberts made announcement concerning reception and inspection of building operations for Friday.)

CHAIRMAN WOEDTKE: On behalf of the Construction Section, Mr. Roberts, I would like to thank your Exchange for its courtesy and kindness and assure you that we appreciate it indeed.

(The secretary then made a brief informal report, which was accepted.

The Chairman appointed as Nominating Committee Mr. W. E. Kimberling of Pittsburgh; Mr. F. S. Robinson of Detroit; and Mr. Sidney J. Williams of Chicago.)

The Chairman of the By-Laws Committee reported as follows:

REPORT OF BY-LAWS COMMITTEE

Name

Section 1. This organization shall be known as the Construction Section of the National Safety Council.

Object

Section 2. The object of this section shall be to promote the science and practice of safety or other activities of the National Safety Council.

among those engaged or interested in, or affiliated with, the building and engineering construction field.

The Section shall at all times act in conjunction with or subservient to the National Safety Council.

Membership

Section 3. Membership shall include all members of the National Safety Council who are interested in the activities and purposes of this Section, and who shall signify to the Secretary of the National Safety Council, or to the Secretary of this Section, their desire to affiliate.

Officers and Executive Committee

Section 4. The officers of this Section shall be a Chairman, two Vice-Chairmen, the chairman of the Bulletin Committee and a Secretary who shall discharge the duties usual to such officers. These officers shall serve until the end of the annual congress of the National Safety Council, or until their successors are elected and have accepted the office. The officers shall act as an executive committee in charge of the affairs of the Section, and the assent of three shall be necessary for action.

Meetings

Section 5. There shall be an annual meeting of the members of the Section held during the period of the Congress of the National Safety Council, notice of the time and place of the meeting shall be posted at the information desk of said Congress. Other meetings of members may be held on due call and notice by the Executive Committee.

Election of Officers

Section 6. Nominations of officers shall be made by a Nominating Committee of three appointed by the Chairman of the Section, which committee shall report at the annual meeting its recommendations, which report shall be followed at said meeting by the election of officers for the ensuing year. At this meeting other nominations may be made by any members. The election shall be by plurality of ballots cast. Nominees should be selected, as far as practicable, to represent various branches of the construction field with appropriate geographic distribution.

Committees

Section 7. The Chairman shall appoint the chairman and members of a Bulletin Committee and such other committees as may be authorized by the Executive Committee or requested by the National Safety Council. The Chairman of the Section shall be a member of all committees of the Section except the Nominating Committee.

Amendments to By-Laws

Section 8. These by-laws may be amended at any meeting of this Section.

(The By-laws as read were adopted.)

CHAIRMAN WOEDTKE: It gives me pleasure to introduce to you, Mr. F. L. Hurlbutt, of E. I. du Pont de Nemours and Company.

IS ACCIDENT PREVENTION IN CONSTRUCTION A SOURCE OF PROFIT OR A HOBBY?

F. L. HURLBUTT, E. I. DU PONT DE NEMOURS AND COMPANY,
WILMINGTON, DEL.

The title of this paper would lead one to infer that serious doubts are entertained by some people as to the worth of accident prevention in the construction field. Certainly every safety engineer is aware of the almost limitless possibilities for accident prevention in this field. If any such persons do exist, I feel positive that they are numbered among those who have never made an honest attempt to try it out in their own work or those who have never seriously looked into the subject. It is to the latter that I trust this paper may open up a new field of thought and act as a stimulus toward the starting of accident prevention work in their own companies.

The writer proposes to treat this subject from the data and experience of the construction forces of the Du Pont Company which he represents, due primarily to the fact that the war has made such exacting inroads on the time of all in this organization that little opportunity has presented itself to get in touch with the activities of others in the same field. I trust therefore that you will pardon the continued reference to the Du Pont Companies' endeavors.

In the Du Pont Company, safety on construction work is divided into two distinct branches; namely, home office and field work, each of which is in such close contact with the other as to benefit by the other's experience and ideas.

WORK OF HOME OFFICE BRANCH

The work of the home office branch covers cooperation with the design division of the Engineering Department in the initial stages of all contemplated construction work and later with the drafting-room forces when actual drawings are being prepared. Close contact with the design division is absolutely necessary in order to get preliminary data on manufacturing processes involved in which there may be industrial poisoning hazards, the necessity for ventilating systems, the possibility of explosive hazards necessitating proper barricading and separation of buildings and quick escapes for operatives; in short, all such important points as require special investigation and decision before judicious recommendations can be made to the drafting-room forces. By conference with members of the design division all these points are threshed out and decisions reached, so that no delay is experienced when the work has gotten on the drafting boards. Too great stress can not be laid on the importance of carefully reviewing all projects for safety in the de-

sign or formulative stage. This is particularly true when construction work is to be done for such highly specialized industries as the chemical, steel, and explosive branches. At this stage the incorporation of the necessary safety and health features can be included at about one-third the cost of doing them than as additional work after the job is completed. Furthermore they can never be done as satisfactorily or made as effective when done afterwards due to the layout of apparatus, equipment, stairs, and elevators within the buildings. One member of the safety office is detailed to the drafting room to check drawings for safety and to advise the draftsmen on the application of the safety standards where complicated situations arise or where unusual conditions make deviation from the standards necessary.

The review of the contemplated work and the check in the drafting room are in the main to cover structural plans and layouts of equipment for safety and not the mere noting of locations for safety devices which is primarily a field job. To insure the inclusion of this work in the finished job a formal note is placed on every drawing stating that all equipment is to be guarded in accordance with the standards, thereby giving the field engineer authority to carry out this work and at the same time freeing the drawings from a mass of notes and sketches of machine guards.

The actual installation of safeguards and safety devices by the field engineering forces in the case of large undertakings is supervised by the safety engineer assigned to that particular construction job and in the case of small jobs by trips by members of the home safety office.

FIELD SAFETY WORK

This brings us to a consideration of the second phase or actual field safety work. On all projects requiring a field force of 500 men and upward it has been found not only desirable but essential to include on the engineering staff a safety department, the personnel of which must be varied as conditions dictate, from a single man to as many as eight men devoting their full time to safety, supplemented, if necessary, by an injury clerk and accident investigators with adequate clerical and stenographic help to maintain full and accurate records of all injuries. Such a department as this last may seem unnecessarily large but I want to assure you that on our two largest construction jobs where such departments were maintained, the members were about the busiest individuals on the ground. Not only must physical inspections be made of the work under erection, the unloading and piling of vast quantities of materials, inspections made of railways, cranes, tool rooms, and what not, but educational safety for the field forces must be carried out, accidents investigated in order that preventative measures may be applied and full data surrounding the accident secured. Thorough accident investigation has proven of enormous value and is one of the most important duties of all our safety departments. As in all professions, an accurate determination of causation will generally bring to light the proper remedy.

Up to this point I have dwelt at considerable length on our manner of

working safety into a job from its inception in the home office until it has reached the field, and I have briefly outlined to you the kind of an organization by which we carry out safety work in the field. I now want to show you how the carrying on of safety work through complete field organizations has justified itself and what enormous dividends it has returned in actual cases.

SAFETY ORGANIZATION FOR LARGE CONSTRUCTION PROJECT

In the early part of 1918 the Company undertook its largest construction project; namely, the complete design and erection of a smokeless powder plant for the United States Government. Some idea of the magnitude of the undertaking may be gained from the fact that an average working force of 25,000 men was maintained. Like all war projects this was a rush job and had to be carried out in the face of the very serious labor shortage and consequent high labor turnover that existed at that time.

At the outset the question arose as to how safety and injury work should be handled. Two courses presented themselves. First, to carry liability insurance with an outside company and waive any further responsibility in the matter, or second, to carry our own insurance and organize a complete safety department to carry on accident prevention work. The former scheme might have been adopted in view of the difficulty of getting good safety men on short notice at that time, but the excellent results attained on our other big jobs completed prior to this country going to war justified our pursuing the latter course. As a result a safety department consisting of a safety engineer, an assistant safety engineer, seven inspectors, a personal injury clerk and assistant, two accident investigators, and five stenographers was organized. As in the case of all successful safety work the resident engineer gave the department his unqualified support and "put safety on the map" from the start by stating his stand at the weekly staff meetings and seeing to it that his division engineers were carrying out their share of the responsibility of accident prevention. This he was able to do through the daily accident reports forwarded him by the safety department. The policy of carrying out safety work through the organization rather than allowing the safety department to do it all was the basic principle followed. Meetings of the division engineers and their assistants were always attended by a member of the safety department who showed the results accomplished and brought up points to be rectified. Again, foremen's meetings were held in the various divisions at which the division engineers put the proposition of safe working conditions for the men and accident prevention squarely up to the foremen. And right here let me digress for a moment to emphasize the importance of the foreman in any accident prevention work no matter whether it is an operating or construction job. Only when your foremen are whole-souledly behind the safety movement which you are pushing will you effect permanent accident reduction. These men are the most important factors in your campaign and the bulk of your efforts should be directed to

wards winning them to your ideas. You look to them for the desired speed of the work and for its quality; why then should you not look to them for the safety of the workmen entrusted to them? But to return to our subject. Without going into too great detail on the methods followed by the safety department suffice it to say that the department, in addition to the educational work carried on through engineers' and foremen's meetings made daily physical inspections of the work, posted thousands of bulletins and superintended the installation of over 3,500 safeguards for mechanical equipment.

The injury department through its investigators investigated every accident and submitted complete reports on them. The result was that the number of court cases resulting from injury was very, very small.

This is a phase of safety work on construction in non-compensation states which, if carried out effectively, pays a handsome return. If all accidents are reported and immediately investigated and the injured brought to the hospital for treatment, the likelihood of the cases being taken to court is greatly minimized. It only takes about one or two court cases where a verdict is rendered in favor of the plaintiff, to pay the entire cost of a safety department on a fair-sized job.

Some of you will say that it must have cost a good deal of money to maintain such a large organization. It did, but remember, too, that this was a big job. Now let me show you the results accomplished.

On March 23, shortly after the start of construction activity, the safety engineer arrived on the job and began building up his organization which had by the latter part of April assumed working proportions. By this time the department had started an effective, organized safety campaign with the following results. During March and April, the period of organization for the department, the "lost-time rate" expressed in days had steadily increased until it stood at 2.27 days lost per man per year. By May 31, one month after safety activities had been prosecuted in earnest, this figure was reduced to 1.28, the next month saw it lowered to .744, the following month it stood still, but the next month saw a further reduction to .684, then came a drop to .351. In the next thirty days we find the only upward trend in our curve, when the figure went up from .351 to .441, really an excellent figure in itself. But again, with the last month of activity, we find the downward tendency resumed with the result that the lowest figure of all was attained; namely, .216. Reflect for a moment what this means. In the seven months of the safety department's activities the lost-time rate had been reduced from 2.27 to .216, a 90 per cent reduction which is truly a remarkable record, when you consider that it was made in the face of a very high labor turnover and with a working force almost entirely new to the Company. The total frequency rate calculated on the annual basis after the federal practice was 58.9. The fatality frequency rate calculated on the same basis was 1.0.

In order to show what this really means to those who are unfamiliar with accident statistics, let me use another illustration. When this gigantic project was first conceived a rate was quoted the Company for

carrying liability insurance on all the construction employees. Using this rate the cost of insurance against injuries, both fatal and non-fatal to the Company would have been \$452,752.00 as against the actual cost of \$66,161.00: which includes hospital costs, doctor's salaries etc. a saving of \$386,651.00. Deduct from this the cost of maintaining the safety department, \$50,000, and we have a net saving of \$336,651. On the construction of a large shell-loading plant where similar safety efforts were carried out by the Company though not on quite as large a scale equally impressive figures are available. Here the success of the safety work resulted in the actual cost of injuries being but \$5,733.00 which includes hospital costs and doctors' salaries, as against a figure of \$103,545, had we chosen to carry liability insurance with an outside firm. This gives a saving of \$97,812 from which the cost of maintaining the safety department, \$10,500, must be deducted giving a net saving of \$87,312. Here the total frequency rate was 47.8 and the fatality frequency rate was zero. Please understand that the figures quoted are meant in no way to deprecate the practice of carrying liability insurance. Most assuredly such a policy is a meritorious one on small and good-size contracts, but when an undertaking assumes such gigantic proportions as did the construction of the Government powder plant just mentioned, one is faced with a proposition which could never be as satisfactorily met by any outside agency as by a department which is a part of and co-ordinating with the contractor's own organization.

To digress a moment from monetary savings, let me relate an interesting accident prevention story that occurred in connection with the powder plant construction and one which carried good evidence of whether real safety work pays on construction. In May, 1916, during a temporary lapse in construction activities in his particular line, one of our best construction engineers was made safety engineer on one of our largest plants, where an average operating force of 12,000 men and a construction force of 700 men was then being maintained. For two years he acted in this capacity and became a real convert to the safety cause. When construction work was started on the Government powder plant, this individual was made a Division Engineer in charge of the "Miscellaneous Division" which comprised a force of from 2,500-2,800 men. This was exactly the opening he wanted—an opportunity to practice as an engineer on construction what he for two years had been preaching to other construction engineers. Were his preachings vindicated? His record will answer that question. From March 16, 1918, to Sept. 1, 1918, his working force of 2,500-2,800 men had but one major injury.

To many of you such examples as I have cited may seem to be of such an unusual character and the work carried on under such abnormal conditions that it is not fair to use the results obtained therefrom in arriving at a decision whether safety work pays on construction. To allay any such doubts let me tell you of the accident prevention work and safety campaign with the excellent results attained which has been carried on during our construction of a large chemical plant these past eight months.

FOREMEN RESPONSIBLE FOR SAFETY WORK

This construction was under the direction of a resident engineer with ten assistant engineers on his staff. The average number of full time workers employed, using the Federal basis of calculation, for the first eight months of the year was 692. Directly under the resident engineer was a field safety engineer with an assistant and one man acting as an accident investigator, clerk and stenographer. In outlining the safety campaign it was decided to try two schemes, both of which were new to us on construction work. These schemes differed only in application, the basic thought behind both being to hold the foremen and general foremen responsible for carrying on the safety work with the safety department functioning in a stimulating and advisory capacity to the engineering organization and foremen.

The construction was divided into two divisions, which, for convenience in explanation, we shall designate as "A" and "B".

In Division "A" there were scheduled foremen's safety meetings twice a month for the various crafts, each meeting being presided over by the general foreman of that particular craft and attended by the safety engineer solely in an advisory capacity. This division had a safety committee made up of its seven general foremen, one of whom was appointed permanent chairman and another secretary by the division engineer. The personnel of the committee was not rotated. Every other Saturday afternoon from one until three o'clock they made a safety inspection of the construction work in their division and submitted a written report of their findings to the division engineer with a copy to the safety engineer.

In Division "B" there were scheduled weekly safety meetings of the foremen and general foremen of all crafts in this division presided over by one of their own number and having a secretary appointed by the division engineer. This division had three safety committees of three men each—each man serving six weeks, with one man being dropped every two weeks and a new member appointed by the committee chairman who was elected by ballot. These committees made inspections every two weeks of the construction work in this division and submitted written reports of their findings to the division engineer.

THE SAFETY HOUR

After the two schemes had been tried out for five months it was seen that the first or meetings of crafts was not as successful as the second in which the foremen and general foremen of all crafts met together. This was attributed to the fact that each meeting was too small, there being only six to ten foremen at a meeting and also because the competitive spirit shown at the meetings of the various crafts was entirely lacking. As a result a reorganization covering the entire construction was effected along the lines of the second scheme wherein the foremen and general foremen of all crafts held a safety meeting at a regular hour on the same day of each week. This particular time every week came to be known on the job as the "safety hour."

The procedure followed at these meetings is of interest.

1. Roll call—(attendance averages 90 per cent; 10 per cent absent due solely to rush work).
2. Reading of minutes of last meeting—(copies go to Resident Engineer and Home Safety Office).
3. Safety Committee Chairman reads inspection report which is followed by open discussion.
4. Chairman asks for any suggestions.
5. Safety Engineer gives brief talk on current accident news; and the length of time which the various crafts have gone without accident.
6. Frequently an injured man is brought in to the meeting to tell in his own words how he was injured.
7. Every third meeting a speaker from the outside is secured to give a short talk on some particularly interesting phase of safety work.

The safety engineer always made it a point to give assistance to the Chairman outside of meetings so that he could keep them going smoothly and in the proper channels. The safety engineer's stenographer recorded the minutes and acted as Secretary under the new scheme. At all these meetings the safety engineer kept himself in the background as much as possible, but he was ready, should discussions lag or subjects be found wanting, to start something new and keep the meeting alive. In all the meetings held he had occasion but once to take the initiative. The great virtue of these foremen's safety meetings was to give safety work a serious place in the workmen's eyes.

Although the safety committees submitted written reports of their findings at the next meeting and copies went to the resident engineer it was their endeavor to take up on the spot with the foreman affected—not with the men—all points needing correction. In the majority of cases this was possible, because on construction work a foreman is generally to be found near his men. Of prime importance was the follow-up of the committees' reports subsequent to the meeting at which they were presented and prior to the next meeting at which the status of the recommendations was always given. Nothing will kill a safety committee's interest more quickly than to see no action taken on its recommendations. The safety engineer made this follow-up and went directly to the division engineers, when necessary, to see that the recommendations were carried out. When a recommendation was turned in which it was impracticable to carry out, the safety engineer had the division engineer come to the next meeting and state frankly why it could not be done. Frequently this resulted in some excellent discussions.

You need have no fear of construction safety committees swamping you with a lot of impossible suggestions bearing on structural changes. On the contrary you will find that their recommendations bear chiefly on safe working conditions as applied to ladders, scaffolds, shoring, walkways, tools, and equipment. In this respect, we have found our construction safety committees far more practical than those used on operations. But let me caution you in dealing with your committees to be absolutely frank and always acknowledge their suggestions with honest

reasons, if you find it necessary to turn any of them down. We have also found that the men appreciate a designating mark for their service on the committee, so we give them a safety committee emblem.

Again on this job the effectiveness of the safety work was shown in the difference between the actual costs including compensation, plant hospital maintenance, doctor's salaries, and the cost of maintaining the safety department, amounting to \$8,695 for seven months as against the premium of \$16,768 which we would have had to pay on employees' liability insurance carried outside—a net saving of \$8,073 for the period. An average annual frequency rate of 100.1 and an average annual severity rate of .50 calculated on the Federal basis was maintained for the first eight months of the work. I regret that the September figures are not yet available.

In concluding this paper I want to add just one more fact vindicating the worth of safety work on construction. During the year 1918 our injury records for the entire construction branch of the Company were lower than those of any one of the four operating branches where safety work was prosecuted just as diligently as on construction.

Gentlemen, the accident prevention field in construction is practically a virgin one, and if you will but take the time to investigate what has been accomplished by those companies who have undertaken activity in this field, you will be fully convinced of its worth.

DISCUSSION

CHAIRMAN WOEDTKE: Gentlemen, I do not believe there is any doubt now in the minds of any of those present, if there was any in the beginning, that accident prevention is not a hobby but is a source of profit and something well worth while. Mr. Hurlbutt has covered that field in a splendid manner.

MR. F. A. DAVIDSON (Westinghouse, Church, Kerr, and Company): Mr. Hurlbutt spoke of ladders and scaffolding and the different tools you work with. Do you follow the old methods or do your engineers plan other ladders and other scaffolding different from what you used formerly?

MR. HURLBUTT: We have improved on our early construction work. We came to the conclusion before the war, before the United States got in it, that the only way to handle the ladder situation successfully was to prohibit the manufacture and use of home-made ladders on the job, and to purchase ladders from the outside. But that doesn't solve the difficulty. One of our construction engineers bought through a local concern a number of outside company ladders all of which came up to our own specifications so far as rungs, stringers, etc. went, but when the ladders were delivered it was found that practically all the stock in the stringers was cross grain stock. As a result, of six ladders bought as a test, four broke in three weeks on the job.

In short, if you are going to buy outside ladders and not make your own, buy the best. We can prove to you from our own figures that to buy the best ladders is cheaper to say nothing of the safety involved.

MR. A. E. DAVIDSON (Chesebro-Whitman Co.): Do you use what is called the cleat ladder, or slat ladder?

MR. HURLBUTT: We haven't bought any cleat ladders from outside manufacturers.

MR. J. L. NAYLOR (Manitoba Bureau of Labor, Winnipeg): Frequently in our construction work, for the main ladders on a building they will construct big double ladders. The upright is commonly made of two by six, or two by eight, or even heavier, and the cross slats are usually made of two by four material. Do you ever use that?

MR. HURLBUTT: Perhaps I should have qualified my statement when I said we purchased outside ladders. On some jobs we have done just what you said. On the ladder going up the scaffolding we have used two by six, and in some cases used three stringers. In some cases we have notched the rungs into the stringers, and in some cases put a strip between the rungs on the stringer.

MR. A. E. DAVIDSON: I would like to ask Mr. Hurlbutt if, in his work, they have tried workmen's committees.

MR. HURLBUTT: As I told you in the case of this chemical plant, which I gave figures on, we didn't use workmen's committees but we used foremen committees, the idea being in our safety work to try to work through the organization and not at the men, exactly the same way you work through the organization for your desired quality, and your speed. In other words make safety a part of your undertaking, not a separate distinct phase.

CHAIRMAN WOEDTKE: The next speaker has a topic which is most interesting to all of us, especially to those of us who have been trying to get safety on the map in the construction field. You hear it said sometimes that it isn't much of a trick for a big contractor to put safety on the map in his organization, it is a good thing for him to do from a dollars and cents viewpoint, or to reduce rates. The medium sized or small contractor will often say, "That stuff is too deep for me."

What we want to get over and get over thoroughly, and it is going to be some task and it will need every one of us to get it over, is to convince the little fellow, or the medium sized contractor, that there is a place for him in that field. Mr. Rutherford, who will talk on that subject, is a local builder in Cleveland, a gentleman who has come in contact with all kinds and types of contractors and who is well qualified to cover this subject.

IMPORTANCE TO THE CONTRACTOR OF PREVENTING MINOR ACCIDENTS

GEORGE A. RUTHERFORD, PRESIDENT, THE GEORGE A. RUTHERFORD COMPANY,
CLEVELAND, OHIO

Safety authorities tell us that 80 per cent of accidents are caused by carelessness. To prevent carelessness it is necessary to promote caution and vigilance. This being admittedly the case it should be the purpose

of any discussion of the subject to suggest ways and means by which carelessness may be reduced and caution and vigilance increased.

As you understand, this paper is to deal with the minor class of accidents rather than with the larger and as many persons may think the more important class. This fact should not cause any one to presume, however, that the study of smaller injuries is of minor importance. Just as in the realm of disease many ills at first regarded as unworthy of even passing notice, if neglected may lead to very serious developments, so in the handling of accident cases the experienced adjuster of claims recognizes that no injury however slight can be overlooked either from the standpoint of the injured person or of the one responsible under the law for safeguarding employees. In a recent report of the Ohio Industrial Commission the statement is made that cases of fractured skull resulting in permanent total disabilities are not infrequently diagnosed as scalp wounds. The same report says that fully half of the recorded cases of fractured vertebrae were treated as "sprains" or "bruises" for weeks or months before the X-Ray revealed the true nature of the injuries. To be more comprehensive, the report declares "Few cases of either permanent total disability or permanent impairment of members were recognized as such within eighteen months after the date of the accident."

The importance of paying attention to the smaller accidents is further emphasized in the broadening scope of most state compensation laws in manifesting greater liberality toward the injured person. Formerly compensation was rarely paid, for instance, for the impairment of one eye because it is seldom possible to prove direct lessening of earning ability by the impaired vision of one eye. However at the last session of the Ohio legislature the law was amended to grant compensation under this condition. Still further argument for using every precaution to avoid even seemingly trivial accidents is found in the extension of the merit-rating system by the Industrial Commission of Ohio so as to provide for a return in the form of a credit premium of ten dollars of every one hundred dollars a subscriber may save the state fund below the ratio of the basic compensation allowance and credit premium factor prescribed for his operations. This has the effect of establishing a preferred plus rating for every industrial risk that is able to produce a preferred plus experience. This new plan becomes operative against expirations occurring on and after January 1, 1920, and will apply retroactively for the preceding six months insurance period. Thus a more direct financial incentive than heretofore is brought into play as an inducement for employers to cooperate with the fund.

As for the classification of accidents of all kinds it is significant to observe from a recent Ohio report that of a total of 359 cases, 220 were of fractures, indicating the comparative frequency of this kind of accidents. Among the other large factors in the claims considered by the State Commission were the loss of eyes or the loss of fingers or toes. While no statistics are at present available to show which particular industry is chargeable with these unfortunate mishaps it is certain that the building industry is responsible for a considerable share.

PREVENTION MEASURES ON BUILDING WORKS

It is difficult to produce anything that is new in accident prevention. About the best that can be done is to reiterate well-known methods and perhaps by repetition keep them constantly before the public with resulting emphasis. In brief I would recommend the following as prevention measures on building work:

First: A closer contact by contractors with their men with a view to personal education in safety rules. Impress upon superintendents and foremen their responsibility for the safety of those who labor for them, the necessity of warning them of danger and also to impress upon them the necessity for scrupulous care in handling appliances and tools.

Second: A periodical inspection by the contractor or his superintendent of daily used appliances—such as ladders, ropes, tackle, hoists, mixers, and other machinery.

Third: The insistence upon keeping all jobs free from debris, which is one of the greatest causes of small accidents.

Fourth: Making it compulsory that all openings in floors be immediately provided with railings; that all staging, especially where bricklayers and masons are working, should be provided with toe-boards or screens to prevent falling of brick and other material.

Fifth: The display of "Safety First" signs on every building, printed in foreign languages as well as English. These signs in addition to being a constant reminder to workmen, would also serve a like purpose to the employer.

Sixth: The distribution, at frequent intervals, of circulars or small cards to be inserted in workmen's pay envelopes. Various brief exhortations may thus be taken without offense. To use every effort, not only to avoid accidents themselves, but to assist others in doing so. This latter may be done by the prompt reporting of any defect in or about a building that may lead to an accident. How often do men continue to be in danger after they fear something may happen until it actually does happen and then declare "I was afraid of that all the time" or "I told you so."

There is no doubt need of an awakening of interest in this very important matter. May it not be that employers are being lulled into a sense of security by the fact that come what may the state or the liability companies will take care of their troubles. Those who take this position should remember that financial compensation for an accident is only poor recompense at best and that the element of human sympathy and interest in the welfare of employees are factors that should not be overlooked. From a purely selfish standpoint this is the better policy as injuries may not only weaken the employer's ability to achieve his greatest success but a business reason is apparent in the reduction of premiums if his experience is found worthy of such recognition.

GROUP ORGANIZATION FOR SAFETY

It probably is not possible for those in the building trades to deal with the subject as well as employers having all their employees under one

roof with first-aid and welfare department well established, and it obviously is not possible for the average contractor to employ a safety engineer, but in all cities of any size there are associations of employers in the building trades and it would be practicable and possible for these groups of employers to provide a safety department in charge of an expert safety engineer who would be a member of the National Safety Council, and whose duty it would be to gather and disseminate information on safety matters among members of the association, to provide for periodical inspection of jobs including machinery and equipment, to make reports and recommendations directly to the members, to provide posters, safety signs, etc., in fact to do for the group of contractors what the safety engineer of a large contracting company does for his corporation.

I am told by one safety engineer, who is present at this meeting and who represents a large contracting firm, that in three years his company has by these methods, improved their rating in three states with the liability companies to such an extent as to result in a saving of 33 per cent in premiums paid last year. If the safety engineer for one company can accomplish this, why is it not possible for a group of contractors to obtain similar benefits in a financial way, and at the same time prevent much human suffering.

DISCUSSION

MR. F. A. DAVIDSON: Mr. Rutherford tackled one of the real problems in the latter part of his paper, and I have been thinking it over and I almost think he has solved it. The small contractor can not employ a safety engineer, but a group of them in a town can have one.

MR. HURLBUTT: I would like to ask Mr. Rutherford whether the cost of carrying on safety work has kept you from going into safety work to any extent, or whether it is because the majority of the builders are ignorant of its possibilities.

MR. RUTHERFORD: I don't feel that the matter of safety work has been brought to the attention of contractors in this locality at all. I have been in touch with most of the builders' organizations and I have never heard of the Safety Council myself, only occasionally through the papers, and didn't know there was such a thing as a Construction Section, but I think it would be of great interest and importance to the contractors.

CHAIRMAN WOEDTKE: One thing I can say that would help you out in this matter. I am not a safety engineer at all—that term is too much abused; I prefer to call myself Director of Safety. We don't have any safety engineers but we do make the insurance companies who cover us, inspect the work. All the insurance companies have high class safety organizations. They study this game all the time and it is to their monetary advantage to help you reduce accidents.

I have inspectors from the insurance companies inspect our jobs once a month, and on large jobs, twice a month. I take his recommendations and send a copy right back to the superintendent, giving him forty-eight hours to carry out those recommendations or advise me specifically where they are impractical. Ninety-nine times out of a hundred he carries them out, very rarely does he say that it can't or should not be done. You

gentlemen want to remember that you don't need hire a man for that purpose, every one of you have some bright young fellow in your office, or your field, who can take this safety work on too. Don't get discouraged and think you have to hire safety men. Out of the four thousand firm members of the National Safety Council, I don't suppose over five per cent have safety engineers.

MR. S. E. RICHARDSON (Department of Labor and Industry): My work is investigating accidents throughout the western part of Pennsylvania. Have you a code or standard in the State of Ohio for digging deep ditches, and things of that nature? We have had a lot of accidents from that very cause in Pennsylvania.

MR. RUTHERFORD: I think it is up to the contractor. Of course, we have the factory inspector and that is about the only inspection that has come to my attention. They come to the shop and see that the machinery is provided with all the necessary guards; I have never seen them inspecting out in the field on mixers or hoists.

MR. RICHARDSON: I had a very bad case at Neville Island, Pittsburgh. Two young colored fellows were sent down eighteen feet into a ditch that was being dug for a sewer. They were sent down with curbing, one two by ten every six feet. Those boys were buried alive in there and were in that hole five hours before they could get them out. Falling material is another thing that we have had a lot of trouble with. We have a state standard passed by the Industrial Board but we haven't got it working yet the way it should be.

CHAIRMAN WOEPKE: I am now going to introduce to you Mr. C. M. Talbert.

PROTECTING THE PUBLIC AGAINST ACCIDENTS ON NEW BUILDINGS

C. M. TALBERT, DIRECTOR, DEPARTMENT OF STREETS AND SEWERS,
— St. Louis, Mo. —

I have found with several years of experience that contractors are a fairminded group of men, and that they are willing to coöperate if given a fair chance. The contractor after all is a man who has about as much humanitarianism as any of us and is perfectly willing to do anything if he can be shown it is the proper thing to do and not unreasonable. I have found, too, that the difficulties we have are with the small contractor, the large contractor gives the least trouble we have in carrying out suggestions for the protection of the public.

In getting up this paper I had first in mind how many accidents had happened. I have two men who are almost constantly on the down town streets. It is a peculiar situation in St. Louis; our police force is not a city force, but a state organization. Consequently the handling of traffic and the protection of the public in handling materials, and protection of every type is not done by the Department of Police but by the department that has charge of the highways. I asked these two men in charge of this district to first ascertain how many accidents had happened in

the last two years. The first report that came in said there had been no accidents. I thought surely within the past several years there must have been somewhere a record of the accidents which occurred on building construction. So, I asked them to consult the coroner's office, and different places, and make a list of all the accidents which were fatal. Very much to my surprise and still more to my gratification I found there had been no accidents, during those several years. There have been a number of accidents in outlying districts, places we didn't look for them, places where we had not been giving care and supervision we thought necessary. We found then that the down town district had no accidents of any type but there had been quite a few suits against the city and against contractors outside this district. Why they occur in one place and don't in another I will try to show you.

In the wrecking of buildings, construction of buildings and excavations adjacent to public highways, excavations including conduits, sewer mains, sidewalk construction, etc., I found that the accidents that might happen to the public were of the following general nature: Falling of material overhead; dropping of material being hoisted; stepping into unprotected openings; stepping on nails, glass, etc.; and for the pedestrian, collision of pedestrians when passageway is narrow; collision with supporting columns:—those, so far as I was able to tabulate, comprise almost entirely those things to which the public is liable. Now we have governing those things but one Ordinance I have been able to find, and that is the ordinance that requires canopies protecting the sidewalks to be erected for buildings more than four stories high and I don't believe I have been able to use that ordinance in the past five years.

In other words our protection to the public is not a matter of law but common sense application of those things that both the contractor and those responsible deem proper and advisable.

I am going to have these slides run through as rapidly as possible. These are taken from our photographs which were meant to illustrate the suits brought against the city. Most of them will not need an explanation.

SLIDES ILLUSTRATING SUITS BROUGHT AGAINST THE CITY

This particular one is hardly representative of the conditions. The rough looking canopy in front is meant to show the protection that was placed there to keep water from off the walk, not so much as a matter of safety but as a matter of convenience so the dirty water would not fall on the people.

Another common cause of trouble is placing the building materials in the street and leaving them unguarded. The small rack at the right hand is meant to hold a lantern. No accident occurred at that point and it is merely given as an example of building material on the street.

Bear in mind that these first are not considered satisfactory. It is our endeavor to keep all advertising off the side. If a man puts up a proper type of protection and the type of protection we think is best, we allow him to put his name on it.

CHAIRMAN WOEDTKE: What are those bulletins?

MR. TALBERT: Those were theatrical bulletins, and had to be removed or further permits would be refused. If the contractor has been difficult to control, the next time he doesn't get any permit.

CHAIRMAN. WOEDTKE: Would you refuse any safety bulletins, if that is the most advantageous point?

MR. TALBERT: We would go just a little bit further and make it obligatory, bearing in mind it wasn't an advertisement. We don't want the town to become littered with billboards to make it look like a circus, and we ask the contractor to cooperate with us and we meet him very frankly, and we feel to our mutual advantage.

That one readily shows its own story. The bricks were piled too high and not straight, some boys climbed up on the pile and were injured, and they had a damage suit against the city and the contractor. If that had been a down town district, we would have had an inspector to see that the brick were piled in rows.

This next one is an accident where the person tripped over a board projecting from the building. More careful supervision of the placing of the building material would have been the proper thing, to keep the passageway open. That board caused a combined damage suit against the city and contractor.

This is another almost identical with the first, in which the old brick were piled insecurely, some boys climbed on them, they collapsed, and I believe it resulted in a broken leg.

In that one, the office building was satisfactory, but the sign question again came up and we had the entire office building removed and took away the contractor's privilege of any use of the highway. This was done in case it should be brought into court.

There is one which pretty well tells its own story; building materials scattered along the sidewalk, boards insecurely placed. I don't recall whether or not that resulted in a damage suit but I believe it did. These photographs resulted in practically all cases, in throwing the blame on the contractor.

That is the down town district in which the conditions seemed to justify the stopping of all sidewalk traffic. The construction demanded a tower on the sidewalk. We never ask the contractor to meet impossible conditions but we ask him to place towers and pile material inside the building, if it can be done without extraordinary expense. If it can't be done we will close the walk, and we see he takes the precautions that we think he should.

There is an example of construction work in the down town district in which it was absolutely necessary to place the office building structure on the sidewalk space. We elevated it to make the pedestrian passageway.

There is a matter which you are all familiar with; I consider that unsafely guarded because there is but one red lantern on the outmost projection. The next time he came in for a building permit no further permit would be given until we were satisfied he would take reasonable care of his material on the highway.

There is an example of what I mentioned a while ago when I said

the proper coöperation with the contractor would permit us to allow him to place his name on the boards. That canopy was put up in the best shape and he availed himself of quite a good deal of storage space by putting in complete plans to the city, showing joists, girders, columns. We examine the plans and then issue a permit to load it up to so much per square foot. I consider that to our mutual benefit and with absolute protection to the public.

Here is another example of an enclosure. There is nothing particularly interesting about that, it is an excavation which we required to be protected by a high board fence. An open gate in a place like that is an invitation to the public to stop, look, and listen. If they would do that as much on railroad tracks as they do on buildings under construction there wouldn't be so many accidents.

That picture is an excavation in an outlying district. I have seen several examples here in Cleveland where excavations went to the curb line—we require them to provide a pedestrian way in the street.

This is a down town district. The interesting point is that at the top they were raising that building one story and we allowed the contractor to put a protection at the top floor.

There is a building which was wrecked recently in which we found it necessary to close the sidewalk during the wrecking of the upper stories. It is merely typical of some of the down town conditions. When we had to wreck an old building in a retail district we found it necessary to close the sidewalk during the time it was coming down to the second story until all the material was out of the building line.

There is a pedestrian way over a very deep excavation that was over a combined sewer and railroad track and is merely protecting the public on that type of construction work.

Now those, as I say, are merely meant as examples of the every day condition that we meet and, to my mind, emphasize that the public can be taken care of whatever the circumstances may be. If you have the proper coöperation of the contractor and the public, and these things can be done without unreasonable cost to the contractor, I think it is a good investment for him because it relieves him of a great deal of responsibility. If we give these things fair thought and consideration and can present a fair plan, it is much easier to defend a case in court on the part of both the city and the contractor. I was only able to ascertain one action in the down town district. One lady tripped where the nails had been allowed to work up and the case was settled for ten dollars, I believe.

CHAIRMAN WOEDTKE: Bulletin No. 8 of the Construction Section that was sent out sometime during the past year illustrates some of those things that Mr. Talbert has discussed.

Is there anything you want to ask?

DISCUSSION

MR. J. L. NAYLOR (Manitoba Bureau of Labor, Winnipeg): I would like to ask Mr. Talbert what means he takes for protection of the public

against falling of the booms on boom derricks. Do you fence off the street to a distance equal to the radius of the boom when in a horizontal position?

MR. TALBERT: We do one of two things. If there is any element of danger of falling material or falling booms, we ask them to do their hoisting within a specified time and during that time we put officers at the street intersections and stop traffic. That is the only way to do it. We give them an hour in the forenoon and an hour in the afternoon.

MR. NAYLOR: Suppose it is a question of laying heavy stone where one hour would not be sufficient to do very much.

MR. TALBERT: We have figured that the dead weight of the stone would be enough to break the fall of any load taken up, and we have practically daily inspection of the hoisting rigging itself. But if there is any unusual thing, iron columns, or anything like that, then we stop traffic during that time. In other words we would much rather cause inconvenience to the public during any limited time than to take a chance on some one being injured. We even stop street cars; it would be a calamity if one of those beams should fall on a street car.

MR. A. E. DAVIDSON: Is there any law governing sidewalk bridges?

MR. TALBERT: When buildings are over four stories in height they must put a canopy over the sidewalk.

MR. DAVIDSON: Until a few years ago in the city of New York, they worked as you did in St. Louis, then Mr. Rudolph Miller came in and sent out specifications and plans of bridges that are put up now in every place they are needed and the public is protected. The contractor has a fine place for storage and in my opinion it pays the contractor and it certainly is much safer for the public.

MR. TALBERT: I think you must take into consideration the use the public have of the walks. I know of a case in which a man erected an eight story building at a corner where on one side there was considerable pedestrian traffic, and on the other side there wasn't much. In that case we closed the street, which was comparatively narrow. In other words, there is no reason why the public who used that street should have a canopy on the busy street and leave it off on the other, so we closed the busy street and let them use the side street on the theory that it would cost four or five hundred dollars to erect the canopy. In those matters it is cooperation and common sense rather than carrying out the ordinance. The ordinance to my mind should be held as a club, however, if necessary to make them do it. I have told them repeatedly that whatever their difficulty is we will help them out.

CHAIRMAN WOEDTKE: Mr. S. C. Hill, of the Engineering News Record, has been a very kind and good friend of this baby section. He came out to St. Louis last year and sat through our two sessions and has given up valuable time in coming here, and I will ask him to say something to us.—Mr. Hill.

NEED FOR PUBLICITY WORK

MR. C. S. HILL: Mr Chairman, I will take a very few minutes because you have business much more important. I have watched the growth

of this Section very carefully. The great thing that you need today is publicity in the sense of informing contractors of the country that there is this section in this association. The technical papers can do something in aiding you to get that publicity, but it strikes me that there should be some arrangement made by which the section can circularize. The contractors of the country can be sent this matter in the way of letters or short circulars telling what the purpose of the organization is. It has been mentioned several times here this morning by men who have spoken, especially the contractor from Cleveland, that he didn't know there was such a thing. I find in traveling around the country that there are hundreds of contractors that don't know there is such a thing and there is something I think that the section should do to spread that information and knowledge. Just what it is I am not prepared to say. The technical papers can do a certain amount of it, but the technical paper is not interested so much in that particular thing as it is in telling the new things. And after they have told the new ones they haven't very much space for repeating the things and it is repetition that is necessary.

I hope that sometime during the year the directors of the section will consider that problem and see if they can't get some scheme for advertising the association to the contractor.

CHAIRMAN WOEDTKE: Now, getting down to the round-table, just forget that you have any dignity, or any formal objection to getting into a red hot argument, and let us find where we are on this matter. If you have a problem that you want to get over, or something that seems to be bothering you, just speak it out.

MR. JOHN B. MORGAN (William B. Pollock Company): In regard to fixed ladders, I understand from some of the remarks here it is compulsory in the State of Ohio to have an enclosure around vertical and portable ladders. How about stack ladders and overhead ladders?

MR. HURLBUTT: We don't enclose stack ladders; I understand, however, it is compulsory in the State of Ohio to do so. At the present time we enclose the majority of ladders of thirty feet in height. We enclose all of our ladders on hoists, the same on coal bunkers.

MR. MORGAN: We ship all over the country and our highest State standard will not pass in Pennsylvania or Massachusetts and we are up against a proposition there.

CHAIRMAN WOEDTKE: We take the stiffest requirements we can find and we have our boilers meet that.

MR. NAYLOR: In Manitoba we have a very brief code governing the safety of employees and the general public. Excavations of over five feet in depth must be shored up but the shoring must meet the judgment of the inspector. Sidewalks must be protected by a fence if the building is within seven feet of the sidewalk line, board fence six feet high. If the building is within three feet of the sidewalk our regulations call for a covered canopy. We have periodical inspection by our Bureau of all buildings of any consequence.

STANDARD CODE FOR CONSTRUCTION WORK

MR. BUSH: I have endeavored during the last few months to collect the codes of all the states, and I find that only a few of them have very much along the line of construction work—Pennsylvania, Massachusetts, Wisconsin, California, and some of the other states. It seems to me there is a very great need for the State Commissions to get together on a joint committee, possibly acting with the Bureau of Standards of the National Government, before this state and that state and the other state get up codes which will vary so, and have one standard code gotten up for construction work, just the same as they have a standard code for the electrical construction for this country. The best mind and best talent prepared that code and as soon as it was gotten out was accepted as a standard.

MR. NAYLOR: I have a recent experience on bulletins. I was inspecting a building job in Winnipeg and I took one of the bulletins of the National Safety Council in regard to derricks, it gave some statistics of accidents. I went on the job and saw the subforeman and he had it tacked up. As I was leaving the premises I met the superintendent and called his attention to the bulletin and he immediately became very sarcastic and said, "That sort of thing is all bosh, that makes men afraid and when a man is afraid he is unsafe." Of course, I don't agree with his point of view.

I know from our personal experience we have had a good many accidents of men injured through falling beams. I think hoisting engineers should be licensed. In the case I speak of a man came along and represented himself as an experienced hoisting engineer. He was given a very brief tryout by the foreman and seemed to get along all right but it developed afterwards he didn't have the necessary experience; he lost his head and fumbled the levers, letting the beam fall, killing two men.

MR. DAVIDSON: We heard the statements upstairs this morning that the propaganda among men had almost reached its climax and it wasn't necessary any more. That might be true among other sections but it isn't true in our section; our bulletins are brand new and a good idea.

CHAIRMAN WORDTKE: Which in your mind is the lesser of two evils, to incur the displeasure of the boss on the job because he doesn't like the idea of a bulletin, or doesn't like the idea of any one showing him anything, or, to pass him by and post your bulletins and try to educate your labor? The foreman perhaps doesn't need any education about that beam, but he is only one unit, he isn't the body politic. I think you can resolve it down to that, which is the lesser of two evils, to offend a foreman or to let the workmen go by uneducated. Bulletins have been decided in every industry as being one of the most simple and best vehicles of educating the employees in accident prevention, in fact bulletins are nothing new, all houses use posters of some kind to advertise theatrical performances, and the United States Government used them all through the war.

MR. NAYLOR: I think there was just a shadow of reason in the position he took. For instance, if a man is walking on a steel beam and you

shout to him "Look out"—it will make him conscious he is in danger. I think you will probably add to the danger but in most cases it is a mere shadow of reason because under ordinary circumstances to explain to a man where danger lies is a different thing altogether from getting him excited and making him afraid. I think you hit the motive of that man when you suggested he didn't want any one coming around there introducing anything he didn't originally think of. He wanted to be the king bee, and didn't like to be told anything.

MR. DRESSER: I think possibly the superintendent was peeved. Personally, if I had to deal with such a man I would get rid of him.

FRIDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M., Mr. L. D. Woedtke presiding.

CHAIRMAN WOEDTKE: The first speaker this morning is a gentleman who is well qualified to discuss the subject of his paper, "Safety in Steel Erection." Colonel Gibbs has been known for many years to be a leader in his own field. Steel erection is one of the vital factors in construction; it presents many problems and there is altogether too little attention given to steel erection these times. Mr. Gibbs has gone to considerable trouble to get his paper together, especially in view of the fact that he was serving Uncle Sam a short time ago. It is with decided pleasure that I introduce to you Colonel E. A. Gibbs.

SAFETY IN STEEL ERECTION

COL. E. A. GIBBS, THE MCCLINTIC-MARSHALL COMPANY, PITTSBURGH, PA.

Steel erection, presents in general, the same problems regarding safety encountered in other field construction work.

Like other outside construction work, it is done under more different conditions than shop work, for the reason that the conditions are varied and continually changing, while in the shop many conditions affecting accidents are fixed. The weather plays a much more important part in the field than in the shop. The force of workmen is much less stable in the field than in the shop. With the field force constantly changing, it is much more difficult to educate the men to safety and to avoid getting men who are unsafe on the work.

There are, however, certain differences between steel erection and general construction: the loads are generally much heavier and handled under more varying conditions at a greater distance from the ground. There is an element of risk in every lift. While the derrick may have been tested throughout and proven safe, an accident may be caused by a bridgeman making one careless hitch on a load of beams.

The appliances for erecting steelwork have been developed and increased greatly during the past twenty years and erection is relatively

much more safe. Nevertheless, many new difficulties have arisen. The average weight of pieces to be handled has greatly increased while certain limiting features have remained unchanged, such as track clearances and gage. A girder may increase in weight but the derrick car that handles it must run on and be supported by the same track as previously. This increased weight has had one benefit. Heavy members cannot be juggled and handled in any manner that the foreman desires. The equipment can be designed to handle these in only a few ways and the foreman must be governed accordingly. Therefore, the work is likely done as the design of the equipment contemplates and with corresponding safety.

Accidents are divided into two classes: real and preventable. Real accidents are those which occur through no neglect on the part of the workmen or the employer which could reasonably be expected to be foreseen and prevented. Preventable accidents are those which could have been avoided, had either the men or those in authority over them exercised the proper amount of vigilance. It is conceded that well over half of all accidents are preventable and the proportion is probably higher.

We are, of course, concerned with both classes of accidents but particularly with those that can be prevented. There is no question about the desirability of preventing accidents. The problem is how to accomplish it.

PREVENTABLE ACCIDENTS

Preventable accidents may be divided into three classes:

1. Accidents due to workmen themselves by reason of being physically incapacitated: ignorant, inexperienced, intemperate, careless or reckless, acting the fool, or actual disobedience.
2. Accidents due to foremen:
 - Improper selection of men placed in charge of work or doing the work.
 - Inadequate instruction to workmen.
 - Putting men or allowing them to go into dangerous places unnecessarily.
 - Lack of vigilance and orderliness on the work.
 - Failure to investigate questions of safety made by workmen.
3. Accidents due to superiors: by reason of improper selection of foremen, safeguards, equipment for doing the work and instructions regarding its use.

It is believed that the greatest difficulty is with the men themselves. Construction companies long ago recognized the necessity of having proper equipment, and that phase of the situation is in relatively good shape.

The foreman, while still skeptical as to the value of certain expedients for safety, can be educated more easily as they form a small class, and as their tenure of employment depends on the results they produce it isn't hard to impress them with the effect of accidents on their work.

It isn't so easy to get them to enforce safety methods. The conditions on a job are changing rapidly and the foreman is crowded to make time. He cannot do everything and naturally devotes his time to things that speed the work and affect the direct cost. Only constant pressure on the question of safety, and using every accident to point out the neglect of foremen or men will bring results.

The workmen are by nature and training a daring class of men and instinctively feel that their courage and skill is questioned when they are asked to comply with many of the expedients for safety. However, they can and must be educated to take proper precautions to protect themselves and their fellow-workmen. Bulletins, notices, and placards of various kinds containing written and illustrated cautions and effects of neglect are very good. Our company, in 1910, issued a book to its foremen containing instructions and cautions for the prevention of accidents. We also started at that time to post a bulletin with certain of the most common faults of workmen and how to avoid them. A small copy of this bulletin is handed to each bridgeman whom we employ. It contains, several short paragraphs, as follows:

HOW TO AVOID COMMON FAULTS OF WORKMEN

Don't Be Reckless. More accidents occur through recklessness than any other cause. Don't walk on rods. Don't ride a load. Don't ride on a locomotive crane.

Don't Be Careless. Look where you step, and be sure that on what you step is safe and secure. Don't step on ends of loose plank. Don't start to slide down a line unless you are sure the ends are fastened.

Be Orderly. Do whatever you do in an orderly, careful manner. Pile material so that it cannot roll, fall, tumble, or be blown over. Don't let tools or equipment such as bolts, nuts, drift pins, blocks, dolly bars, etc., lie around so that they can be knocked off the work or so that anyone can fall over them.

Unfit Condition. Don't go to work if you have been drinking or do not feel well. If you are lame or have any defect in hearing or eyesight you should not work at this business, as by so doing you endanger your own and fellow workmen's lives. If you are inexperienced in, or unsuited for the work to be done, don't undertake it.

Be Vigilant! Watch What You are Doing. Don't stand or work under a load. Don't go in the bight of a line nor stand in front of a snatch block. Don't work on or about a crane runway when the crane is in use unless there is a stop between you and the crane.

Don't Use Unfit Tools. Be sure the tools and equipment you use are in good working order. If they are not, don't use them.

DON'T WORK WITH MEN WHO DON'T OBSERVE THESE RULES.

The first requirement for safety in erection is to have the proper equipment. Foremen and workmen cannot be expected to take the necessary precaution if they are not provided with proper equipment

in first-class condition. And it is not enough to provide first-class equipment. It must be kept in good condition by constant attention on the job and by overhauling at the completion of the job if necessary.

PRINCIPLES OBSERVED REGARDING EQUIPMENT

Some of the principles observed by our company regarding equipment are:

1. Use no wooden travellers or derricks, except very light derricks and jinnywinks.
2. All castings in erection equipment carrying any strain to be made of steel. We make all of our sheaves for cable blocks, except small blocks for $\frac{5}{8}$ -inch cable, of steel. All castings when bending strains are encountered are made of vanadium steel. Vanadium insures a more uniform casting and tends to eliminate blow holes.
3. Forgings of importance such as the headblock of a derrick car are made of nickel steel.
4. Use the very best manila lines.
5. Use cable slings, instead of chains. Very important.
6. Automatic brake in addition to mechanical brake on all electric hoists.

In the erection of ordinary work the equipment provided, if it is of the best quality, is amply strong for the purpose. It simply requires proper handling and reasonable care.

For the heavier classes of work, heavy and frequently special equipment must be used. This equipment requires good designing and the best materials. Good designing implies a thorough knowledge of how the equipment is to be used, and the provision for all reasonable uses to which it may be put. It is the duty of the foreman, after being properly instructed, to see that the equipment is put to no uses for which it was not intended unless necessary, and then only after proper investigation by an engineer.

Erection equipment should be so designed as to make all stresses as determinate as possible. Even then the many positions in which a load can and will be handled will produce more varied strains and conditions than occur in bridges or other permanently fixed structures. Be sure that all stresses and combinations of stresses are fully cared for. Then, not only make the main members strong enough but pay especial attention to details. Most failures in erection equipment are primarily due to poor details. Booms, with light lacing or lacing improperly detailed are common. Poor detailing often produces very great bending stresses that are ignored.

Erection equipment should be most carefully inspected during its manufacture and test reports required for steel castings, all alloy metals, and steel cables. The assembling and erection of a traveler or heavy derrick should be carefully done to insure that no stresses are introduced by improper alignment. This is extremely important. Booms and traveller hoists should be tested with gradually increasing loads before

using them to full capacity. While in use they should be inspected frequently to see that no weaknesses have developed through wear or other means, and that the equipment is working as designed.

Instructions should be issued as to just how equipment on heavy work is to be used and nothing left to chance. A movement of a very short distance in the setting of a traveler or in the radius of a heavy boom may be perfectly safe as far as the equipment itself is concerned, but may endanger the falsework or the permanent structure.

In the erection of falsework, great care and an accurate knowledge of conditions is necessary. Timber should be carefully inspected and none but of good quality used. In case mudsills are used, examine the soil carefully and provide sufficient mudsills to support the load with ample safety.

The matter of bracing the falsework bents themselves, their connection by bracing and struts, and the fastening of the end bents to the piers or abutments so as to prevent any longitudinal movement of falsework, are all points where too much care cannot be exercised.

CAUTIONS TO BE OBSERVED IN STEEL ERECTION

Following are some cautions that if followed will prevent many of the accidents in steel erection:

1. Select the proper man for the particular task in hand.
2. Do not order men to work in unnecessarily dangerous places, and be on the alert to see that they do not run unnecessary risks of their own volition.
3. Do not allow the men to work on corrugated iron roofs or steel when there is a coating of ice thereon.
4. Walking on rods, riding loads or locomotive cranes, sliding down lines without inspecting the fastening, standing in the bight of a line or in front of a gate block, are all unnecessary risks and should not be permitted.
5. Do not permit men to work about crane runways without placing an effective stop between the men and the traveling crane, and see that the electric wires are properly insulated.
6. Require the rivet boss to inspect carefully all riveting scaffolds. Improperly hung scaffolds have caused many serious accidents. Only the best material should be employed. Clear spruce is the best.
7. Pipe used as needle beams should not be spliced.
8. All scaffold plank should have a stop bolt about 6 inches from each end to prevent it from slipping off the needle beam and if the scaffold is inclined it should have cleats nailed on the plank. All scaffold material should be tested for twice the load it is expected to carry. Even this care will not suffice unless the men are careful. This was demonstrated in a case where a riveting gang used their scaffold as a brace for an air backup. The scaffold—amply strong for its purpose—broke under this sudden additional load and the men fell into the river.

9. On high bridge work, scaffolds should be provided with a railing. This is a requirement by law in some states.
10. Piling of material must be carefully watched, particularly with heavy work. Scaffolds should be simply heavy and level, and the piles not too heavy. Poor piling of material is responsible for a large number of accidents.
11. When it is necessary for men to work above other men, put up a danger sign calling attention to the fact that men are working overhead.
12. Keeping small tools in condition will avoid many accidents.
13. Wearing of goggles while chipping is a necessary precaution but one the men dislike to follow.
14. In the use of cable slings, inspect them frequently and keep them properly oiled, and in handling heavy loads pad the sharp corners to prevent cutting the cable.

DISCUSSION

MR. J. E. GRIFFITH (Du Pont Company): Do you use annealed chains? Can you properly anneal a chain on the job?

COL. GIBBS: We do not use them, but my opinion is that it doesn't make a good job.

MR. GRIFFITH: Are the cards you hand out to your men printed in different languages?

COL. GIBBS: No, because practically all bridge men are Americans. Rarely if ever do you have a foreigner on bridge work who can't read or write English.

MR. GRIFFITH: What is your experience with men falling from high altitudes, on steel erection?

COL. GIBBS: A man rarely if ever falls from a high altitude because if he is at all shaky up there he wouldn't go up, or if he starts to go up the foreman can almost always tell whether he is used to high altitudes, whether he goes up a column or on top. Of course, a man might be taken with a dizzy spell, but that has never occurred with us. We have had a few men killed by recklessness at high altitudes.

MR. NAYLOR: About engineers, for hoisting, do you have them? Much depends on the engineer.

COL. GIBBS: We find it is absolutely necessary.

MR. RICHARDSON: We have a large blue and white enameled sign on both sides—WARNING—STAY OFF THE CRANE—and they are instructed to watch them very carefully. We have had two accidents in the past few years. It is just like riding a freight train—you have got to keep them off. These accidents that happened were mostly in big plants. I would recommend that when moving the crane down the yard they remove the step and the handle at the rear end, and put a step and handle at the end where the men get up to the locomotive.

COL. GIBBS: That would probably be all right for a shop crane, but our cranes go over a railroad and have to stand Interstate Commerce rules, and are detailed down to an inch.

MR. CORBUSIER (California): I would like to ask about the qualifications when a man comes to you for a highway job, what qualifications do you require, and have you any method of procedure? I mean working aloft.

COL. GIBBS: The first thing is to find out how much experience he has had. As soon as a man starts up a column you can tell whether he is a bridge man or not—that is up to the foreman. He can generally tell, and a man who is afraid to go up in the air will not generally try to. There is no real test that I can think of. There is no way of telling whether a man is going to be dizzy when he gets up there. I don't think it is possible to give a satisfactory physical examination for a thing of that sort.

MR. CORBUSIER: There is no physical examination that has been shown as satisfactory.

MR. W. G. McDERMOTT (Bethlehem Shipbuilding Corporation): Have you any specific statistics in regard to examination and testing of cables?

COL. GIBBS: It is examined whenever it is brought into the tool house—they look it over very carefully; and it is examined frequently on the job. We don't keep a record on the job, we do in the tool house.

CHAIRMAN WOEDTKE: One question Mr. Gibbs raised struck me very forcibly, and that is his company has got to the point where they don't use chains, they have adopted cable slings. That is a mighty important departure as I view it. I would like to ask the question, does he consider the use of chains safe for light work, or prefer the use of cable swings exclusively?

COL. GIBBS: I think I would keep on the job five-eighths and three-quarter chains. There are some cases where a load isn't a factor, where the chain is more convenient to use than a cable, especially where you have a light load which sometimes a cable isn't convenient to handle. If it were not for that, I would abandon them altogether. Any place where the use of the strength of the sling is a factor I would use a cable.

CHAIRMAN WOEDTKE: The next speaker, Gentlemen, is to discuss for you a subject which, while it may not seem one to interest the ordinary contractor, certainly has so much in common with the contracting practice and procedure that undoubtedly there are many things which the speaker may say which will affect your business.

During the war hundreds of ship building corporations throughout the land engaged in building ships for Uncle Sam. In our country, of course, the ship building industry prior to the war had faded into almost nothing. When we got into the war and ships had to be built with crews of green men, that entailed a tremendous problem from the safety viewpoint. Mr. Bonsib, the speaker, handled that end of the game with remarkable success throughout the war period until after the armistice when they shut down a great many shipyards.

RESULTS OF SAFETY WORK IN SHIPBUILDING AND HOW THEY WERE OBTAINED

ROY S. BONSHIE, DIRECTOR, INDUSTRIAL BUREAU TANNERS' COUNCIL OF THE
U. S. A., FORMERLY WITH EMERGENCY FLEET CORPORATION,
SOUTHERN PACIFIC DISTRICT

The building of ships is a contract job, therefore contractors are interested in it. It has been sometime since I was in the ship building game; of course, during the war I was quite active.

I can't give you much information about the organization because I haven't had time to prepare a paper. What I shall say will be simply the results of my own experience on the Pacific Coast. As you probably know, some of the best records in both the reduction of accidents and also the building of ships were made out there. For convenience in handling the gigantic problem that the Shipping Board was under, the United States was divided into eleven districts. In each district a safety engineer was appointed. This man had supervision of all accident prevention activities in both shipbuilding plants and machinery plants in the Southern Pacific district. We hadn't only steel construction but also wood and concrete.

Before this work was started, bookkeepers, ribbon clerks, and men from all lines of activities absolutely foreign to construction work flocked to the shipyards from patriotic motives, and probably other motives. They didn't know any more about building a ship than I did about medicine. Where a man is ignorant he is going to get hurt. I am told that on the Pacific Coast before the Safety work started that there were from one to two men killed every day in the whole district; that throughout the country there was enough lost time from accidents to build twenty 3,500-ton ships. After the safety work started I am pleased to say that fully eighty-five per cent of the injuries causing lost time were eliminated and the fatalities almost disappeared.

This work was accomplished through personal visits to the managements. On the Pacific Coast at the time we first started our work only two of the plants had safety engineers. That is, I wouldn't say safety engineers because one of them wasn't an engineer but a practical man who was looking after safety work. The other was an insurance man who was a very clever man and did excellent work. Our big idea was to sell accident prevention to the managements. They came back at us and said, "We haven't got time to fool with that sort of junk. We are building ships." But it didn't take long to show them it was to their interest to keep the men on the job. They finally became interested and I am pleased to say that most of the companies in the Southern Pacific District at the close of the work had men delegated to accident prevention work exclusively.

The Emergency Fleet Corporation gave general instructions to the safety engineers which I haven't the time to go into, but the big detail of just how the work was accomplished depended upon the man who was

in charge of the work. Each man was allowed to follow the method which he was naturally best fitted to carry out.

In my own case, my method was, after getting the management interested, to talk to the men during the noon hour. I found that very effective. The big trouble in accident prevention work in talking to men is first going on to great spurts of oratory and pounding the air, and after the safety man is through pounding the air nothing has been accomplished. You want, in talking to men, to show them where they lose by getting hurt. We are so constituted that if we lose by doing a certain thing we are not apt to do it. I would tell them that while here was compensation, there was no compensation that would compensate for the loss of wages, to say nothing of the pain and suffering and worry they caused their folks, and during the war it was their patriotic duty to be on the job and stay on the job. That seemed to get them more or less.

ILLUSTRATED REPORTS BY PHOTOGRAPHS

Then following our visit we made written reports along with recommendations showing what we had done and calling the attention of the management to the hazards and telling them how they could be remedied. In my case I illustrated this report by photographs. It took me two weeks to get pictures of the shipyards. I had to see everybody from the Secretary of the Navy to the night watchman, and carried about ten letters of introduction and every time I started taking pictures there was a regular letter reading contest. But I found the pictures showed more than you could write in two or three thousand words, and the beauty of this was that I would catch the man doing something, report him and they would call him in and he would say, "Why no, the man is mistaken, it wasn't me." Then I would feel like a darn fool. But when I had the photographs I would say, "Is that your picture?" He would say, "Well, I guess I did do that."

I found that the way to maintain interest after getting the interest aroused was to issue what I called a Safety Paper. It was issued every time I got a chance to write one, at which time I called attention to the various things that would be of help. This was illustrated by photographs or blue prints. I finally succeeded in getting some of the yards to print plant papers. I am a strong believer in employees' publications. All those who attended the luncheon yesterday were shown absolutely why it paid to have employees' publications because it not only builds that spirit of "our plant"—when you get a bunch of men talking about "our plant," you have got it—it also gives you a chance to put over certain things you want to put over. In those plant papers I ran a series

FABLES IN SLANG

of so called Fables in Slang. The way I murdered the English language was a sin but the men knew what I was talking about and they read them, because after the issue of the publication when I would go to the yards they would speak to me about it. One was called, "Dousing the Glims of a Wise Guy" in which I attempted to show the folly of not

wearing goggles for chippers and caulkers and holders on underneath the hulls. One of my methods was to walk up to a man and ask him if he knew what it was to be blind; of course, he would say, "No," and I would tell him, "Just hold your eyes shut for a minute." I would wait about ten seconds and say, "Now, isn't that a helluva sensation? How would you like to be that way all your life? If you don't wear your goggles, some day you are going to get something in your eye and you are going to be in the sidewalk tin cup holding class. Now wouldn't you look pretty on the sidewalk with a tin cup?" You notice I didn't tell him to wear goggles. If I had said, "you wear goggles"—he would have said, "Like hell I will." But if you show the reason for wearing goggles then they will wear them in spite of the inconvenience. They are inconvenient, but you should be careful all you men who have the goggle problem, to see that the goggles are fitted to the man's eyes, that they aren't any more uncomfortable than is necessary. You can make them comfortable if you make them fit the man's physiognomy, and also get the type that fits the work. In some places they are all the same kind, not any more adapted to the work than the glasses I am wearing. Also be very careful to see that the plane of the lenses is exactly parallel because unless they are, you have oblique refraction, resulting in headaches. I am going to take the liberty of suggesting that Mr. Corbusier of California tell his method of getting them to wear goggles—it is a peach.

Another article was "The Bolt That Went Wrong" in which I attempted to show the danger of allowing loose bolts and nuts and things like that to lie around on the staging: "The Land of Never Thought"—showing how accidents are caused by people not stopping to think: "A New Year's Reverie"—the reverie of a man who hasn't been careful; "The Awakening of Big Bill." in which I attempted to show that when a man got hurt it hurt the foreman. The poor old foreman is jumped on by everybody—the manager, the safety engineer, the insurance man, and everybody in the plant. That is the wrong method; I have found the best way to get at the foreman is this—"Now look, Bill, you are responsible for a certain amount of production, you have got to get this hull in the water, haven't you?" "Yes." "Well, when you have a man hurt you are deprived of his help, aren't you? Now, Bill, isn't it better to watch that man, keep him on the job, than it is to let him get hurt and try to get a green hand? Lord knows we have enough green hands already." He saw the point. By talking to the foreman and showing it is to his selfish interest to safeguard his men, he is going to look at it in a different light instead of thinking it is just an extra burden on him.

BIG HAZARDS IN SHIPBUILDING

The big hazards in ship building are falling, rolling, and flying objects, and improper staging. It is one of the hardest fights to get people to see the importance of proper staging in ship building, especially during the rush of war. I have been on a lot of ships where I have found one plank with a bunch of men working on it and every time a man wanted to get

down he had to crawl around the people on the plank. It was a waste of time. We recommended a staging of three planks and found that to work very well. Then it was hard to get the men, especially the bolters up, to quit leaving bolts and nuts on the staging; instead of picking them out of the bag one at a time they would dump the whole thing on the staging and then would keep running back and forth. They couldn't see it was not only dangerous but inefficient. Most safety practices are efficient measures. We were finally able to get them to see that to be a dangerous practice and we provided boxes and did away with the bag.

Sprung wrenches cause a lot of trouble until we got the management to see the importance of examining the wrenches. Another common trouble, especially in the wood yards, was cuts, stepping on nails and spikes. About the only way to handle the nail problem was to get the men together and show them the nail, then ask them what it would do if anybody should step on it. That was a very elementary and foolish thing but it is effective. Then remark that you know of an instance where a man stepped on a nail and he is in the graveyard. Now don't say, "Why don't you bend the nail down?" Call their attention to the result of the thing and you will find it works. One company in southern California devoted ten minutes a week to this particular subject. The whole force was turned loose to bend down all nails and as a result the punctured nail wounds dropped about ninety-eight per cent. It was a good practice and a few of the other companies followed it. That was made a regular weekly practice you have to keep hammering at the nails and also at the people all the time to get them to see the importance of not only other people's safety but their own. If you show the workmen where safety helps the pay envelope, he is going to be interested in it. If you try to show him it is his duty, that he is his brother's keeper, he hasn't time to listen.

Another big hazard was the ladders. That was one of the hardest fights, to get the companies to build proper ladders and also to see that they were used properly.

Uncovered switches was a big hazard. It was almost impossible to get the management to see that the uncovered switch on construction jobs is an evil. They excuse themselves by saying it is only temporary. It is a well known fact that sixty volts will kill a man unless he is in good condition. It is not only an accident hazard, it is a fire hazard. It wouldn't take much to provide a lined asbestos box and there is no excuse for leaving the uncovered switch on construction jobs.

Another common practice that you will find on ship building jobs is riding on loads, especially those being raised by cranes. The only way I see to stop that is just to lay the man off the second time he does it, if he isn't laid off by the Higher Power, because there have been a lot of people killed and injured by the foolish practice of riding on loads. It can be stopped, it has been stopped. I can't think of any yard on the Pacific Coast where, after three months of our work, I saw any people riding on our cranes, and I have a large number of photographs taken previous to that, of men riding on the loads.

CHAIRMAN WOEDTKE: There are a number of ship building men here, I know, and we put Mr. Bonsib on our program for your benefit. We can very well devote ten or fifteen minutes to discussion for the benefit of the ship building men or men interested in those problems. It is quite plain to me that ninety-eight per cent of the hazards discussed by Mr. Bonsib are common to all contractors.

DISCUSSION

MR. CORBUSIER: Mr. Bonsib spoke about the ignorance in the yards; that is what we have to contend with principally. Men come into the hospital. You say, "What is your name?" "4123." "Where do you live?" "Mr. May." (That is his foreman.) "Married?" "Bolter up." (Laughter.) One of our future board of directors. (Laughter.)

The little stunt that Mr. Bonsib spoke about was in the matter of wearing goggles. I said to Mr. May one day, the foreman of the riveters, "Why don't you make that man wear his goggles?" "You can't, he hasn't got sense enough to wear them, all he can do is drive rivets. I don't want to fire him because he is one of the best riveters I have." I said, "I bet I can make him wear his goggles." "I'll bet you can't." "I bet you ten dollars by tomorrow noon that man will be wearing his goggles." He took me up. I had a little brown glass eye and I walked up to this man who wasn't wearing his goggles and I looked down at him and he looked up at me and finally he quit his work and said, "What sir?" I said, "You understand glass eye?" (He nodded his head.) "Fine. But, you got blue eye, this is brown. Haven't any blue eyes, can't get them—account of war—I want to see what size you wear"—and I measured his eye. (Laughter.) I said, "One blue eye, six and seven-eighths. Well, I will try and get it for you." He said, "I don't want a glass eye." "Well, you will get it because every man driving rivets like that in one month, two months, never more than two months, he comes to the hospital with steel in his eye. For one piece of steel in the eye, glass eye—brown eye, goodbye." (Laughter.) That afternoon after lunch that man drew a pair of goggles. I took Mr. May out and said, "Give me my ten dollars." He said, "My God, how did you do it?" I got the ten. (Laughter.)

That was one of the stunts I did in making a good riveter wear his goggles. Afterwards I went around and told him there were certain places he didn't have to wear them, that it wasn't so dangerous where he was working, but underneath and on the side he must wear them. I got that man to wear them all the time; consequently all the foreigners around there wore them.

The nail stunt: I found a nail sticking up. I put up a piece of red flannel, put up a sign—STEP ON THIS NAIL AND THEN GO TO THE HOSPITAL. There were no more nails around.

SAFETY GUARDS

MR. BONSI: There was one thing I forgot to mention in my talk and that is, the question of committees on construction jobs. It is almost

impossible to have a safety committee, due to the shifting of your personnel. Mr. C. W. Hill, of the Moore Ship Building Company, originated the plan of organizing what he called Safety Guards. It is one of the best methods that I know of in handling safety work on ship building or any other construction job and I am sure if you will write to Mr. Hill he will be glad to give you the details. He would pick out the more intelligent men, watch them, see which one showed a tendency to be careful, and then he would have the superintendent ask that man to come to the safety office and he would proceed to give him a great speech, about what a great honor was to be bestowed on him, they wanted to make him a safety guard. He would say, "Now I don't want you to take this job, I want you to think it over, but I want to give you this button and these rules and if you think you are able to handle this work, let me know."

Mr. Walsh here had charge of the Southern Gulf District and he will tell you also, that the safety guard is the solution of your getting the workmen interested in the job. I haven't told Mr. Hill, I'm far enough away now that he can't hurt me, but I'm sure he would be glad to give you any information he can. C. W. Hill, Safety Engineer, Moore Ship Building Company, Oakland, California.

MR. THOMAS A. WALSH (Merchants Ship Building Company): I was fortunate enough to have charge of the Gulf District, and most of our success was put over by the foreman and the men in the yard. We made our surveys, as Mr. Bonfib said, and after our surveys we held meetings every two weeks in the various yards. After that we took it more on a production basis; we went to the managers and showed them where they were losing money on accidents and showed where the Government was losing tonnage each month. We set the yards on a competitive status, and a copy of that report was sent to the manager of each yard. That report was brought up before the foremen's meetings and read to them. After getting the yards on a competitive basis we got the various hulls and shops on a competitive basis, and we were successful in getting around the problem. All the time we were resting on the foremen and the men in the yards. It wasn't due to any individual, it was coöperation. If every one of the foremen wasn't on the job we fell down; if the manager wasn't on the job we went down.

We had one case where the general manager said it couldn't be done. All I asked him was, if he would let me take hold of the thing I would go to it. We called a meeting of the foremen and showed just where their help was needed. The result was, inside of four months their accident frequency rate came down thirty-five per cent. About six to ten per cent of the accidents were results of shop trouble, mechanical detail; the balance of them were outside, poor stages, ladders, piling of material, etc.

CHAIRMAN WOEDTKE: The next speaker is one whom you should be keenly interested in, not only because of his own personality but because of the fact that he is representing the largest association of construction firms in this country, the Associated General Contractors of

America. We have succeeded in getting Mr. F. C. Dresser of the Austin Company of Cleveland to deliver a paper this morning on "Coöperating on Safety," which is well worth your time and consideration and is valuable in that when he speaks he is representing an association of thousands of contractors throughout the country.

COÖPERATING ON SAFETY

F. J. C. DRESSER, THE AUSTIN COMPANY, CLEVELAND, OHIO
(Representing Associated General Contractors of America)

It is only in recent years that any discussions whatsoever have been had in reference to the hazards of building construction, and aside from statistics issued by the several insurance companies, no organized effort has been made by the contractors generally to exchange ideas toward the elimination of accidents. However, the present day finds that several of our larger contracting organizations include a so-called Bureau of Safety, and their results have shown a remarkable reduction in the number of accidents, as well as an immense saving of lost time and money.

In order to develop a proper safety campaign for the particular job in hand, an analysis is necessary, for the work itself is suggestive of the major portion, or rather kind of possible accidents you will be obliged to combat. I do not mean to say that you can immediately eliminate all accidents, but certainly a study of former accidents on a similar piece of work will help greatly in a reduction of accidents on future work. To just such work, namely, analysis and issuance of instructions, is a safety bureau dedicated.

Of course, there are and always will be special pieces of work that must be accomplished which are different from any former, but I still maintain that the same fundamentals apply and that an analysis still can be made and preventive measures applied.

To follow this discussion briefly, and to support the former statement that the work in hand will suggest possible accidents, it is evident that the sewer or grading contractor, for instance, can, by a series of test holes, determine the character of soil he is obliged to excavate, and plan his working methods accordingly. Such procedure will tell him quickly what he must provide in the way of equipment and protective measures, and has the further advantage of not catching him unawares as far as unforeseen ground conditions are concerned.

The present day of multiple-story buildings, when radical changes in their construction methods are being employed, finds us facing the source of the greatest number of accidents, as is attested by the high insurance rates. Usually the public comes in for consideration, as far as safety methods are concerned, and in fact no other class of structure requires more consistent planning or forethought as regards accident prevention, unless it be in tunnel or subway work as installed in our larger cities. For this work it is plain that proper and substantial equipment must be provided, that possesses a good, safe factor; the sidewalks and streets must be covered; riding loads and in hoists must be forbidden; stairways

and ladders must be liberally provided; mechanical safeguards installed; rapidly moving load lines and signal cords boxed or otherwise protected; safety belts and scaffolds provided; and even a man's clothing must receive attention, for many a man has lost a hand by reason of his wearing a gauntlet glove, and others have lost arms and life because of a loose sleeve or glove which dangled into revolving drums, or shafting, or which were caught by a broken strand in a cable.

Heavy foundation work requires the same care in accident prevention study, both in bridge and in building work.

Pile driving is another hazardous piece of work, where moving timbers and lines are responsible for many avoidable accidents.

Wrecking and underpinning are other sources of accidents, and more numerous undoubtedly than should be because they do not receive the attention of an engineer as regards a plan, or in other words, the average wrecking contractor does not have a staff or an engineer in his service to make calculations before doing work. As a result, defective material is often used and insufficient underpinning installed, causing accidents, of course.

Heavy rock excavation requires care in handling dynamite, and precaution against flying rock and destruction of property.

Industrial building work is the source of possibly the greatest variety of accidents, but usually not as disastrous to life and limb as the previously mentioned classes of work.

An analytical study in the direction of safety, no matter what the class of work, will certainly produce results if undertaken with the same spirit that a construction engineer plans his layout and schedule.

EMPLOYEES

In a large measure the application of safety methods depends on the employee. The more intelligent, the less liable is he to accident. In this respect, the ironworker or steel erector is possibly the most versatile in that he thinks of the possibilities of things happening in connection with the work in hand, and is not so easily caught unaware. The brickmason and carpenter are usually on more substantial footing and inasmuch as their work is usually more regular, do not have occasion to give "possible happenings" much thought. No other mechanic requires good judgment more than the hoisting engineer, especially be he engaged on multiple-story building work or heavy bridge construction. The common laborer, however, requires more watching than the trade mechanics, and in this respect much depends on the intelligence of the foreman who directs his movements. All workmen, however, can be schooled in safety methods as has been demonstrated by leading contracting companies that have safety bureaus. For instance, Fred T. Ley and Company began this work in 1915, and their reduction in accident rate per 1,000 employees for 1916 was 25 per cent, and in 1917 was 55 per cent, which is indeed encouraging.

CHARACTER OF ACCIDENTS

Our records, from a recent piece of construction, which involved steel erection, heavy concrete, brick work, and grading, also trackwork, show,

from a total of 242 accidents, that: 73 employees sustained bruised fingers from handling material, 37 employees sustained punctured feet from nails, 11 employees sustained cuts on head from falling material, 7 employees sustained sprained ankles, slipping and misstepping, 7 employees sustained cuts on hands, and the balance were minor injuries. This work comprised the erection of a large engine terminal, and this record conforms in the average to the class of accidents which we must safeguard against in the course of our regular industrial building construction.

I find in comparison with figures as derived by other concerns, that the accidents in the main are similar in character, but the percentages vary, due undoubtedly to the character of the work in hand.

The greatest number of accidents, we find, come during the handling of material, and are confined to hand injuries; second in number come injuries to feet from protruding nails; third, employees falling, by reason of misstepping or stumbling over strewn material, causing sprained or broken ankles, broken arms or legs; fourth, falling material, causing cuts about the body and broken limbs. These are the four main causes as we find them, and it is natural, therefore, that preventive measures be provided in the order named.

I believe it goes without question that a job properly planned, and scheduled whereby one phase of the work closely follows the other, where material is received and handled in the same order and where orderliness prevails throughout, is rewarded by the least number of accidents.

Receiving and storing of material is a study in itself, for naturally the best position must be selected for hoists, and also for storage. One should be near the other to avoid rehandling and increased costs, and minimum handling also reduces the possibility of accidents, as is plain. But often they are far apart, causing long runways to be built and arranged, in and out, around or through a building, as the case may be, creating a state of disorder and interfering with the other divisions of the work. The ideal, of course, is one where, for instance, structural steel can be placed from car to position, eliminating rehandling in field; and on large operations where space is available, this can often be done with steel as well as other material, if hoists and material tracks or roads are given some attention as to layout and position before work is started in the field. The main object is to eliminate distance, for work is really distance versus resistance, as the definition goes, and the further application of all possible mechanical means to handle material from cars or wagon to position is another factor which results in a great reduction of accidents.

Our second consideration being given to nails, we find that orderliness in handling of lumber containing protruding nails, eliminates foot punctures by the score. Plank or forms of this character should be stacked with nails down and not be allowed to be strewn all over the job. In order to re-use the plank or board, the carpenter must drive the nails back, and their removal as soon as the plank or brace is taken down is undoubtedly the best practice. As regards concrete form lumber that has been stripped, if it has no further use in the building as fabricated, it should be stacked and nails removed by the cleaning gang, if there is one, as soon as possible to make it available for other use, for certainly the

re-use of lumber these days is economy, and a carpenter usually will take a new piece rather than stop to remove nails. In a multiple-story concrete building, forms are usually stripped and immediately placed in position for the next floor, and the same applies to braces, so that the immediate removal or driving back of nails is necessary and foot punctures are made less possible than on the ordinary timber or house job. Elimination of strewn lumber will reduce nail accidents and its reclamation should be taken in hand at once in order to make it fit for re-use, which in itself will cause a saving in the final lumber bill.

To avoid employees falling, railings should be erected on staging and scaffolds; runways of sufficient width provided; and material generally should not be strewn promiscuously about the job. Openings should be covered or railed and good stable ladders built. Climbing up or down hoist towers should be forbidden, and all moving lines boxed so as to avoid tripping. Working aisles should be kept clear of waste and surplus material.

To avoid falling material, storage of the same should be confined to the interior aisles, and scaffolds provided with a sideboard to prevent brick especially from going over the edge.

In discharging debris, closed-in chutes should be installed, wheeling runways to be of sufficient width and overloading of wheel-barrows forbidden, especially when bricks are being moved.

Naturally the safety movement must begin with the management itself, and if contractors generally will review the results obtained by those contractors who maintain Safety Bureaus, they will readily see that it is a paying branch of the organization. The gratifying results obtained by Fred T. Ley and Company, of which Mr. L. D. Woedtke is Director of Safety, have already been mentioned. Inasmuch as the work covers a period of only three years, they are indicative of the immense amount of good work that can be done in accident prevention in general contracting, as propaganda of this kind is really in its infancy in this field.

The next step for an organization to undertake is the addition of a Safety Bureau, under whose direction the work is carried on. The first consideration must be given to the field organization itself, meaning the engineers, superintendents and in fact the entire rank and file, for coöperation must exist; and foremen generally must see that the safety rules are observed.

As a further matter of coöperation, the construction department should turn over to the safety man a complete schedule of the job in hand, showing the progress expected, this being the first step. Second, a set of safety rules should be issued applying to the work or particular job in hand, which are set up after due analysis of the conditions which are to be met. The third is, of course, the enforcement and application of these safety rules.

First of all, any job employing 125 men or more, dependent, of course, on character of the work and location, should have a first aid attendant and small field hospital. We find it pays decidedly by eliminating lost time.

Second, the job organization should appreciate thoroughly the mean-

ing of this safety work and they will in the end discover that lower unit costs will result from the observance of the safety rules.

EDUCATE THE WORKMEN

To educate the workmen themselves can be done in different ways, and first of all, I believe, he should be taught to observe safety rules provided as a precaution against the first or possibly the second classifications, which are most liable to happen. His education in this respect should be gradual or progressive as the work goes on, and his foreman, of course, should see that the rules are observed.

Descriptive photographs are an immense help in avoiding accidents and educational work, and should be in keeping with the class of work in hand.

Periodical bulletins help greatly, as do also signs which should be of such size and meaning as can be understood by all. A sign that can be read only a few feet distant is not of much use; it should be readable at a considerable distance—the farther the better.

Another idea is to have progressive signs, or those which move forward with the work, cautioning what in particular may result from the work in hand at that time. These signs should be right on the job and not posted on the office door, which may be a mile away from the job.

These are, of course, just the means by which the idea can be conveyed, and various methods can be adopted as results may suggest; the same to be chosen by the Safety Director himself. In addition, safety meetings should be held on the job by the foremen and a plan of action or procedure decided upon before particular pieces of work are undertaken, also work covered should be reviewed, ideas exchanged, and the work encouraged in every way. In this way, the best methods can be secured.

EQUIPMENT

Needless to say, the equipment for the particular job in hand should receive the same careful attention, first to be assured that it possesses the necessary safety factors to handle the work generally, and that it is in good repair at all times, and receives the necessary periodical inspection while on the work as well.

On all our work, for instance, we carry boiler insurance; the boilers receive periodical inspection by the insurance company and, of course, must conform to the state laws.

Around the plant generally, guards should be built which will eliminate the possibility of employees coming in contact with the moving parts and lines, and the same consideration must be given to hoists and hoist lines. To operate plants efficiently requires good mechanics, and a contractor, who maintains a staff of experienced operators in connection with his organization has done much toward the application of safe methods, for the accident, as a rule, happens to the green man, no matter whether he be mechanic, laborer, or machine operator, and it is necessary to observe such men very carefully, until such time as some experience has been gained.

Safety rules further will establish under what conditions a machine is to be operated and how, and will also establish signal codes to be observed, for very often the operator cannot see the other end of the line or the top of the hoist, as the case may be.

At any rate, common sense application tells us that above all else you must have experienced machine operators, and none other should be permitted to be employed, yet many times you will find some man out of the gang running a machine, the principles of which are entirely foreign to his understanding.

The whole work, however, as regards both employees and equipment is to be reviewed and inspected by the Safety Engineer, who will suggest precautions and safety rules that are to go hand in hand with the working methods decided upon for the handling of the job. This is further beneficial inasmuch as a man from general headquarters sees many things that a man on the job does not deem important.

Generally speaking, this subject is one that is becoming more important each year, and the increasing obligation to cooperate with safety is plain, considering the fact that in 1917, in our United States, 300,000 men were disabled and 3,000,000 minor accidents occurred in our industrial army.

It means work and a general adoption of the policy of accident prevention wherever man is employed in industrial work.

To this end, it is gratifying that the contractors generally are becoming more interested, for certainly it is a work that is worthy of the fullest recognition, and we hope to record with the National Safety Council next year a remarkable improvement in our work.

DISCUSSION

MR. HURLBUTT: One of our safety engineers brought in some rather interesting figures that bear out a point in Mr. Dresser's paper. We are doing a construction job in the State of Michigan where we are using in the neighborhood of four thousand men. The contract called for a thousand houses in four months, with a bonus for time saved, necessarily increasing the accident hazard. As a result of having a complete first aid hospital on the job, immediately following an injury the man was taken to the hospital, and as a result we have had only two serious accidents from nail punctures—which shows the worth of medical attention to do away with the possibility of infection.

CHAIRMAN WOEDTKE: If there is no further discussion of Mr. Dresser's paper, before getting into the round table discussion I would like to have you listen to the report of the Nominating Committee if they are ready.

REPORT OF NOMINATING COMMITTEE

MR. KIMBERLING (Pittsburgh Construction Company): The Nominating Committee recommends for officers of the Construction Section of the National Safety Council the following:

Chairman, L. D. Woedtke—Fred T. Ley Company, Springfield, Massachusetts.

Vice Chairman, W. F. Austin—W. E. Wood Company, Detroit, Michigan.

Vice Chairman, F. L. Hurlbutt—E. I. du Pont de Nemours and Company, Delaware.

Secretary, Edward W. Bush—Aetna Casualty Company, Hartford, Connecticut.

Chairman of Bulletin Committee, J. H. Schults, Jas. Stewart Company, Inc., New York City.

(The report was adopted and the Secretary was instructed to cast a unanimous ballot for those nominated.)

The Chairman then appointed standing committees on Membership and on Standardization and Statistics for the coming year.)

CHAIRMAN WOEDTKE: With that business out of the way we will proceed to the round-table discussion.

ROUND-TABLE DISCUSSION

MR. COFFEY: You spoke about slings and chains and cables. What is the practice here in regard to lumber? Some of our men say manila rope is better than the cable, from a safety standpoint I mean.

MR. DRESSER: We use the cable sling, except that on light loads—such as thirty or forty pieces of two by six, twenty feet long—we use rope.

MR. COFFEY: That is what they say, that the rope is more pliable and grips the lumber better and you won't have any falling out.

MR. DRESSER: It doesn't, that is true.

CHAIRMAN WOEDTKE: Rope will bite better. Some people, if they don't want to damage the timber, use a canvas shield or a piece of soft wood. Those are common practices.

MR. DRESSER: On big jobs we have made a cradle with a chain binder.

MR. GRIFFITH: In regard to cleat ladders, I would like to tell a little story. I saw a foreman directing some work and a man was putting up a home made ladder. I didn't say anything to the foreman but just looked at the ladder and he immediately told the man to go to the tool room and get a round rung ladder. The home-made ladder is all right, it may be just as safe as any other ladder, but the next fellow who comes along and uses it may get hurt. The Du Pont Company insists that home-made ladders shall not be made on the job, and if they are made by small, yet we try to do away with them entirely.

some contracting firms they will probably be made of any kind of lumber not inspected properly. Although the percentage of accidents is very

CHAIRMAN WOEDTKE: A year ago the problem of testing manila rope was raised at our round-table. It is a pretty thorny one, and it hasn't been solved yet. Manila ropes have been subjected to considerable damage through the action of muriatic acid and its fumes. During the past year I have taken that matter up with a number of different people, including a number of college presidents who I thought might use the material in a thesis and have something definite worked out.

There are two tangible methods, one of them being to treat the rope by brushing, painting, or soaking with a chemical compound which will

resist muriatic acid and its fumes. The other seems to be the well known mixture of wax and castor oil which is difficult to apply. We got to the point where we have furnished the United States Bureau of Standards with the required quantities in lengths of various sized ropes, both in new rope and used rope, and they are working on the test to the end that we may have a scientific and definite report of what a proposed chemical compound will do. That report will be ready soon and will be sent to the members of our Section in a news letter.

If you have any other method in mind other than treating the rope by soaking it or brushing it with a compound, or by the use of a combination of castor oil and wax, let us know now what it is, because the Bureau will go through any tests you desire and which we will submit to them.

Mr. Williams of the National Safety Council has come in, and I would like to call on him. He was instrumental in getting this section formed a year ago and then wished it on me to keep it going.

MR. WILLIAMS: It certainly did my heart good to see the crowd you had here yesterday. There was only one thing the matter—we made the mistake of not having the Construction Section build a hotel especially for the convention. We got the largest hotel here, and there are but few cities in the United States that have more hotel room. We will try next year to have better accommodations if we can possibly get them.

We have been giving you every two weeks a Construction Section Bulletin dealing particularly with construction hazards. It has been somewhat of an effort to get material for those bulletins and I beg of you to send us what material you can in order to keep this service going. You are going to have a Chairman of the Bulletin Committee this year, but it isn't fair to have him do it all himself.

Our general series of bulletins that go to all our members contain a good many things applicable to construction work, so don't think for a minute the special construction bulletins are the only ones you are supposed to use. For example, we used in the general series the picture Mr. Woedtke sent in, on the danger of using tools with mushroom heads—something that is found not only in construction but other lines.

One of the most valuable features of National Safety Council membership is the fact that we have in Chicago the most complete collection of information on accident prevention problems in the world. Every year we get about three thousand letters asking for information on this or that particular problem, just like this one of protecting ropes and ladders. When we answer those questions we dig up every thing we can and even go out and ask people we think might be able to help us. In many cases if you have some particular problem that confronts you in your work, if you will write us just exactly what the situation is we will find that somebody else has had that same problem some other time, some other place, and has succeeded in solving it, and we will pass it on to you.

MR. PARISH: The men who are looking for safety devices don't know where to get them or what to get and they welcome that information even in the form of an advertisement.

MR. WILLIAMS: If you write to us asking what kind of a guard to use in a particular situation on a circular saw, for instance, we, of course, can't recommend you a particular guard that so and so is manufacturing. We have to be impartial on that, but, we will send you, if you should ask for such information, advertising circulars of all the people that are making that kind of a guard and then if we thought we ought to recommend some guard that was home-made that wasn't on the market, we would give you information about that. In other words we will send full information about commercial guards to any one who asks for it. We have a large supply of advertising literature in our library.

MR. DAVIDSON: A little point has been worrying me in connection with the compiling of statistics—what shall we do with subcontractors and their men? In compiling our records do we regard the subcontractor as of our own organization for the time being? I have tried to devise a scheme for putting jobs on a competitive basis, and I send out to all the jobs each month and to all the superintendents, whether they have jobs at that particular time or not, the record for the preceding month with the jobs rated, the best job standing at the head of the list and so on down. If a superintendent has had an accident on that job which occurred in the subcontractor's gang, he comes back at me pretty hard.

CHAIRMAN WOENTKE: I have found it is impractical in every way to include in your own data, especially if you are going to use it for competitive or comparison purposes, anything except accidents which occurred to your own men. The subcontractor has no more relation to your superintendent on the job than if he were a thousand miles away; he has his own problems, directs his own work, and if his men are injured that has nothing to do with your job superintendent.

MR. J. J. COFFEY: We have some statistics for 1916, 1917, and 1918. The Compensation Law went into effect January 1, 1916. Through the cooperation of the Department of Labor and Industry and the various plants with safety engineers, the accidents have been reduced from 252,000 lost time accidents in 1916, to 223,000 lost time accidents in 1917. It was reduced in 1918, to 180,000 lost time accidents. Now our records, which Mr. Walker, Chief of our Bureau has with him, show that there are about 89,000 reported accidents for the first nine months of this year. All this reduction doesn't come about through the safeguards which we are putting on the various machines because they will only cut down your accidents twenty-five per cent. if it does that. But this reduction was brought about, three-fourths of it, by the work of your men, safety engineers. Any of you can cut it down sixty or seventy-five per cent by your safety campaign.

Pennsylvania some two or three years ago, got out a ladder code and if any of you men want a copy of the Pennsylvania ladder code write to John H. Walker, Chief of the Bureau of Inspection, Department of Labor and Industry, Harrisburg, Pa.

CHAIRMAN WOENTKE: We are hoping that by the time 1920 comes around we can have everybody on the same statistical basis, because if

one fellow uses one method, and another some other method, they are not comparable.

The National Safety Council and the United States Government have been trying to standardize methods, which you might modify to suit your own industry, and would still be in line so it would be comparable to everybody. If anybody has anything in the room here in the way of actual statistics or a formula for recording them I wish you would announce it so the stenographer can take the name.

MR. HARP: I would be perfectly willing to get you any statistics for the next year you want.

Mr. F. Marshall Harp
The Employers Mutual Insurance Company of New York
502 D. S. Morgan Building
Buffalo, New York

MR. E. W. CALLEN: Our report will be ready for publication soon.

Mr. E. W. Callen
Building Inspector
Wisconsin Industrial Commission
Madison, Wisconsin

MR. ROBINSON: We would be glad to send any information we could.

Mr. F. S. Robinson
General Builders' Association
Detroit, Michigan.

CHAIRMAN WOEDTKE: When we come together next year I think we shall have a big attendance. I think you will admit the discussions and papers we have had yesterday and today have been excellent. As soon as possible the proceedings of the National Safety Council will be printed and bound and distributed. If it happens in your firm you are engaged with, that a big boss gets the mail that comes from the National Safety Council, tell him when that book comes in you want it because in it will be the reproduction of the papers and the discussions given here, and it may help you.

I urge you to try and get this safety idea over in the construction field. Send us in your experience and photographs that look good to you; we will work them into a news letter and we will try to keep you together in spirit as you have been here in body. Don't think your officers can continue this Section and make a whirlwind out of it without your help, because your officers have a job to take care of the same as you have.

I am glad we had such a good showing here today and yesterday and it certainly is indicative of increased interest among contractors. I want to thank every one of you for your time and courtesy, especially the speakers and those who took part in the discussions.

(A vote of thanks was then given to the Chairman for his services after which the meeting adjourned.)

Electric Railway Section

October 2 and 3, 1919

H. B. ADAMS, Chairman

Safety Supervisor, Aurora, Elgin and Chicago Railroad Company,
Aurora, Ill.

JOHN H. COX, Secretary

The Cleveland Railway Company, Cleveland, Ohio

THURSDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M., Chairman H. B. Adams presiding. Chairman Adams read his report.

REPORT OF CHAIRMAN

Officers: At the 1918 meeting of this Section, Mr. H. B. Potter of Boston, Mass., was elected Secretary. It was impossible for Mr. Potter to accept the position, and your chairman appointed Mr. John H. Cox of Cleveland, Ohio, to fill the vacancy—Mr. Cox is here and right on the job.

Soon after the Annual meeting the following appointments were made:
Chairman Membership Committee, D. E. Parsons, East St. Louis & Suburban Railway Company, East St. Louis, Ill.

Chairman Program Committee, R. N. Hemming, Fort Wayne & Northern Indiana Traction Co., Fort Wayne, Ind.

Chairman Bulletin Committee, H. W. Clapp, Columbus Railway, Power & Light Company, Columbus, Ohio.

Mr. Clapp had been the very efficient chairman of the Bulletin Committee for more than two years but, owing to his acceptance of the vice-presidency of another traction company, the duties and responsibilities of his new position prevented him from continuing as Chairman of the Committee and his resignation was accepted. Mr. John H. Mallon, The Metropolitan West Side Elevated Railway Company, Chicago, accepted the appointment as Chairman of the Bulletin Committee to fill the vacancy.

Bulletins: During the year you have received each week a bulletin particularly designed to call attention to Electric Railway Hazards, to

gether with the weekly letters from the National Safety Council Headquarters, and various general bulletins covering many phases of safety work.

News Letters: Beginning December, 1918, monthly News-Letters were sent to all members of the section.

These letters were intended to encourage you in the noble work of accident prevention and many of the items and suggestions were furnished by energetic safety workers within our organization. Most of these letters contained an enclosure of some form of safety literature which was in use by certain companies.

We wish heartily to thank the several members who have assisted in these letters by their contributions.

Rule Books: In July we requested the members to send in a copy of their Rule Books, with the idea of appointing a committee of expert operating men to examine the different Rules and draft a set of Standard Rules. A copy of such draft to be sent to every member for criticism and suggestions, the committee later to revise the draft and prepare a set of Standard Rules to present to the Section at the Annual Congress for adoption. Members were slow or indifferent in sending in their books, only eleven having been received up to this time. The response was so limited and the time so short that the work could not be completed in time for this session and no committee was appointed.

Membership: At the 1918 Annual Congress the Electric Railway Section was composed of 129 Electric Railway companies, operating 13,564,474 miles of main line track.

During the past year 22 memberships have been cancelled and 12 new members have been added. This shows a net decrease of 10 in the number of members while the decrease in mileage has been 427.

We now have 119 member companies operating 13,137.23 miles of main line track.

In the face of the extraordinary financial and operating conditions affecting Electric Railways throughout the country it is a matter of great satisfaction that this Section has suffered so slight a decrease in its membership.

Safety Campaigns: During the year several of our member companies have put over special campaigns for prevention of accidents and in each and every one of them the results have been highly gratifying.

National Headquarters:—During the year we have received several requests from members for help in special safety problems on their particular properties and the entire staff of the National Safety Council Headquarters have freely assisted in helping to solve these problems.

I wish to express my thanks to the entire office force and especially to Mr. C. W. Price, General Manager, and Mr. F. M. Rosseland, Safety Engineer, for their great interest in the welfare of the section and the valuable help given to your Chairman.

Publicity: It is gratifying indeed to note the generosity of the trade papers in giving space to accident-prevention work, especially the activities of the Electric Railway Section in the publication of news which is of great importance to members. I am thinking par-

ticularly of "The Electric Railway Journal," "Electric Traction," and "Safety Engineering." Reporting new developments, progress and results of organized safety work in the columns of these progressive and influential periodicals is of definite value to them and to the safety movement.

In Conclusion: I also wish to extend my thanks to the officers and chairmen of committees for their courtesies to me and for the work they have done for the Section in their respective positions.

Let us now look forward with the firm determination to make the coming year a banner year in the prevention of accidents and the constructive reorganization of our beloved nation by the persistent and systematic conservation of life and limb among our immediate associates.

Our thanks are due to Mr. R. N. Hemming, Chairman of the Program Committee, who has had almost sole charge of the preparation of this excellent program. The Committees have no special reports to make as the points that they have been working on have been covered by the report of your Chairman.

Next in order is the appointment of a Nominating Committee. I will appoint Mr. W. F. Weh, Mr. John H. Mallon and Mr. R. E. McDougall. This Nominating Committee is to present names for the offices of Chairman, Vice-Chairman, and Secretary tomorrow morning at 9:30. The first paper on our program, "The Human Factor in Safe Operation and Maintenance of Rolling Stock," is a subject in which we all ought to be deeply interested. Mr. F. R. Phillips, Superintendent of Equipment, Pittsburgh Railways Company, Pittsburgh, Pa., will now deliver that paper.

THE HUMAN FACTOR IN THE SAFE OPERATION AND MAINTENANCE OF ROLLING STOCK

F. R. PHILLIPS, SUPERINTENDENT OF EQUIPMENT, PITTSBURGH RAILWAYS
COMPANY, PITTSBURGH, PA.

The Human Factor in whatsoever relationship it may be considered, is the most important question now before the minds of the people of all nations.

Dissatisfaction with the present order of things is rampant. It manifests itself in many ways, but rarely survives cold, clear light of reasoning. Nevertheless the minds of all the people are yearning for a "something", which seems to be lacking in our social and political structure, a remedy for which, economists and other students of the problem have so far failed to provide.

It is not our purpose at this time to engage in an academic discussion of this most perplexing situation. It may well be left to minds better equipped and developed than that of the writer. It is mentioned here and at this time merely for the purpose of directing your attention to the fact that when considering the question of the human factor in its relationship to the safe operation and maintenance of rolling stock, we

have to reckon with a new force of which we have little positive knowledge.

A Superintendent of the Motive Power Department of an electric railway, if he would attain the full measure of success, must be, in addition to his other duties, a thorough student of human nature. It is not enough that his plant and equipment be provided with the most effective safety devices, nor is it enough that his system of inspection and supervision be the last word in the art. He must know men—must know their weak and strong points and be able in some measure to define their various moods.

Be your safety equipment and organization ever so efficient, or your campaign of education in accident prevention, ever so complete, one dissatisfied employee (and in these days there are many such) or one, who because of outside environment, worry and ill health, or because of home and family conditions, which for the time being throws him out of joint with the existing conditions, may in an unguarded moment, through act of commission or omission, be the means of a holocaust or shambles.

While I strongly advocate the use of the most effective safety devices and urge a comprehensive, thorough, and continued educational campaign through the medium of shop talks, committee activities, scare-heads and bulletin boards, I am convinced that the ultimate may be reached only through a personal appeal to individual employees.

THE PERSONAL APPEAL

A personal appeal, however, to be effective, must be clothed with sincerity and earnestness of purpose. We must neither preach, patronize nor command. Moreover, if a personal appeal to an individual is to be productive of the greatest good, we must first establish the right to make such an appeal. The mere fact of your being the superior officer does not give you that right. How, then, shall we establish that right?

At this time of the golden harvest when the sower is reaping his reward, may we not with profit look to our farmer friend and his method. When he desires to secure the greatest result from his effort, does he take the seed haphazardly and plant it with no thought than since he is the owner of the seed and soil, therefore, by right of ownership and superiority to seed and soil, success must come. Hardly. He adopts more practicable and sane methods.

He first chooses the field which gives the greatest promise and is best adapted to the particular crop under consideration. He plows and plows deep, and in a certain way, and at a certain time. He discs, harrows, and drags the soil, until it is mellow and sweet. In other words, he carefully prepares the seed bed. Furthermore, the seed is chosen after much thought and experiment before planting. Then he cultivates again and again, and in the fullness of time, his efforts are rewarded, we are told, an hundred fold. The plant endures through hail and wind and storm. Sometimes his efforts fail, but rarely.

If we are to be successful in our relationships with men, we must eschew subterfuge and insincerity, and without other purpose than mutual good meet them on their own plane. Cultivate their acquaintance until we know them and know them by their first name. Know their families,

their associates, and home surroundings—their hopes, joys and sorrows. In other words, there must first be prepared the seed bed of mutual understanding. Judgment and due regard for the other's welfare and viewpoint must be exercised in planting the seed of desire, and the growing plant must be nurtured and cultivated until it blossoms forth into the maturity of accomplishment. Then my friends, may the winds and storms of demagogism, bolshevism, and all the other isms of social unrest come, a relationship founded upon such mutual confidence and respect will weather the storm.

Perhaps the importance which a personal appeal to the individual occupies in safety work may best be emphasized by reference to the results of observations made by the writer during the pre-war period. A personal examination into the underlying causes of a large number of accidents of major and minor degree covering a period of several months, showed that over 93 per cent were the result of man failure and less than 7 per cent to equipment failure. In practically all of the accidents charged to equipment, there were evidences of lack of proper care on the part of some individual. I can recall but two or three cases directly chargeable to defective material. One, a broken brake rod—one, a frozen air brake, and—one, a defective axle, which developed in the gear fit. The accidents under observation included collisions, derailments, controller burnouts, and others of a similar nature.

EFFICIENCY OF SAFETY EQUIPMENT

With respect to accidents to employees in the shops and car houses, you will pardon me if I mention the fact that the Bureau of Factory Inspection of the Department of Labor and Industry of the State in which our property is located, has made my company the object of special commendation because of the completeness and efficiency of our safety equipment. Moreover, we make the most of the literature and bulletins issued by the National Safety Council. You will find them conspicuously posted in prominent places throughout the shops, car houses, sub-stations, and at all places where our men congregate. At our weekly staff meetings and monthly round-table conferences, safety discussions are a permanent item on the program. Without this equipment and these activities, we would feel delinquent in our duty. Nevertheless, we hold to the statement that the personal appeal is productive of more efficacious results than all of the others. If I were required to relinquish all but one of the prime requisites of safety promulgation, I should cling to the personal appeal to the individual. Let me illustrate:

The great majority of plant accidents are, incipient local infections due to slight cuts and bruises, and minor accidents resulting from neglect to use goggles to protect the eyes when grinding or chipping, or when cutting rivets or bolts. Accidents, which are extremely simple in their nature and easily avoidable, and I may say here that all of our plants are equipped with first-aid kits, in charge of one or more men trained in first-aid methods. At our principal shop a first-aid department is maintained in charge of a capable, experienced graduate nurse, and, at our main office, which is centrally located with respect to the whole sys-

cisms must be of a constructive nature and should never be allowed to become ill natured or show jealousy or be in the nature of a "knock." These criticisms or suggestions should be made to the official to whom the employee reports and should then be referred until it reaches the general superintendent or general manager, to be taken up by him with the head of the department about which the criticism was made. They should never be made directly by the employee of one department to an employee of another. This latter method always engenders ill feeling.

All employees should be impressed with the thought that all suggestions should be of a constructive nature and that they are all made and *must* be made for the general good of the company and that personalities must never enter into any of them. Probably the most effective method of promoting a feeling of friendliness and co-operation between departments is that of having periodical meetings of men—not only heads of departments but the rank and file as well. This gives a chance for discussion of individual problems and helpful suggestions and is always productive of good results. On a large property these meetings have to be in sections but the results are the same. The Safety First Organization, of course, has such meetings, but all organizations should have them, whether they are called Safety First or something else.

The personality of the general officers and heads of departments has much to do with the question of a harmonious working of the organization. If these men cannot make the employees feel that they belong to a happy family, each one working toward a common end, there will be constant friction. An official does not have to lose his self respect, or power to have effective discipline, to have the good will and respect of his employees. Any company is fortunate that has officials who can command the respect and good will of every employee under them.

I have spoken, in a general way, of the principles necessary for a smooth-working organization and have probably not kept close to the text of my subject. However, the details of the work of coördination between transportation and equipment departments will work out themselves if the main thought is worked out successfully, and that thought is encompassed in just one word—*harmony*.

CHAIRMAN ADAMS: The subject is now open for discussion.

DISCUSSION

MR. V. J. WALTZ (General Claim Agent, Toledo Railways and Light Company, Toledo, Ohio): I should like to inquire of Mr. Jeffries, or of any other member of the Section, whether they have had any difficulties in securing the attendance of the employees from the different barns and shops at safety meetings. In Toledo, we have had a great deal of difficulty in getting attendance from our four sectional barns. In fact, it dwindled down so that we discontinued our meetings last year, but we intend to resume this Fall and continue through the Winter, and I would like to know the best method of securing attendance.

MR. JEFFRIES: Our men are scattered over a large portion of the state and it is harder to get them together because some have to travel quite

a distance to get to the place of meeting. We don't have any set dates for the meetings. We get them together whenever we think the proper time has arrived and we do not get them together in large numbers because that is impracticable. The most good, I think, comes from having a general, heart-to-heart talk instead of a set program at these meetings.

MR. R. N. HEMMING (Supt. of Transportation, Ft. Wayne and Northern Indiana Traction Co., Ft. Wayne, Ind.): If the organization gets too big, when you attempt to solve minor details you lose out. It has been our experience that by smaller groups we have accomplished more, in less time, and with more pep. However, in dealing with the trainmen, it has been my policy to hold two meetings, one to catch the early men and the other to catch the late men. We cover everything with short talks and give the men some statistics as to the number of our accidents, the money loss, and the character of the accidents. We follow this up with a talk on precaution.

We have sifted the organization down from seventy-two to fifteen. The old organization of seventy-two was so large, that we were going around in a circle. By bringing it down to smaller groups we have accomplished greater results. That is manifested somewhat in the reduction of the cost of accidents. Last year this cost was 3.4 per cent of the gross receipts and this year, from January to June, inclusive, it was 1.6 per cent of the gross receipts. We feel that is a creditable showing. Another plan that we use—it is in practice on many other properties—is that of charging up the accident to the man responsible for it, whether he be a conductor, or motorman, or other employee. He is also given a report showing how much money he has cost the Company through accidents, and it certainly brings about better results.

When this man feels that he is not getting enough money, we reverse the proposition. We show him how much, as an individual, he is costing the Company. He becomes a more careful man because he then realizes that he is robbing the Treasury and thus his own pocketbook.

MR. JEFFRIES: We have found a very effective method of keeping our men in line on the Safety proposition by having appointed, some years ago, a first-class man who was well liked by all the trainmen—he is an old timer himself—as a traveling trainman. He travels over some part of the road every day and criticizes unsafe practices in such a way that the men don't take any offense. That, I think, does perhaps more good than occasional meetings. I am quite sure it saves us a good deal of money.

MR. HEMMING: I would like to hear from others here on experiences with traveling trainmen or safety engineers. I haven't attempted that myself, but have given it some thought as to its practicality.

MR. G. G. HELLMUTT (Chicago, North Shore & Milwaukee Railroad, Chicago, Ill.): My road since 1916 has been under the supervision of the Bureau of Safety, which sends a man, experienced in safety work, to all our meetings. We have shop meetings, electrical meetings, and trainmen's meetings and we get all the men. We have day sessions and night sessions for the trainmen. One of the greatest difficulties in getting the men in is the fact that we bring them in on their own time mostly. We

are able to do that by putting it up to the head of each department to bring his men in and he, in turn, puts it up to the foreman. Having gotten a particular meeting going, we let the men introduce their own topics as far as they wish. The meetings never lack life.

By bringing the meetings down to individual groups we can keep our fingers on the men who are interested in the welfare of the road. We did have for some time, and doubtless will have again, general meetings. We would rent a big dining room at a good hotel and our president would attend the meetings. We would bring all the men in who could come and have a good dinner, smokes, entertainment and Safety talks. That created a great deal of good will. The speed of our cars has been increased very materially, and speed is a big factor in accidents. Yet we have reduced accidents, I can safely say, between fifty and seventy-five per cent. That shows what can be done. We have been without a serious collision since 1917.

Under the receivership we passed through many communities having heavy automobile traffic and no gates. All our crossings were grade crossings and we used to have many auto accidents. This year we have not had a single serious auto accident, partly due to the installation of gates and partly to the carefulness that the safety campaign has brought about among the men. I am strong for gates, first as a means of avoiding accidents and, secondly and largely, a means of cultivating good will among the towns through which the road passes.

HOW TO ATTRACT ROAD MEN TO SAFETY MEETINGS

MR. HOMER J. HODSON (Safety and Fire Inspector, East St. Louis Ry. Co., East St. Louis, Ill.): A gentleman here asked a question that has never been answered and I am very much interested in it: How to attract employees to the safety meeting, especially, the road men. I find it much easier to get the shopmen together than the platform men. You can get a vaudeville act or two—I am trying it now—at the noon hour. By this means it is easy enough to get the workmen together and then bring in about ten minutes of safety work. I am also organizing a glee club in the office force and once a month to sing for the men in the shops. That gives us a chance to get them together and to get in just a few minutes' work on safety.

Another thing that proved successful was a general entertainment by the office force of the Alton District for the shop and platform employees and their families. This brought the two organizations together. Mr. Sawyer, our President, dropped in. It was such a wonderful meeting the workmen are calling for others like it. Within the last six months I have shaken hands with every man on the job. I go out and call him by name.

I would like to ask Mr. Jeffries what his idea of a safety committee is. How do you pick your committees? Do you have a committee in each shop, on each division, or a general committee?

MR. JEFFRIES: We have no regular safety organization. We simply get together informally whenever we can.

MR. HODSON: We have a regular safety organization. Our men elect their own secretary and appoint their own officials from each of their smaller safety organizations. We get out bulletins to our trainmen through the Department of Transportation when we want them to come in to safety meetings, and we get out notices through the master mechanics to our shopmen.

LAURA M. ROADIFER (Philadelphia Rapid Transit Co., Philadelphia, Pa.): We have recently tried motion pictures to arouse the interest of the men at our barns and it proved most successful. I produced a small amateur motion picture reel on safety. The response was so great that we have now installed a permanent motion picture equipment and at various times invite the men from other barns to these entertainments. I suggested that they produce their own motion pictures on Safety and a remarkable number of responses have come in.

MR. C. L. TURNER (H. L. Doherty & Co., 60 Wall St., New York City): I would like to ask any of the members present if they have had any experience with paying men for the time which they spend at the safety meetings. We pay our men during their time in the instruction school and it seems to me that this safety game is largely one of instruction to the men for their benefit and for our benefit.

MR. SAMUEL H. REID (Bureau of Safety, Chicago, Ill.): We have had no extensive experience in paying men for the time spent at safety meetings, but our experience has not yet led us to believe that any hard and fast rule can be made along that line. I think that is to be determined largely by local conditions. In several places we found it almost impossible to get the men together on their own time and in such places the meetings were held on the company's time and the company's expense.

A THOROUGHLY ORGANIZED SAFETY DEPARTMENT

I want to say a word further about this organization that one of the members just spoke of. I think the Chicago, North Shore and Milwaukee Railroad has the most thoroughly organized safety department that I know anything about. There are four general departments: The Transportation, the Mechanical, the Maintenance of Way, and the Electrical. On that property there are approximately six hundred employees and those are all organized in the Safety Leagues according to their departments.

In the Transportation Department there are five separate Leagues, each League having its own officers who are elected for one year. All meetings of the Transportation Department are held on the men's time and they are not paid for it.

The Mechanical Department meetings are held usually at the noon hour. Some are held in the evening, but those are held partly on the company's time and partly on the time of the men.

The Electrical Department is divided into two Leagues. They meet once a month in the evening and the men are not paid for the time they spend at the safety meetings. This has been tried out for more than three years and we have had very little trouble in keeping up the

interest among the men. I think the attendance at such meetings depends largely upon the man in immediate charge of the department.

In order to make the men feel that they had some real part in it, they were invited to make suggestions. It was realized from the beginning that the workmen knew more about the conditions and causes of accidents than anybody else. Sometimes their suggestions were passed upon in a formal way and occasionally a recommendation submitted by a member would be voted down. If it was adopted by the Safety League, it then went to the Central Safety Committee, which consists of the nineteen Department heads. The details of the work of that Committee are delegated to an Executive Committee of four members. The man who makes a recommendation is informed as to why it was turned down and, therefore, doesn't feel badly about it. We have found that method very successful.

We have received 1,786 recommendations from the men and it is safe to say that 1,100 of these have been carried out. Occasionally we have a moving picture but it is not made the main thing. The thing that is emphasized most is safety. The moving pictures, cigars, and things of that sort are considered a side issue. Occasionally, we have a meeting of the men and their families. That has proven to be a good thing.

The Central Safety Committee has a dinner occasionally at which the officers of the Safety Leagues are brought in contact with the higher officials of the Company and are made to appreciate the dignity and the importance of the safety work.

MR. PHILLIPS: Mr. Chairman, I think Mr. Hodson struck the keynote of the whole situation when he said that in the last six months he was shaking hands with every man on the job. I think that is the foundation of all success in any movement which involves the men or the employees of the departments of the company. He also made some remark about the success of some of the meetings for which the employees were largely responsible. In other words, they were the moving factor in the meeting. No superintendent or manager, nor a group of superintendents or managers, can force workmen to come to the meetings. You might force them with a police department but it would do you no good when you got them there, so why have the meeting. You must get the support and the interest of the men first.

We had an experience of that kind shortly before the war. We thought it would be a good thing to have a picnic in the mechanical department of the railway. After long pleading with officials of the company, I secured enough money to pay all the expenses of the picnic and it was the poorest picnic that I ever attended. The next year the boys had a picnic and it was their picnic; they paid all of the expenses. There were 4,000 people there.

I might offer some encouragement to the young lady from Philadelphia with respect to the display of moving pictures. Our company has five reels of accidents. As a matter of fact, all of the accidents were fakes but they illustrated all the kinds and characters of accidents that we have ever experienced in all their various phases. You would be surprised at the interest that was created among the workmen although the

pictures were not taken for that purpose. We took them to educate the public and we had better results in educating our own employees than we did the public.

CHANGE THE PROGRAM

CHAIRMAN ADAMS: I believe that in order to keep up interest among the employees we should continually change the program. We can't follow a set plan from year to year or even from month to month now. By having little meetings like this, where we find out what the other fellow is doing, we are enabled to go back to our plants with new ideas and new inspiration. That is one of the greatest benefits of the National Safety Council's annual congress. I attended a meeting of the Chicago, Milwaukee, North Shore Railroad and their president was there and made a heart-to-heart talk to those boys. I don't think he exceeded five minutes but he gave them to understand that he, the directors and the stockholders of that company were with the men for the prevention of accidents and the saving of their lives and their limbs, as well as the friends of the claim department of the company.

I believe that one of the first requisites of successful safety work is that our presidents and directors must have the safety thought in their own minds. It is up to some of us underlings to get to those men and teach them the principles and full meaning of safety. The National Safety Headquarters in Chicago has a large number of stereopticon slides, movie films and even phonograph records, on accident prevention. What they have in the National Headquarters are yours and mine and I believe that if you people who need films or slides, will get in touch with the general office they will be glad to act as an exchange for you. You can get the other fellow's films and he may want your films. The National Safety Council is rendering such service daily. I want to call your attention right here to the part that we, as railway men, should take in the Public Safety Section. We traction people are the ones who naturally benefit most financially from the prevention of street and home accidents. I understand that about seventy or eighty per cent of the accidents throughout the country are home and street accidents.

Thus far, America has not done very much towards educating the public along the prevention of home and street accidents but this Congress is going to put Public Safety on the map. We will now hear Mr. C. P. Proctor.

WHY DOES NOT EVERY ELECTRIC RAILWAY HAVE A SAFETY ORGANIZATION?

C. B. PROCTOR, CLAIM AGENT, MEMPHIS STREET RAILWAY, MEMPHIS, TENN.

It seems strange that it should be thought necessary at this time to discuss the above subject, because it is remarkable that any electric railway should now be without a safety organization. The more thought we give to the value of such an organization, the greater difficulty in understanding why one is not maintained by every electric railway.

To my mind there can be but one fundamental reason for such failure

and that arises from a failure to understand its purposes. In view of this fact, it is wise to inquire what a safety organization is and, of equal importance, what it is not.

THE IDEAL SAFETY ORGANIZATION

The ideal safety organization is composed of a select body of men representing every department of the railway; men of intelligence; men whose ambition it is to render to the patrons of their railway, safe and courteous service; men who do their utmost by example and influence to develop in themselves and associates a high state of efficiency; men who practice the Golden Rule, and endeavor to persuade their fellow workmen to do likewise; men who teach safety by precept and example, first, last and all the time; men who are loyal to their country, their fellow employees and their Company; men who so act because it is right and are actuated by the desire to bring happiness instead of sorrow, to prevent, instead of cause, pain and suffering; at the same time realizing that such conduct redounds to the pecuniary benefit of themselves and their company.

The safety organization is most emphatically not a collection of spies. It tries to down no one, but to elevate all. It wants to get no man's job, but aims to help him keep it and improve both the man and the job. It purposes to interfere with no one's rightful prerogatives, but hopes to better the service by pertinent suggestion. It intends in no way to interfere with the administration of discipline; nor is it to be used as a disciplinary measure. It tries to accomplish nothing through compulsion, but endeavors to get results from education and appeal to the higher principles that are implanted in all. In it there is no room for personal malice, no place for the backbiter or the disorganizer. Its purpose is not to disorganize or breed strife, but to unite and promote harmony. The successful safety organization must have the hearty support of both the management and the organized employees.

The foregoing briefly outlines the ground plan of a hundred per cent efficient safety organization. It is admitted that we rarely reach the hundred per cent mark, but it has been proven beyond cavil that with the assistance of a live safety organization, accidents with their attendant loss in human life, in pain and suffering and in cold dollars and cents, can be reduced fully fifty per cent.

MISCONCEPTION OF USES AND PURPOSES OF THE SAFETY ORGANIZATION

When we consider what the electric railways are facing today it seems incredible that the management or organized employees of any electric railway should fail to avail themselves of such a valuable adjunct. Such failure can only come from a complete misconception of the uses and purposes of the safety organization on the part of either the management, the employees, or both. It is, I believe, fear of its misuse that prevents the universal adoption of the safety organization.

If a personal reference may be pardoned, I had the pleasure of serving as chairman of a safety organization from January, 1913, to December, 1918, at which time circumstances beyond our control made it necessary

to suspend, for a time, its operation. We are now working out the details of a reorganization and expect to have them completed in the near future.

From experience we have learned what can be accomplished with the aid of the safety organization. It is not a panacea. As before stated, it in no way interferes with the administration of discipline, nor does it operate to any man's hurt, but it does provide a medium for the getting together of officials and employees on a friendly basis. It does promote harmony and co-operation and it certainly aids materially in reducing to the minimum risks of operation and cost of maintenance.

I would respectfully suggest to those, if there are any such, who are opposed to the safety organization, that they study the question carefully and inform themselves fully as to its proper function. If this is done opposition will be supplanted by enthusiastic support.

CHAIRMAN ADAMS: The subject is now open for discussion.

DISCUSSION

MR. HEMMING: I don't think it would be amiss at this time, for me, as Chairman of this Program Committee, to knit together the purpose of these three subjects as presented this morning. They might be summed up in this manner: The first subject, "The Human Factor in Safe Operation and Maintenance of Rolling Stock."

Having recently held the position of superintendent of motive power, having a large property operating, both city and interurban, and being active in the safety work, I saw the likelihood of failures in the Mechanical Department. Likewise, through that safety organization did I see the co-operation between the Transportation and the Mechanical Departments. From that we pass on to, "Why Does Not Every Electric Railway Have a Safety Organization?"

I communicated with electric railway companies affiliated with the National Safety Council and endeavored to interest them in this safety movement in order that we might make this section one of the biggest sections in the National Safety Council. I received replies from various companies to the effect that they could not get the Mechanical Department and the Transportation Department together. There was a friction that engendered enmity between the two departments in these companies and they finally concluded to disband their safety organization. To me it appeared that there was something wrong up at the top.

As Mr. Hodson and Mr. Phillips said, get right down under the heart of the individual and say, "How are you today, Tom, Dick, and Harry." Stick your hand out and ask about their families and then switch the subject over and say, "Well, what are you doing for safety today?" Have a little heart-to-heart talk with a man along that line and he will open his heart and tell you some of the difficulties—the difficulties you want to find.

Men, in analyzing the thing from time to time, I have found one obstacle and that was the fact that we were trying to cure all of the ills by mechanical devices. Mechanical devices are no better than the

human factors behind them. It is the human factor we have to deal with and if that fails, your mechanical devices fail. We might take as an object lesson the block signal down the line, conducted ever so scientifically, operating on one hundred proper tests ever so successfully, yet something happens and it gets out of order. The man who was in charge of that equipment failed to inspect properly or to repair it and the device throws the wrong signal. Thus we have the failure of the human factor. Mechanical devices will, in many cases, prevent accidents, but as I said before, they are not a curative.

The first thing you have to do before you can accomplish results is to sweep the trash from in front of your own door.

We tell the men that if anything on their cars or along the railway is defective mechanically, or otherwise unsafe, we want them to report it. We started on that basis and it proved very successful. When the first accident happened, the man, when questioned as to how the accident occurred, replied, "Why, the brakes failed." I said, "Did you turn in a defect card?"

"No. I told the fellow out at the shop it was bad," he said.

"Whom did you tell?"

"Well, I told some fellow out there."

Now right there, men, is where the two departments began to clash. The trainman said he reported the defect and the shopman said he didn't. We have one man's word against the other.

A defect report should have been made. The motorman's excuse of brake failure didn't go; it will not go in court nor before the Railroad Commission. It was worn out years ago.

We now require the filling out of defect cards in triplicate. One comes to my office, one to the Superintendent of Motive Power, and the other remains on the car until it is shopped and no matter how many times you change trainmen on that car, the defect cards are made out. If we expect to master the subject at hand, it behooves every one of us to get busy with our neighboring properties and our friends who are in the railroad business to become members of this association so that we can do things on a bigger scale and master this traffic situation; otherwise, I don't see how we are going to do it.

COMPELLED TO VIOLATE THE LAW TO MAINTAIN SATISFACTORY SCHEDULE

In conclusion I want to say that we have in this Congress another section known as the Public Safety Section. These two sections have so much in common in the prevention of accidents that we should have a joint session. Through the medium of the two organizations we should be able to bring about legislation that will materially help both the Public Safety and the Electric Railway Sections. There is one thing I want to call your attention to in that respect, and that is this: All over the country we have ordinances saying that you shall not operate your car over eight miles an hour and yet if you were to reduce your maximum speed to eight miles an hour, you would have the greatest howl that ever came from your citizens. In order to maintain a schedule satisfactory to the public, we are compelled to violate the law every

second and to operate probably in the neighborhood of twenty to thirty miles an hour maximum. If we are compelled to give the public fast service, then we should be permitted to operate a schedule without violating the law.

MR. JOHN H. MALLON (Safety Engineer, Chicago, Ill.); It seems to me that coöperation in safety work on an electric railway should come from the top; that is, the example should be set by the heads of departments. Some years ago I worked under a general manager who had been with a steam railroad and his idea of railroading was to keep the various departments fighting all the time so that they couldn't get together to frame up something. He was working, we now realize, against himself. The real big success of our organization is due to the character of our officials. Some three or four years ago our President, Mr. Budd, called in the heads of the departments and instructed them that in disciplining the men of whom they were in charge, the greatest patience was to be shown. "Don't suspend a man on slight provocation; don't impose a hardship upon his family," is our rule. We have gotten wonderful results. I met our president last Monday when he came back from his vacation. He was in a hurry but when he saw me he let the elevator go, came back and said, "Hello, Jack, how are you feeling?" That is the spirit that is all through our organization. You can't set yourself on a pinnacle because you are a step above the other fellow. That day has gone. When the boys began to return from the war, the president of our company said to me, "I want to see any of those boys who come back. I want to say hello and to shake hands with them."

He would say to them, "How do you feel? Do you need any money? If you do, Jack will fix you up."

If they needed any money I would give them advance pay until they had an opportunity to get settled again.

I think the most effective way of getting real safety results is for the man who observes a violation of safety rules to tell the man at the time that he has done wrong. Strange to say, few of us have the nerve to do it. Instead, we go to the office and write a letter to some one else to tell him about it.

CHAIRMAN ADAMS: Now, Gentlemen, you know that we have been told by the medical men that we ought always to leave the table just a little bit hungry. Now we have a lot of good things left to eat in this Electric Railway Section and we could continue at this meeting with a great deal of benefit to all of us, but the time has come that we must stop. We will now take a recess until 9:30 tomorrow morning.

Adjournment—11:45 A. M.

FRIDAY MORNING SESSION

THE meeting was called to order at 9:40 A. M., Chairman H. B. Adams, presiding.

CHAIRMAN ADAMS: Mr. McDougall will present the report of the Nominating Committee.

proper standards to be recommended; or which will lead to the appointment of some existing organization for the same purpose. One such organization, and the one which is probably the most logical of those which could be considered at the present time for this work, is the American Electric Railway Association, or possibly a committee appointed by and working under the auspices of this association. I believe that the most advisable means would be the forming of a committee with, if possible, the recognition and support of the Federal Government for the express purpose of nationalizing and standardizing accident prevention. It may develop that this committee would work in connection with the U. S. Bureau of Standards, as was the case in the preparation of the National Electric Safety Code.

The methods of establishing the proper standards of accident prevention, and of nationalizing these standards when accepted, is the problem which is probably the most difficult of those connected with this entire question. You might say this matter is disposed of with the appointment of the commission or organization to carry on this work—but was it? Are we to appoint a body to carry on this work and then sit back with the feeling that the matter is now out of our hands? I think not. The fact that this is the most important step toward our ultimate goal should spur us on to an active interest and part in the outlining or suggesting of plans for the guidance of this newly formed commission, or for the carrying out of a new work of a present existing organization.

A THOROUGH INVESTIGATION THE FIRST DUTY

The first duty of this commission would be to conduct a thorough investigation of the best and most practical ideas and methods which are now in practice, and which have been proven to be of value in reducing accidents. Let this investigation include an exhaustive survey of modern accident prevention methods with a view to gleaning from the whole the best and most efficient means which are now employed. The action taken from this point on will be governed largely by the results of this investigation. It will undoubtedly develop that the need for education which is not now fully appreciated will be emphasized. I can truthfully say, without fear of contradiction, that the city and interurban lines in Indiana and Kentucky with which I am connected were, so far as I know, the first electric railways to carry on safety work in the thoroughly organized manner that has in the last ten years been so productive of good results and extended to so many public utility companies. This plan lays emphasis upon the educational feature of safety work, and includes in proper groups every employee of the company.

My opinion is that the branch of the work which is most needed by the majority of companies is that which has to do with proper organization, instruction, and education of employees, as the specifications for equipment, station installation, etc., is at present standardized to a great extent. The support or cooperation of the companies to be affected by such a plan will in a large measure determine its success. The most capable commission obtainable may draft the most efficient, practical, and modern

methods of accident prevention, yet unless these methods are endorsed and applied by the companies for whose benefit they are intended the value and results of the entire undertaking will be negligible. The necessary steps should be taken by this commission to insure the proper cooperation of the utilities concerned.

Let us suppose that the need for nationalizing and standardizing accident prevention has been fully appreciated; that the proper organization has been appointed, or a competent commission established for the purpose of conducting the necessary investigation and setting of standards; that this body has completed its work in an efficient and satisfactory manner; that the support of the companies concerned has been assured: What is now to be expected as a result of this progress, and just what are the benefits which may be looked for? Any advance statement as to the results to be attained by the electric railway business as a whole must necessarily be speculative in character. Those who have had experience with accident-prevention work on individual properties know that the results are very definite and encouraging. One of the traction companies with which I am connected, and which operates city and interur-

REDUCTION IN NUMBER AND COST OF ACCIDENTS

ban lines, reduced their accidents 75 per cent, and their accident costs 80 per cent since the safety work was first organized. Another interurban electric railway in Illinois, conducting their safety work upon the same plan, and under the direction of the same Bureau, reduced their accident costs \$57,000, or 62 per cent in one year. The reduction in number and cost of accidents occurring in connection with the operation of the street railways of the country under a standardized plan of accident prevention would be a certainty. The amount of this reduction cannot be estimated with any degree of accuracy.

There is one class of electric railway company which would derive a special benefit from this plan. This class includes those smaller lines that feel (and many of them are justified in the feeling) that they cannot afford to employ a safety engineer. These companies would have the opportunity of adopting accepted methods which have been tried out and found to be practical and effective, and would have uniform outline of the safety plans which could be followed and carried out by their present organization.

MR. HARRY REID: I had intended to follow this paper by giving you a brief outline of just how safety work is carried on on our property but inasmuch as Mr. Scott, Mr. Mallon, and Mr. Samuel H. Reid, and others connected with the Bureau of Safety, of Chicago, and men who are working under that Bureau gave such a detailed description of how the work was carried on, yesterday, I hardly think it necessary to take your time.

We have a safety manager on our properties for Kentucky and Indiana, Mr. James Harmon, who is present at this meeting. All the employees are organized in separate groups and each group has its president, vice-president, secretary, and treasurer.

CHAIRMAN ADAMS: The subject is now open for discussion.

DISCUSSION

MR. HEMMING: The paper is very comprehensive, yet I believe there is room for discussion that will bring out many points on this thing and lay emphasis on the necessity of nationalizing and standardizing. That can be done, to my mind, in a very effective manner through the various electric railway associations scattered throughout the United States.

There is the New England Railway, the Illinois Railway, the Central Electric Railway, and many other kindred organizations that, in so far as I know, do not have any safety organizations.

I don't know, as I said yesterday, of any organization that should give more acute attention to safety work than the electric railway properties.

I would like to hear some discussion on this from the other corners of the globe. I believe every one of these papers ought to be entered into very thoroughly.

MR. B. D. HASKINS (Claim Agent, Chattanooga Railway & Light Co., Chattanooga, Tenn.): I think that we have missed, in this discussion, one point that is very vital, that is, the educational phase of conducting the safety work. We all agree that it is a good thing and that every company ought to engage in it, but no one has gone into the details, and it is the details that I think we want. A gentleman, yesterday, Mr. Reid I believe it was, touched lightly on the details of his organization, and the chairman of our program committee intimated that his property also had a fixed program, but no one has given us any light on what they think the best procedure after the safety organization has been established.

I want to tell you of my way of operating and then I would like to hear others here give their methods. We begin with the highest officials of our company, the general manager, the assistant general manager, the superintendent, the assistant superintendent, the inspectors, and then we have the committeemen from all of the different branches of the property. I, as a Claim Agent, am permanent Chairman. We change our committeemen every six months. We find that in the course of six months we have inspired them with the work sufficiently to turn them loose and take up some one else.

We call for suggestions, for instance, and when a man makes a suggestion it is numbered. The name of the man making the suggestion is carried in the minutes and when the suggestion is disposed of, it is shown in the minutes so that its author can keep track of what has become of his ideas. We have reduced our accidents. The cost in the Claim Department last year was \$108,000 and this year \$50,600.

MR. SCOTT: It is difficult to give the details of the safety education of the trainmen so as to cover all conditions, but I will pick out a medium-sized road and explain as best I can what is done there to answer your question.

Instead of having intermediate committees, as you seem to have, we

have a large central committee on safety, composed of the various operating heads and the chairmanship is delegated to the highest official available so as to give that committee a standing. In the case I have in mind, the assistant to the president is chairman of the safety committee. That committee meets after the meetings of trainmen so that it can pass upon anything that came up in the trainmen's meeting.

The men are organized in groups with reference to the hours of employment and with reference to their duties. The shopmen are organized separately from the trainmen. The officers for the employees' groups are changed every year, but the members of the Central Committee continue their office without interruption unless there is a change in the organization. At the employees' meetings, suggestions are received verbally. For instance, a man gets up and says, "I think it would be a good idea if we would standardize the location of the whistle signal", or something of that sort, and then the question is thoroughly discussed. If a majority of trainmen present believe that this is a good thing, that recommendation is transmitted to this Central Committee to be acted upon. If a majority is opposed to that recommendation, it goes no further than that particular meeting and that discussion. Here is an important thought. In every instance, the group is advised of any unfavorable action on any of their recommendations by the Committee and the reason is given for it. If the group makes a recommendation that requires the expenditure of a lot of money, and the committee decides that they can't afford to put it into operation at this time, they frankly say so. The recommendations that come from these groups of trainmen to the Central Committee are very carefully tabulated by a secretary and given a serial number. All recommendations that are not complied with are kept alive on a sheet and at each meeting of this Central Committee all of the back recommendations that haven't been acted on definitely are considered.

As to the education of trainmen, that is done through the group meetings. It is considered rather important that the superintendent of transportation and the trainmaster attend the group meetings. Their influence helps to maintain the interest of the employees and they are there to answer questions. We make it a point to have at these meetings, if possible, a talk upon some particular phase of the operation. We have some outside safety man come in occasionally to make a few remarks. Does that answer the question?

MR. HASKINS: That is very good. I appreciate it very much.

We have, perhaps, an advantage over a larger property in that we have between 500 and 600 employees. We don't have a Central Committee because I insist on the general manager and all the other officials being right there in the meeting to thrash these things out. We have two committee meetings a month, lasting one hour only. We have a meeting once a month for all the employees and at that meeting there is a general discussion on anything that any one wants to talk about. Our effort is to educate the men and have them educate us.

CHAIRMAN ADAMS: I see by our slips of attendance that we have here a Mr. Wilson, of the Northern Ohio Traction & Light Company, of

Massillon, Ohio, with the title of motorman and conductor instructor. I would like to have Mr. Wilson give us a few ideas along this line.

MR. HUGH WILSON (Northern Ohio Traction & Light Co., Massillon, Ohio): The position that I now hold is a new one entirely to me and I came here to learn. Perhaps later on I may have more to say.

CHAIRMAN ADAMS: We will be glad to hear from you, Mr. Wilson, and we wish you success in your work along that line.

MR. HARRY REID: May I suggest appointment of a Committee to take up with the several electrical railway associations this matter of standardizing accident prevention as suggested by Mr. Hemming and then if the committee from this section of the Council is successful in getting the electric railway associations interested in this work of standardizing, that they might go to the American Electric Railway Association and get a committee appointed there. Then perhaps in the course of a couple of years we will get this national movement on foot. I would like to make such a motion.

MR. SCOTT: I want to second that motion.

AMERICAN ELECTRIC RAILWAY ASSOCIATION

CHAIRMAN ADAMS: I know that the headquarters of the National Safety Council in Chicago are making every effort to bring the American Electric Railway Association into connection with the Electric Railway Section of the National Safety Council and the American Electric Railway Association has asked for recognition by this section. Of course that association should get in touch with this section and I believe this kind of a suggestion coming from us will help to bring about an affiliation for the good of accident prevention between the National Safety Council and the Electric Railway Association and if you will put the gist of your motion to me in a few words, I will be glad to entertain it.

MR. REID: The motion is that this section of the National Safety Council appoint a Committee to confer with the several district electric railway associations affiliated with the American Railway Association with the view of getting their interest into a nationalization and standardization of accident prevention as applied to the electric railway industry.

MR. McDUGALL: As I understand Mr. Reid's motion it is that the committee be appointed from the various district or state associations. Am I right, Mr. Reid?

MR. REID: I think, Mr. McDougall, that if the Chair saw fit that it might be well to select on this Committee men from the several associations. For instance, from the Central Electric Railway Association, I would suggest Mr. Hemming. There may be a man in the New England Association who is affiliated with this body and these district associations are all more or less affiliated with the American Association. If the local association, for instance, the Central Electric Railway Association would take enough interest in this thing to get a standard and then this Committee would go to the American Electric Railway Association with the backing of all these local associations, I believe that we would get started in the right direction.

MR. McDUGALL: If I may be permitted, before that motion is put, I would make the suggestion that the committee be appointed at this time.

MR. REID: I don't think it can be done. I don't think we can go to the American Electric Railway Association and get enough interest there to have them pass it back down the line.

MR. McDUGALL: I might say this, Mr. Reid, that the Electric Railway Association will meet next week at Atlantic City and this is one of the things that is to come up. I think I can promise you that a committee will be appointed sometime during the next week and it would be a good thing if this association could appoint a committee to meet with that committee sometime during the coming year and then be ready to report at the next year's congress.

MR. SCOTT: I have represented Mr. Budd on accident prevention committees on several occasions and I believe that Mr. Reid's idea in bringing this to their attention would be a very strong force to get what we want.

MR. HEMMING: I have had quite a bit of experience in association work and particularly with those mentioned, the Central Electric and the American. I have had considerable to do with engineering some of these problems through and I agree absolutely with Mr. Reid that the place for this to start is here, then through the avenues of the other associations and then up to the American. It is like trying to build a roof on the house before you build the foundation, and I know that you are going to get quicker results by taking it from here on up than you will by attempting to take it through the American Association on down.

Now I don't say this to criticize either Association but I know that it will work quicker the other way because the American Association is so large in its scope that it takes anywhere from two to three years to get a problem through.

CHAIRMAN ADAMS: Gentlemen, you all understand the motion and the object of it. I will put that motion.

The motion as stated by Mr. Reid was seconded and carried.

CHAIRMAN ADAMS: The appointment of that committee, I believe, ought to rest with the incoming chairman and he can have between now and 11:45 to decide upon the members for that committee.

Next we have our dear friend, Mr. McDougall, of Rochester, N. Y. He has something to tell us about "Electric Railway Hazards—Causes, Effects and Remedies."

ELECTRIC RAILWAY HAZARDS — CAUSES, EFFECTS AND REMEDIES

R. E. McDUGALL, CLAIM AGENT, NEW YORK STATE RAILWAYS,
ROCHESTER, N. Y.

There is no business where there are so many possibilities for accidents as that of running an electric railway, nor any business where there may be so many different classes of injuries, both to employees and the public. Criss-crossing cities, towns, and country as traction

lines do, with the possibility of injury not only to employees and passengers but to pedestrians and the general public as well, it is not surprising that traction men are interested in accident prevention—and not only interested to the extent of spending their money and time in this work, but are firm believers in the good that can be accomplished by education along safety lines.

Under the head of "Hazards" on electric railways we have three main classes of accidents, viz.:

1. Accidents to employees
2. Accidents to passengers
3. Accidents to pedestrians and others using streets and highways

ACCIDENTS TO EMPLOYEES—CAUSES, EFFECTS, AND REMEDIES

Electric railway employees may be injured in many ways, such as: wagons; falls in our houses and repair shops; being run over by equipment; blood poisoning; being struck by falling objects; collisions between cars and vehicles; eye injuries from flying particles; falls from cars, falls into excavations, etc.

Investigation of accidents similar to above show a part of them are caused by defective equipment or conditions over which the employee has no control, but the most of them are chargeable either to carelessness on the part of the injured employee, his co-employee, or foreman, or the failure to make and enforce safety rules.

An employee's accident record quickly demonstrates who is the careless and chance-taking man and this record will be of value in helping to make employees more careful. An employee known to be reckless or willing to take chances in regard to his own safety or that of a co-worker, is dangerous on any property. In the selection of employees some thought should be given to this phase of a man's character.

Very often failure by the injured employee or his foreman to give proper care and attention to slight injuries results seriously and is followed by infection and blood poisoning, and may be the cause of losing a limb and often a life. The old saw, "A stitch in time saves nine" certainly holds good in this connection. A small first-aid kit with disinfectants and bandages should be procured and kept where easily accessible, and the foreman and men should be impressed with the necessity for giving minor injuries attention.

Sometimes it is the small things that lead to the most serious accidents. One of the most distressing cases of this kind that has come under my observation recently, was due to a car on the road with a faulty trolley retriever which could have been repaired in five minutes time. A line tower truck was standing near where the car in question had to pass; two men were on the tower and the wind swung the trolley rope so that it caught the top of the tower, throwing the men to the pavement, badly injuring both and probably permanently injuring one; as a result, two men were laid up for months, one perhaps for life, with a cost to the company of several thousand dollars. I might recite a number of instances of this kind, but if you will give some attention to

a study of the conditions which lead up to most of this kind of accidents, you will find it is the little things and careless acts that pave the way to bad accidents.

ACCIDENTS TO PASSENGERS—CAUSE, EFFECTS, AND REMEDIES

Traction managers and accident adjusters have found that the public believes it is the easiest thing possible to receive a serious injury on a street car; negligence lawyers are also active in propagating this idea. As a matter of fact, when you consider the number of passengers carried yearly by traction companies, with the possibility for accidents, the percentage killed or seriously injured is not nearly so high as in industrial plants.

There are of course, a great many ways by which passengers can be and are injured. Investigation shows the three most prominent causes to be:

- (a) Improper operation of car by employees
- (b) Run down condition of equipment, track, etc.
- (c) Carelessness on the part of injured person
- (a) Improper operation of car on part of employee often causes:
 - Collisions
 - Derailments
 - Premature starting, thereby throwing passengers in cars, or while boarding and alighting
 - Collisions with other vehicles at street intersections
 - Striking passengers who have alighted from cars going in opposite directions, etc.

We are all familiar with this type of operation and its results. The human element is the big factor in causing and preventing accidents. Motormen and conductors are as willing as the rest of us to do their share and the big thing is to secure their cooperation. Here, in particular, the record of trainmen is of value. If it is found that a trainman is making an undesirable record for himself the use of an itemized record in pointing out the number of accidents he has been responsible for and what they are costing the company in dollars and cents, will be of great assistance in educating that particular employee. Personal education of each employee along accident prevention lines will prove a big investment for the traction company that is willing to spend the money to do it.

It can afford high class men to do this work properly, and find at the end of a number of years that its accidents have decreased in number and have cost less. This will be the only comparison of any value that can be made, for the reason that if an accident has not happened you cannot satisfy anyone that you have prevented it.

- (b) A high standard of maintenance with reference to equipment, track, loading platforms and other portions of the property that the public comes in contact with has much to do with preventing accidents. You do not have to be told that when your tracks are not in good shape you are going to have more derailments and collisions with cars; that

when equipment does not work properly you are going to throw more people daily in and off the cars. Money spent on upkeep means less accidents and reduced expenditures.

Holes and depressions in the pavement or at points where cars stop to take on and off passengers are a very common cause of accidents, often serious. Cooperation between the municipality and the company will prevent many accidents of this nature and at a comparatively small cost. A close watch of the conditions will save both much more money than the cost of proper upkeep.

Sometimes it pays to make conditions fool-proof. As an illustration: On the property I am connected with, for some years prior to 1913 every summer we had from five to ten cases of broken arms due to passengers, when windows were up, resting their arms on the window sill and projecting between the iron bars, which were about four inches apart on some of our equipment. The breaks were caused by coming in contact with other cars in curves, trees, sides of bridges, or other vehicles. It was costing us anywhere from two to five thousand dollars a year fighting these cases in court or adjusting the injured party's claims. In 1913 and 1914 at an expense of about four thousand dollars we added enough bars and screens to the sides of the cars so that it was impossible for a passenger to get his or her arm outside the car, and we have had but one accident of the kind since.

For years all the warnings of railway operators and the many examples of injuries due to getting on and off moving cars had no effect on the public; it was not until folding steps and doors came into common use that any reduction could be made of the class of accidents known as "Boarding and Alighting." The closing door and folding step are not necessary to the transportation of passengers, but today you cannot find a manager or operator who would say they are not worth much more than they cost in the money saved his company so far as accidents are concerned.

(c) I believe I am safe in the assertion that one-half of the accidents occurring to passengers on street cars are caused by the passengers' own carelessness or contributory negligence. They will get on or off a moving car if permitted, and invariably when doing so face the wrong way. Without looking they will step from a car directly in front of a moving auto or other vehicle. They will do a thousand and one things that are risky. Many women's shoes and skirts cause nasty falls resulting in broken bones or sprains that lay them up for weeks. Tight skirts and high heels cause more women to be thrown than the operation of the car. Passengers will jump off a car, cross directly behind it, and onto the track in front of a car going in the opposite direction without looking or paying the least attention to what they are doing.

ACCIDENTS TO PEDESTRIANS AND OTHERS—CAUSE, EFFECT, AND REMEDIES

The accidents that the public (not including patrons) are involved in come within the following classifications:

- (a) Pedestrians struck by cars

- (b) Pedestrians falling into excavations, over defective track, material left in street, hit by falling poles and wires

- (c) Occupants of vehicles in collision with cars

(a) Many of the individuals struck by cars are children playing in streets and their injury is due to thoughtlessness more than anything else. They will chase a ball onto car tracks without a thought of a car; they will catch a ride on the rear of a wagon or truck and drop off in front of an approaching car; they will ride a sled or a bicycle down an incline across tracks, never giving a thought to the possibility of injury. Their elders also get hit for the same reason. They do not think, and rely on others to look out for their safety. Intoxication is quite a factor in this type of accident, particularly on interurban lines.

While the motormen at times are responsible for injuries to pedestrians, the majority of them are chargeable to the injured party. They could be avoided generally by the use of a little judgment or common sense. Some individuals will hurry to cross ahead of a car and then stop and watch it go by; they will step from the curb between two automobiles or pass behind one car directly into the side or in front of one going in the opposite direction.

(b) Most accidents under this head are caused by employees leaving materials and excavations improperly guarded and lighted. Fortunately at the present time most municipalities have ordinances requiring proper guarding and lighting, and in the event of neglect or oversight on the part of employees their attention is soon called to it by the police.

(c) The increase in the number of motor vehicles in the past few years has resulted in an enormous increase in accidents between them and electric railway cars, and a long list of killed and injured. The most serious occur at grade crossings familiar to the auto drivers and with every opportunity to see and know of the approaching car or train traveling at high speed. Early this summer in a three weeks period, fifteen people were killed in three accidents of this type, within a radius of fifty miles of Rochester. One car was being driven by a girl of seventeen who was learning to operate the machine, one was being driven by a boy of fourteen, and the third was driven by a man who could see an express train approaching him at right angles and deliberately tried to beat the train to the crossing. Notwithstanding the fact that you read of this kind of fatality in every paper you pick up, it seems to and will continue as long as high powered automobiles are permitted to be operated by irresponsible or reckless drivers. Signs, warnings or signals will not prevent these accidents occurring; the careful, prudent driver will not take such a chance.

In order to reduce the number of street accidents the main thing necessary is education—education that will teach everyone (be he employee, passenger, pedestrian or auto driver) what it is that leads to accidents and how they can be avoided; particularly education of the young child and the school boy and girl regarding the value of life

and limb, the wastefulness of unnecessary haste and neglect; education of the men and women by the passing and strict enforcement of reasonable ordinances; and education of the drunken driver and persistent chance-taker by a straight jail sentence.

CHAIRMAN ADAMS:—The paper is now open for discussion.

DISCUSSION

MR. HEMMING: I just want to say that Mr. McDougall is from Rochester where they carried on the most extensive safety campaign for six months. I believe Mr. McDougall can give us some very valuable information.

MR. MCDUGALL: I don't know that I can give you very many details except to tell you in a general way what was done in Rochester.

Rochester is a city of about 300,000 people. We are running a street car system with about 400 cars during rush hours. The National Safety Council first organized in Rochester a small Local Safety Council. I believe it was in 1914. That Safety Council was affiliated with a Safety Committee of our former Chamber of Commerce. It was made up of representatives of big industrial plants, public utilities, and some professional men. The Council specialized on industrial accident prevention until March, 1918. At that time, through the efforts of Mr. Cameron and Mr. Price, we launched a public safety campaign. A great deal of publicity was given through the newspapers. Much work was done in the schools. The policemen made a special effort on the enforcement of ordinances, particularly among automobile drivers. Dangerous corners as far as possible were cleaned up. There were some five or six sub-committees under the General Accident Prevention Committee.

The result was that our report at the end of the year (I may not be absolutely right on this) showed fatal accidents in Rochester had decreased sixteen per cent and up to July, 1919, as compared up to July, 1918, showed a further decrease of eighteen per cent over 1918. These figures were taken from the coroners' records.

As far as our street railway is concerned, our accidents in 1917 were 842 and in 1918, 685. Fatal accidents have decreased, on our street railway, about eighteen per cent.

CHAIRMAN ADAMS: Has any one else anything to say on this subject?

MR. MALLON: I don't think that real results can be obtained by a railway company in reducing accidents to passengers and pedestrians until you get the cooperation of the community through which you operate. I want to state some of my experiences along that line.

COÖPERATION OF COMMUNITY NEEDED

In Cook County, in the City of Chicago several years ago, there was inaugurated a safety organization known as the County and City Safety Organization. It was fathered by Coroner Peter Hoffman for a considerable time, in fact, up until the present. It was known somewhat as a political organization. However, beneficial results were obtained. On a

great many accidents, such as we in the railroad industry are familiar with, the coroner would select members of this organization to act as jurors, and I presume I have acted as a juror for fifty or more inquests. Recommendations were made by the jurors, and strange to say they were never acted upon; that was as far as they ever got and I think the reason why they never got any further was due to the fact that there wasn't enough pressure behind the organization. In other words, it was not big enough.

I was at the inquest in a case where a motorman of the surface lines of Chicago ran into an ice cream wagon. One of the men on the wagon who was riding on the rear end was knocked off and killed. On that jury there was a Bolshevik, as far as street car operation is concerned, and he wanted to hang the motorman. He was one of many who felt that the corporation had lots of money and all the jurors should do was hold the company entirely responsible so that the widow would have this means of getting money out of the company in a law suit.

Another case that came to my attention was that of a slight, frail lady who was driving an electric car along Forty-Seventh street. When I saw the woman at the inquest I felt she ought to be in a hospital. This car got away from her, she ran over a six inch curb, struck a baby carriage that was standing outside of a grocery store with a baby in it, and killed the baby.

We made the recommendation at that time that no person should be permitted to drive a car without first taking an examination the same as any chauffeur. Nothing was heard of the recommendation.

I understand that there is a movement on foot in Chicago to get the support of the Association of Commerce behind this organization of which we are members. Now a body of men of that kind backing up an institution like ours can accomplish a great deal. I think that is the only logical solution, to get the biggest men, or the biggest organization in the municipality to cooperate with you.

CHAIRMAN ADAMS: It is time to close the discussion on this paper. Next we have the subject "Safety Before and After the War."

We all know what we went through during the war, and in these days of reconstruction the electric railways have an important duty to perform. We will now listen to a paper by Mr. Schneider, of Cleveland.

SAFETY BEFORE AND AFTER THE WAR

E. F. SCHNEIDER, GENERAL MANAGER, CLEVELAND, SOUTHWESTERN & COLUMBUS RAILWAY COMPANY, CLEVELAND, OHIO

It was with the greatest reluctance that I finally consented to write a paper upon the above, and I have found the subject has become a more intricate one for me to discuss than I expected or anticipated, on account of conditions having changed so materially; it being impossible to arrive at a satisfactory conclusion.

After the armistice was signed it was very natural indeed to look for-

ward to a rapid return to more nearly normal conditions in the labor world. We certainly anticipated a lowering of prices on food stuffs and on necessities, and after the smoke had cleared away, after the strife and struggle were over, after our boys began to come home, and by reason of our wonderful achievements, a general feeling of complacency and satisfaction was with good reason confidently hoped for and looked forward to—but alas, none of these things came to pass. Labor is scarce, much more arrogant in its demands, and a great deal harder to handle. Contracts with labor unions have been broken with impunity, invariably, I believe, against the advice and orders of their national officers. Prices of food stuffs and necessities have not been lessened, but have really advanced. The general feeling of unrest has been greatly intensified. There seems to be an almost universal sentiment, regardless of consequences, which either openly avows or covertly insinuates a “I am going to get mine while the getting is good” policy.

I find it impossible, therefore, to make the analysis which, upon the acceptance of the invitation to speak upon the subject, I expected to make. I will, however, confine myself to the conditions as I have found them and believe them to exist.

I have gathered statistics upon this question from all over the United States and Canada in my efforts to present this subject correctly, having written two hundred and ninety letters to that number of railway companies, and received one hundred and fifteen responses.

My replies cover 17,565 miles of city and interurban electric railroads.

Statistics are usually such dry lies that I hesitate to use them. You can prove anything you want to with statistics. You know the schoolboy compared lie as an adjective, i. e., lie, damn lie, statistics.

I will, therefore, curtail the use of them as much as possible and have you assume that I am telling you the truth, even though my figures are comparatively few.

There is perhaps more to be said regarding safety before the war, and safety during the war, than there is to be said of safety after the war. As a general proposition the question of safety, so far as the application of the fundamental principles as usually understood is concerned, reached its highest state of perfection before we entered the war.

TO MAKE THINGS FOOL-PROOF

The use of well-known safety devices and appliances, the installation of block signal systems, the display of cautionary signs, the use of moving pictures—all these and other methods had a tendency to carry the propaganda of SAFETY FIRST, or the prevention of accidents, to the most successful conclusion known up to that time. The great idea has been to make things as “fool-proof” as possible; my understanding being that these methods, it is estimated, have reduced the accident account some eight per cent in our industrial world. That, of course, makes it worth while. I naturally do not wish to deprecate the use of any device which will eliminate accidents. I do, however, wish to take this opportunity to protest against the abstract proposition which we seem to be

striving for, i. e., to make things fool-proof. This is a common expression. I do not think we should have fools working for us in responsible positions, handling intricate machinery which requires safety appliances, even if apparently made fool-proof. We should not try to make automatons out of intelligent employees. We should not hire wooden men or cigar signs for skilled workers. We need men who are honest, industrious, painstaking, and careful. The best safety device known is a careful man.

Before we entered the war we did not have that strained and intense feeling which was so marked and prevalent everywhere after war was declared.

The employee who had a son who was of draft age, or one who had enlisted, was of necessity on the anxious seat all the time. The irregularity of the mails and oft-times the negligence of the soldier boy in not writing to his parents, and the waiting for reliable news, all had a tendency to distract the sensitive and over-wrought nerves of a father, who as a natural consequence, would not be in as good condition to carry on his work as he would be in normal times.

SHORTAGE OF MEN DURING THE WAR

The shortage of men on account of those entering the service of the Government, either as soldiers or marines, and on account of those employed in industries which were held essential to the winning of the war, made a vast difference in the working personnel of street and interurban railways. It also made a big difference as to the attitude of the men toward the company employing them. They realized they could get a job any time and were not slow in letting you know it. It became necessary in order to keep the lines filled, to break all former precedents and rules. The turnover was large. An applicant was not questioned closely, his recommendations were not scrutinized, the age limit was not recognized. Young men of eighteen years of age were hired as conductors. Older men, as high as fifty years of age, were installed as motormen. Coupling this disadvantage of disregarding the age limit with the inexperience of the younger man and the inability of the older man readily to adapt himself to the work, caused a condition which gave those who were responsible very grave concern. It was simply impossible to get efficiency out of either class of these men. They were willing enough, perhaps owing to the lure of higher wages than they had been able to get, but they were not dependable—the one was too young to learn, the other was too old to learn.

Those who applied and were of a proper age, were as a rule undesirable men—floaters and men who drank, perhaps periodically—at any rate there was a constant turnover, men leaving on the slightest provocation. There was no attempt to enforce anything like the ordinary and regular discipline. It was largely a matter of standing it as long as one could and then firing a few, all of which, of course, tended toward the demoralization of your forces in all branches and departments. This would seem as though the officials in charge were letting the men run the road, and I confess it came mighty near being true. As an illustration of the attitude of men regarding discipline: One of our superintendents in disci-

plining a trainman for an offense said to him, "You will have to serve ten days." He came right back saying, "Oh you go to hell", and turned in.

EMPLOYMENT OF WOMEN AS CONDUCTORS

There was a moderate amount of relief from this state of affairs, however, in a few cities, brought about by the employment of women as conductors on city lines. There was considerable comment and a great deal of discussion regarding the morality and efficiency of women who would hire out as conductors on a street car line. We who have had for years to deal with the morality of men engaged in similar service, know that morally there would be no reason why a woman would not be as much of a lady in the capacity of a street car conductor, as a man would be a gentleman under exactly the same circumstances. Personally, I confess that after watching the operation of street cars by women as conductors, and also from reports gathered by those who employed them, I am convinced that they conducted themselves as ladies at all times, and took care of their part of the business carefully, intelligently, politely, and with fewer accidents than men. Whether after years of service women conductors would have maintained their efficiency or not, I do not pretend to say, but they certainly made a good record as far as they were able to go. One street railway president asserted that the men themselves were largely to blame for women going onto the cars as conductors, inasmuch as by insisting upon stools and other so-called comforts, they had made a ladies' job of it.

After the war the widespread and pernicious doctrines of the old world, such as I. W. W., bolshevism, socialism, anarchism, and other fanatical isms which are used in order to delude the unsophisticated laboring man into the belief that the millenium is near at hand, put that almost uncontrollable and irresponsible unrest in our midst, the flame bursting forth from the smothered fire here in Cleveland on May Day, showing really the underlying feeling and sentiment which was only waiting for an opportune time to make itself felt, but which, thanks to the better element of our citizens, was so suddenly squelched and put down. This is but one example of what happened in many places.

The results of my investigation would tend to show that there was a slight improvement after the war. The combined mileage of 17,565 miles gave a total of accidents in 1916 as 153,878, in 1917 as 167,806, in 1918 as 144,554, in 6 months of 1919 as 64,108 or at the rate of 128,216 for the whole year, which would show a decrease from the figures of 1916 for the first half of 1919. Whether the whole year of 1919 would show this improvement is of course very problematical. You will also note a slight improvement in 1918 over 1917. The difference in either case is certainly not due to any improvement in the personnel of the employees.

In order to give a clearer insight into the general conditions, I have selected a few individual cases.

One road writes:

"I feel that the increase in accidents, particularly during the war period, was brought about largely by our being compelled to hire young boys and old men. In fact, since the war has closed, we are getting

things straightened out and the accident situation is improving wonderfully."

Another road writes:

"I attribute the decrease of accidents to passengers to the work of our school, where attendance is compulsory on the part of our employees, together with the operating changes indicated above. I might add that I also feel that we will make a better showing when some solution is reached which will end the labor unrest, and the company can get the cooperation of its trainmen as a body."

Another:

"We noticed no marked difference in the number of accidents occurring during the period when some of our more experienced men were in the army and had to be replaced by less experienced men."

Another:

"You will note that if the ratio for the remaining five months of 1919 holds the same as during the first seven months of 1919, the year 1919 will show the greatest number of accidents during any of the three years, due we believe to the large number of young men who have returned after service in the army and who are reckless and indifferent to such small risk as being injured by electrical cars."

Another:

"I enclose herewith another sheet marked 'B', showing for the year 1919, the labor turnover. From that you will note that 243 men left our employ and 304 new men were taken into service. This in itself added greatly to our burden and prevented us from obtaining as pleasing a result as I am sure we would have obtained had we been able to wage our campaign under normal conditions."

Another:

ACCIDENTS REDUCED IN SPITE OF TURNOVER

"During the period of the war, we were of necessity obliged to hire large numbers of inexperienced men and lowered our age limit of conductors from 21 to 18 years, and raised our age limit of motormen from 45 to 50 years. In spite of this factor (inexperienced men) you will note that the accidents for 1918 were materially reduced compared with the previous year. While this may seem unusual, yet I believe, the practice of this company in having the Claim Department instruct new men before entering upon their duties, as well as the care used by the Transportation Department in breaking in new men, impressing them with the necessity of unusual care, were primarily the reasons that the number of accidents were reduced, together with the work done by our Safety Boards in our various Divisions."

Another:

"During the year 1918 on account of war conditions we were obliged to hire a number of younger men, some of them not of full age, losing a number of our experienced men on account of the wage attraction of the munition plants located in our community. This materially increased the number of our accidents, and especially I think in the collisions with vehicles. This year we have been able to dispense with the class of employees referred to, and have been able to get a more reliable class of

men and a material improvement would seem to be indicated by the number of accidents for the first six months of 1919."

Another:

"You ask whether there were any unusual conditions. We have been adversely affected by shortage of labor, with its consequent impairment of efficiency, on account of the great industrial activity which has been most acute in this vicinity, due to the European War. For the last two years we were further demoralized through this Country's entry.

We first employed women as conductorettes, in April, 1918, and have had as many as 235 out of the total platform force of 4,000, but I do not think this materially affected the situation.

	Public Accidents	Employees Injured
1916	50.65 per million passengers carried	1,671
1917	52.42 per million passengers carried	1,675
1918	57.27 per million passengers carried	1,495
1919 (6 mo.).....	49.14 per million passengers carried	674

INEXPERIENCED EMPLOYEES MORE LIABLE TO ACCIDENT

Another:

"In connection with the third paragraph of your letter in which you ask if any unusual conditions obtained in 1918; The records show that the increased accident frequency in 1918 was due to the extensive war activities on Long Island in that year which caused an unprecedented congestion both on the railroad and on the public highways. Another important factor in the accident experience was the employment of inexperienced men and women, in which connection it may be stated that 16 per cent of all employees killed and injured on the ——— Railroad in 1918 had been in the service less than one month, while 37 per cent of the killed and 39 per cent of the injured had been in the service less than six months."

Another:

"There seems to be some unknown force or influence working among the working class of men for the last three or four years that has been bad. They are careless and indifferent, and seem to have no interest in their work. Every one of the accidents on this report was absolutely caused by the negligence and carelessness of employees. None caused by failure of the working of any parts of the equipment."

Another:

"I do not think the war has had a particle of effect upon the men. The strict discipline in the Army does not apply to civil life. In civil life, men are free agents, and they are governed in their actions by their natures. If they are prone by nature to be careful and faithful in the performance of their duties, we may have little trouble with them, but if on the other hand they are prone to be negligent and selfish, having no patience with other people, we will always be in trouble with them.

Having all this in my mind, I am fully aware of the fact that we can never relax for one moment our efforts to improve our men by careful training and constant admonition.

Though we have increased wages, the prices the men have to pay for

the necessities of life, leave them in about the same condition financially as before the war on a lower scale of wages.

We cannot, therefore, claim that we have done more than meet the changed conditions, nor can we ever make any substantial improvement until they realize that their efforts to hold in place incompetent men is the real cause of this disability on the part of the Public Utilities to pay a higher scale of wages.

About all I can see that you can learn from the above is that down here in the Southland we are just as rotten as in any other part of the U. S. and that year after year our accidents run about the same in number and cost."

Another:

"The total accidents per 100,000 revenue passengers, excluding transfer and pass passengers, for the years in question are as follows:

1916	7.5
1917	9.6
1918	9.2
1919	8.5 ¹

The number of accidents per 100 employees, taking number of employees as on last day of period, is as follows:

1916	20
1917	26
1918	28
1919	12 ¹

The unusual conditions which affected our figures given above, were, first—a strike of employees in September, 1917, which necessitated the training of almost an entirely new platform and shop force which materially affected the number of accidents during the latter part of 1918: second—the shortage of good labor which existed during 1918 and necessitated the employment of inferior labor and had no doubt a marked effect in increasing the number of accidents."

Another:

	Passengers Injured	Employees Injured	Passengers Carried
1916	5428	2443	335,752,271
1917	5978	2951	338,265,376
1918	3579	2334	297,764,544
1919 (6 mo.)	1645	885	163,024,951

Another:

ACCIDENTS	
Passengers and Employees	
1916	190
1917	158
1918	154
1919 (6 mo.)	109

¹1919 figures given on yearly basis obtained by multiplying accidents for the first six months by two.

Another:

"Personally I prefer middle aged men, rather than young men, as our experience is that they are as a rule more careful than younger men.

If you had asked with reference to passenger suits, I could make quite a lengthy report, as we now have about twenty imaginary passenger personal injury suits pending in the _____ County Courts."

One-man cars are largely a result of conditions brought on by the war. Wherever used they have materially decreased the number of accidents.

A great many roads were compelled to cut down their mileage in order to reduce operating expenses during and after the war. This would of course cut down the hazard in proportion.

INCREASED NUMBER OF AUTOMOBILES INCREASE NUMBER OF ACCIDENTS

The great increase in the number of automobiles has, however, correspondingly increased the number and severity of automobile accidents.

There are many ways to be progressive but one is sufficient if along proper lines. What are the proper lines to prevent accidents? We do not have advantage of sufficient regulatory laws, but even if we had they would mitigate only in a small degree. We have the benefit of safety boards, safety appliances, warning signs, etc., which is a great help as far as it goes, but they do not prevent the majority of railroad accidents. The day is past when men can be driven by the old bull-dog method. We have never gotten the benefit from rigid discipline as ordinarily enforced, one reason being, the new man employed is just as liable to err as the one discharged, and the men remaining do not profit by the example set.

The principle of SAFETY WEEK extended through the whole year is perhaps the only solution. To bring forcefully to the mind of every employee the moral obligation resting upon him to preserve human life and human limb, inculcate that by continuous education, relying upon the fact that all men have that within them which will naturally keep from harming those entrusted to their care and those who come within their zone of danger.

By our individual effort and by our combined efforts let us make today a safer day than yesterday, and tomorrow a safer day than today.

There is but one temple in the whole universe and that is the body of man. The duty we owe ourselves is to preserve this most sacred temple of the universe. The duty we owe our fellow man is to help him preserve this most sacred temple.

DISCUSSION

CHAIRMAN ADAMS: We certainly appreciate the efforts Mr. Schneider has put forth. Just think of the number of letters that he has written and received, the tabulation of these statistics, and of boiling it down into such an article as he has given us here today. I think he is entitled to our thanks.

If I remember, Mr. Schneider said he was successful in getting 115 replies from 290 letters he wrote asking for statistics. He was a great

deal more successful in writing to strangers and people not affiliated with this organization than your chairman was in writing to his personal friends who are members of this association for a few little statistics on one point.

You will remember, I asked each company to let me know simply the total number of accidents from August 31, 1917, to 1918 and 1919. I got one lone reply. Now just think, out of 129 people in this organization, only one of them sent in their report and I will not tell you who that was because it really didn't come up to what I thought because he really had an increase in accidents in that year. As for our own Company, we have 170 miles of track and we came within one of decreasing the rate one per mile.

MISS ROADIFER: Mr. Chairman, I don't want to impose on your time, particularly since Mr. Schneider's paper was so splendid, but I feel almost duty bound to give my opinion.

We began creeping in with the safety organization among the school children. After one season of work of that kind we went to the Superintendent of Public Schools and asked him if in six months time we could show a material decrease in accidents to children of school age, whether he would permit us to come into the schools and through the medium of story telling get the story across. Of course, any man that has a heart with regard to humanity could not help but grant us that permission. During the first year we decreased accidents fourteen per cent.

JUNIOR SAFETY COUNCIL

After a while organizations were started, such as the Junior Safety Council. In Philadelphia we won recognition from the members of the Chamber of Commerce and they gave us permission to met in their assembly rooms once a month to discuss ways and means by which we might make Philadelphia a healthier and safer city.

The Junior Safety Council, made up of school children, demanded coöperation from the Chamber of Commerce. The appeal from the children was so strong that after several attempts they gave us coöperation. A committee composed of school children put up safety signs for us. Of course, after the Department of Public Safety gave the children their support, the mayor of the city and the Police Department had to follow it.

After four years' work, we showed a deduction of thirty-seven and one-half per cent in fatalities to children of school age and a general decrease to pedestrians, for through the children the safety lessons are taken into the homes.

If you don't have the support of the community through which you operate do not let that make you hesitate in starting a safety campaign, and I know that the first year you will find that your Claim Department alone will save enough to repay you.

CHAIRMAN ADAMS: I thank you very much, Miss Roadifer.

You see Miss Roadifer has just given us another inspiration to get behind this educational movement among the young people and the children in the schools. These people will have to take our places in not

very many years. You know they begin to work in responsible positions earlier now than they used to when we were boys, and we must start them along the right road.

MISS ROADIFER: It was this safety movement, this humanitarian movement that helped to make Philadelphia realize that after all the president of the company was sincere when he expressed his endeavor to improve the service and I am sure that was one of the things that helped put it over in Philadelphia.

MR. HEMMING: Pardon me for taking the floor again. I am not going to trouble you to read all of this but I am going to leave it on the table that you may see it. It is quite interesting. The title is "Classified Accident Report and Traffic Survey of the Transportation Department." This is a six months' report, up to June inclusive.

You may find these statistics interesting for the reason that they are divided up in this manner, though it is not new.

CLASSIFIED ACCIDENT REPORT

We record the time of day the accident occurred, the age of the motorman or the conductor concerned in the accident, period of employment,—company service, sex injured, line or division on which accident occurred, day of week, type of car, zone in which the accident occurred, weather and track conditions.

This division is made for psychological reasons.

First of all, it is important for your men to know, likewise the public, at what time of day the greatest number of accidents occur.

I have addressed a large number of school children on various occasions and I asked them, in their opinion, at what time of day the greatest number of accidents occur. It was surprising to know how much interest they took in what I had to say. I received all kinds of answers except the right one. Their answers were mainly "noon". I asked them why they thought that noon was the most dangerous period. They said, "because there are more people on the streets, more traffic and congestion."

I showed them that they were wrong. The greatest number of accidents occurred, according to United States statistics, between ten and eleven o'clock in the morning, and three and four o'clock in the afternoon, and seven and ten o'clock in the evening. We find that statistics on our own property bears that out.

The age of the motorman and conductor is another important factor. We find that accidents run higher for the young man. The older man seems to have settled down to a more conservative and common sense way of doing things. We find an almost equal ratio of accidents in regard to sex. The day of the week is another interesting thing. We find that Saturday is the most hazardous day; though that is a little bit contrary to United States statistics. Our report shows these accidents: Monday, 73; Tuesday, 92; Wednesday, 75; Thursday, 96; Friday, 85; Saturday, 127, and Sunday, 61.

The type of car is something we are all interested in. Our investiga-

tion bears out what Mr. Schneider said, that the one-man car has fewer accidents than the other type of car. It is strange to say that even in the case of the pay-as-you-enter, muzzle-loader, and near-side type they have more accidents than the one-man car and yet there are two men on the other cars. It is a splendid argument to use in your community where they are opposed to the one-man car.

We have divided all our cities out into zones. I asked the children where they thought the greatest number of accidents occur.

"Why right down there by the court house," was almost a universal response.

I said, "No, that is where you have the least. The greatest number of your accidents occur in Zone 'C'".

I wanted to bring before them the thought that when they were near the outskirts of the city they should be most careful, because there is where the automobile and even our own trainmen take the opportunity for gaining headway as the traffic is less congested. There were 130 accidents in Zone "C", the next to that was Zone "E", but right down in the heart of the city in each one of these places there were only 75.

Weather conditions show that the greatest number of accidents occur during fair weather and the greatest number on dry tracks rather than on slippery tracks. There were 560 on dry tracks and 180 on slippery tracks.

I want to leave this thought with you, we have to go back to that old Biblical saying, "A little child shall lead them."

CHAIRMAN ADAMS: Has any one else anything to say on this paper? If not, I want to thank you for the interest you have taken in safety work during the past year; for your courtesies throughout the year, and for the honor you conferred upon me by electing me as your chairman a year ago. I thought at the time it was a mistake and I feel yet that it was not a success, but in any event I have given my heartfelt interest to the work of the Association and this special section.

The safety movement, as represented by the National Safety Council, has been close to my heart for six years. I have been a member of the Council for six years and have attended every one of its annual conferences and I expect to continue as long as I can.

It now gives me great pleasure to announce that Mr. Hemming, a man whom you all know, was the prime mover in the preparation of our program this year. This year's electric railway program has been far ahead of anything we have ever had before, and the same is true all through the Congress.

The movement for safety is constantly gaining interest. It is like the snowball, the farther it rolls, the greater it grows.

This Electric Railway Section is growing, growing in spite of the fact that we lost 427 miles out of a mileage of 13,000. The last year has been one of the most strenuous years the electric railways ever had to contend with. The days of reconstruction have started and the electric railway business is one of the important businesses of this nation. You gentlemen are the ones who have to reconstruct that whole structure of operation

and the safety work will have to be started all over again in a way, with the knowledge and the experience that we have already as a basis.

I am proud to know that we have such a man as Mr. R. N. Hemming, Superintendent of Transportation, Ft. Wayne & Northern Indiana Traction Company, Ft. Wayne, Indiana, to take the place as Chairman of this section. Mr. Hemming will you now accept the Chair?

(Mr. Hemming took the Chair.)

MR. WALTZ: I move you that this section, at this time, give a rising vote of thanks to Mr. Adams for his services during the past year.

(A rising vote of thanks was given Mr. Adams.)

CHAIRMAN HEMMING: I thank you, Gentlemen, for this honor you have conferred upon me and if I can do half as well as the out-going Chairman I think I shall feel very happy. We have a lot of work ahead of us this year, especially with the nationalizing and standardizing proposition and I am sorry I am not able to give you the names of the committeemen of the various associations who will have to try to get this proposition through. I will have to announce that Committee later. I want all you men to take back home with you this one thought: If your company is not spending enough money, in your opinion, for the prevention of accidents: if your company feels that it is not worth while to get into the National Safety Council, or if you have a neighboring property that has the same attitude, take this thought with you: It is a matter of advertising in the prevention of accidents and it is a matter of advertising to get business. If you will spend a lot of money to get special traffic to put money into the treasury, why not spend some money to keep it in there after you get it there? That is the stuff that counts.

Employees' Benefit Association Session

October 3 and 4, 1919.

F. H. ELAM, Chairman
American Steel Foundries Company, Chicago, Ill.

FRIDAY MORNING SESSION

THE meeting was called to order at 10:10 A. M. by Mr. F. H. Elam, Chairman.

CHAIRMAN ELAM: It is now past the hour for the meeting to convene, and we shall begin in the hopes that the gentlemen who are on the program and who have not indicated their presence will arrive later. We will ask the first of our speakers, Mr. Joseph N. Redfern, to discuss the best form of management of employees' benefit organizations and associations.

BEST FORM OF MANAGEMENT

JOSEPH N. REDFERN, SUPERINTENDENT, RELIEF, SURGICAL AND EMPLOYMENT DEPARTMENTS, CHICAGO, BURLINGTON, AND QUINCY RAILROAD, CHICAGO

The best form of management, as I think we all feel, is that which will insure to the employee the benefits which he or his family expects to derive. We can have that assurance only by the guarantee of an employer whose financial position is such that it will make the employee feel that the benefits will unquestionably be paid; and in making that statement in the few words I have to say, possibly I shall touch on some of the subjects to be discussed later, although I don't intend to.

Taking the case of the railroad with which I am connected, and, of course, with which I am most familiar, the form of management is this:

The employees elect one-half of the members of what we call the Advisory Board, which is an executive committee. The railroad company selects the other half, generally officers of the company, and an officer of the company acts as chairman. That gives the company seven representatives on the committee and six to the employees. Once in a while someone questions the advisability of the company having a majority, but, as a matter of fact, it is very rare that the full representation of the company is present at any meeting of this committee while it is extremely exceptional, on the other hand, that any of the employees' representatives should be absent; so that, practically, the employees have a majority. But it is necessary that the company have a majority vote to prevent any

amendment being made without the consent of the company, because of the guarantee of the company to pay benefits.

When we established our relief department, in 1889, we followed the plan of the Pennsylvania Railroad. The company agreed to pay any deficit created in any three year period. At the end of the first three year period we had a deficit of something like \$26,000, which the company charged off to itself and started the first of January, 1892, with a clean sheet. Again at the end of the next three years there was another deficiency of some \$18,000, which the company again wiped out. Since that time there has been no cash deficiency.

We went on and accumulated a considerable cash balance, so large that it was thought we should do something with it. The question of increasing the benefits was taken up. I put the matter before the Advisory Committee as to whether they would agree to do away with the three year period and simply have a guarantee to pay benefits. The position of the employees' representatives was that they didn't care one way or the other, all they wanted to know was that if they died their beneficiaries would get the money, and as long as the benefits were paid, they didn't care whether there was any deficiency or not. The value of a guarantee is most important.

We all know that the insurance companies are governed by the laws of the state, so the people that pay premiums or make contributions will be protected. In order to secure and to hold a considerable number of employees the most important thing is to have a guarantee that the benefits will be paid. During the epidemic of influenza last year—I don't know what your experiences were—we ran behind some \$200,000. Ordinarily that would be enough to frighten the average benefit association or fraternal insurance organization, but our employees didn't care anything about it. There was the Burlington Railroad back of them, a big corporation, and they knew the matter of money would be taken care of and that all the benefits would be paid. There was a guarantee back of it, and that is the crux of the matter. That guarantee on the behalf of the employee, with the balance of power in the hands of the employer for his financial protection, is what makes all the difference.

FEW CASES APPEALED

A word as to how our plan worked out. We have had 385,000 cases of disability since we started thirty years ago. Under our rules, an employee who is not satisfied has the right to appeal to the superintendent of the Relief Department and from him to the Advisory Committee, whose answer is final. A question came up recently as to how many appeals we have had. We went over the records and found that there have been seventy-two appeals in the thirty years that we have been doing business.

In other words, the cases of dissatisfied members have been so rare that only one man out of fifty-three hundred has found it necessary or advisable to appeal from the decision of the superintendent. In saying that, I don't mean that every one was satisfied; but the superintendent was able to convince them that they received all their contract called for.

Now that brings me to this point: To whom should the superintendent report? Under our rules the superintendent reports to the president of

the railroad company, except in such matters as are under the control of the Advisory Committee.

The thing is, in making your selection, to get some one who will stand between the corporation on the one hand and the employees on the other. There ought not to be any real differences of opinion, because what inures to the benefit of the employee's welfare must necessarily inure to the corporation itself.

My time is almost up. I want to impress these two thoughts upon your minds. The first is that the management shall rest jointly between the corporation and the employees; and, secondly, that the officers be as nearly independent as possible so they can act in a fair and impartial manner in any question that comes up.

DISCUSSION

MR. THOMAS D. LAW (Safety Engineer, Oneida Community, Ltd., Oneida, N. Y.): I would like to ask Mr. Redfern a question. What are the benefits paid to the members of his association, and what are the dues received from the members?

MR. REDFERN: In the first place, the corporation pays all the expenses of management and carries on the work, so that the employees are relieved of all expenses and details. If there is not enough money to pay the benefits the company advances what is necessary. The total contributions from employees run from 75 cents a month to \$2.25 a month, which covers disability benefits of 50 cents to \$2.50, and death benefits of \$300 to \$6,000. The death insurance rate is \$12 per \$1,000 per annum. A man in the lowest class contributes 75 cents a month, or \$9 a year. Arbitrarily we apply 45 cents of that for disability and 30 cents for death benefit of \$300.

After three years of service, and after one year's membership, an employee who leaves the service for any reason whatsoever is entitled to continue his death benefit insurance but not the disability. We have in the neighborhood of \$1,500,000 insurance which we carry for former employees, and which is continued at the old rate. These men realize the value of this insurance.

MR. C. T. DEARBORN (Dennison Manufacturing Company, Framingham, Mass.): Will you kindly repeat what the benefits are?

MR. REDFERN: The contribution is 75 cents a month for the lowest class. There are five classes, each class carries with it a death benefit of \$300 and members of each class have the privilege of carrying extra death benefits. The first class has \$300 death benefit, and the fifth class has \$1,500 death benefit. The total additional benefits must not exceed three times the death benefit of their class.

A man in the first class can take three additional death benefits. They cost him 30 cents each. This allows him to carry an additional total death benefit of \$900. Now, that goes on up proportionately, so that the man in the fifth class could take fifteen additional death benefits, making a total of twenty death benefits. His rate would be \$8.25 a month, but of that \$2.25 would be for disability protection, and \$6 per month, or \$72 per year would be for the death benefits.

The railroad relief work is a different kind of work from that in other industrial lines. We have in some respects very heavy casualties, and our employees are scattered over many thousands of miles of railroad. The problems in industrial plants differ also.

MR. CHAPMAN (International Harvester Company, Chicago): I would like to ask a question as to the death benefit feature of your association. Do you find that when your employees leave the service of your company they continue their membership for death benefit only?

MR. REDFERN: In some localities we find that more men are disposed to keep up their death benefit after leaving the service, than in others; the only way we can account for it is that in some of the old communities where conditions are more settled, the question of insurance is a little more pronounced. As a rule, the young people don't care much about it; it is only those of mature years, and, as a rule, those of mature years don't leave the service. The territory through which the Burlington runs is getting to be an older territory, and we don't have the great change that we used to have twenty-five or thirty years ago.

There isn't, on the part of the rank and file, an inclination to give as much attention to the matter as there is on the part of the officers. I don't know whether it is due to the superior intelligence of the officers, but I think they realize more clearly the cheapness of it. We have today scattered around among the different railroads of the United States a great many of our former officers and men who hold our insurance. The fact that they keep up their insurance is the best proof of its stability and value and cheapness.

DR. S. WATSON FOX (American Engineering Company, Philadelphia): I would like to ask you, Mr. Redfern, about the physical examination. Do you make a physical examination of all applicants for insurance and disability relief, and are there any cases where the man is not accepted at all?

MR. REDFERN: Doctor, our medical examiners act in a two-fold capacity. For many years it has been a rule of the Burlington road, that no one should be employed, except unskilled labor, who could not pass a satisfactory physical examination. That same examination covered admission to the relief benefit. Occasionally we accept a man for employment that we do not accept for insurance. But generally speaking that examination is the same as a life insurance company requires, or, rather, serves the same purpose.

We do make exceptions. For instance, a man is accepted for employment if he has a rupture which is protected by a truss and does not interfere in the performance of his duties. We have had people come into the service with such things, say: as an ankylosed finger, if it did not interfere with the performance of their duties. In those cases we would make out a release exempting them from paying the benefit dues.

DR. FOX: Who pays for that physical examination?

MR. REDFERN: That is part of the expense that is borne by the railroad company. The employees are not taxed a cent for the examination or anything of that kind. It is part of the contribution of the railroad toward carrying the benefit relief work, equivalent to the same contribu-

tion that the employees make. Take accident insurance, for instance. You will find that from fifty to sixty per cent goes as expenses of management. If the railroad did not contribute all the work, it would double the cost of the insurance. By going outside and buying the same insurance the men would have to pay double, and if they didn't want to do that, the benefit would have to be cut in two.

MR. T. H. JONES (Walworth Manufacturing Company, Kewanee, Ill.): Do you pay in full or make allotments to the beneficiaries until the amount of the benefit is paid out?

MR. REDFERN: We pay in full. I think it is the best policy. It has been my experience that most women know how to handle money better than men.

MR. F. F. OGDEN (Hooker Electro Chemical Company, Niagara Falls, N. Y.): My experience has been that the state, the insurance commissioners, or other authorities, require people doing an insurance business to put aside a cash balance or reserve. How long must an individual be in your employ before he is able to join?

MR. REDFERN: The contract is made between the corporation and the employees. He applies for membership, and on behalf of the railroad I accept it and issue him a certificate of membership. It makes a contract enforceable at law, but it is not an insurance contract, and is subject to no state laws governing insurance. No state has attempted to class us under the insurance laws. Two or three times the question has come up. I have in mind a case that came up not many years ago, State of Ohio vs. Pennsylvania Railroad Company. It was decided by the Supreme Court of Ohio that it was within the province of the Pennsylvania Railroad Company to make contracts with its employees in the course of its business.

We do not go outside of our business, and so we make no reports to any insurance commissioner, to any state body, or to any one. Several other courts have taken practically the same position that Ohio has taken.

At the time the man is employed the question of the benefit association is taken up with him. Scattered, as we are, over nearly ten thousand miles of railroad, we have a provision whereby a man makes a preliminary application. That protects him against accident from the time he signs it until he has had an opportunity to be examined by the doctor; so, from the time he signs that paper he is protected against accident, and from the time he is examined he is protected against both sickness and accident.

It used to be the plan to keep a man in the service a month or more before we acted upon his application. But some of the employees who were more or less green would get hurt during the interval.

MR. OGDEN: I believe the speaker misunderstood my reason for asking that question. I do not care whether it is within the province of the corporations to insure their employees without state supervision. My reason for asking that is this. The insurance companies must conform to the laws of the state within which they operate. Just because you are able to pay your men the benefits and reliefs at the present time is no indication that your company is going to be in as good a financial

condition five years from now. How do you know your company isn't going to go bankrupt, and your employees who have been contributing for fifteen or twenty years get nothing, because you are not able to pay.

Now, for these reasons, if you are going to make an enforceable contract you will have to do as any of the insurance companies do. You will have to put up security, so that in the event of your company becoming financially embarrassed those employees will not suffer.

MR. REDFERN: We have \$22,000,000 or \$23,000,000 of insurance on our employees; maybe it is nearer \$25,000,000 now and it would seem absurd for a corporation with a surplus of nearly \$100,000,000 to be obliged to put up security. The position of the courts is that should a large corporation like the Burlington go into the hands of the receivers, the relief and benefit funds would be the first funds to be protected and would be set aside to cover such liabilities.

MR. JONES: Mr. Redfern, within what time do the benefits begin?

MR. REDFERN: The sickness benefit starts after six days, and in case of accident the benefit begins immediately.

MR. E. F. VARNUM (Commonwealth Steel Company, Granite City, Ill.): I would like to ask in regard to accidents in your plant; would a man get anything from the benefit association, covering an accident in your plant?

MR. REDFERN: In states which have the workmen's compensation act you are always required to pay the compensation prescribed. Generally speaking, in railroad work, our cases of accidents fall under the federal act rather than under state acts. The line is not quite clear between the interstate and intrastate; but where a man, working for a steam railroad, is injured, through an instrumentality of interstate commerce his case falls under the federal act. In the shops themselves we have both kinds of cases; but, answering your question directly: In Illinois there is a state compensation act; the man gets the compensation and he gets the relief benefit, if he is a member of the relief benefit association.

MR. B. L. ODLE (Flint Vehicle Factories Mutual Benefit Association): I would like to ask how you conduct your investigation in regard to accidents, and also whether or not there is any medical aid given.

MR. REDFERN: Every employing officer is provided with a form to report the deaths of members of the relief fund either by sickness or injury. One copy of that form goes to our medical examiner and another goes to the central office. The medical examiner calls upon the disabled person, makes a report to our office, and at the end of the month makes up a claim for benefit. That is certified by the employing officer. When the disability terminates, he issues a form certifying to his physical condition and that he is able to work.

Our men are not allowed to resume work without the certificate of a doctor, and in that way our medical examiners see the men but do not attend them, although as a matter of fact our medical examiners do give a great deal of advice to employees; but if the case is at all serious, the patient is supposed to have his own family physician.

In the case of an accident, the Relief Department contract provides for the payment of surgical attention, and that includes not only the

surgical treatment but also hospital care during the time necessary. In June, 1903, a man fell off a car and his back was broken. He has had to have an attendant, and this has cost the relief fund \$30,000. He drew for one year \$1.50 a day. He has drawn since then the benefits of 75 cents a day and \$125 a month for his care, and he gets a great deal out of life. Occasionally I get a letter from him. When things are going wrong and troubles popping up, all we need is a letter from this fellow, who never gets out of bed, and it cheers us up considerably. He is the most cheerful man I have ever known.

MR. JONES: I corroborate that statement of Mr. Redfern. I met that young man about ten years ago and had a nice visit with him. He has a very sunny disposition.

DR. FOX: Mr. Redfern stated that the medical examiners rendered medical attention in the cases of accidents, that is, shop accidents, but not on the road.

MR. REDFERN: The railroad has a staff of surgeons to attend accident cases. Some of our medical examiners do a little of the work when they can. We have four or five hundred surgeons.

MR. T. H. PLATT (Endicott-Johnson Sick Relief Association, Johnson City, N. Y.): I would like to ask Mr. Redfern whether the rate has been sufficient to meet the requirements of the present time.

MR. REDFERN: No, sir: We don't insure any one over forty-five years old. We had a higher rate for those over forty-five, and that didn't pay. The rate is not sufficient from an actuarial standpoint.

In the war risk insurance, I saw a list the other day on which I think the lowest rate of war risk insurance scheduled was for a boy of sixteen.

CHAIRMAN ELAM: I am sure that this discussion has been very profitable as indicated by the interest that has been taken. We have been fortunate in having Mr. Redfern speak to this section and to lead the discussion because there is no one who can speak with greater authority than he.

Interest in the employees' benefit associations seems to be growing from year to year and we find that there are many associations that we do not know about, that is, that the National Safety Council does not know about. If we can get the names of all of them located in the country and can collect the experiences and the methods on which they do business, it will be certainly very helpful in the propagation of the association's beneficial work.

ARE EMPLOYERS' CONTRIBUTIONS ADVISABLE?

As Dr. Geier is not present, it might be profitable for us to discuss informally the fundamental things in connection with Dr. Geier's address on "Are Employers' Contributions Advisable?" Mr. Redfern could possibly lead the discussion, and possibly be followed by Mr. Chapman. I think we can get a great deal out of the subject. Will you give us your opinion, Mr. Redfern?

MR. REDFERN: Mr. Chairman, as I have indicated before, I believe the employers and employees, as we generally term them, ought to go along hand in hand.

Speaking about the class of men with whom I have come in contact,

I know of no word more objectionable to the average man than the term "welfare". If a man comes in and asks what we are doing in the welfare line, we tell him we are not doing anything of the kind. It is to the interest of every company to have its employees contented for the purpose of having them do better work. Money that the employer spends along that line comes back to him many times over, and the money that the employer gives doesn't amount to so much as the spirit and the manner with which it is given. Our experience has been that the best way is for the employer to carry on the expenses of the plan and not have the employee feel that the officers are spending money at his expense.

CHAIRMAN ELAM: Mr. Chapman, have you anything to tell us on this subject?

MR. CHAPMAN: The whole idea is along those lines. The International Harvester Company made it a part of the rules and regulations that they would make a contribution if seventy-five per cent of the shop employees belonged to the benefit association, and that annually the company would donate \$50,000 to the fund, the understanding being that \$50,000 is for expenses only. The benefit association of the Harvester Company has received from the company each year for ten years \$50,000, which represents a half million in the benefit fund.

In a personal way, I have had members come into my office and discuss it, and invariably they have touched upon the company's contribution as one of the good things. I think all employers who organize a benefit association for their employees should make a donation to the fund to be used in paying the expenses of that association. Our regulations say that the contributions of the members shall not be used for paying expenses but shall be paid solely for the benefits.

I agree with Mr. Redfern that the tendency of employees is to get wrong impressions if advances are made to the employees along the line of trying to give them something that they have not earned, and I have seen cases where that has led to a point where the employees try to see if they can't get a little bit more out of the employer.

MR. CHANDLER: If the employer can confine his contributions to the administration expense, that is a good plan.

Our organization had been running twenty-five years on the basis that the officers must absolutely keep their hands off. There should be no Paternalism—absolutely none. But it developed in these twenty-five years that they needed advice from men who had a little more experience. At the end of the twenty-fifth year it was decided that the organization should have the benefit of the experience of such men as had more experience in the financial and business world, so the by-laws were revised.

Prior to that time the members had been electing shop men—sometimes foremen—to serve as secretary of the association. The dues were collected through the payroll, but the secretary was about the only man who was expected to secure members, and the men busy in the factory had too little opportunity to carry on that part of the work, the result being that the membership represented a very small percentage of the total number of employees.

It seemed clear that the secretary of the association should be some one

whose duties permitted enough freedom that they might circulate among the employees, particularly the new ones, and who, when occasion demanded, should be able to visit the homes of those who were drawing benefits.

There was in the office a young man especially qualified to serve as secretary. However, he was a salaried man and if the company should suggest that he be made secretary some doubting Thomas might start a rumor to the effect that the company was trying to dominate the association.

When the revision of the laws was up we told this man, "Now, Luke, you are the logical man for this job, but the men must choose you. You take an interest in the organization and help them in the work." He stood out prominently and when the time came to choose a man to head the work they said they wished they could have Luke. We all took the reverse attitude, but he stood out so prominently that he was the choice. If we had said that we wanted Luke put in there as secretary, the men might have taken a different attitude toward him. Now they think he is the greatest thing that ever walked.

We pay the expenses. The employees have no idea how much it costs us; we don't want them to know, and we don't want them to calculate how much it costs the Dodge Manufacturing Company.

CHAIRMAN ELAM: May I ask how you collect your contributions?

MR. CHANDLER: That is all done through the pay roll. As an illustration, we bought a factory in New York a couple of years ago. It had been the practice of their association to have the financial secretary collect dues from each man. The result was that a lot of them were behind in their dues from time to time and there was a scrap on all the time. When we took the plant over we suggested that if they were willing, we would be satisfied to do the deducting of the dues and of course it suits them all right.

MR. M. R. MARSHALL (National Lamp Works, Nela Park, Cleveland): May I ask how many employees there are in your organization?

MR. CHANDLER: Membership in the organization is voluntary and includes about 80 per cent of our employees.

MR. MARSHALL: We have about 3,500 employees out of which 1,000 are members of the benefit associations. I wonder if that number is large enough to justify the hiring of a secretary to handle the work. I wonder if there would be enough work for a secretary to devote all his time to the interest of the members.

DUTIES OF RELIEF ASSOCIATION SECRETARY

MR. CHANDLER: In our case, we use our Relief Association, as we call it, for a number of activities. If there is something on like the sale of Liberty Bonds or something along that line, the Relief Association handles it. For instance, we have a Thrift Club. We conceived the idea four or five years ago that the men ought to have some organized incentive for saving money, so we organized the Thrift Club. We said, "Here is a thing the Relief Association can handle." During the war a lot of such work was done through the Relief Association secretary. On the other hand, the secretary has to do the work of getting new employees to join.

\$36,000 in cash, and the company donation the equivalent of \$86,000, for twenty-nine thousand members. We operate sixteen plants in the United States and Canada.

CHAIRMAN ELAM: I don't think there is any question that the contributions through services that have been given by the employer are of the greatest aid, and if that aid were withdrawn, many of the associations would have to go out of business, raise their dues, or decrease their benefits.

MR. JOHN L. MASTERS (Pres., Relief Association, Warren City Tank & Boiler Co., Warren, Ohio): We have an association that we formed two years ago this month. We have about 400 members at the present time. We have a fund now of \$18,000. We pay our secretary \$120 a year. We have within a very short time secured all of our employees as members of the association.

MR. CHAPMAN: How much do you pay into the benefit, may I ask?

MR. MASTERS: A dollar a month for thirteen successive months. Death benefits, \$400 for a married man and \$225 for a single man.

MR. V. R. CURRIE (Houston, Texas): I would like to know, if, in cases where the employees themselves conduct the association, it is due to a lack of confidence that they sometimes fail. That has been our own experience. The employees themselves started such an association, but they did not succeed. There seemed to be a lack of confidence in the association, and we later took charge of it, reorganized it, and put it on a 50-50 basis. As manager of the association, I frequently find that there is a lack of trust on the part of some of the members and some of the employees that are not interested. I wanted to know whether there has been any similar feeling experienced by you and what you have done to stop it. It is something that should be taken into consideration at this time. Of course, we understand human nature has many foibles, and a great many persons are suspicious of anything, but these associations must be popular. They must be like Caesar's wife, above suspicion, and I find it is one of the hardest things to inject into our association a spirit of confidence that will keep down the outcroppings of suspicion. A statement like this is frequently made: "I wonder what the company is doing with that money and where it goes. Where do we get off in this thing?"

MR. JONES: Not only are those people suspicious of the company's officers, but they are also suspicious of the officers of the association; even those who are liked by the men themselves are subjected to suspicion. Our company, when I first came with it, was an independent concern. Some of the members of the organization made the statement that the officers appropriated the funds from the treasury, at that time, notwithstanding the fact that we made regular reports. The truth of the matter was that we invested them in common stock, where they are still standing.

COMPANY CONTRIBUTES ENTIRE AMOUNT OF BENEFIT AND INSURANCE

CHAIRMAN ELAM: Might I ask if there is any one present representing a concern which contributes the whole amount of the benefit and insurance, and in which the employees do not contribute any money?

MR. CHANDLER: I understand that Sears-Roebuck have been the only corporation doing that.

MR. CHAPMAN: The American Telephone and Telegraph Company does it. I think they have set aside \$3,000,000 for the purpose.

CHAIRMAN ELAM: There seems to be a drift towards this method of handling the matter. There are a good many things drifting in that direction nowadays, and I suppose the employees' benefit associations will have to go through the same process. There seems to be a getting away from that old established rule that anything that is worth something to you should cost you something; and it is one of the many things that I expect most of us are studying at the present time.

Reference was made to Sears-Roebuck & Company. I don't believe that I shall be violating a confidence in speaking of their experience. They have had an association, run by the company, with which the employees who belonged to it were supposed to be satisfied and which they were supposed to be joining voluntarily and wishing to keep up. Later on, they found that the members were not satisfied and the association was discontinued.

SATURDAY MORNING SESSION

THE meeting was called to order at 10:00 a. m. by the Chairman, Mr. F. H. Elam.

CHAIRMAN ELAM: We are going to deviate from the regular program this morning, because one of the gentlemen we expected is absent, and we are desirous of having the help of Mr. F. S. Crum of the Prudential Insurance Company, in formulating the report of the Committee on Statistics. Mr. Crum has an engagement at 11:00 o'clock, and we have decided to ask him to discuss the subject of statistics at this time.

I will read the report of the Committee on Statistics. This is simply a tentative report, and was compiled by your Committee with the thought that it would be a foundation upon which to build up and reconstruct a new statistical chart.

REPORT OF COMMITTEE ON STATISTICS

Employees' benefit associations seem to be growing in interest all over the country, and those who are at the head of, or conducting, such associations are asking for information regarding the different plans. Now, we find that the association idea could be greatly advanced by a more uniform method of collecting statistics, and by giving these inquirers the information they want, we could help the association cause in many ways. We are seeking to decide on some form of record that will be useful and that can be kept by ordinary associations. It is suggested that such a record should include the following data:

STATISTICAL DATA RELATIVE TO EMPLOYEES' BENEFIT ASSOCIATIONS

1. Records to be kept on basis of ages of members
2. Age of members to be indicated as of nearest birthday
3. Record of sex
4. Record of nationality

5. Record of outside insurance other than E. B. A. carried by member
6. Record of insurance other than E. B. A. carried by deceased members, as shown by information on claim papers
7. Records of sickness disability and accident disability to be kept separate
8. Record of number of days sickness disability one to seven days, per year
9. Record of number of days sickness disability beyond seven days, per year
10. Record of number of days accident disability one to seven days, per year
11. Record of number of days accident disability beyond seven days, per year
12. Record number of days sickness per member, per year
13. Record number of days accident per member, per year
14. Percentage of disabled members receiving benefits to total membership, per year
15. Record of sickness and accident experience by ages, per year
16. Record of sickness and accident experience by nationality, per year
17. Number of cases and days duration of each disease causing disability
18. Number of deaths caused by each disease

CHAIRMAN ELAM: Now I am going to ask Mr. Crum to lead the discussion in regard to what this report and this tabulation should consist of, and why. Mr. Crum is Assistant Statistician of the Prudential Life Insurance Company, and knows more about the subject than most of us.

MR. F. S. CRUM (The Prudential Insurance Company of America, Newark, N. J.): This, as I look at it, is one of the really big things in this conference. They say safety education leads: prevention of accidents is second, and you are not worse than third.

As we look at it, we are interested in sickness experience and accident experience not merely from the standpoint of insurance, but also from the standpoint of public health. We have been attempting for a quarter of a century to get this information from every possible source, from both the living and the dead. We have even gone so far as to go into cemeteries, and get vital statistics in such sections of the country as have no registration.

Nine-tenths of the work of our department is for public purposes, and if I do say it, the information is used more by outside organizations and individuals than by our own company, though our company does make considerable use of them, that is, these statistics and figures.

Now, as I look at it, this particular experience of employees' benefit associations gives sources of valuable information, which, when compiled, will give us the best, most accurate, and most complete sickness experience anywhere in this country. We should study all sorts of classifications, but the important thing is to have your blank form for reporting individual accidents as complete as possible. After that is done you then have your mine of information, which can be used either by yourself or outside sources, which possibly have better machinery for tabulating the

facts than you have. For it is the mechanical method that puts this information into shape to be used.

You have there a mine of information which will also be a good guide if your fundamental blank is correct and perfect.

Now, as I take it, this outline which Mr. Elam has just read is a blank form and tabulations from such form, but I want to insist again to have the blank complete so that you will have it right. On your original put the classifications, and they will have no limit if your blank is what it ought to be. Now to the blank form you should carry the essentials. You won't need any blank for the age. You should have the "sex" first, because it is the logical first classification; but the sex should always be recorded with age, and the age on your blank form should be the exact age. You can group your age classification any way you want to after that. The member's age should be given as the year nearest his birthday; that is, if he is twenty-one years and four months, his age would be given as twenty-one years. The record of nationality would include the race or color as well as nationality. It is important to have the race. That is the fundamental classification of personal injury and sickness.

I think the items covering insurance are sufficient to begin with. The records of sickness disability and accident disability should, of course, be kept separate. Now, on your original blank form you would have the exact number of disabilities. If you have that on your original blank you can tabulate with greater detail. If at all possible, for your own purposes, and to get a really large experience, either for industry or state, it is trebly important to know what percentage of the total disability cases is under one day, two days, and so on. Then your classifications beyond that should be considerably more.

There should be a classification in your tabulation of sickness disability running into the second week, third, and so on up to the fourth, and then one month, three months, seven and nine months to a year to eighteen months. You should be able to divide your blank for disability in much more detail, and if you have the exact information on every blank form, that can easily be done. The same holds true for accident items under No. 10. That would take care of items No. 11, No. 12, and No. 13.

The ratio of disabled members receiving benefits would be stated not as a percentage (i. e., per 100), but rather in figures per 1,000.

Under No. 16 you should again have race or color as well as nationality.

No. 17 is taken care of by the criticism above. The number of deaths by each disease should not be left out. Your regular blank form should indicate the number of deaths. It would be very interesting, also, to have the number of days given from the time the illness starts, or at least from the time of the discovery of the illness, to the time of death. Let me explain why that is important. The Interstate Commerce Commission uses a method, and I think it is a very poor one. In railroad accidents, if the insured person lives thirteen hours and dies, it is still tabulated as death from disease. For illustration: A man is run over by a train and loses both legs, and lives longer than twelve hours and dies.

That is an illustration of the importance of keeping information in that way. You know the date of injury; and, also in the reports of sick-

ness it would be a simple matter to put on each report the period between the date on which the illness began and the date of death.

These are all important points. Another thing I want to mention that is extremely important is that the members of these organizations should get together and standardize their original blank report card, or sheet, or whatever it is they use. It is extremely important to use the same items. It is extremely important for these reasons: Very frequently, and more now than ever before, those seeking this information will want to combine. Secondly, the signal subject before the country today is the subject of health insurance. It would be extremely valuable to know just what exactly the facts are, and you people will have the finest experience in the country to offer if you can get together and make your blank reporting form uniform and otherwise standardize it.

If you will do that, you will not only make your own information to be used for your own purposes, but it will be much more valuable, because you can then compare it; but, as I said before, you will have to make the body of your blanks uniform.

CHAIRMAN ELAM: Mr. Crum, there will no doubt be some questions that some of those present would like to ask you.

I understand that one of the things that is being taken up is the classification of each individual disease. Not infrequently we have one disease that will run into another. Do you classify them as compound disease, or disability?

CLASSIFICATION OF DISEASE

MR. CRUM: By all means use the dual classification. That is now being used by my office, and is being practiced to a considerable extent. You should have your primary cause, and you should have your secondary cause. Take the recent influenza epidemic. If we had had that dual classification then, it would have been of tremendous value. It is known as the Budapest classification, worked out by Dr. Karris of Budapest, and valuable classifications can be had from the Census Bureau at Washington. They issue a pocket index that will give you such information, and I am sure that the Census Bureau would be glad to supply you all with a copy of that classification.

MR. CHAPMAN: That is especially true of cases of bronchitis and also tuberculosis.

CHAIRMAN ELAM: Are there any questions regarding this statement that Mr. Crum has brought to our attention?

MR. CHANDLER: I think the question of this dual classification is a very interesting one, and I would like to look into it.

MR. CRUM: You mean the Budapest classification? If you will give me your name and address I will be very glad to send you a copy of it.

CHAIRMAN ELAM: Is that what is known as the International list of diseases?

MR. CRUM: Yes, it is a part of it.

DR. FOX: Will they furnish a complete classification? I would also like to ask regarding the cause of disease. Take a concrete example: Suppose a man be injured, and he loses a lot of blood and afterwards develops pneumonia due to that injury and dies from pneumonia. If you

write out a death certificate with accident as the cause, it will not be accepted; you are expected to report pneumonia as the cause. If a man dies from pneumonia caused by the injury, I should think it would be proper to give pneumonia as the cause.

MR. CRUM: I think I can answer that question. The theory is that the man probably would not have died from pneumonia if it had not been for is decreased resistance to disease due to the accident, and in some of those cases you can't possibly say whether the man would have died from pneumonia if the accident had not taken place; but in the great majority of such cases, the man would not have died if he did not have his resistance and vitality reduced.

CHAIRMAN ELAM: Yes, the primary cause is the injury.

MR. CRUM: That is generally the present ruling.

MR. CHAPMAN: Along that line, take the case of a man who dies from septicemia after his hand has been injured. The classification of it is listed as septicemia, a disease; contributory cause, injury to hand. That is the method used:

MR. CHAPMAN: Have you a card that could be used in a tabulating machine suitable for the purpose?

MR. CRUM: Our card would not be of any use to you, except as regards deaths. As regards disability from disease, of course, we don't sell sickness insurance. The Travelers would have such a card, or any of the large disability insurance companies.

MR. CHAPMAN: Do you know whether any of the leading fraternal orders use them?

MR. CRUM: I don't think they do. Probably the Brotherhood of Locomotive Engineers and Firemen is the only organization of that kind using it.

MR. CHAPMAN: What I meant was a chart that we could use as a guide.

MR. CRUM: Well, you might get that from the Travelers or the Aetna.

CHAIRMAN ELAM: Has any one else anything to offer on the question how the reporting of statistics might be improved? I want to say that while this tabulation idea looks formidable, I do not believe that it will have the terrors under actual working conditions that it might seem to have in theory. For instance, when we specify here a record of the number of days of sickness under seven, and those over seven, that is simply an arbitrary division that has been adopted because of the associations that have a waiting period of seven days.

If you can get a report of men who lay off for a day and then recover, it may be worth while keeping such records, and more so for periods ranging from two to six days. If enough associations keep such records, the data will have value.

MR. JONES: Unless a man is off during the whole waiting period, there are many of us who never know he isn't at work.

CHAIRMAN ELAM: We understand this is one of the difficulties that associations have to contend with, as well as the employment departments in these plants. The only suggestion I can offer is that if such information of the man's absence does come to hand, it will be worth while to use it. In our association, for instance, every sickness that has been reported, irrespective of the fact that it doesn't run into the waiting period, is recorded. If you have a man who is sick three days this month,

and three months later he is sick four or five days and then comes up later with a sick spell, maybe, of ten days, you have a history that would indicate that his health is failing and he is not going to be nearly the man next year that he has been in the years that have gone by. It can be readily seen that there are many ways that such records can be used by your associations. Keeping a record of sicknesses and deaths and the reporting of them is a problem which all employers have to contend with, and it is especially a problem with an employer whose workmen live in widely scattered localities. I know of a factory with employees living over a radius of fifty miles, and you can readily see that such a concern is greatly handicapped in attempting to find out why its employees are not at work.

THE SICK COMMITTEE

MR. MASTERS: This matter that you are speaking of is particularly interesting to me. We have attempted to keep track of disabled or sick employees. We have cards which we give our employees, and which are returned in case of sickness or disability to the secretary of our association, who is supposed to notify the employment department, but we found we couldn't depend upon that. So, as soon as a man reports, or is reported to the secretary, a card is at once issued by the secretary to a member or two or three members of the Sick Committee. There are three of them, and they appoint twelve others as an auxiliary sick committee to serve in the different geographical sections of the town, or surrounding country; that is, the factory district is divided into four sections. There is a member of the committee in each section, and the injured must get in touch with that man.

We have been doing this for nearly a year, and we have found that it works better than any other system we have ever tried.

MR. CHANDLER: One thought that comes to me is that while it is sometimes possible to hear from a good number of the employees as to why they are off, the information as to what is the matter with them is rather unreliable. We have been sending our nurses to round up these men and find out why they are off. It is very difficult to get any reliable data on their cases. At the same time, for all those cases we do get data on, we have a blank and fill it out with the information, provided we know it is correct. There are a great many cases that are not reported. For instance, we would have relatively few reported cases of absences, of one, two, or three days.

I make a motion, Mr. Chairman, that the Committee on Statistics be continued, either with the present members, or with a different committee which the incoming chairman may select.

MR. CHAPMAN: I would like to offer an amendment to that motion. That the committee that is to be appointed or continued use its best efforts to obtain from health insurance organizations, or leading fraternal orders, or health insurance companies who operate the combined health and accident policies, samples of the record cards that are used in compiling the statistics on which they base their computations and reports, and that the committee then get together and draft a suitable form for benefit associations.

MR. CRUM: I want to say, Mr. Chairman, I happen to be the chairman of a sub-committee of accident statistics (public accidents), and we are doing exactly that same thing. We are doing it in every city where we can get it over, and that is exactly what you want to do. We have got a stiff job and we are going to take care of it.

While I am about it, I will say that the waiting period ought to go on every blank.

MR. ODLE: Will we have to wait until the convention next year, before we get the report of this committee? It seems to me that if it is of so much importance, that after the Statistical Committee has acted, it might be possible for the national office to print such forms and send them to the different members. Whether that is a possibility or not, I don't know, but it seems to me that the Statistical Committee should so inquire.

MR. CHANDLER: Mr. Chairman, if this body here this morning would be willing to give that committee power to act, it could make up such a form and have it issued to the members through the Bulletin of the National Safety Council.

CHAIRMAN ELAM: The amended motion has been moved and seconded: are you ready for the question? We will then take a vote on the amended motion and resolution combined, as you have heard it.

(The above amended motion and resolution were unanimously accepted.)

CHAIRMAN ELAM: I think that closes the subject. The next subject that comes up is that of Benefits to Ex-Employees, the discussion to be led by Mr. W. L. Chandler.

BENEFITS TO EX-EMPLOYEES

W. L. CHANDLER, ASSISTANT SECRETARY AND TREASURER,
DODGE MANUFACTURING COMPANY, MISHAWAKA, IND.

In a research including six hundred associations we only found two cases where the associations became insolvent to the extent that they had to disband or quit doing business, and it was very interesting to know why that happened. In one case it was very clear that it was the fault of the corporation. It had lost all interest in the association, and it gradually petered down due to the fact that no one was trying to get members.

The other case was where one-third of the members were not employed in the corporation: they were ex-employees, but that one-third of the membership received two-thirds of all the benefits paid, and that explains why it became insolvent. A number of corporations have large benefit associations which permit ex-employees to maintain death benefits. In fact, most of those which do retain ex-employees as members are permitting the carrying of death benefits only; but here is the thing that seems to me to be alarming.

Statistics of benefit associations show that 6.7 per 1,000 is the average death rate of about 250,000 members, which is a pretty fair basis for figuring your benefits, while I understand the death rate of the country is about double that. That shows that the death rates in the memberships of the benefit associations is only half of the normal death rate of the country.

Benefit associations, therefore, profit from the fact that their members cease to be employees prior to the time of their death, because ceasing to be employees means ceasing to be members of the benefit associations. Therefore, those death losses are not assumed by the associations.

It would be very desirable to continue those death benefits; that is humanitarian. I am not arguing that I believe in abandoning these benefits, because I don't. But it is a fact, nevertheless, that those associations that permit the carrying of the death benefits after the employee leaves their service are approaching insolvency.

We must look that fact squarely in the face, and first find out whether or not those employees should be allowed to retain their benefits. Then if they are, how can they be carried without endangering the solvency of the association? I think the members of any association, if the matter was put to them properly, could be brought to see that the cost of carrying those benefits must be made up in the dues paid by those ex-employees.

It has been stated many times that employees' benefit associations need very little reserve because of the fact that the employees cease to be employees prior to the time of their death in such a large number of cases. But if we are going to change our rules to include those members, who become ex-employees? Then we will approach very closely, if not entirely, to the death rates of the country, and we get into the same line of business that life insurance companies are in, and we must have the same reserves, we must have ample reserves.

In other words, if you must be great enough to carry the losses which are going to come later on, you must provide for them. We are now, in some ways, like the fraternal orders. They have been working along those lines in former years, and many of them are working along these lines now; but they have found that their rates must be ample enough to take care of the losses caused by the deaths of the old members, and large enough to give them a reserve for this purpose.

In leading this discussion, I realize that my function is merely to start the ball rolling, and I hope that before we leave the subject, we may be able to arrive at some definite conclusion, so we may know how best to prevent the insolvency of associations that want to carry on the humanitarian work of taking care of the employee who has been with the concern for years. We wish to grant those employees really what they ought to get.

MR. H. A. THOMPSON (Union Switch & Signal Company, Swissvale, Pa.): The Westinghouse Air Brake Company had been running our plant for some years before we bought it. They were running the benefit association for two years previous to the time that we took it over. They increased the benefit, didn't increase the dues, and they went under. Before we took hold of it, they raised the dues, and I think there was something like \$484.00 in the treasury. The company thought the old men who had been paying for some years should be permitted to carry their benefits.

CHAIRMAN ELAM: Then you feel that the contributions made by these old members are going to pay for the increased death benefit liabilities?

MR. THOMPSON: By making them pay a little more, when the employees wish to carry it out, on the year's balance. These ex-employees were permitted to carry their benefits after they left, but the rate was raised a little. I think they were allowed to carry only one class of benefits.

CHAIRMAN ELAM: That is for sickness alone, isn't it? You have no death benefit.

MR. THOMPSON: We have a death benefit of \$150 for outside members, and a much larger benefit for the members.

CHAIRMAN ELAM: Then the old employee, or the superannuated man, would come in under it as being carried for a death benefit or a disability. Mr. Chapman, what have you to say?

MR. CHAPMAN: The proposition of retaining the members leaving the service of the company and permitting them to carry a membership thereafter for the death benefit only, held by them during the time they were active members of the association, is one point which has given the trustees of our association considerable concern.

Originally, when the committee drafted our regulations, which were put in force in September, 1908, regardless of his age or physical condition, a man was entitled to a membership without physical examination. We took them in at the rate of one thousand a day for the first nine days, and the highest age was seventy-eight. We took them in with all kinds of ailments that had not caused disability up to that time.

Very shortly thereafter we had men disabled from different causes, and we began paying right off the bat. The committee took this view, with reference to allowing members who left the service to continue their membership for death benefit only: that, in joining the association, a good many of the men who were between the ages of twenty-one and thirty-five were then probably carrying insurance in various other organizations that paid sick and death benefits; that, in joining our association, which we knew by actual comparison paid more in benefits for the contributions—I use the word "contributions" because we don't allude to premiums or policies or anything of that nature that is used by insurance companies—they might give up some membership that they were then carrying; that they might continue thus for a period of several years, at the end of which period their membership would automatically terminate; and, that, thereafter, they may continue their membership for the death benefit only, if they want to carry it, but not to exceed the death benefit held by them. Now, that ranges from \$400 up to \$2,000. That cost them, when we started out, at the rate of 10 cents per \$100 per month; in other words, \$12 per \$1,000 per annum.

At the end of two years I showed the Board of Trustees whither they were drifting, and that nearly every member of the association drawing benefits for 52 weeks was afflicted with an incurable disease. We were rapidly going into the hole, so we raised the rate. We couldn't do more than to double it, because of the old-aged man, the man who was sitting around the house or out in the yard, not able to do anything in the line of work to increase his income; it would be a great hardship to him if we increased it more than double.

That rate applies irrespective of age or physical condition, so we are

now carrying a death-benefit-only membership of 800 members with a liability of over \$1,000,000.

Now, the other class of employees, members who are shrewd, take death-benefit-only classification. They are the employees who, for one cause or another, leave the service of the company to go with some other concern, for other causes, continue the death benefit. The percentage of members of this classification who allow their benefits to lapse is considerable.

We adhere very strictly to the regulations with reference to termination of membership on failure to pay contributions within the time limit. That is our safeguard in that matter, and at the last meeting of the Board of Trustees of the association, there was an amendment made to the effect that if the contributions were not paid on the date due, membership lapsed and could not be reinstated. To limit further that class of memberships, we have changed the rule, so that a five-year membership is essential instead of three.

When we changed it from one year to three years, we immediately reduced the number of applications. It was cut fifty per cent and now with the five-year period we are going to decrease it another fifty per cent. It is only the old-time boys who are going to be eligible to that class of membership. Our statistics show a great reduction in the liability and as time goes on it is going to be diminished still more.

There is one other subject that Mr. Chandler did not dwell upon, and that is the payment of disability benefits to employees who had left the service of the company, and who reported disability after they left the service. In our experience we have had a large number of cases where the members claim they were disabled thirty to sixty days after membership had lapsed, due to their having left the service either as the result of sickness or accident. The claim has been made that the man was sick at the time he quit service. We have had no end of trouble in getting away with those cases. In fact, we have had several suits against the association, and in one case we carried it to the Supreme Court of Illinois and won the decision. That decision is now cited by a great many fraternal orders which are subject to the same kind of claims. It was a test case, and at my earnest solicitation our legal department carried the case up. It cost us some money, but that has saved us a good bit since in enabling us to maintain our cause against imposition and attempted fraud.

CHAIRMAN ELAM: We will proceed to the next subject, "Selling the New Employee."

SELLING THE NEW EMPLOYEE

F. E. CHAPMAN, SUPERINTENDENT, EMPLOYEES' MUTUAL BENEFIT ASSOCIATION, INTERNATIONAL HARVESTER COMPANY, CHICAGO.

I want to state, in the first place, that membership in the benefit association of our company is not compulsory. It is optional with the new employee. He is informed that the employees of the company maintain a benefit association, of which about eighty per cent of the employees of

the company are members. Our plan is not what is called a class plan. A great many of the benefit associations throughout the country, and especially the smaller ones, are operated on the class plan, that is, after payment of a specified amount of dues, the member is put in a particular class; if he pays a little more, he is put in another class and so on and so forth. The class plan permits of a change of classification as wage or salary increases. That is constantly happening, and necessitates changing the classification of the men. If a man's earnings are reduced, he is reduced to a lower class unless there is a provision which permits him to retain the last classification.

The Harvester Company plan is called the per cent plan. The member employed in the factories pays on the basis of his earnings of two thousand dollars per annum and under. He pays into the association on the basis of wages or salary earned and benefit is figured in the same way. If the man is earning \$1,500 a year, he pays on \$1,500. If he dies, his beneficiaries draw \$1,500. If he becomes disabled and his disability runs for a period of 52 weeks, he draws \$750. He pays for that at the rate of one and a half per cent of his earnings. They do not, under any circumstances, draw benefits on account of accidents which arise out of and in the course of employment, which would bring them under any state workman's compensation law. We handle only accidents outside the shop, and those which do not arise out of and in the course of employment. There are many such accidents that do not come under the industrial compensation laws.

We considered, at one time, a change that was suggested by members, through the elected Board of Trustees—that we switch over from the per cent plan to the class plan. When that matter had been up for discussion, we were convinced that the only equitable basis was the per cent plan and for that reason our regulations have never been changed.

EXPLAIN FULLY THE ADVANTAGES OF MEMBERSHIP

Now, to get back to employment and members. Before a new employee is sent to work, he is told what the benefits of the association are, what it costs him, how the money is paid into the association (i. e., it is taken out of his pay by the pay roll department), the amount to be indicated on the pay envelope. He is also fully informed of the amount of the benefits, the nature of them, the special benefit for the loss of hands and feet, and the death benefits due to sickness or accident. He is asked to join the association. If he is a foreigner, he generally replies, "I don't want it. I belong to the National Polish Alliance," or "I belong to the Modern Woodmen" or some other organization. We have a list of so-called health organizations. They have no capital, they have no surpluses they are fly-by-night, so to speak. Then, if he belongs to anything that we do not consider a responsible organization, we ask him how much he gets and what guarantees he has if he becomes disabled, and how much his beneficiaries would get. Generally he can't tell you anything about it. Some solicitor called around and gave him a fine story and he signed the application. We tell him, "Here is the Harvester Company, with its millions back of its benefit association. There is a signed agreement by

which you are protected. We have the money with which to pay the benefits and there has never been a time when there wasn't ample funds for all purposes." If at any time any state insurance commission wishes to investigate us we have something to show that we are not going busted.

We explain the plan to the man in detail, if there is time. Sometimes the employment department is rushed and can't go into details and he is sent out to his department to be put to work. After he has been there two or three weeks, if he stays that long in these days of rapid turnover, his foreman or his time-keeper, or some employee of the company, goes to him and says, "Well, John, what do you think of joining the benefit association? You remember we talked to you about it and at that time you didn't want to sign up." Sometimes he will say, "I am still of the same opinion. I have all I want to carry." That interview is ended, and later on he is solicited again. It is just the old story of finally getting him in by keeping after him. Now, in a great many instances we are unable to close with him, and we simply let him go to work. We can't force it on him. He can't say he had to join or get out. It has been claimed by labor leaders, as an argument against employers maintaining associations, that employees were forced to join. This can't be said of the Harvester Company.

HOW TO GET FOREMAN TO HELP

There is a spirit of rivalry between departments. The superintendent calls a foreman and he says "Mr. Jones, you have a thousand men in your foundry and the time cards show that only 60 per cent of them are members. Here is a list of those who are not members. See what you can do." In that way a canvass is made in each department, and through that medium the next month the list shows the department has increased its membership. The foremen are kept advised of the progress of the different departments. If one foreman sees another department getting ahead of him, he says, "I am not going to let anybody get ahead of me." In this way they keep up their membership right along through a spirit of rivalry.

Also, a good time to get them in is when they get a raise. When a man gets a raise, an application is handed to him, and he is invited to join.

Physical examination is required for membership in the benefit association. If the employee has been in the service for some time before he indicates a desire to join, he is subject to a re-examination.

Is there anything else, Mr. Elam, that you would like to have me touch upon?

CHAIRMAN ELAM: I don't think of anything at the present time.

MR. ALBRECHT: It seems to me that if the foreigners who belong to the Polish Alliance and such organizations could be gotten to join the benefit associations, it would be a great step toward their Americanization, and that there is great power behind the benefit associations. The foreigners should be gotten away from those foreign organizations if they are going to be Americanized.

MR. CHAPMAN: I am very glad you mentioned that. The Harvester Company is doing an Americanization work among its foreign employees.

As you probably know, the Harvester Company has an Industrial Relations Department where there is workman's representation in the management, in the conduct of the shop matters and on other things in general. Each plant has a works council. Where there is a preponderance of foreign nationality we have started a campaign through the works council and through intelligent foreigners to show these people what it means to belong to a good organization.

We built up a surplus that enabled us to go through the influenza epidemic. We have had a net loss of \$63,000, approximately, but we didn't have to sell a Liberty Bond or any other security to pay off our obligations.

MR. JONES: One of the obstacles we find in getting members among foreign workmen is the fact that if a member of their organization dies the rest of the members voluntarily donate a dollar, which is the death benefit that they pay. And, of course, where there are several hundred members, they receive a larger benefit than we are able to pay from the dues we can collect from our members. I have had that thrown into my face several times as an inducement for these members. They retain their membership in the foreign organizations.

MR. CURRIE: I would like to ask, Mr. Chairman, if they have a time limit or a specified time after which an employee can join the association. I believe it is the experience of all present, as it is with our company, that the turnover is so rapid that the men are continually coming and going.

MR. CHAPMAN: The only trouble we have is the volume of work that is required to act on the applications. The turnover of labor makes a big lot of work. There is a short waiting period for membership to become effective. For instance, a man passes the physical examination for membership. The plant sends the application in. It generally reaches my office not later than three days after it is sent, and it is acted on generally the day it is received. We make all of our memberships become effective on the first day of the succeeding pay period. There is no way of telling how long the new employee is going to stay. He may be gone before we can act on his application. We have a system whereby we are immediately notified of the employee leaving the service who has made an application and no action is taken on that. I aim to get that application acted on and the certificate in the hands of the man on the first day of the following pay period. Does that answer your question?

CHAIRMAN ELAM: Mr. Chapman, do you ever have a criticism of the association's rules in regard to this necessary waiting period?

MR. CHAPMAN: Oh, yes, and our answer is that we reserve the right to examine the application and ascertain if the man was ever a former member of the association.

CHAIRMAN ELAM: I have had quite a number of cases of that kind in our association, and they come along with the plea that in ordinary life, the insurance company makes your policy effective the date of the application and the employees benefit associations should do the same thing. But there is little to that. I am in favor of this waiting period. It gives us a chance to do our advance work in an orderly manner and sometimes gives us a check where somebody has slipped.

MR. CHAPMAN: The value of a waiting period lies in the fact that, as

you have stated, a check of the man's previous record can be made. We find there is a large percentage of the employees who leave the service and come back within two or three months. They have gone somewhere else, and come back and want either their old job back or one just as good. We have had cases where new employees have made application for membership, taken sick, and died before the day on which their membership was designated to become effective, and there has always been the howl that we are holding out on them, from widows especially. The man goes home and tells his wife he joined the Harvester Company's benefit association, and if he dies she will get so much, equivalent to one year's average wages.

We will say the employee made his application on Monday, and he wasn't feeling well but he didn't disclose that to the medical examiner. We don't stick a thermometer down his throat and take his temperature unless there is something about the man's appearance which indicates everything is not right, then his temperature is taken and he is given a thorough going-over. In 1909, we had our first case of that kind and it resulted in a lawsuit. It was contended that this man became disabled and his death subsequently followed. We told the dependents that he was not a member and that he hadn't paid any dues. They took the case to court and lost, of course. But to forestall that in the future, we amended our application. We have a book of rules and a copy of it is given to every member when he joins the association. If he can't read English and can read Polish, we give him a copy translated. If he speaks Polish, Greek, Italian, Lithuanian, or German, we give him a copy that he can read. We print it in nine foreign languages that are used in our shops now.

There is no argument about it. If he can't understand it we say "Here is an English copy: get somebody who can understand it and have him interpret it to you."

MR. THOMPSON: I agree with Mr. Chapman that to get a man into the relief association the first day on which he is in the employ of the company is a good step. In our company we feel that the benefits derived from this association will be a benefit for him. When a man comes in and wants to argue, (but there is only one out of about 620 who does that) we first explain the system, and if he doesn't join, we mark his card "non compos mentis" and send him out.

ELECTION OF OFFICERS

The Nominating Committee, consisting of Mr. Chandler, Mr. Eaton, and Mr. Chapman, reported the recommendation that Mr. Joseph N. Redfern be elected as Chairman of the Employees' Benefit Association group, and that he appoint such committees as he may deem necessary to assist him in conducting the work of this group during the coming year.

This report was adopted and Mr. Redfern unanimously elected.

Employees' Publications Round-Table Discussion

October 2, 1919

E. A. WANNER, Chairman

Assistant Editor, "Jeffrey Service," Jeffrey Manufacturing Company,
Columbus, Ohio

THE meeting was called to order at 1:15 o'clock, Mr. E. A. Wanner, Assistant Editor, "Jeffrey Service", Jeffrey Manufacturing Company, Columbus, Ohio, presiding.

CHAIRMAN WANNER: I am sure that this large turnout is gratifying to all of you people who are interested in employees' publications because it shows how important these are becoming. I am sure we are going to have so many people who will want to speak today that there will be some disappointment because our time is so short.

After each speaker we will allow, say, three or four minutes for discussion. Please bear in mind that we have no time to wait, so if you have anything to say, get up immediately and say it. Let this be, if I may call it such, a "pop-corn" meeting. When a speaker sits down, jump up and say what you have to say, because there will be a lot of suggestions presented and a lot of questions asked.

"What Benefits Should a Corporation Expect to Derive from an Employees' Publication?" — I have asked Mr. H. H. Matthieson, Safety Engineer of the Crown Willamette Paper Company, Portland, Oregon, to speak a few minutes on this topic, and while he is speaking, if you find any questions you would like to ask in regard to this subject, please be preparing them so that we can put a lot of pep into the meeting.

WHAT BENEFITS SHOULD A CORPORATION EXPECT TO DERIVE FROM AN EMPLOYEES' PUBLICATION?

H. H. MATTHIESON, SAFETY DIRECTOR, CROWN WILLAMETTE
PAPER COMPANY, PORTLAND, OREGON

There are many types of house organs and house newspapers published to-day, and while we are talking about house organs, I want to differ-

entiate the various types and deal entirely with the house organ for the employees.

By way of introduction, I might say that some house organs deal with methods of advertising and selling goods to the public. A second type is published for the stockholders, to keep them in touch with what is going on. Another is the employees' publication, published for and by and with the employees—for the individual man, for his own benefit, for his home, his family, and his children.

As I said a moment ago, there are house organs and house organs; they are of many shapes and forms and varieties. Some show great care and attention and expense in compilation; others do not. Sometimes I think it would be better if some of them were not printed because they are a waste of good printer's ink, time, and money. However, we are all striving to reach the individual workman through these papers.

What benefit can we derive from it? Of what benefit is it to the company? Is the employees' publication merely a fad or is it worth while?

Before going on to that discussion, permit me to digress a moment again. One thing to take into account is the amount of money one wishes to spend upon the house organ. That determines its character, but no matter what the expense is, give it good printing. Good printing is the cheapest printing there is. Nothing is more distasteful than a paper gotten up in poor form and poorly printed.

Now then, what are the benefits to be derived from these publications?

First, one can present in the right way the policies of the company and the information that one wishes to pass out to the employees. I know that those of you who heard the speeches yesterday afternoon thought they were very impressive. I enjoyed every word of them, but last night when I went to my room, I read the printed copies of these addresses. That gave me a chance to study them.

Around the plant employees hear talk of safety work, service and welfare work—rumors that float about. No one has the inside information about it. The plant paper can put that information across with authority, and do it authentically.

Second, the plant organ promotes harmony and a clearer understanding. One can promote harmony, set forth the policy of the company, and enlighten the employees about problems of management more satisfactorily through this paper than through spoken information, rumors, or what not.

Third, it gets close to the home. I always size up a publication that I am trying to work on by counting the number of copies I can find thrown away after the edition is distributed. I think that is a good method to ascertain whether the publication is worth anything or not. If you hand your copies out at the gate and then when you are through, find half of them on the ground, thrown aside, you have failed in your efforts. But if those publications go home where they should go, where the man can take time to read them over and the children can read them over, you are getting in touch with that most vital part of society—the home. And that develops plant family spirit. I like the idea of a

plant's talking about the A, B, C family. I like the idea of talking about our plant family and trying to consider our organization as one big family with the president or manager at the head, and the rest as members of that family. Your plant organ can develop that spirit more than any other thing.

I like to put in at least one article touching upon the minor technical side of the work carried on in the plant. You will be surprised to learn how little the families and, in fact, some of the workmen themselves, know about the great organization to which they belong and what it is trying to produce.

In the paper industry I had that brought home to me very clearly not long ago. I was in our San Francisco office and we were running a series of publications telling how paper is made, from the tree to the finished product. One of the stenographers said to me, "I never realized before just how paper was made. I have never been near the mills." There were a great many other people in our mills who did not know what the departments other than their own were doing.

The paper is an advantage in an educational way, and I might say the most important thing it will accomplish for the company is to develop a "pull together" spirit. I like "pull together" better than "co-operation". I think the latter term is overworked. I remember when I was a boy I was in a logging camp. Two oxen were hitched to a log. One of the oxen lay down and wouldn't work. The other was straining himself in a futile effort trying to pull the log. Finally the driver got the first ox up, and then the other one, which had been doing the work, lay down. Well, it took a great deal of talking and, as is customary in logging camps, a great deal of strong language to get those two oxen to pull together. The same is true in our industry today. We need more of this "pull together" spirit, and this "pull together" spirit can be developed through the plant organ, if it is presented in the right way, better than by any other method.

CHAIRMAN WANNER: Now, let's have some direct questions or suggestions, but make them snappy.

MR. SCHNEIDER (Goodrich Rubber Company): I would like to ask what the best method of distributing these papers is, because this question has just recently been brought up. We feel that every employee should read these publications and they must, therefore, be properly distributed.

CHAIRMAN WANNER: I might speak for a firm of several thousand men. Possibly 3,000 of our employees receive the publication. We have two gates that the men use in leaving the plant, and we have our messenger boys there—three at each gate—to pass out copies to the men as they leave the plant.

We did try at one time to have them piled up on a box so that the men could help themselves, but there is one bad feature connected with this plan: sometimes the men get the papers before the hour for quitting and, consequently, they are tempted to read them during working hours. Brown will have his paper and the men in his department will gather about him to see what the reports are; this tends to break up the dis-

cipline in the department. We found that in distributing the papers when the men were leaving the plant, we were following the better plan. That, of course, will take care only of an organization of a few thousand men. Where 10,000 men are employed, the question might be somewhat difficult.

MR. ASHE (General Electric Company, Pittsfield): We have 6,500 employees. We have been publishing a works bulletin for six years. We distribute the paper by first being absolutely sure every month that it comes out on the first of the month. It is distributed in the different factories as the men go home, and of more than 400,000 distributed, we have found only twenty-two that have been thrown away.

CHAIRMAN WANNER: That is a very good record.

MR. REESE (Firestone Company): We have approximately 40,000 papers to give out weekly. We have tried two methods. First, we sent slips to the various departments asking how many papers were wanted. After we got this information we sent the required number and obtained a written receipt in return. That plan didn't work. It might have worked if we had not thought of a better one. We found the papers blowing about the department, so we got a magazine rack similar to those found in a Y. M. C. A. or railroad station, consisting possibly of twenty-five sections. Then the men and women in going out on Friday afternoon take their papers from this rack. I think very few take them when going into the plant. We find that the papers handled in this way do reach the homes.

MR. MEACHAM (Goulds Manufacturing Company): We print about 1,200 papers every week and distribute them by giving them to the foremen and making them responsible for the distribution among the men in their departments.

There is one phase of this benefit that employers may gain that I want to speak of, and that relates to safety work. I have been very much surprised to see, in the great number of employees' publications that come to my desk every month, that comparatively little space is devoted to discussion of safety work.

When we started our paper last April, I was told that I might have a column in each issue for an article on safety. A column consists of 888 words. Believe me, I know it makes the safety engineer scratch gravel to fill a column every week! It not only gives your men good, reliable information on accident prevention in the various departments, but it is a mighty good thing to develop your safety engineer.

CHAIRMAN WANNER: Mr. Ashe said he issued the plant organ on the first of the month. I think the better plan is to issue it on the last Saturday of each month. When the paper is given out on Saturday, the men have Saturday afternoon and Sunday in which to read it over. We have a great many men who work nights, and when we gave it out in the evening, they would read the paper instead of watching the machines.

MR. MOREY (Commonwealth Steel Company): I have heard that Procter & Gamble Co. sells its paper.

MR. WINGFIELD (Procter & Gamble Co.): We publish a monthly magazine consisting of forty-eight to sixty-four pages, which we sell to the employees at a nominal price: five cents a copy for the regular issue, and ten cents for the big issues, such as the Christmas number. These are sold at the pay line by the office boys and by girls from the different departments.

We do this not to make the publication self-sustaining or to make money, but merely to keep our magazine out of the hand-bill class. It costs a great deal more than five cents a copy to print this paper. We charge this nominal price only to make sure that the men will take the papers home and not pave the streets with them. The charge is made because of its effect in getting the men to appreciate the magazine.

MR. PERRY (Eastman Kodak Company): How many employees has your firm.

MR. WINGFIELD: Three thousand employees. The publication is for the home plant at Cincinnati. The Ivory town has about eight hundred, of which two hundred are English-speaking.

MR. MOREY: What percentage of the workmen buys the paper?

MR. WINGFIELD: Fifty per cent buy it at the home plant. The percentage in the other plants is smaller.

CHAIRMAN WANNER: The next topic, "What Can Employees' Publications Do to Promote Industrial Good Will?" will be discussed by Mr. Myron J. Jones, of The Sherwin-Williams Company.

WHAT CAN EMPLOYEES' PUBLICATIONS DO TO PROMOTE INDUSTRIAL GOOD WILL?

MYRON J. JONES, DIRECTOR OF PERSONNEL, SHERWIN-WILLIAMS COMPANY, CLEVELAND, OHIO

My only right to speak on this subject is that the Sherwin-Williams Company, which I have the pleasure of representing here today, has had a house organ for twenty-eight years, and it has, therefore, had a little experience in the value of it.

I am bound to say that the company has made its own progress by buying the good will of the public through advertising, as we all know who know what the "Cover the Earth" proposition means, and we figure that if it is worth while to spend \$500,000 a year in getting the good will of the public for our goods, it is worth something to get the good will of the people in the making of our goods and in the selling of them. In the progress of the company's effort along these lines, I am very glad to say today that from the standpoint of experience we think the "Chameleon", which happens to be the name of our publication, has been absolutely worth while. The present managing editor of "Printer's Ink" was the editor of the "Chameleon" up to last November.

I say that the house organ is no better than the people who make it and the stuff that goes into it. The stuff has to come from the concern

about whom it is published. In other words, if you have nothing to talk about, you have nothing of interest to the employees.

In the six good points laid down by the previous speaker, I think he has given the answer to what a publication may do to promote industrial good will. If it does those things, it promotes industrial good will, whatever that is.

After all, I believe industrial good will must get back to the home. Following all the other human interests named, when you have a publication that can help sell the proposition of Procter & Gamble, or the Eastman Kodak, or Goodrich or Goodyear or Sherwin-Williams, or anything else to the man's family—the mother, sister and younger children—that is, in my judgment, a criterion of the worth of it.

This gentleman (pointing to the chairman) who edits this paper (holding up a copy of "Jeffrey Service") has set the pace for a lot of us. The "Jeffrey Service" is one of the good ones. I say this to you not because the assistant editor is here, but because the editor and manager is a man I have long known and admired, and who started with the Sherwin-Williams people but who found something better than paint and varnish to take up his employment.

I am going to tell you the secret of this thing is the fact that it gets back to the fundamental element, the human interest in the family.

In conclusion, if the corporations of the United States are justified in spending millions of dollars annually in getting the good will of the public for their products, by the same theory they are justified in spending good money—spending it well through good people, qualified and experienced to do it—to gather news, put it out, and thus promote the good will of the employees toward that company, toward its products, toward its service, toward all that makes it worth being in existence at all.

The plant organ is no better than the company's program of putting excellent brains into it. I was delighted the other day when a firm from Rochester came to Cleveland and offered the now munificent salary of \$5,000 for such a person. I hope they got him. There is a fellow here who looks as if he might fill the job, and he represents the company.

MR. PERRY (Eastman Kodak Company): They are still looking.

MR. JONES: I happen to be the director of personnel of our company, so I am interested in employment. I gave them the name of a likely young man. The Plain Dealer immediately raised his salary and he is still writing "Labor" in the Plain Dealer, although he didn't write the article in today's paper. Of all the lopsided propositions that ever came through, that is one—the failure to interpret a session on employee representation.

Gentlemen, let's make our plant publications for the employees on the level with the best that can be done. The best is none too good, and I will say the good is enemy of the best. You have got to have the best, at least the better to prepare your plant organ.

If there are any questions about this publication that you would like to ask, I will be glad to answer them. Our editor is here today, but he is

not very familiar with the work as yet. As I told you, "Printer's Ink" took our editor, but we are glad he is doing a good job.

MR. DRAPER (American Multigraph): I spent some years in the newspaper business, and I found that one cardinal principle is: They don't want to read it. Since I have gone into the house organ business, it has been even more impressed on me. On checking up distribution, if your pay roll clerk addresses a copy to each individual, you find out, first, what employees do not read the house organ; you have the very fine criticism in reply to "Why do you throw these away?"

CHAIRMAN WANNER: The next speaker is going to give you some information that will partly explain a statement just made, viz., that some house organs do not hold enough interest to get the men to read them.

Now, I think that Mr. Sayler, our next speaker, will tell you what kind of news to put into your house organ, and will tell you the kind that your men are willing to read. Mr. Austin C. Sayler of the O. S. Hubbell Printing Company will speak on "What Kind of Material Is Needed to Make the Plant Periodical a Success?" I might add that Mr. Sayler has had a good bit of experience along this line and he knows whereof he speaks.

WHAT KIND OF MATERIAL IS NEEDED TO MAKE THE PLANT PERIODICAL A SUCCESS?

AUSTIN C. SAYLER, THE HOUSE OF HUBBELL, O. S. HUBBELL COMPANY,
CLEVELAND, OHIO

The subject is very broad and it is pretty hard to keep to it because there are so many phases which govern the contents of a trade paper.

The trade paper certainly must contain sincerity and individuality. Every plant has its individual problems, and every item, every line, in that house organ should apply directly or nearly so.

It is hard to find, in reading a hundred house organs a month that come across my desk, why a lot are printed. They apparently don't have a policy. Now, without a policy you have no way of gauging whether your house organ is a success or not. The mere fact that you are printing shop news isn't going to repay you for the effort and money that you are putting into it. The house organ should have a policy or a reason for being, something that will make the man understand that he is a reason for the success of the organization as a whole.

I have made a list of what I believe a house organ should contain. Now, it should contain matter that will accomplish the big purpose, as I see it, of every real house organ. One of the purposes, to my mind, is to create loyalty to the company. To create that loyalty you have to give the men reasons why they are working for the best company that there is in existence. You want to tell the men, for instance, about concerts; getting in the community affairs; dances; picnics; baseball games; bowling; music, if you have a band or orchestra; the hospital in the plant, or arrangements at the near-by hospital; visiting nurse; insurance;

benefit association; restaurant; store; a clean place to work; well-lighted; nothing in the aisles to stumble over; convenient location of the plant; transportation; steady work and good pay.

Reproduce and expatiate your national advertising if you are doing any. Explain the bigness of the Company. Articles along those lines will automatically create a loyalty to the company.

Another reason for the house organ is to stimulate interest in the work and pride in the quality of the product. Articles on the following subjects will create this feeling: the quality of the product you manufacture; suggest prizes for bettering them; and then your representatives' sales talks—what the customer wants and expects and what he thinks of our products: tell him why our product is the best; the ultimate use of the product; why used and how used; the necessities of being perfect; what an imperfect article means to the sales department; show the cost of materials generally, not minutely; what it means if a man spoils a part, the delays, the reorder of material in small quantities to replace it; how delays affect sales; quality talks.

I heard this statement the other day from a man who is an authority. He says "Quality talks will automatically produce quantity." I believe that is true.

Another reason for a house organ is to foster initiative. Inspirational articles: how a mechanic by an idea made some money; suggest giving remuneration for suggestions about improving the machine, the location of the machine, the method of operation, or the method of handling material.

Another reason is to create a spirit of coöperation between departments. Show how slowing up affects other departments. Show how imperfect parts stop production. Give concrete examples. There is no use talking about what they are doing in other cities. Confine all your articles directly to your own problem.

Create a spirit of coöperation between factory and office. Personal stories about executives, if interesting, are good. Have articles on the troubles of your executives because if you show the workmen that the men in the front office have real troubles their own personal little troubles aren't going to look quite so large. Give articles on the necessities of a closer coöperation.

Another reason for a house organ is to create a friendly spirit among the employees. Tell *all* the news to *all* the employees regularly. I don't believe in Procter and Gamble's scheme of selling unless you have a hundred per cent distribution. If not, you are going to lose some place. If I can't make the house organ interesting enough for every man to take it home, I haven't accomplished fifty per cent of what I started out to do. I want every man in the plant to read the house organ. Give production records: department news; new employees; new equipment; men who have been advanced and why; small group snapshots; stories of employees; illness; vacations among hour help, not the office (the man in the factory would say, "He gets paid for it"); new automobiles; pianos.

victrolas, etc., in the homes; original verse and cartoons (and, don't let them put something over on you there); new homes.

Another reason for a house organ is to teach Americanization and the benefits of naturalization: short historical sketches; opportunities in this country; advantages under our form of government; comparisons with other forms of government; short biographies of successful men; serial articles on naturalization. There is one house organ that ran the best naturalization story I have read. There are very few editors who can write the kind of article that Jack Patterson of the Hydraulic Pressed Steel Company has written. It is quite a proposition. He had to go through it himself and he knows. If there is anybody who wants good material on naturalization, he should get the series that appeared in the Hydraulic Press. You can't do any better. I believe if you had the space to run a question box on naturalization, it would be a good thing, but be sure of your subject.

Another reason for a shop paper is to foster desire to save money and own a home. Give examples of what employees have done, preferably the lower salaried ones. Show table of what small savings amount to; W. S. S. propaganda; articles about men carrying money in belt, or money hidden at home; being robbed; show the advantages of putting the money in savings banks.

Another reason for shop papers is to describe safety in the plant and home; being members of the National Safety Council, you will, of course, get good material from this source, but, better still, give concrete examples, if you have had any accidents in your own plant.

Here is one of the most important reasons: Create desire of the wife to want her husband to work for you and want her son to follow his father. Publish articles on why he should work here; why this is the best place to work; articles descriptive of community affairs; social affairs; about your visiting nurse; about your insurance (give concrete examples).

I know a company that, when an employee dies, makes a complete investigation of what becomes of the money that is derived from his insurance. They tell that in their house organ and it has a good effect on the wives and other employees. It is a concrete example.

Some house organs use this and others haven't the space: Home Economics. Our friend, the White Automobile Company, make quite a section of suggestions by wives of employees, none other. Don't take a clipping out of a daily newspaper for a recipe, but if you have a real, honest-to-goodness thing that one of the wives did, put it into the house organ.

I read an article the other day of a man criticizing house organs. He said that he had seen several hundred of them, but that apparently there wasn't a woman in the whole outfit who had ever made anything unusual. I believe it is true. I see a great many, and I don't see where a woman has suggested a single thing to help the man or other employees in the plant. If you have the room, give them these recipes on cooking, general health notes, care of the children, etc.

Here is another thing: the most interesting thing in the house organ and that which we need to make it an interesting carrier is a Want—For Sale—Exchange column. You would be surprised to learn of the number of things the employee has that he wants to get rid of. That made the success of the New York Evening Telegram. About the time they were slipping, they started an exchange column and it ran into four pages. That is what the men like. If they can't get their names in the paper any other way, they will have something for sale.

Another reason is to create desire in the man on the outside to work for this company. I know a house organ that was so effective in this that the day after its first issue was distributed, they had eleven men from other factories apply for jobs. One of them said, "I didn't know before that you had such a hell of a good place to work in." And, at that, this place wasn't so much better to work in, but the house organ made them believe that it was. That is just another reason for a house organ.

CHAIRMAN WANNER: Mr. Sayler has crammed a whole lot of things into his talk, I am sure, and if you remember just half of those, you will have a lot to carry away with you—and don't forget what he said about the recipes.

The next topic is "How to Obtain News Items for a Plant Publication." Mr. C. H. Wilson is going to speak on that. Mr. Wilson is the Safety Engineer for the Utah Copper Company. Mr. Wilson has the floor.

HOW TO OBTAIN NEWS ITEMS FOR A PLANT PUBLICATION

C. H. WILSON, SAFETY ENGINEER, UTAH COPPER COMPANY,
SALT LAKE CITY, UTAH

It is not difficult to obtain news items for a plant publication if you can get your company to devote some kind of prize. The company that I have the honor to represent gives three prizes for each issue, and through that method we have been able to interest practically everyone inside of the plants. We employ 6,000 men at our works, and the prizes consist of \$10 for the first prize, \$5 for the second, and a safety first honor button for the third.

We have made it a point not to issue our safety first honor button indiscriminately. Everyone who obtained one of these buttons had to win it. We have eighty-two in circulation at the present time, and each one of those eighty-two men who are wearing those buttons has either contributed an article to the plant periodical or has rendered some valuable service to promote safety by offering a safety suggestion or by preventing some one from getting hurt.

Now, the method of obtaining the news items: if you can get your plant management to set aside an appropriation of that kind, I should say it is quite easy. We will assume that the men in charge of your management, if they have attempted to issue a publication, must have a

large enough force to make your magazine worth while, and that you have a number of departments. At our works we have selected in each department a representative who has been solicited by the editor and by the general superintendent of the plant to collect news for his department and send it in to the editor. So far we have had very good success with that campaign. We are attempting at the present time to go a little farther. We are trying to raise the prize from \$10 to \$25 and make the second prize \$15 and the third \$10 instead of the safety first button.

Our plant periodical may not cover the same things that you men all have in mind. Our publication is strictly a safety periodical, and the matter that goes into our publication is controlled by the Safety Department. There are no others that pass censorship.

I have found that the only satisfactory way to collect news (and we have tried a great many different methods) is to call upon some particular man in each department, and to get the general superintendent or your general manager to follow that request up with a personal appeal of his own. We have tried to make it plain to the men that the periodical is theirs. It is the employees' magazine. The company pays for it. What goes into that periodical is strictly up to the employees.

Adjournment.

Health Service Section

October 3 and 4, 1919

Dr. CHARLES A. LAUFFER, Chairman
Medical Director, Westinghouse Electric and Manufacturing Company,
East Pittsburgh, Pa.

F. H. ELAM, Vice-Chairman
American Steel Foundries, Chicago

Dr. C. D. SELBY, Secretary
Formerly, Consulting Hygienist, U. S. Public Health Service,
Washington, D. C.

FRIDAY MORNING SESSION

CHAIRMAN LAUFFER: The deliberations of the Health Service Section will proceed according to program. Your Chairman has been invited by the home office of the National Safety Council to prepare a paper, which will constitute the report of the Chairman. The Secretary having no report to make, and there being no committees to report, we will proceed to items of new business.

Attention has been called to the fact that in the safety lessons prepared for public schools by Dr. Payne of St. Louis, where resuscitation is referred to, the discarded method is recommended. The Prone Pressure method has been quite universally adopted; it is approved and used by the National Electric Light Association, the Bureau of Mines, Safety and Sanitary Commissions of industries employing upwards of five million men; the Army, the Navy, the Life-Guards, the Red Cross, the Y. M. C. A., the Boy Scouts—all are swinging around to the practically unanimous acceptance of the Prone Pressure method.

(Motion was made, seconded, and unanimously carried, recommending that the Prone Pressure method be described in the text-books prepared for schools.)

The names of those appointed on the Nominating Committee are: Dr. H. L. Davis, Chairman. Dr. E. R. Hayhurst. Dr. C. E. Ford. These three gentlemen will please get together and deliberate on the matter and report to the section at 9:30 tomorrow morning.

SECRETARY SELBY: We will now proceed to the scientific program of the morning. I have the very great honor of introducing the first speaker, who is our Chairman. Dr. C. A. Lauffer will speak upon "Industrial Health Hazards."

INDUSTRIAL HEALTH HAZARDS

DR. CHARLES A. LAUFFER, MEDICAL DIRECTOR, RELIEF DEPARTMENT, WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, EAST PITTSBURGH, PA.

The human dynamo generates a fixed quota of energy. If speeded up, it stands a determinable overload with immunity; if given rest periods, kept in repair, and properly sustained, the human dynamo will last three score years and ten, probably longer. The overloaded dynamo develops heat, in consequence of which wear and tear is greatly accelerated; if temperature readings show that the dynamo heats up too much, an early breakdown can be definitely predicted. The same applies to the human dynamo in which physical defects and psychic maladjustments, as well as speeding up, overloading, and shortened rest periods, develop "heat," known as fatigue.

Modern industrial developments, collecting vast multitudes of men and women in industrial establishments, bring to the forefront the problem of health hazards. The vast exodus from rural to urban life, during the past generation, forcing into indoor occupation, individuals whose ancestors for generations lived out of doors, has further emphasized the problem of health hazards.

A study of these problems is vital to the employee; health, long life, and happiness are involved. It is fundamental to the employer; increased production; diminished labor turnover; contented ranks of healthy, happy, veteran employees—all tending to increased profits.

The employee asks for himself, and his sons: Is it a safe industry in which to seek employment? Is there any special liability of incurring a trade disease? Or of suffering early impairment in health? In short, what are the health hazards of this and that industry?

INDUSTRIAL HEALTH HAZARDS OF EMPLOYEES

I. The industrial health hazards of the employees may be grouped as arising from:—

1. Poisons, dusts, fumes, gases.
2. Heat, humidity, ventilation.
3. Lighting.
4. Crowding.
5. Fire peril.
6. Association with diseased employees.

The Harvard Chart gives a readily accessible grouping of the industrial poisons; a consideration of all of them would be out of place in this connection. Lead, arsenic, and mercury cause definite toxic effects, when absorbed by workers in these metals. The most used poison is lead. Not every employee who handles a paint brush, however, gets lead colic; some

paints are innocent of lead, yet employees, who have never touched lead, will bring in diagnoses of "lead poisoning," merely because an attending physician knows they are painters. Lead storage in the tissues may ensue when lead is carelessly handled, yet lead poisoning is practically unknown in large plants handling hundreds of tons of lead every year. The extent of industrial lead poisoning, we know, is much less than some reports would have us believe. Employees who cannot be taught to wash their hands before eating, and who never clean their finger nails, nor care for their teeth, are particularly liable to lead poisoning. Lead cannot be eaten with immunity, within or without the industries, but with individual coöperation, plus careful industrial supervision, the lead hazard can be mitigated. Precautions in handling lead reduce, almost remove, the health hazard from this source. Individuals who have once developed toxic lead symptoms should be given other employment, as the poison is accumulative, and is never entirely eliminated, hence relapses readily occur, making permanent transfers to other lines of work necessary.

Persons having a tendency to eczema, or furunculosis, may develop a skin rash from the solvents employed in removing varnish, shellac, and various insulation dope. Cutting oils, recovered by centrifuge methods, provoke skin infections; forced filtration through successive layers of filter paper removes minute metallic spicules, and filters out bacterial flora, that affect the skin. Cutting compounds are often culture media for pathogenic bacteria, and may require sterilization,—by heat, chemical, and filtration methods. Minute burns from flying hot chips; abrasions by metallic spicules in dirty cotton waste,—used in rubbing hands and arms—rough scrub-brushes or caustic soaps, may provoke such dermatitis. Every industry has its own problem, or succession of problems, in this line. Persons manifesting such susceptibility should be transferred to other lines of work; some individuals can work in chemicals for months without developing trade dermatoses, while others develop such trouble quickly. When 150 employees are subjected to the identical exposure, and only three develop industrial dermatoses, the factor of personal susceptibility is suggested. Attention to the toilet—thorough, careful cleansing of the skin—tends to reduce industrial dermatoses.

Dusts and fumes are drawn out of their source, in the well-equipped modern factory, so that the factory atmosphere is, or can be made, relatively clean. There is justifiable grounds for pride, where a wholesome factory atmosphere is maintained. The competition between factories, to make working conditions the best possible, has not yet been over-worked, and can be promoted to the mutual advantage of both employee and employer. It is up to the initiative of employers, coöperating with architects, ventilating, heating and lighting engineers, and employees' committees, to make working conditions safe from the health standpoint.

Pulmonary tuberculosis should be mentioned, in its relation to dust and fumes. Dusts in themselves are not infectious. Dusty air is not salubrious, but with the dust evil minimized, as in modern industries, there are few occupations that can be condemned as unfit for healthy men.

We are told that guinea pigs, kept in cement mills, develop no calcinosis, and employees seldom do. While the controversy over cement

dust still rages, its dangers are less excessive than some have imagined. The dust menace in other trades is, in comparison, relatively negligible. Coal miners develop more or less anthracosis; iron workers may develop siderosis. Marble cutters formerly developed calcicosis, which health hazard is now much reduced by suction devices for the removal of dust at its source. The inhalation of foreign particles,—such as coal, iron, stone, textile fibres, animal hairs and furs, grain dust,—gives rise to pigmentation of the lungs. This pigmentation in itself is of no consequence and everybody has it to some extent.

Dusts are mostly filtered out in the nose; if the dusts reach the bronchial tubes, they are caught in the bronchial cellular cilia, and coughed up, being expectorated with the bronchial secretions. It is contended that none of the dust reaches the alveoli. Particles that reach the peribronchial lymph-nodes, and the mediastinal lymph-nodes, penetrate through lymph channels from the bronchi.

Pulmonary pigmentation, and lymph-node infiltration, is not dangerous, until tubercle bacilli have been implanted. Where has this or that victim of pulmonary tuberculosis acquired his disease? There is no definite period of incubation for pulmonary tuberculosis. So much time elapses between the exposure to the tuberculous infection, and the frank incidence of the disease, that the real source of infection may have passed unobserved. The tubercular area can be walled off for many years, lying dormant all that time, but finally there may occur a dissemination from the old focus of infection. Some observers go as far as to say that the primary tubercular invasion occurs before the fifteenth year, before tissue immunity is established, and that the tubercular manifestations of later life are but recurrences of the earlier tuberculosis.

A survey of pulmonary tuberculosis in a textile industry, in which dust inhalation was the alleged cause of the disease, demonstrated that 85 per cent of the cases investigated showed a tuberculous near relative, or other immediate household source of infection. The remaining 15 per cent had a more remote source of tubercle bacilli infection, not revealed in this casual survey. The modern consensus of opinion has declared organic dust harmless; there is, consequently, no tuberculosis hazard from the textile industries. A study of pulmonary tuberculosis incidence on the basis of occupation, as afforded by the great sanitarium at Cresson, Mount Alto, and Hamburg, Pennsylvania, conclusively demonstrates that no occupation is exempt; the great white plague can be fastened on no single industry, nor group of industries.

The classes of employees that recruit the tuberculosis army are chiefly those that have relapses of old tuberculosis; those with tuberculous wives; those living in houses, infected with tubercle bacilli; those that have in other ways been exposed to the insidious, slow-acting infection.

Associating at work, or anywhere else, with persons having active pulmonary tuberculosis is a menace to health. Non-tuberculous employees should be spared the hazard incident to working near employees, who are coughing and spitting, in the active stages of pulmonary tuberculosis. Health service measures within the industries prevent their employment, and endeavor to isolate employees suffering from active pulmonary

tuberculosis and other communicable diseases. As no such supervision is exerted over the home life, street cars, theatres, etc., it follows, that the factory environment is relatively free from the peril of tuberculosis, and other communicable diseases.

Tuberculous individuals often gravitate to industries where the jobs are light, and the work within their ability. In the quiescent stage of their diseases, these men should be employed. Moreover, many employees work indoors that should work outdoors. The high incident of pulmonary tuberculosis attributed to certain industries requires appreciative consideration, as an industry is scarcely responsible for an injudicious choice of occupation on the part of an employee, suffering from, or predisposed to, pulmonary tuberculosis.

Tuberculosis is a house disease; indoor life is largely responsible. It cannot be fairly classed as a trade disease. The purely industrial diseases are but a fraction of a per cent of the sum total of industrial morbidity; they are but a drop in the bucket. The preventable diseases, non-industrial in source, loom large in comparison. Teeth and tonsils, "coughs and colds" cause a hundred times as much sickness in the general industries as do the industrial poisons.

The segregation and isolation of persons with "colds" is considered good practice, as "colds" are "catching." "Coughs" and "colds," moreover, are communicated by crowding together in factories, and susceptibility to such infections is heightened by poor ventilation, drafts, overheating, neglect of humidity control. These problems of engineering, successfully solved, make the factory atmosphere safe, and minister to the health and comfort of all parties concerned.

INDUSTRIAL HEALTH HAZARDS OF EMPLOYERS

II. The industrial health hazards of the employers may be grouped as:

1. Decreased production; machines lie idle; sick employees are irregular, discouraged, lack "pep."
2. Excessive labor turnover, due to ill health, unfitness for jobs assigned, prevalence of epidemic and infectious diseases.
3. Increased accident compensation expenditures, due to sickness masquerading as injuries. Cases arise daily, where conditions are pathological, but trauma is alleged; or in which a minor trauma has provoked a prolonged period of disability or an unusual degree of permanent impairment follows injuries, not in consequence of the gravity of the injury, but owing to intercurrent disease, or the previously impaired vitality of the traumatized individual.

The government employs only healthy men for the fighting line, whose ability to recover from wounds is 100 per cent plus. The industries necessarily employ many aged and feeble men, suffering from latent diseases and infirmities, having enfeebled powers of resistance, and incurring delayed recoveries, when injured. The industries are consequently entitled to sympathetic consideration, in the vast economic problem evoked by injury plus sickness. A term of disability may start as an industrial accident, the trauma being admitted, yet the period of dis-

ability is prolonged indefinitely by complicating sickness, due to latent disease, activated by the trauma, or is prolonged by sickness arising from other causes, or from preëxisting diseases, unrelated to the trauma sustained. Fully "fifty-seven varieties" of sickness are presented as industrial accidents in entering compensation claims. Among these may be mentioned tuberculosis; syphilis—in various disguises; rheumatism—teeth, tonsils, gonorrhoea,—each contributing their quota. These latent diseases, and others, are readily activated by trauma.

REMEDIES SUGGESTED

III. Since these health hazards face the industrial manager, what can be done about it? How can they be avoided? Measures to this end are:—

1. *Industrial Health Clinics.* group diagnoses; health service measures; repairing defects; reclaiming those disabled by diseases, as well as those crippled, and fitting them into selected positions in the industries; health education.
2. *Legalized releases for defects that cause abnormally long periods of accident disability.* Hernia, varicocoele, varicose veins, healed tubercular foci in joints, lungs, etc., valvular heart defects, eye defects, amputations, etc., should be charted, and an employer not made financially responsible for defects and diseases arising from causes unrelated to the employment, nor for aggravations of the same.
3. *Obligatory Post Mortems.* When the cause of death is in dispute, the report of the post mortem should terminate the controversy. So many deaths, occurring from pathological causes, but reported as arising from accidental injuries, received in the course of employment, make post mortems essential, if justice is to be done all parties.
4. *Federal Health Charts.* Transient employees lose a day, undergoing the physical examination that precedes their employment. A Federal health chart, renewed annually, valid everywhere, would be invaluable for the transient worker, as well as for the continuous worker, who remains loyally by his employer year after year. The onus of the physical examination should be removed from the industries. Proper placement in industry requires the truth about physical defects. The truth, concealed, works the greatest health hazard to the prospective employee.

An annual health inspection by the staff of a Diagnostic Clinic, for every citizen between 18 and 55 could be achieved under federal supervision. The surgeon general's office could establish in every community a Federal "Good Health" station, emphasizing diagnosis, and could recommend such remediable measures as the health maintenance of every citizen of draft age requires, both for industrial service, and for war. The early correction of defects is desirable; the early recognition of incipient diseases leads to successful treatment.

Annual reëxaminations would constitute a splendid follow-up system,

to ascertain whether recommendations made as to teeth, tonsils, hernia, varicocele, etc.; diet, exercise, etc.; had been followed out.

Nation-wide federal health service, devoting its energies to diagnosis, would not interfere with existing agencies for the treatment of medical and surgical cases, hence would not in any manner antagonize practitioners of medicine, existing sanatoria, and hospitals. A federal educational propaganda for good health, however, could rapidly reduce the percentage of remediable defectives in the nation, by thus recommending, and so arousing public opinion as to enforce remediable measures in the incipient stages of defects and disabilities.

Federal health charts, with photos, finger prints, and complete data of physical findings, would aid employment agents in rapidly placing men in the industries, so that they would stay placed; health charts would not debar worthy men from the industries, but would facilitate in so placing them that their defects, and morbid tendencies, would militate least against them.

The proposed health charts could be the means of tabulating the availability of men for military service, hence would serve the exigencies of war preparedness, when men of draft age are again called out; they would likewise serve the industrial purposes of peace.

The day may be near, or remote, when a United States cabinet officer presides over a Department of Health; or when the Surgeon General of the Army is represented by a personnel as numerous and as widely distributed, as that of the Postmaster General. Federal Health Charts, however, and the Universal Diagnostic Clinic service, which would make such charts possible, are, however, devoutly to be desired; and until obtained, physical examination must be conducted within the industries, as at present, in a fragmentary and incomplete manner,—or extended, if possible; if conducted with the frantic haste that too often has characterized these examinations in the past, the same indifferent valuation will adhere to this service as heretofore.

IV. Employees encounter health hazards apart from industrial service, that revert back, affecting their industrial life. Such health hazards may be grouped as:

1. *Inherited Tendencies:* bad or indifferent physical and mental endowment.
2. *Family Problems.* Unhappy home life menaces industrial safety and health.
3. *Financial Problems.* Worry over bad investments, high cost of living, wife's or children's extravagance, or other matters, may induce more fatigue than the day's work.
4. *Social Life.* Employee may belong to too many things, and be too popular, losing too much sleep. An employee's occupation may have less to do with his health, and his continued industrial efficiency, than the way he spends his evenings.
5. *House Problems.* Individual houses are desirable, afford every family its own home, in sewered towns with paved streets. Crowded tenements and boarding houses contribute to health impairment.

6. *Community Health.* The acute infectious diseases encountered in the industries of any community are a reflection of the diseases then prevalent in that community. Measles, mumps, typhoid fever, scarlet fever, influenza, grip, "colds," bronchitis, pneumonia, smallpox are encountered. Isolated cases of these diseases, sometimes endemics, or epidemics, occurring in industrial plants, are traceable to community sources of infection.
7. *Neglect of Personal Hygiene.*
 - (a). *Neglected teeth.* The neglect of teeth among industrial workers is appalling. Putrescent stumps, dental abscesses, pyorrhoæa, and incomplete dentures are common; money is spent more cheerfully for most everything else than for dental prophylaxis and dental repairs. The teeth constitute the first line of defense in conserving the digestion; swallowing food swarming with myriads of bacteria from putrescent teeth causes indigestion. No man would buy a horse that has lost its teeth. "Life is digestion"; our strength and energy come from our food, yet some men are so unreasonable as to attribute their ill-health and impaired strength to their work, while neglecting their teeth, thus denying their bodies the rejuvenation that comes from wholesome food, thoroughly masticated, and thereby properly prepared for assimilation.
 - (b). *Diseased tonsils.* Tonsillar infections, both locally and by referred manifestations, cause much loss of time in the industries. The alleged injuries, in which there are no visible nor palpable evidences of trauma, such as alleged sprained back (lumbago), alleged sprains of shoulder, elbow, wrist, ankle, as well as the several types of arthritis, rheumatism, and neuritis, have the tonsils as possible portals of entry for the infection.
 - (c). *The venereal peril.* All three venereal diseases, in their infectious stages, should bar employees from industry. Stricture and other complications cause lost time years after the gonorrhoeal infection has been forgotten. The bone injuries of old syphilitics, with case reports; syphilitic leg ulcers also masquerading as injuries; gummata and sinuses, presenting long terms of disability, arising from slight injuries; and serious results in mild eye injuries, if recorded in detail, would attest the excessive liability to injury, and the poor recoveries registered by syphilitic patients in the industries. Wasserman tests, as a routine hospital measure, are in order.
 - (d). *Physical defects,* such as hernia, eye strain, etc., known to exist, yet repair and corrective measures are postponed.
 - (e). Constipation, woefully neglected.
 - (f). Neglect of home sanitation, ventilation, etc.
 - (g). Balanced diet, unobserved.
 - (h). Deficient sleep.

Most men before thirty are second-raters, or third-raters; physical defects exist, and morbid processes are implanted from early life, frequently before the industrial age. Physical examinations in the public schools are often farcical; many remediable defects are overlooked, those encountered are merely reported to parents who infrequently act upon such suggestions. Consequently, the industries receive multitudes of second-raters, who develop into third-raters, who, had their defects been corrected early and had their mode of life been more hygienic, could give a better account of themselves.

An employee spends only 8 or 9 hours in industrial service; in his home life, community, and social life, during the other 15 or 16 hours of the day, he likewise incurs health hazards. The superior lighting, heating, and ventilating systems installed in many modern factories make these industrial plants more hygienic from a public health standpoint than the homes, movie theatres, and churches, many of which are more crowded and worse ventilated. To be consistent, homes, boarding houses, hotels, theatres, clubs, etc., in which employees spend more hours than in the factory, should be scrutinized and inspected as industrial plants now are, in probing sources of health impairment, and routes of infection from communicable diseases.

The industrial sick rate is augmented by a variety of physical defects, most of which are remediable, and those that cannot be cured can be adequately relieved to enable employees to keep at work, if they so elect. A man must be reasonably healthy to be an efficient worker. A small maladjustment, a minor neglect, will sometimes lead to serious complications. An employee with a toothache, whose attention is thus distracted, will give more thought to his tooth than to his job. An ingrown toe-nail is preventable; through neglect or improper treatment, it may cause lost time. Elementary hygiene, and the proverbial "stitch in time", must be observed, if a man in industry, or out of it, is to maintain his health and efficiency.

While there are industrial health hazards, and while the zeal in discovering and eliminating them is commendable, the facts remain that the purely industrial diseases are very rare in the general industries; that preventable, non-industrial ailments are the preponderating cause of sickness disability and health impairment.

INTERRELATION OF SICKNESS AND ACCIDENT DISABILITY

The daily contact with industrial disability, both sickness and accident, brings one in touch with their intimate interrelation. Septic absorption from such foci as teeth, tonsils, prostate, accessory nasal sinuses, peribronchial lymph nodes, etc., cause much of the disability improperly labeled as injury; patients like to be told that their occupation does not suit them, that their work disagrees with them, but they may resent it if told that their teeth need repair, that their tonsils should be removed, that correcting lenses should be worn for their failing vision, or that arch supports are required.

This leads to the question of industrial fatigue. If a man works hard enough and long enough he will naturally get tired. Industrial fatigue

may not be excessive, but the fatigue from other sources, combined with the industrial fatigue, may prove detrimental to an employee. For a man to be fair with himself and with his job, he must ascertain to what extent his job is tiring him out, and to what extent his fatigue arises from emotional causes (as domestic affairs, financial cares, worry, etc.); from septic absorption (as teeth, tonsils, prostate, etc.); from physical defects (as eye-strain, impaired hearing, flat footedness, hernia, etc.); from latent diseases (as incipient tuberculosis, etc.); from acute infections (as grip, nasal catarrh, bronchitis, etc.); from improper diet; from unhygienic home conditions; from loss of sleep; and from other potent factors that may enter into the equation, in the accurate estimation of his total fatigue.

A worker who is constantly fatigued from any cause, or any combination of causes, will lose time now and then from sheer exhaustion. The fatigued worker is more susceptible to infectious diseases, from which he makes a retarded recovery; he becomes more stupid, and because less alert, he more readily meets with accidental injury, from which he recovers slowly, since he has impaired vitality, and we have injury plus sickness to deal with.

THE INDUSTRIAL CLINIC

There being this interrelation of sickness and accident disability, constituting the twilight zone of sickness and injury, it naturally reverts to the Industrial Clinic to find out the sources of fatigue, to evaluate the factors that contribute to the fatigue total, and to facilitate the recovery of the individual, in the manner indicated by the findings of the inquiry.

There arise specialties in industrial practice, when an Industrial Diagnostic Clinic is organized; specialization is needed, employing diversified talent and training, such as required on a hospital staff. Beginnings of the Industrial Diagnostic Clinic are observed at many places; the scope of specialties now covered are: (1) Operative surgery, clean; (2) Septic surgery; it is ill-advised to allow the doctor who treats boils, and infected wounds, to care for fresh injuries, or redress clean cases; (3) Physical diagnosis—special reference to heart and lungs (4) X-ray service, developing into an ever larger field; (5) Dental service; (6) Pathologist, for sputum, urine, blood, Wasserman examinations, tissue staining, vaccines, etc.; (7) Oculist—injuries and diseases of the eye, and optical service. In addition to these special lines of medical and surgical service, the Works Dispensary, as occasion demands, consults with orthopedic and general surgeons, internists, alienists, neurologists, dermatologists, oculists, ear, nose, and throat specialists, endeavoring to establish correct diagnoses, and cooperate in every legitimate way with the best available agencies for speedily restoring the disabled to health and to industry. Where the plant employs but few industrial physicians, group diagnoses, the collective findings of a diagnostic clinic, may be accessible elsewhere. The multiplication of such centers, within and without the industries, in the interest of health conservation, is much to be desired.

COMMUNITY HEALTH

The Coördination of industrial and municipal health activities, as in Akron, Ohio, offers a solution of the problem of controlling epidemic diseases. With the community health problems solved, the industries will be spared the absenteeism from this cause, and the slackened production incident thereto. The works dispensary can become an out-station of the City Department of Health, with test tubes for throat cultures, so that suspicious throats may be swabbed when the patients are sent home, and no delay be encountered in getting reports on findings to attending physicians.

SOCIAL SERVICE WORK

The control of industrial health hazards is entirely up to the initiative of the industrial management. Health engineering experts—consulting physicians—specializing in the reduction of the health hazards are being employed by the industries, in conjunction with engineers in associated lines, to reduce these hazards.

Educational effort from within the industries strives to stimulate the initiative of employees into foresightedness along health lines. To what extent the industries can enter into community activities without becoming paternalistic is a debated question which we will not discuss. Model house building enterprises—helping employees acquire their own homes—building and loan associations, banking, stores and restaurants on the no-profit basis, clubs, social centers, playgrounds, hotels for employees, industrial and technical schools, apprentice courses with technical schooling, athletics, bands, and glee clubs are among the forms of community enterprise fostered by many of the larger industries, and which have the endorsement and approval of employees.

The new spirit abroad recognizes participation in industry as in the nature of a social service; constructive good-will,—based on mutual confidence, and real justice,—alone can operate effectively to solve the problems to which industry gives rise. In the trinity of production, Capital, Labor, and the Community must unselfishly coördinate their common functions of serving one another.

There are Health Hazards within the industries, that industrial initiative should control; within the communities, that the coördination of industrial and community health service can control; and within the scope of the individual, there are health hazards which require his personal initiative to combat successfully. With such coördinated efforts, the human dynamo will generate energy uninterruptedly; the worker, secure in the enjoyment of a fair share of the rewards of toil, can live to a ripe and honored old age.

DISCUSSION

SECRETARY SELBY: This very comprehensive paper is now open for discussion. There are many features which will bear emphasis. I desire to call your attention to the point Dr. Lauffer made in regard to federalized physical examination—the centralization within the Federal Government of the power for the physical examination.

DR. E. R. HAYHURST (State Dept. of Health, Columbus, Ohio): *Fatigue*: I think a distinction should be made between the term "fatigue" and what is usually meant, "strain." Fatigue is the person's feeling, the symptomatic feeling, "tiredness". Objectively, fatigue is shown by inaccuracies in execution and less aptitude to work.

Usually, correctly used, the term should be "strain." Persons can be severely strained and show no signs or symptoms of fatigue because they have an emotional factor there that is stimulating them to the point of covering up this show. Interest, in itself, hides "fatigue."

Tuberculosis in Industry: I don't agree with the speaker at all in the relation of work to tuberculosis. His conclusions do not agree with the vast amount of evidence to the contrary. In Great Britain, in Bristol in particular, studies have been made to show workers in certain lines of industries who were not in those industries previous to the war, immediately ran a high tuberculosis rate. People living in those same vicinities who did not go into the industries did not run a high tuberculosis rate.

In our office we have from insurance companies statistical charts showing findings of tuberculosis industries. In brass workers (15 to 24 years old) for instance, 72 per cent of the deaths are produced by tuberculosis. Is that the usual tuberculosis prevalence in people from fifteen to twenty-four years of age?

In the United States Census, figures for 1910, the latest we have, painters run twice the tuberculosis that carpenters do.

The National Industrial Conference Board which has been working on, and studying the conditions among silk workers, wool workers, and others, say that taking into consideration that housing and recreation have an immense influence, there is still something inherent in the industry that they cannot find that makes this disease greater in the wool working industry than other things outside can account for.

Federalized Physical Examination: This has been advocated by the American Federation of Labor. Samuel Gompers went on record in favor of some such scheme in connection with the Public Employment Bureau. Criticisms have come from industrial managers who fear a man might be able to get any sort of a record made for him in a given bureau. Until the time comes when people are willing to stand behind the Federal Government and believe in its doings and findings, we are going to have to contend with that piece of sophistry. We should get these physical examinations made not as a burden upon industry, but as upon the public—the Government.

Personal Hygiene: Personal hygiene means that people should learn how to protect their health. It is much more important than industrial hygiene. The Public Health Association is creating a section on Personal Hygiene, beginning this year, with a meeting in New Orleans. "Every man his own health officer" should be the slogan to further a great deal of health preservation and maximum health.

Frequency of Industrial Ailments: Let me say this: Deaths due to industrial sickness are very rare according to statistics I can get together. Specific occupational diseases are rare, although a great deal more fre-

quent than death. Sicknesses, partly due to industry are numerous, while health complaint—headaches, coughs, constipation, backaches, etc., in connection with industry,—practically everybody has these complaints.

DR. ALEXANDER HAMILTON (American Radiator Co., Buffalo, New York): I want to ask a question in regard to the physical examination. In view of what we hear so much about now, the labor unrest, is this an opportune time for a company that has not had physical examinations to introduce them? I would like an explanation on that.

SECRETARY SELBY: Dr. Hayhurst, will you respond to that, please?

DR. HAYHURST: Well, yes and no. If you can show that it is not for selective purpose, for ~~scrapping~~ a lot of men. If you can show that you are going to place men except for certain prototypical reasons (communicable diseases or epilepsy, etc.) that you won't place a man who is blind, if you can't safely do so; that there are such types that you cannot use at all in your plant; but that you will place every other man that you possibly can, then you will get away with it.

DR. HAMILTON: What do you say to blocking men with varicella, varicose veins, and hernia.

DR. HAYHURST: I would place them. The ~~special~~ ~~drugs~~ ~~has~~ been laid upon these defects.

DR. J. S. KLOSER (Chairman Washington State Safety Board, Olympia, Wash.):

I would like to answer that question because in my department I am brought very closely in relation to the labor union and the employee element of the state. There has been and is in all of the laboring groups throughout this country, a decided opposition to physical examination of men for industrial employment. We are rather loath to push that subject within our state although we feel the importance of it, and at this time are endeavoring to promote an educational program within the state to get the employee element of the state in the frame of mind that they, themselves, are going to demand it.

The mistake has been made, where physical examination in industry obtains, of making that examination, to a large extent, for selection and elimination of men from industry. That should not be considered for one moment excepting where the applicant is a person affected with a communicable disease that will be dangerous to his fellow-employee.

But there is the point: Do not examine a man physically for elimination. Do not examine a man physically for the purpose of trying to fit him to a job so much as trying to fit that job to the man. You catch the distinction, don't you? A man to give his best service to his employer must be happy, if you please, in his work and if that man is not happy in his work he does not give all that is expected of him. An examination that is held for that purpose is fraught with good results. The State of Washington takes this stand on hernia: They give full and complete medical services to their injured workmen without limit of time and expense. We give every man in the industry in the State of Washington full and complete treatment to the point of his recovery, regardless of what that period may be. We operate on hernias, on men who are

going into new employment, at state expense, that is, regarding their medical services. We do not operate at state expense regarding time lost. We do not pay that. Our rule is this: Where a man reports hernia, he must prove, in order to obtain time lost, that his hernia was coincident with his employment at that moment and accompanied by pain. That is very easy for any man to establish and if he establishes that, then the State of Washington operates it and pays him time lost during the period of his disability.

DR. F. E. SCHUBMEHL (General Electric Company, West Lynn, Mass.): In regard to the last speaker's remarks about the objection on the part of employees: We have examined 13,000 employees each year, for a little over four years, and there has never been an objection except in twelve cases. Those twelve cases had good reasons for objecting to being examined. The objection to physical examination does not come from the employees, it comes from the agitators.

DR. A. M. HARVEY (Crane Company, Chicago): I quite agree with the last speaker in examining employees for a period of about fifteen years. How about suiting the job to the man: Here's the position: It's open to a man and he is selected by your employment office and he goes through your examination. That man is going to be used on a height and he has epilepsy. How are you going to suit that job to that man? You've got the one job. Isn't that the process of elimination? You are going to eliminate that man from that job and you are going to do it rightfully.

DR. C. M. HARPSTER (Doherty Company, Toledo, Ohio): About five years ago I tried to get our companies to adopt the examination. This paper has gone into the discussion of the merits of physical examination, so I will say a few words. I want to agree with the last speaker. We have been using physical examinations for about three years and the method of the examination, I think, is important. If you put an examiner to work from eight o'clock in the morning until six o'clock at night, I say the examination records and his work are not satisfactory.

I am chief surgeon for all our industries and I have gone into the examination office and examined for three or four hours myself. I say three or four hours is enough of that kind of work for any physician to do and do it properly. Unless these examinations are made carefully and conducted properly, they are absolutely useless. We have a superintendent of employment and he has a number of clerks, stenographers, and aids. First of all we try to analyze the man. I don't think you can fit the man to the job nor the job to the man.

I will give you an illustration. I was selected as chief surgeon for a large interurban station not connected with the Doherty organization. The views of the different doctors were asked regarding the merits of the physical examination. I have been for many years a strong advocate of the physical examination of the workmen and I think you have to educate the employer first. I think opposition or lack of cooperation often comes from the employers and not from the employees.

I find the greatest objection on the part of our employees is due to the fact that they object to having all of the clothes removed at once. If you take the portion of the body from the chest up and make an examina-

tion carefully and then from the waist down afterwards, in other words, do it piece-meal, the objection is not so hard. The unions in our town objected to our methods of physical examinations at first because we brought the men in nude, purely to save time. We corrected this objection and as far as I know, they are now satisfied.

DR. C. F. SCHRAM (Fairbanks-Morse Co.): I think we are swiping the thunder of Dr. Selby for this afternoon. I would like to know if anything has been done by the government towards this examination.

RESPONSIBILITY FOR INDUSTRIAL ILLNESS

DR. E. B. STARR (Dept. of Health, Columbus, Ohio): I am a little disappointed in the paper in view of the apparent disposition to shift the responsibility for industrial illness almost entirely on to the circumstances that are extraneous to industrial life. I think most fair-minded men of experience will agree it is impossible to put all responsibility on one side or all on the other. We will agree to this: It is impossible to draw a short line of demarcation between the responses of the influences outside of the industry and those incident to the industry.

Frederick Hoffman has made a very careful study of this question, in several trades, from a statistical standpoint. Dr. Hoffman brings out very clearly, I think unmistakably, the fact that industry, especially certain industrial processes, have a marked deleterious effect on the workman. I think it is highly important that we understand this one point: That industry is already paying a great price for ill health among the employees, whether responsibility for that ill health is to be assigned to the industry or employers or to outside influences.

When it comes to morbidity, we have statistics as to all public health work to show in actual figures the actual facts in the case. However, any medical man who has studied this matter or any other person who has taken this matter up for careful study will recognize this fact: That they are paying a tremendous price for what they are getting. Considering it from a purely selfish standpoint, the industrial manufacturers recognize that they are paying a heavy price and they are taking the best means to overcome that condition. That means first, to determine the status of their employees, and I think the papers that will follow will show clearly the value of that determination on the basis of physical examination. If you place the matter squarely and fairly before the employees, it is only a matter of time before they will be heartily in favor of physical examinations and will insist that they be made.

SECRETARY SELBY: I will now call on Dr. Lauffer to close his discussion.

FEDERAL HEALTH CHARTS

DR. LAUFFER: With regard to the gentlemen's question covering the Federal health charts, I don't think there is any serious move being made by the Federal Government to put through any such arrangement. The idea has been advanced by others, but the thought as I presented it to you, I claim responsibility for; it is the gist of a paper I wrote about two years ago, and which I read in New York before the Conference Board of Physicians. I am firmly of the opinion that the physical examination of

employees is a burden to which industry is not equal, particularly in prosperous times, and during war emergencies, such as we have passed through, when industrial workers were very migratory, and when every employer was trying to pay a little higher wages than the other fellow, in order to steal his workers.

If these men in migrating from one plant to another could pull Federal health charts out of their pockets and say: "We are 'Class One,' or 'Class Two men', they could be fitted into industrial plants in positions where they belong.

On the other hand, we have the military side to think of. I have particularly stated the industrial side. It was a spectacle of colossal unpreparedness when we went into the war with our draftees unexamined. Why shouldn't the Surgeon General have authority to tabulate all men of military age, year by year, so that in case of a necessary call to arms, within twelve hours there could be an army of 4,000,000 called to the colors? Federal health charts are entirely within the range of possibilities, and would serve the industries in peace as well as assure national man-power preparedness for war. It would also serve public health purposes.

Many people have been thinking along the same lines but as yet Federal diagnostic clinics, and Federal health charts, are day dreams that we indulge in, and until we attain them, industrial physicians will have to keep on in the old way, doing the best we can, in examining employees who present themselves at the gates of industry.

I must say that working men welcome physical examinations, and it is very unusual for a man to refuse such examination. We examine approximately 15,000 to 20,000 a year. We have reason to suspect that individuals refusing to be examined have some communicable disease, and do not wish to be turned down, so they put up the matter of indisposition, or refusal, merely to avoid being rejected.

With regard to the statistics of higher incidence of tuberculosis, and higher death rates in certain trades, I have endeavored in my paper, to state that lead storage in the tissues, likewise brass and mercury—as well as health impairment from whatever source—must be discovered and combated, and the patient transferred to other lines of industry. The physical examination, the industrial clinic, is the remedy being applied.

Pulmonary tuberculosis is a terminal disease. It is a universal menace. It strikes those with impaired vitality, whether that impairment comes through industry, or other sources. I am not blaming industry entirely, and am far from excusing industry. Statistical studies prove that alcohol is chiefly responsible for pulmonary tuberculosis; other group studies show that the victims of gonorrhea and syphilis quite generally acquire tuberculosis as a terminal disease. The great multiplicity of factors in the production of tuberculosis makes it incumbent on the industries to tabulate these cases, since the appreciative viewpoint, as to what the industries are up against, is lacking in the library studies of those who read statistical reports, but who lack the industrial contact. During their quiescent stages, tubercular patients demand and obtain industrial employment. Ninety-five per cent of all postmortems show pulmonary

tubercular foci in one stage or another. Most persons have had industrial employment; their tuberculosis, however, may have been implanted before the industrial age. This being true, why make industry the scapegoat for tuberculosis?

FATIGUE

As to the manner of fatigue. Fatigue does pass through many stages. There is a stage of fatigue in which we are merely tired, and we become sleepy. There is a further stage of fatigue in which we are much excited, and we cannot sleep. This latter stage of fatigue, when the ability to rest is lost, is by many called "fatigue delirium." We see fatigue delirium in the mother who sits up with a sick child for many days and nights, and loses much sleep. As soon as the child recovers, the mother may collapse.

There is the delirium or fatigue in the soldier who undergoes prodigies of valor and wades through physical impossibilities. He could not undergo such hardships under ordinary circumstances, but the excitement of the occasion spurs him on. When he gets a chance to rest or to sleep, he may sleep two or three days. Dr. Crile and others of our medical men, who have been writing up this subject of fatigue through the medical press, have emphasized that fact. Fatigue, as we understand it, is largely a matter of blood stream toxemia; an accumulation of waste products formed more rapidly than eliminated. There are certain toxic substances produced by effort. Certain tissue cell elements break down, there is heightened metabolism, and all these toxins of the increased mental, emotional, or physical effort depress and tire, or may excite and cause fatigue delirium. What I have been contending in my paper is this: For a man to be fair with his job, he has to ascertain to what extent his fatigue is coming from the work he is doing; to what extent it is coming from that bad investment in oil stocks, family cares, or other outside concerns.

DR. KLOEBER: If in your physical examination department you have an applicant who, for instance, would have moist rales; you find lymphatic nodular condition, but he makes a denial of specific infection, do you give him laboratory service?

DR. LAUFFER: Unless the disease that you mention is in an infectious stage, we accept him for employment. We coöperate with agencies that do give those laboratory tests. We find three or four a week, who have venereal disease, that we refer to the public health service in Pittsburgh.

CHAIRMAN LAUFFER: The next paper on the program is by Dr. Alfred Stengel, Professor of Medicine, University of Pennsylvania, Philadelphia, on "The Subnormal Worker". Dr. Stengel could not be present, but we will be very glad to hear from Dr. Schubmehl who is scheduled for discussion on this paper and we hope he will make a few remarks that will open discussion on this interesting subject.

THE SUBNORMAL WORKER

DR. F. E. SCHUBMEHL: Inasmuch as there is no paper to discuss, I am going to give my time, which I would have taken to discuss his paper,

to the general discussion from the floor after one or two remarks. I hope you will all take advantage of that opportunity and I am sure it will be much more beneficial to you all than if I were to discuss a paper that does not exist.

The subnormal worker, pathologically, of course, as you physicians all know, is with us in large numbers. They are the men and women who give us a great amount of trouble through their negligence to attend to the small injuries or conditions that happen to them in the employment. Largely, they are the ones that neglect themselves, their jobs, and everything else. They are subnormal workers. The more people I examine the more I am impressed by the percentages that are shown. The examinations of the boys in the army who were the best and healthiest class, for example, showed a large percentage. They are not being eliminated from employment, however, by the discovery of those subnormal conditions.

There has been an intimation that one of the reasons labor objected to physical examinations was because of the tendency to exclude men from employment. I want to say right now that the majority of the physicians I have come in contact with in industry, do not examine the men for the purpose of eliminating them from a job, notwithstanding the statement made by Mr. Stewart, the head of the Labor Statistics Department. They have all been doing their job pretty well and I know we make the examination for the purpose of determining what the subnormal condition really is. When we find it, we recommend such jobs as are open in the factory, where they will fit in. The physician in industry today, who is recognizing the subnormal worker, is the best element we have got in industry. He is placing the men around on jobs where they can do the best work.

CHAIRMAN LAUFFER: We shall be pleased to hear from other gentlemen who wish to speak on this subject. The time is limited to three minutes.

DR. J. FRANK KAHLE (Berger Manufacturing Co., Canton, Ohio): The question so often in my mind has been in my examination of employees as to what should be done with the individual who is subject to tonsillitis, or the individual who is negligent with the care of his mouth in a general sense. I have noticed that that class of individual is a subnormal representative in production, generally speaking. The question is what to do with such cases.

CHAIRMAN LAUFFER: Our Company has an employees' beneficiary association and when we run across these subnormal individuals of the type you mention, with putrescent stumps, pyorrhea, and imperfect dentures, bad tonsils, etc., we accept him for employment but deny him membership in the employees' beneficiary association. If we admitted such persons, who neglect personal hygiene to such a marked degree, the beneficial association would soon find itself bankrupt.

DIFFERENCES BETWEEN INDUSTRIAL AND MILITARY EXAMINATIONS

DR. KLOEBER: I want to bring up the military service as applied to industrial service examinations. I think too much emphasis is laid upon the fact that military service examination and industrial service examination should be the same. I object to that. I have the honor of being

at the head of 278,000 workmen in the State of Washington, and the experience is great. At the same time, it was my privilege during the war to have charge of a large number of the drafted men. In military surgery, anatomical conditions with accompanying symptomatic relations were always rejected. In industrial surgeries, there should never be an anatomical disqualification under any circumstances. As an illustration of that, I will mention flat-foot. Flat-foot has no significance in industrial employment unless it is symptomatic in character.

A point that has not been brought up, and one that is going to be considered within the next few years by all of you, is the relation of hypothyroidism to industrial employment.

You in the Middle West here do not have the toxic goiter as we in the mountainous sections of this country. Hypothyroidism is today the most important subject with which we have to deal in fitting our men in employment, and in that, again, I am going to ask that when you do examine and particularly when you examine for goiter and find that you have a toxic goiter, by all means get your relations definitely between your hypothyroid goiter and your small goiter that is producing accompanying syndromes. It is an important subject and I want to impress it upon you.

DR. F. M. FURLONG (Commander, Medical Corps, U. S. Navy, Retired, 60 West 58th St., New York City): The last speaker questioned the differences between industrial and military examinations. He also mentioned flat-foot. It is well known that the Negro race are all more or less flat-footed, which does not seem to interfere with their capacity for work.

The reasons military surgeons are so fussy about flat-feet is not so much that they hurt or incapacitate the individual, but it is used as an excuse. That is why we are so careful about persons who have affections which later on may be used as a pretext to evade some irksome or disagreeable job or to prevent being sent to some remote foreign station.

If one man hobbles into the sick-bay of a battleship alleging disability on account of flat-feet and he is placed on the sick list, you will have to put many others on the list with him. The only thing to do is to eliminate persons from the start who have defects which they may later on use as a pretense to escape their legitimate duties.

In the industrial field the services of many persons with physical defects can often be used for selective work though it is desirable to record their imperfections at the time of the physical examination in order to prevent them from being used as the basis of a claim for damages later on.

DR. KLOEBER: Instead of putting the flat-footed man, who appears, on the sick list, put him on his toes for a few minutes.

DR. FURLONG: I would like for you to try it, doctor.

CHAIRMAN LAUFFER: The time for discussions has terminated. We will proceed with the third paper—"Industrial Dermatoses" by Dr. Wm. Allen Pusey of Chicago, who is so well-known in his specialty, as to require no extended introduction.

INDUSTRIAL DERMATOSES, THEIR SOURCES, TYPES, AND CONTROL

DR. WILLIAM ALLEN FUSEY, PROFESSOR OF DERMATOLOGY, EMERITUS,
UNIVERSITY OF ILLINOIS, CHICAGO

There are two sorts of factors that act in the production of industrial, as well as of other skin diseases: The first are the individual or predisposing factors; the second, the specific exciting causes. It may clear the ground and save time if, before taking up the exciting causes, which are our chief concern, we consider for a moment the first group—the personal, predisposing causes.

PREDISPOSING CAUSES

The predisposing causes are the factors in the personal equation which make the skin of varying resistance in different individuals. And these factors are many:

The protection afforded by the skin varies greatly in different individuals and under different conditions. The youthful skin is more delicate than that of the adult. The skin also shows senile changes—that may occur prematurely without reference to other senile changes—which lower its resistance. The woman's skin approximates the youthful skin and is more sensitive than the man's skin.

Local conditions in the skin, as for example, vascular disturbances, may weaken its resistance; the skin in which the circulation is poor is of increased vulnerability. The skin which normally sweats profusely is more resistant to some external irritating influences than the dryer skin, but is more vulnerable to others. Previous injuries to the skin, as for example many reactions from some external irritants, may permanently damage its protective quality.

THE SKIN SHOWS RACIAL DIFFERENCES

The greasy skin of the Negro, Mexican, and Indian is tough and can endure exposure to many insults that damage the white skin. Individuals show even greater variation. At one extreme we have the normally tough skin whose resistance is remarkable; at the other we find the individual whose skin is so sensitive that blisters and ulcers are produced by slight blows and pressure that are harmless to the normal individual.

We also have variable personal susceptibility to irritants. What is one's skin poison may be harmless to another. Every one knows that poison ivy, for example, is not poison at all to many persons, while in others it produces an inflammation of the skin of extremest severity. We see manifestations of this personal susceptibility to particular irritants constantly in industrial dermatoses. Often, after repeated exposure, the skin will acquire resistance to an irritant. Unfortunately, also, it may become sensitized after repeated exposure, so that we not infrequently see persons suffering from inflammation of the skin from irritants which formerly were harmless to them.

These factors of varying susceptibility come constantly into play in in-

dustrial dermatoses; and they must be borne in mind as an essential part of the problem whenever we are considering the exciting causes of such conditions.

EXCITING CAUSES

The exciting causes of industrial dermatoses are beyond exact enumeration. These causes, however, may be classified into a few groups, and by briefly considering these we may obtain, perhaps, a suggestive orientation of the subject. More than the briefest consideration of these various groups is impossible within the limits of this paper.

The exciting factors of industrial skin diseases may be included in the following classes: (1) Heat; (2) cold; (3) weather; (4) posture, friction, and pressure; (5) parasites; (6) infections; (7) mechanical and chemical irritants.

HEAT

The direct action of heat is not a common cause of trade dermatoses, except as it produces scalds and burns, which are in most cases surgical injuries involving more than the skin. Radiant heat may irritate the skin to the point of producing inflammation—dermatitis—either chronic or acute; we see this, for example, in the form of an eczema of the forearms and face in bakers. Occasionally, after long habitual exposure, heat may produce structural changes in the skin, shown by pigmentation, dilation of the capillary blood-vessels and thinning of the skin—a condition that sometimes occurs in stokers whose legs are especially exposed to the effects of heat. Rarely, it excites one of the uncommon skin diseases, such as lupus erythematosus. But on the whole, the dermatoses resulting directly from habitual exposure to heat of endurable intensity are surprisingly few.

On the other hand, the indirect action of heat in producing sweating is a frequent cause of skin disease. The skin sodden with sweat is a vulnerable skin. It chafes and develops eczema; and in it trivial diseases, such as mild seborrheic eczema, become exaggerated into troublesome ones. A habitually sweaty skin is also a favorable soil for bacteria; and infections frequently occur. Pus infections are commonest, resulting in boils, forms of purulent infections of the skin, and certain sorts of eczema. Other sorts of infections are also not infrequent, particularly forms of ringworm of the crotch, and of the hands and feet that at times become disabling.

It is very difficult to counteract the damaging effects of radiant heat on susceptible skins. Some protection is afforded by covering the skin to protect it from direct radiation and more can be done by interposing an impervious screen between the worker and the source of heat, where this is possible.

The bad effects of habitual continuous sweating can be minimized by frequent bathing and other measures to promote cleanliness, and by intelligent attention to beginning skin diseases, particularly to beginning infections. The bad effects of sweating are shown chiefly on the hands and feet and in the deep folds of the body. Much can be done to control trouble in these locations by intelligent medical care.

COLD

Prolonged exposure to cold is apt to damage the skin by producing permanent damage to its vascular structure. These permanent changes occur chiefly in terminal areas of circulation such as the ears and nose, and especially the hands and feet. Every one is familiar with these manifestations as chilblains, but not so familiar is the condition of chronic passive congestion of the extremities that shows as cold, clammy, purplish hands and feet and is very common in outdoor laborers in rigorous winter climates. It is the same condition as chilblains but to a lesser degree. It greatly lowers the resistance of the skin and is important because it is a frequent predisposing cause of trouble. This condition and chilblains are of so common occurrence that they constitute occupational dermatoses of considerable practical importance.

The early experience of the great war with so-called trench-foot—which is chilblains—has shown that there are several factors in the production of this condition: First, prolonged or habitual exposure to cold, especially if the extremities are covered by wet clothes that give off heat rapidly by conduction. Second, hardship, in the sense of overfatigue and failure to get proper food, including at least one hot meal a day. Third, the wearing of clothes that by constriction interfere with the return circulation, such as tight shoes or tight gloves. In passing, it may be said that the wearing by soldiers of puttees which shrink when they get wet and then bind the legs were found to be particularly bad in this respect.

The application of these facts to the prevention of the bad effects of cold of the skin in industry are obvious.

WEATHER

It may seem to be going far afield to refer to industrial dermatoses that are due to exposure to the weather; but they are a real occurrence. You are familiar with the weather-beaten skin of old sailors and farmers and others whose occupations have kept them exposed to wind and sun and cold for years. The skin is wrinkled and ruddy and rough. In those more susceptible to these influences, the cumulative effects of many years of exposure produce serious degenerative changes. They are results of wear and tear and they cannot be guarded against; but they are truly the result of occupation. Fortunately the skin cancers that result in these cases can usually be easily cured if recognized early.

POSTURE AND THE EFFECTS OF FRICTION AND PRESSURE

The familiar callouses and corns and thickening of the hands in workers which occasionally produce disability can only be referred to. More important are the vascular disturbances of the legs which may result from habitual standing and which is a common source of skin troubles. These troubles are due to varicose veins. Varicose veins, and the passive congestion of the skin of the legs that the condition entails, sooner or later leads, almost invariably, to more or less dermatitis of the legs and not infrequently to ulcers.

There are some uncommon dermatoses which are occasionally excited by standing; but these are so rare as to be of little practical importance in comparison with the very great practical importance of dermatitis and ulcer in the skin caused by hypostatic congestion.

Varicose veins cannot be guarded against. They may be the result of inherently poor vessels (our blood-vessels are very much like rubber tubing and they vary in quality in different individuals) more frequently they are the sequel of disease.

Men with varicose veins cannot make efficient workers in standing jobs and should avoid them. They do better in jobs that require a reasonable amount of walking; but they are not good workers for these jobs. Varicose veins are common in women as a result of child-bearing. Women with this condition are likely to suffer eventually from its effects on the legs and should avoid standing jobs.

PARASITES

The damages of parasites to the skin occur in those occupations which involve the collection of groups of men in intimate association, as in work trains and labor camps. Under these conditions, the ravages of vermin are almost inevitable. Fleas, bedbugs, lice, and itch are more than an annoyance; they lead to infections of the skin that produce disability to an important extent. For example, in the allied armies on the Western Front, under conditions of heavy warfare, where measures to control the pests could not be applied, the ravages of itch and lice, and the secondary pus infections which follow them, produced more disability than any other form of disease. Practical measures for the control of vermin are well known and they should be applied to their extermination in industrial camps.

The causes to which we have referred above, while they produce a very considerable quota of industrial dermatoses, are relatively unimportant in comparison with the two great causes we have yet to consider, viz., Infections and External Irritants.

INFECTIONS

In the practical consideration of infections of the skin, we will leave out of consideration, as one of the factors in their occurrence, lowered individual resistance, although this is a factor of importance in infections of the skin, as of infections of other tissues. For infections of the skin to occur, there are at least two other essential conditions:

- (a) A break in the skin surface through which organisms can find entrance.
- (b) The presence of pathogenic organisms.

For all practical purposes, it may be said that an infection cannot occur without a break in the skin. Infections therefore occur most frequently in rough occupations.

Bacteria and other microscopic organisms require for their growth organic matter, either vegetable or animal. Infections, therefore, are most frequent in those whose occupations expose them to more than or-

dinary contact with organic matter. Pus organisms are everywhere and pus infections occur in all men; but even infections of this sort are much more frequent among those whose occupations are, speaking bacteriologically, dirty. Although pus infections are far and away the most frequent of disabling dermatoses, there is a formidable list of other infections of the skin which occur in industry. These specific infections occur preëminently in those whose occupations bring them into intimate contact with organic matter, whether live or dead, such as manure, soil, grasses and moulds, live and dead animals, furs, hides and hair, meats and fish. These bacteriologically dirty occupations furnish almost exclusively a large group of troublesome and often dangerous specific infections of the skin.

To guard against these specific infections in practice, is an exceedingly hard problem. It is the more difficult because these infections are often sporadic and of infrequent occurrence, although in the aggregate they cause a large toll of disability and death.

The two essentials in reducing infections are to maintain an unbroken skin, as far as possible, and to prevent infection when breaks occur. It is a matter of practical importance for workers to guard against slight wounds of the skin and, when they occur, to take proper care of them. Superficial breaks in the skin which are not infected, should be sealed to prevent infection. This can be done by covering them with flexible collodion or with clean adhesive plaster or by a clean bandage. Before sealing them, they should be disinfected.

The industrial custom, now common, of having all wounds disinfected with tincture of iodine might be very well extended to encouraging the use of tincture of iodine in disinfecting all small breaks in the skin. It would be an equally useful measure, I believe, to encourage in workers the custom of protecting, either by sealing or by some dressing, all minute breaks in the skin, particularly about the hands. Flexible collodion is as practicable to keep accessible and to apply to the surface as is tincture of iodine; and if the custom were fostered among workers of sealing with collodion all minute breaks in the skin, the result would be almost as important as that which has followed the habitual use of tincture of iodine to disinfect immediately trivial wounds. There is one caution that must be used, however, in sealing wounds. Penetrating wounds—that is wounds going beneath the skin—should not be sealed, particularly wounds from objects which have been in contact with the soil, because of the danger of lockjaw and of other serious infections which occur especially in soil and grow freely only when excluded from contact with the air.

EXTERNAL IRRITANTS

A list of the irritants that produce industrial dermatoses would include practically all known local irritants. Such irritants may be mechanical or chemical.

The mechanical irritants are relatively few, but purely mechanical irritants may produce dermatitis, as for example those occurring from prickly or thorny non-poisonous plants or their fruits, and from the

silicious, spiny particles in sponges. The origin of such inflammations of the skin may be quite unexpected and difficult to determine, as is illustrated by a baffling epidemic of dermatitis which occurred among stevedores in Bristol, England, and which Wills finally demonstrated to be due to fine vegetable prickles on barley barbs.

But by far the greatest number of irritants that affect the skin are chemical irritants. These may be animal irritants, such as poisonous hairs of some caterpillar; or vegetable irritants, such as poison ivy or sumach, or primrose and other poisonous plants; or lacquers; or the dust of irritant woods, as teak-wood. The list of such irritants is long and of practical importance.

The chemical irritants, using this term in its ordinary sense, range from the oldest known substances used in industry, such as salt, soap and soda, to the newest, such as T. N. T. and mustard gas. Even to enumerate those better known would make a list covering pages. We see their effects in all grades of occupations from the humblest to the most technical.

The damage they do usually expresses itself as a dermatitis—an inflammation of the skin—of greater or less severity. In its slightest degrees it may be only a pinkness or redness of the skin with some itching or burning. It may in other cases be a violent inflammatory process with blistering, swelling, and secondary systemic symptoms. In extent, the eruption may affect only a small part of the body surface, or it may be universal. The severe chemical irritants, such as the strong acids and alkalis, may produce complete destruction of the skin with the formation of extensive wounds or ulcers.

In addition to the irritants that produce the usual inflammatory reactions, there are certain industrial substances that produce lesions in the skin that are not of the ordinary inflammatory type. The substances that do this especially are tar, mineral oils, and greases and their derivatives, and, perhaps, true fats. The commonest lesions which these substances produce are boils and large crops of blackheads and pustules. Such eruptions are seen not infrequently in men habitually exposed to these substances in their occupations. It is a very interesting fact that similar substances are well-determined causes of skin cancer in workers. Chimney-sweeps' cancer from irritation of soot, has long been recognized. More recently, it has been shown that similar industrial cancers may be produced by pitch, tar, paraffin, creosote oils, and other coal and petroleum distillates.

The control of industrial dermatoses manifestly presents many special problems, which vary with the numerous irritants that are involved and with the conditions of their use. Under certain circumstances, practicable measures are available to neutralize the irritants, either before or after they come in contact with the skin. Under certain conditions, it is possible to prevent their effects by the wearing of protective appliances such as ordinary gloves, or rubber gloves, or gloves treated with shellac or other substances to make them impervious. In the manufacture of T. N. T. a varnish of orange shellac which is painted over the hands, forearms, and other exposed surfaces, is said to furnish effective protec-

tion; and is suggestive of similar protective varnishes that might be devised for use in other irritating occupations.

But of course, the only entirely satisfactory protection against industrial dermatoses from external irritants, consists in preventing such irritants from coming in contact with the workers. This may be practicable, or it may be impracticable or impossible. It is sometimes found to be practicable under necessity, where before it was held impossible.

The most practicable way of handling the problem in certain industries, is by the selection of workers who can endure, without damage to the skin, the amount of external irritants which is necessarily involved in the occupation. Some men cannot work at all, where others can work without damage. My impression is, that nothing is gained by trying to keep these susceptible men at work which produces skin trouble. The best thing is for such men to shift their occupation, if possible, when the inability to endure the irritants involved is discovered. When old workers acquire a susceptibility, shifting of occupation may involve heavy sacrifices which they desire to escape. In such cases, unusual precautions and medical care may enable them to continue, but it is usually only at the expense of discomfort and periods of disability.

INTENSIVE STUDY OF INDUSTRIAL DERMATOSES DESIRABLE

I am conscious of the altogether general character of this consideration of the subject. My only hope is that it may suggest the extent and, possibly, the importance of the problem of industrial skin diseases. I think these two facts are not generally appreciated. Industrial medicine is so largely concerned with surgical injuries and serious diseases that it has little time to devote to troubles of less gravity. And yet, I believe that the aggregate of distress and disability resulting from such minor troubles as industrial dermatoses, is so large that it is a matter of great practical importance and worthy of intensive study. It is unfortunately a matter which has not been given systematic study by experts in skin diseases, either in this country or abroad, with the possible exception of Germany. It is, of course, a matter of thoughtful consideration to every conscientious industrial physician, and of sporadic study by expert dermatologists, when circumstances bring such cases within their experience. The experts in industrial medicine are unfortunately not experienced in dermatology, which is a highly technical specialty.

There is an important field here which is worthy of systematic investigation and which promises important practical results. I believe it would be highly useful if a systematic investigation of this subject by experts were undertaken in this country. One practical way of undertaking it, would be as follows: Employ a few men who are trained dermatologists, to devote all of their time to an investigation of industrial dermatoses as they occur in our industrial centers. Competent, younger men of this sort could be found, who would be willing to undertake it. Associate with these full-time investigators, a consulting board of mature experts in skin diseases who would be available for consultation and advice and for special investigations. Such men are to be found in our large cities and are in practical contact with nearly all industrial centers.

I believe a well directed investigation of industrial dermatoses continuing for a considerable time—for several years—would result in an important addition to our knowledge of this subject—not so much to our knowledge of the diseases, because they are pretty fully and accurately known, but of the factors which are important in the production of these diseases and in their prevention and control. It was found possible to do very useful work along these lines in the handling of very complicated problems of disease that threatened our army during its mobilization in this country; and I believe such a system could be effectively carried out in studying this problem in industrial life. It could not be so effectively pursued, even by thorough coöperation, by experts who are all in fixed locations. It requires a certain number of men to be mobile, so that their services may be used anywhere. I avail myself of the opportunity, which this occasion affords, to call attention to this matter as one worthy of being fostered.

CHAIRMAN LAUFFER: We certainly have very much appreciated the illuminating paper on this very troublesome subject, which has just been read; and we are favored by having with us this morning, Dr. John G. Burke of Pittsburgh, Pennsylvania, who will open the discussion.

DISCUSSION

DR. JOHN G. BURKE (Jenkins Arcade, Pittsburgh, Pa.): Dr. Pusey, in his usual brief and concise manner, has covered this subject very thoroughly in the time allowed him, his idea of a commission to study this subject is a good one as it will require some agency that can coöperate between the patient, employer, physician, and manufacturer of the material or supplies that cause the trouble, before we can get much definite data on this subject. A physician can tell a patient that the eruption is due to some irritating substance that has been in contact with his skin, but the physician cannot take the time to go in the mill or factory and endeavor to find the irritant. I have been told by patients that they noticed that a particular lot of material, barrel of oil or lubricant seemed to be irritating while other lots from the same source and with the same label did not give any trouble. If these troublesome lots could be examined and the irritating ingredient discovered, by requiring them to be labeled so that extra precautions could be taken with them, many of these troublesome eruptions could be avoided. No discussion of this subject would be complete without considering the malingerer, a term used for an individual who feigns sickness or who after a trivial injury aggravates the wound or otherwise mutilates themselves so as to receive additional compensation. A brief review of two cases will illustrate the point I wish to bring out and show the extremes of this type of cases. The first case was a girl whose finger was punctured by a piece of copper wire. It made a slight wound which was dressed a few times by the nurse and apparently healed in the usual manner. A few weeks later the girl presented large ulcers on the chest, abdomen, and thighs. The first ulcers healed leaving large scars, but new ones would appear. The company had her removed to a hospital. She also developed some abdominal

trouble and her appendix was removed. She claimed that all her trouble was due to the injury and put in claim for compensation. When I saw her the ulcers were all healed, and from the character of the scars, the history of their sudden appearance, the non-resemblance to the usual dermatological lesions, the sites of the ulcers all being on areas covered by clothing, and the delight the patient took in telling of the number of physicians who had been confused by her case, all convinced me that the skin lesions were self-inflicted probably by hydrochloric acid, and my testimony so convinced the referee that the case was dismissed. The second case was a man who received a cut on the finger which was dressed with a mercuric lotion. This man happened to be an individual who has a susceptibility to mercury and the lotion caused a violent dermatitis of his hand. This was recognized and the lotion was discontinued and the wound and dermatitis both healed under a soothing dressing. About the time he should have reported for work he presented himself with a severe vesicular dermatitis involving both hands, also his neck and face. The eruption would subside and then recur. From the history I was positive that he was applying the antiseptic lotion that he had found produced a dermatitis on contact with his skin, but as it is impossible to differentiate an eruption of this type from a number of eruptions produced by plant and chemical irritants, the man was given the benefit of the doubt and a settlement was advised, after which he had no more recurrences. As most of the states are increasing the allowance for compensation, we will likely have more of these cases to deal with, and we should always suspect malingering when an eruption does not present or follow the usual course. It is rather hard to think that we have people of this type but those of you who are physicians know that a certain number of patients do not want to get well and they will not do anything they are advised to do and will do everything they are told not to do so as to prolong their disability.

DR. MARVIN D. SHUE (U. S. Public Health Service): The United States Public Health Service which I have the honor to represent is conducting an intensive research between the various cutting oils and compounds and dermatoses. The Service is desirous of coöperating with industries experiencing this trouble in order that the best results may be obtained and the cause could be determined. If, therefore, any of the firms you gentlemen represent are troubled with dermatosis, we will be glad to coöperate with you. You can get in touch with us at 3412 Fulton Road.

DR. KLOEBER: I think there is one point that should not go unchallenged. It is a positive menace to the men who are working in the industries of this state to spread a doctrine of sealing wounds by collodion. I say this from actual experience. If you can be absolutely sure that you have not introduced an infection in that wound, or absolutely sure that your application of iodine has destroyed the pathogenic bacteria so introduced, then you can be safe in sealing it, but you can be sure of neither, and particularly is that true of a wound that is of punctured variety that practically always carries some kind of infection with it, which is absolutely impossible to reach by the application of iodine. Our experiences

have been of such character that we have some time ago made an order that excludes collodion, entirely, from those kits.

DR. STARR: I think there was an important suggestion made by the essayist that should not be overlooked. I think we all grant the vast importance of the study of dermatosis as applied to industries. He made a suggestion that a committee of dermatologists be appointed to make a study of these various dermatoses as found in industry. It seems to me this is a mighty excellent suggestion and I would like to make a motion.

I thought I would ask for a discussion, whether it would be better to have this section request the dermatological section of the American Medical Association to appoint such a committee or what would be the best method of procedure in the matter.

CHAIRMAN LAUFFER: We wish to begin and close these meetings on time and consequently it is, unfortunately, necessary to ask Dr. Pusey to close the discussion. In doing so, I wish he would please state what he would consider the better procedure in the matter, and tomorrow morning at the beginning of the session at 9:30, we will have several items of business to consider, among these, advanced work for the new year, and I can see nothing more fruitful before us than for us to enter into an arrangement, probably with the dermatological section of the American Medical Association, and the United States Public Health Service, to the end that we may from all angles investigate industrial dermatoses, because this is really a very annoying proposition to the industrial physician, and to industry.

DR. PUSEY: I am glad Dr. Burke referred to malingerers. Malingering is of course not in itself an industrial dermatosis, but it is a condition that occurs among industrial workers, and when it occurs in the skin it usually requires an expert dermatologist to recognize it. The most atrocious cases of factitious dermatitis as a rule escape detection for a long time and until they are seen by a dermatologist.

As to the proposition of sealing wounds, I am glad it was challenged. The point I made was that breaks in the skin—superficial breaks which are not infected—should be sealed to prevent infection. It is practical to make a distinction between uninfected or probable uninfected breaks in the skin, and infected wounds; and if the uninfected breaks are habitually sealed over it saves an immense amount of infection. I carefully excluded penetrating wounds, and wounds that were likely to be contaminated with soil bacteria. Such wounds should not only not be sealed, but the patients should be given tetanus antitoxin if they have penetrating wounds.

The action I had in mind was that this organization should pass a motion something like this:

"It is the sense of this organization that it would be desirable to have a commission such as that outlined by Dr. Pusey in his paper for the intensive study of industrial dermatoses."

There is nothing to be gained by a committee of the American Medical Association, this organization, or any other organization getting volunteer workers on a committee of this sort. What is needed is a group of

paid workers, expert in dermatology, such as could only be furnished by the Public Health Service or some of the research organizations that could furnish the money for salaries for full time workers.

CHAIRMAN LAUFFERT: We have one remaining paper for this morning to be presented by Dr. Weston A. Price, President of the Research Institute of the National Dental Association, Cleveland, Ohio, on "Bad Teeth and Fatigue." I understand this paper is illustrated and contains some advance information that we, as industrial physicians and general practitioners will be extremely interested in.

DR. PRICE: I deem it a great privilege to bring this message to you, although I feel entirely incompetent to do so. I will ask you to orient yourselves to this problem by thinking with me of the relation of the importance of the dental problems to other problems this week when we are studying the safety of the community.

BAD TEETH AND FATIGUE

DR. WESTON A. PRICE

PRESIDENT OF THE RESEARCH INSTITUTE OF THE NATIONAL
DENTAL ASSOCIATION, CLEVELAND, OHIO.

One of our great surgeons recently said, that of the people who are living today, nine out of ten will die when they do because of a final blow that will be struck by a streptococcal infection. Even though they die with pneumonia, that germ becomes rampant and strikes the final blow. For those who die with pneumonia show the streptococcus germ in the blood. Some one said, "What about the other ten per cent?" The doctor said he was expecting that they will die by accident.

You notice, then, that we have a safety week in which we are putting nine-tenths of the emphasis on one-tenth of the problem. Our responsibility now is all the greater because streptococcal infections that kill people, almost invariably come from focal infections.

The men having the responsibility in your great concerns, in my opinion, should learn the relation of the health and the strength of the individuals to the health of their mouths and I haven't any hesitancy in saying that you haven't the slightest conception, probably you haven't one-tenth of the conception that you should have of that importance and of the facts as they exist, and there is good reason for it. We have all been taught to believe that we could trust symptoms. The greatest menace and the greatest misfortune in this whole problem has been that the teeth that are most likely and surest to produce the grave systemic disturbances are teeth that are giving no trouble to the patient whatever.

TWO TYPES OF FATIGUE

What is fatigue? We may express it as exhaustion or we may go to Webster and find that it is "the condition of cells or organs that have undergone excessive activity with resulting loss of power," in brief the inability to do work. The facts are that fatigue has two particular types.

One is a normal physiological process where the resultant work has made an accumulation in the tissue of the waste products and has not supplied to the tissue the rebuilding structures fast enough, and temporarily, we have an exhaustion of the cells. That very process which is fundamental may be impaired, not by overload of work but by a toxin which is going through that patient's body and which is putting on the brakes.

If you take a strain of streptococci that would produce an involvement of the thyroid gland and inoculate goats with it, it attacks a little group of nerves which control the functioning of that gland. The first effect is a hyperthyroid activity. Later that gland becomes exhausted until the organisms may invade it or we may have a state in which it ceases to produce the proper amount of the secretion. The infection produces the effect on the controlling mechanism, just as the large colon may produce a condition of chronic constipation, not necessarily because of a structural change, but because the infection and the toxin are involving the nerve centers that control that system. It is as though you would turn on the current and leave the magnet of a bell under tension all the time. It puts the muscle of the bowel wall in the state of chronic contraction, and similarly may control the functioning of various organs of the body that have to do with repair and the feeding of the tissue.

Our great problem, then, readily will be seen to be one of studying the relation of the dental infection to these various disturbances which produce fatigue.

TEETH INFECTIONS TAKE MORE LIVES THAN TUBERCULOSIS

You, again, will think of the white plague, tuberculosis, that is killing people. There were more people died, year before last, from heart disease, than from tuberculosis and probably more than nine out of ten of the cases of heart disease are the result, directly, of streptococci infection. The great majority, or a large number of the infections of the heart, come from focal infections. Ninety per cent of the focal infections are said to come from above the collar—teeth and tonsils chiefly. The teeth infections probably take more lives though indirectly than tuberculosis.

But your concern is with the man before he breaks. Fatigue is a quantitative process. We may and do have, large numbers of men who are doing less than the normal amount of work because they are invaded by a streptococcal infection producing a toxin which is disturbing the functioning of those organs or tissues which are involved, and that diminished productive quality of your man or woman is directly caused in many cases by dental infection. It may be a tonsil infection.

What are the lesions that will produce those effects? will be a natural question. In my judgment the time is coming, and very soon, when every corporation that has the well-being of its men in mind, as well as its own well-being, will do, gratis, a complete dental examination, a complete restoration, so far as the elimination of focal infection is concerned, from the mouth. I believe, further, that the time is not far distant when our communities will take that responsibility just as our United States Government does it for our armies.

EFFECT OF INFECTIONS ON MUSCLES

Let us now look at the slides. We will see first an illustration of the effect of infections on muscles. Here is a man who could only lift five pounds with his left hand and he could lift fifty pounds above his head with the right. The difference in the size of the muscles in circumference of the arm is one-half. That man's lesion started when he went into cold water to repair a broken water main and the chilling of his body produced a lowered resistance which, together with the fact that he was carrying extensive dental infections, permitted him to be overwhelmed and he came down with multiple neuritis which put him in bed for weeks and months.

Take rabbits, for example, and inoculate them with a small culture and it will not produce, let us say, arthritis, but if you take one of the rabbits and put it out in the cold, it is more likely to produce rheumatism or arthritis than the others if they are kept warm. If we take others that have not had any inoculation and expose them to cold they do not develop it.

When your worker develops a condition of the muscle which you call stiff-neck, the chances are more than two to one that it is not simply the exposure from the draft, but it is that plus infection. He had resistance enough in that tissue to protect it until it was exposed. Now this man was able, after removal of his dental infection, to swing a pail of water over his head with the hand with which he could not lift five pounds as high as his head at the time we began. He later developed that arm so he could handle a heavy hammer. This repair did not begin until the removal of the dental infection, and his arm was impaired as was his health for twenty years during all of which he carried his obscure dental infection.

You have many people developing involvements of the eye. We have a number of eye specialists that immediately upon seeing certain forms of eye lesions say, "This is caused by a definite focal dental infection." They are so constantly meeting it that without further examination they say, "This type of lesion is from a dental source."

Here is a man who had an Iritis of the left eye and not of the right. That lesion had persisted for months, recurring. A dental infection was removed and it cleared up and did not come back. The important part of that history is that we were taught a few years ago that a very large portion of these cases were syphilitic. Treatment for syphilis did not help him.

DEAFNESS CAUSED FROM DENTAL INFECTION

Here is a woman who had deafness of the right ear. So complete was the deafness that if her left ear was lying buried in the pillow, she could not hear people talking or children playing in the room. That condition had existed for two or three years. Within six weeks after the removal of a focal dental infection, that neuritis of the auditory nerve cleared up entirely and she regained her hearing, and for three years has had perfect hearing in that ear.

The man in this picture weighed only 122 pounds. He had been sent away with tubercular sputum coughing, night sweats, fever and heart involvement. He was fifty-two or fifty-three years of age. After remaining in one sanitarium for six months, he went to two or three other resorts for his health and made no improvement. He was bed-ridden a great deal of the time. After the removal of his dental infection, within six months' time he increased in weight from 122 pounds to 176 pounds. You can judge the man's real improvement when I tell you the cough entirely stopped and he succeeded in taking out a large life insurance. At first the insurance company said to him, "You made application for life insurance years ago and were rejected because you have an organic heart lesion. We cannot give you insurance, although this examination you have just presented seems to indicate that you are all right. We will have to have another examination." They sent him to another examiner who also gave a favorable report, but they would not accept it and sent him to a third examiner who again gave him a favorable report. He then succeeded in getting a large insurance.

If I do not bring you any other message this afternoon than this, I hope you will retain it and that is that as we see it today, there is no such disease as gall-stones; gall-stones are the symptoms of a disease. There is no such disease as stomach ulcer; that is a symptom of a disease, a systemic infection. There is no such disease as dropsy; it is simply the symptom of disturbances. We might go through a list of lesions which are considered primary but are now known to be secondary. The important thing for you to remember is that when one of your men or women shows fatigue, he is beginning to break; in other words, he is beginning to die. Now you may not like this, but I believe it as much as I believe anything; that you and I are going to die when we die because of a fight with a streptococcus infection in nine chances out of ten, and whether it is at fifty or sixty or seventy or eighty, will depend largely on whether the conditions are favorable to the organism and unfavorable to us, or the reverse, so you must put very favorable conditions around your people who are working and you must recognize that that condition of pathological fatigue is approaching death of tissue for that person. It may be they will recover many times before a final dissolution, but it is death of tissue and excess of fatigue breaks the machine. I am now referring to pathological fatigue. To repeat what I have stated, you and I, when we die, will in all probability die from a streptococcal infection, which infection we will probably carry with us as a focus somewhere in our body, and even though we have pneumonia which lowers our resistance, that streptococcal infection will be present to strike the final blow and the important thing is to break up and remove all nests of focal infection. Tonsils probably are the most important for children and the teeth are far the most important for adults.

FOCAL INFECTIONS ARE A GREAT MENACE

There is no greater responsibility on this great convention which is meeting here this week than to teach people that focal infections are a

great menace to their strength as well as to their health, and also teach them they are likely to be so obscure that they won't know they have them.

This picture shows a woman who was dying by inches for about four years. She weighed about sixty pounds. For nine months she had not been able to move a muscle of her body with the exception of a faint movement of the fingers, and within twelve weeks after the removal of dental infection, she was able to be put up in a wheeled chair and she could feed herself and put her fingers into her hair. Not one of her teeth showed marked disturbance about the roots, and for a good reason, which however we have not understood or perhaps suspected.

The greatest mistake we have made in the dental profession is to think that all people react the same to similar focal infections. We have thought we could take dental x-rays and see whether they were likely to be systematically involved by dental conditions as shown by the x-ray. If the patient is making a good fight, there will be a local inflammation, and if there is an inflammatory process, there will be soreness and absorption. If this is continued, there will be pus flowing and gum boils. That person is seldom involved by that type of infection because if you will take the pus from that gum boil, it is very often steril. That patient is making a good fight and is killing the germs at the source.

If you had a source of pollution such as a sewer, wouldn't it be better to destroy it before it got into the lake and from there into the homes? Nature tries to kill those germs at the source, but the people who do not have the normal fighting power, do not kill them at the source and they break down some organ or tissue without any local soreness of the tooth furnishing the infection. This woman's mouth did not show such a condition as would be alarming or even recognized.

The next slide is even more conspicuous. Here is a boy eighteen years of age. You see how his joints are bound up. He has had acute inflammatory conditions existing in his wrists, ankles, and joints. He had been suffering and crying by the hour, day after day since he was twelve years of age. He could not feed himself; he could not do anything. His mother said, "If I could see him die, I would be so happy." That boy today is up and around on crutches enjoying good health. He wrote how he had made \$10.00 whittling, making doll furniture out in the country. He could use his hands, in other words, and before he could not do anything with his hands. The dental infection showed almost no resorption of tissue around the root ends.

The thing that is deceiving the medical and dental profession is because a tooth is not giving trouble and the x-ray does not show much absorption, they think it is not a source of danger, but just the reverse is true in a person with low fighting power and a definite locked streptococcal infection about a dead tooth.

This is the picture of a woman who was carried into my office and could not feed herself. She was a hopeless cripple, and, incidentally, you will be interested to know how her attack came on. She was working in a cold foundry making small parts. She had a lowering of resistance

caused by the chilling of her hands which brought on acute arthritis in her hands. They did not have a properly warmed room for her and that lowered her resistance which was a primary cause of her break, together with the focal infection. As her husband went out with the chauffeur to see where to put the car, she said, "Dr. Price, I want you to do everything you can for me. They have taken my four children away and my husband has told me I must either die or get better or he will leave me."

If you will go with me to their home on the West side, which home is now paid for, you will find her cooking for and feeding five children, not four. She is doing her own house work and she couldn't move her hands before. All that has been done was the removal of dental infections that were not giving her a particle of trouble.

I see no lesion related to the teeth so often as I see involvement of the neck.

INFECTION OF TEETH FREQUENTLY INVOLVE THE NECK

Here is a woman with stiff-neck. There is a picture showing four animals with stiff-neck, inoculated with the infection taken from her tooth, and yet the tooth was not giving any trouble.

This is an infection of the spinal cord, the same streptococci growing in pairs in the roots of the cord. Here is a girl with typical stiff-neck and the dental infection produced in an animal's neck which you will see in the next picture. There is a rabbit with a large abscess in the muscle of the neck.

The next picture shows a magnification of these muscles. There you see those germs right in the muscle itself.

Here is a woman who sat in her chair for eight days because she could not go to bed on account of severe pain in the muscle of her neck, a typical torticollis of the neck with severe pain. The condition in her mouth was that she was wearing a plate which covered the roots of three teeth, the crown of which had broken off, and rather than have the roots removed, she had the plate extended over those roots. Every time she bit on the plate, she pushed the pus up into the tissue. People who are biting on infected teeth are putting a pressure amounting in total to about a ton every twenty-four hours in the process of mastication which directly impresses that infection into the tissues. We can bite all the way from a few pounds to several hundred pounds with our teeth at one time. This woman was pressing this infection through into her system and she remembered after she had associated these events, that within a few months she was not able to turn her head sideways to the window. She also remembered that the condition got continuously worse.

The important thing for you to notice is that when we took out these roots of the teeth and inoculated one or two groups of animals, we produced in the animals a lesion quite similar to the lesion suffered by the patient. We anesthetized her neck, cut into the muscle, took out a piece, made cultures from that and inoculated the other of the two groups of rabbits. The next slide shows the rabbits. To the left you have rabbits inoculated from the teeth and to the right from the neck muscle. Each

produced typical miositis infections of the muscles. Here we have a dissection of the rabbit showing the involvement of the thigh. For two years she had no recurrence. About six months ago that woman had an involvement of the other side of her neck. I found an infected tooth under the bridge. Took off the bridge, made a puncture of pulp which had pus in it and immediately this neck involvement got better. Within twenty-four hours after extraction it was subsided and she has not had a recurrence. I believe her neck involvement was directly caused by her dental infections. You have large numbers of men and women who have involvements less severe than this caused by the dental condition and you don't suspect them and they don't suspect them because their teeth are entirely comfortable.

This picture shows the importance of the study of the teeth in connection with pelvic involvement, particularly in women. We took the cultures from the teeth of thirty-three patients and inoculated them into 430 rabbits and only the pelvic organs of rabbits inoculated with the cultures taken from three patients showed infection. Here we have a distinct infection of the ovaries and uterus of this rabbit. I said only the cultures taken from three patients produced that involvement in rabbits.

Two out of the three patients had been operated for ovarian infection and one had been operated twice and a large number of the girls working in your plants who have a shadow being held over them because of pelvic involvement and ovarian trouble, may be suffering from dental infection which is picking out a weak tissue. It is a matter of very great importance, both for the protection of those people because they are so generally misunderstood and for their efficiency that they be given the best possible service.

HEART INVOLVEMENT FROM DENTAL INFECTIONS

Here is a boy with a very bad heart involvement. Within eight months after this picture was taken, he was dead and buried. When they brought him to me they thought he simply had rheumatism. They had no thought that a heart involvement existed. Cultures taken from this boy's dental infection and inoculated into rabbits, produced heart involvements in 93 per cent of the rabbits and 100 per cent developed acute rheumatism which this boy had.

The responsibility for the care of the heart is tremendously great, for the body has no value to us without a good heart. Since heart muscles will be attacked as readily as other muscles and since heart valves have a great weakness for streptococcal infections it is necessary that we protect the boys and girls from focal infections.

Here is a girl who gave up her work because of a serious heart involvement and rheumatism. Within a few weeks' time after the removal of these dental infections which, incidentally, were not giving her trouble, she had gained twenty-two pounds and had gone back to work. She expressed her delight with her work in this way to me, "I just love to work, now." She was completely incapacitated at the time of the removal of this infection.

This is a picture of Mr. Roosevelt. We speak of him as the greatest human dynamo the country has ever produced and yet when it came to the final fight, the streptococcus was probably the cause of his death. The important lesson to me is this: Not bad dentistry, but the fact that Mr. Roosevelt went to South America and he did just what many of your workers are doing, he submitted himself to conditions which lowered his total resistance. He got fever and after the fever had lowered his total resistance, the pulp died in some of these teeth. We who are dentists know that this tooth never had a root filling, nor this, nor this (indicating.) The important thing was that those dead teeth became the hiding place, the harbor, for the streptococci. They grew, probably, in those places. He did not know it. No one knew it and the result was that they went out from that hiding place and went through his body, selecting the weakened tissues, and finally took his life.

RESPONSIBILITY OF THE EMPLOYER

Your great responsibility, as I see it, is to save those people who cannot save themselves and you can do it by putting into your plants the conditions that will find these focal infections, which means a skilled dental operator with a splendid equipment and then support him with all of the finances that are necessary and all of the assistance that he needs to give the proper relief to these people. It will be the best investment that you will make in your business this coming year. I thank you.

CHAIRMAN LAUFFER: After hearing this excellent address, we would like to listen to some discussion, but the hour is such that we will stand adjourned to reconvene at two o'clock in the adjoining room for the general session of the afternoon.

FRIDAY AFTERNOON SESSION

CHAIRMAN LAUFFER: In opening our program for this afternoon we will be favored with a paper by Dr. C. D. Selby, formerly Consulting Hygienist, United States Public Health Service, of Toledo, Ohio. Dr. Selby will take up the subject of "The Scope of Physical Examinations in Industry."

SCOPE OF THE PHYSICAL EXAMINATION IN INDUSTRY

DR. C. D. SELBY, TOLEDO, OHIO. FORMER CONSULTING HYGIENIST,
U. S. PUBLIC HEALTH SERVICE

Industry exists solely for the purpose of converting raw materials into finished products of marketable value. Labor is employed in industry for the assistance it is in the accomplishment of that purpose, and its value is fixed by the skill and facility of its effort in that direction as manifested by the quality and quantity of its output.

Formerly, when labor was plentiful and the margin between the cost of production and a moderate selling price was sufficient to bring a reasonable profit, industry gave but little concern to labor. Workingmen came and went as they saw fit, were hired and fired as suited the fancy of their bosses, or were let out in dull seasons and taken on again when business improved. No well-thought-out attempt was made to offset unstabilizing influences and practically none to improve skill.

More recently, when labor has become relatively scarce and the cost of production higher, industry has been forced to realize that it has a problem in its labor relations: in fact, industry concedes this to be among the serious, if not the most serious, of its problems. Though old in existence, having been ignored, it is relatively new. Employers do not yet know how to solve this problem. They are groping. They have created welfare departments, employment, service, and sociological departments, have sought to amuse, edify, and pacify the working people, have divided profits with them and have appointed them to act on joint committees in the determination of policies—with little effect as indicated by the present unrest, the greatest the world has ever known.

Employers are still groping, and they are progressing. Labor turnover has been studied, absenteeism investigated, and the cause of spoilage and breakage sought. Information of value has been gained. It has been learned that the most capable and dependable workmen are those who are healthy, physically competent, and are assigned to tasks they like and know how to do rapidly and well. It has been learned that such, working under pleasant conditions void of undue fatigue and hazards to health and limb, are the best producers and consequently the best paid, are the most contented and valued of employees. Industry is now striving to procure such workmen: if unable to procure them in the usual way, to develop them; and, having them, to retain them by offering favorable working conditions and opportunities for further development and advancement.

The procurement of healthy, physically competent workmen may imply the rejection of those who are not so. However, it does not necessarily follow that such should be rejected outright and deprived of the privilege of gainful occupation. There are positions in industry, in fact in virtually every plant of reasonable size, that people of varying substandard conditions of health and body can fill with efficiency, to the profit of their employers and themselves. For example, defective eyesight may justly disqualify a man from operating a machine that requires acuity of vision, yet permits him to supervise a gang of laborers with competency. Again, a chronic bronchitis may render employment in a foundry hazardous and unprofitable, while in the open it may have no detrimental effect. Even the blind and the legless, the tubercular and the nephritic, are capable of productive labor under proper conditions of employment. Only the manifestly unfit and the victims of communicable disease should be rejected, is a growing opinion among employment managers. The procurement of health and physical competency among working people requires that they be selected for and assigned to such jobs as they are or can be adapted to—with rejection a last resort.

The maintenance of a healthy, physically competent force of employees

requires that working conditions shall be such as to safeguard health and limb, that workmen shall have knowledge of how best to live and labor in compliance with the laws of health and safety, and that health and limb shall be restored as promptly and effectively as possible after impairments or disease have occurred.

The service of physicians, originally sought for the treatment of injured workers, has been found to be of use in the procurement and maintenance of healthy, physically competent working forces. Medical knowledge and skill are, therefore, welcome to industry, for anything that is capable of assistance in the stabilization and improvement of working forces is welcome. Because of this, medicine has come to be an important branch in the science of modern industrial management.

The physical examination is the means whereby physicians acquire the information they deem essential to the procurement and maintenance of healthy, physically competent working forces. It is consequently the basis of medical knowledge in industry and is fundamental to the successful practice of industrial medicine.

The scope of the examination should be broad enough to enable physicians to gather the information that is requisite. This means it should uncover defects and diseases that render employment hazardous to him who seeks it or to his fellow workmen. It should uncover imperfections that contribute to inefficiency. It should uncover diseases and substandard conditions of health. In short, the examination should be such as to divulge the true condition; it should be fairly comprehensive.

Although a complete physical examination, with blood pressure readings, urinalysis and other laboratory tests, is a desirable procedure to follow in industry, it is not always practical. In the first place, industry has not found it necessary except in unusual cases and, in the second place, industrial physicians are usually too pressed for time to investigate deeply. Experience has gradually evolved four grades of examination, depending upon the objective sought, which in turn is frequently fixed by the policy of the company immediately concerned. They are as follows:

1. *Superficial Inspection.* This consists of a hasty survey for obvious defects and apparent sickness. It considers height, weight, appearance, deformities, distance vision, hearing, hernia, and occasionally the heart and lungs (stethoscope applied outside of shirt). Its objective is *rejection* of the evidently unfit and *exclusion* of communicable diseases.

2. *Inspection.* This consists of a more complete survey. All parts of the body are exposed and their condition noted. Diagnostic instruments are used when in the opinion of the physician they are needed. This is practically an examination—without urinalysis and other laboratory tests. Its objective is *selection and assignment* of workers.

3. *Examination.* This consists of a reasonably complete survey of the body according to accepted methods, and includes blood pressure readings and urinalysis. It is virtually the same as the examination required by life insurance companies. Its objective is not only the selection and assignment of workers, but *their health supervision* as well.

4. *Special Examination.* This consists of all measures that are neces-

sary to a thorough study of the body, including intra-ocular observations, gastric analysis, proctoscopy, cystoscopy, x-ray interpretations, investigations of the nervous system, blood counts, etc. Very few industrial physicians are prepared to make such elaborate and painstaking examinations. Individuals needing them are usually referred to consultants.

The objective of the special examination is the *diagnosis* of obscure diseases and pathological conditions. It belongs rather to the realm of internal medicine than to industrial clinics.

Inasmuch as by far the greatest number of occasions for investigation into the physical state of industrial workers occur when they seek employment, the inspection would appear to be the most useful of the four grades. It has the advantage of gaining enough information to enable physicians to eliminate the manifestly unfit, if desired, and to advise intelligently in the assignment of others, and to do so with a minimum expenditure of time. Furthermore, it secures enough information for physicians to determine which individuals must have additional study, in the form of the examination or special examination, for the intelligent supervision of their health.

To exemplify the author's conception of the scope of examination or, more properly, the inspection, the routine in use at the Toledo plant of The National Malleable Castings Company is outlined as follows:

The worker is received fully clothed and remains standing until the feet are inspected. He is greeted in a friendly manner, and attempts are made to put him at ease if embarrassed or backward.

1. As he enters gait, carriage, and appearance are observed.
2. He is weighed and measured for height.
3. Vision, both near and far, are tested.
4. The right ear and right side of head and neck are inspected. While this is being done the hearing on that side is estimated by a question in a low voice.
5. This procedure is repeated on the left side.
6. The face is inspected; the condition of the eyes is noted by lifting and depressing the lids; the nares, the mouth and teeth, then also the throat and the anterior surface of the neck are observed. The worker is requested to remove all clothes from the waist up.
7. The chest is inspected and the condition of the heart and lungs estimated by percussion and auscultation.
8. The abdomen is inspected and the condition of the organs estimated by palpation and percussion.
9. The back is inspected and the posterior aspects of the lungs estimated by percussion and auscultation.
10. The spine is palpated and flexed.

The worker is requested to loosen his trousers and undergarments and let them fall down around the ankles.

11. The external genital organs and inguinal regions are inspected and palpated.
12. The sacroiliac articulations are examined and the anal region inspected.

13. All extremities are inspected, mobility of joints and condition of blood vessels being especially observed.

The worker is now requested to draw up his underclothing and trousers, after which he is directed to sit down and take off his shoes and socks.

14. The ankles and feet are inspected. If there is any doubt about the arches, impressions are taken.

15. Blood pressure readings are taken (optional).

16. A specimen of urine is obtained (optional).

The worker is now dismissed. During the inspection, as defects appear, the physician is expected to inform the worker of their presence and to give him such advice as may seem wise, an interpreter being used when needed. Special features are emphasized immediately before departure and further advice given if necessary to enable the worker to do his work without hazard to health.

In commenting upon this procedure, it may be said that inspections by this method may be made superficial or thorough, as desired, with minimum expenditures of time and effort. The inspection moves easily, without offense, from the exposed parts of the body to those the blunt exposure of which can prove embarrassing to the worker. It meets the requirements for job placement, and prepares the way for subsequent examinations essential to the supervision of health. When accompanied by appropriate advice, when the information obtained is properly used in assignments to work, and when those found defective are afterwards helped through medical and social service and continued advice—then the inspection contributes to the health, earning power, and peace of mind of the workers, and its scope may be regarded as being adequate.

In some establishments applicants for work enter the examining room stripped. If this can be done without offense, the physician's time may be thereby economized to the extent consumed in undressing and redressing. This is an advantage where large numbers are hired, but the tendency of physicians, speeding from one to another, is to slur the educational feature, which is of exceeding importance. On the contrary, if the doctor is forced to wait, he has the opportunity to discuss with the workers their conditions and therefore no real excuse for not doing so.

That which has been said applies to the inspection of men. The inspection of women is quite another matter and, although the same general plan may be followed, considerable tact and discretion must be used. The thoroughness of the inspection must frequently be dictated by discretion, and it is wisdom always to have a woman nurse present. Good judgment really indicates that women should be inspected by women physicians.

For the further exemplification of the author's conception of the scope of the inspection, a form which has been devised for recording the information is presented, as illustrated. This form has been evolved from experience in the physical inspection of school children, the inspection and examination of applicants for employment and, during the war from studies of industrial medical departments and the forms used in sixty-four of them. The form will not be described as, with the exception

of the code at the top, it is self-explanatory. The code, it may be said parenthetically, is a part of a plan in use at the Toledo plant of The

NOTE:—USE V TO INDICATE DEFECTS THAT DO NOT REQUIRE MEDICAL MEASURES. X THAT REQUIRE MEDICAL MEASURES BUT DO NOT DISQUALIFY. D THAT DISQUALIFY. DESCRIBE X AND D ON OTHER SIDE, USING REFERENCE NUMBERS AND DIAGRAMS WHERE NECESSARY.

One side only of this form is here reproduced. Diagrams of the human figure with numbered sections are printed on reverse side of original form.

National Malleable Castings Company for determining the kind of operation an applicant for work is physically fitted; a description of this plan and an explanation of the code is not appropriate to this discussion. The principal advantages of the form are as follows:

1. It provides for specific mention of conditions most usually found providing also for the recording of unusual conditions.
2. It records finding practically in the order of inspection and indicates at a glance the side of the body involved.

3. It permits recording with a minimum of clerical effort.
4. It permits tabulations and compilation of reports with a minimum of medical knowledge and clerical effort.
5. It permits diagrammatic representations of abnormalities and amplified description of special features.
6. It permits the recording of three subsequent inspections in direct comparison with the original. And
7. It has a wide range of adaptability in the recording of information secured by means of any of the various grades of examination, except the special examination.

In the use of this form, the physician may himself register his observations or, better, he may memorize the numbers and indicate to his clerk the findings by their number. The latter method is of course quicker and easier for the doctor.

It will be said in closing that neither the procedure for physical inspection, as outlined, nor the form is regarded as final or conclusive or in any sense a finished product. Minor changes and additions are constantly being made in both, as experience indicates their need. They have been presented here today primarily for the purpose of exemplifying the author's conception of the scope of the physical examination in industry. It is hoped, however, that their presentation may stimulate this organization to take further steps toward the standardization of the examination and the form, and a promulgation of a better conception of the relation of the examination to industrial medicine and of that to the needs of industry and labor.

CHAIRMAN LAUFFER: Discussion on this paper and the papers to follow will be taken up in order at the conclusion of the four papers.

The next paper is that of Dr. D. L. Edsall on "The Industrial Clinic." In the unavoidable absence of Dr. Edsall this paper will be read by Dr. Harvey of the Crane Company of Chicago.

INDUSTRIAL CLINICS IN GENERAL HOSPITALS

DR. D. L. EDSALL

DEAN, HARVARD MEDICAL SCHOOL, CAMBRIDGE, MASS.

Clinics in industrial plants for the immediate care of injuries and medical ailments have become of undisputed value and laws are even being passed to require them. They need no argument now with those of open and educated mind and I have no need to discuss them as they are outside my personal field. The character and extent of the service that they will render may ultimately go far beyond what is now done in most plants, though this is of course a very debatable question, since it is by no means certainly desirable and because it conflicts with the established interests of medical practitioners. But however far this may progress, general hospitals will for an indefinite time to come, if not always, be the centers for groups of experts in the various clinical and laboratory lines that are now essential in the diagnosis and treatment of patients and in the study of problems of health. Individual industrial establish-

ments can scarcely be conceived of as having each within their own employ a group of leading men in all the various lines of clinical and scientific medicine. Hospitals, particularly those connected with medical schools and with the staffs that the latter have, will always therefore need to be centers for the study and treatment of difficult cases and for the investigation of problems, however far health establishments in industrial plants may progress.

At the present time, however, the general hospitals receive and they will long continue to receive not only complex cases but the every-day routine sort of case for ordinary diagnosis and treatment, and they have in their clientele all told a greater number of industrial workers than any other organized establishments for the care of the sick. In performing their simple daily round of duty then, as well as in acting as consultation centers, the hospitals can not give proper service unless they have on their staffs persons familiar with industrial hazards and their results who will be alert to recognize these and capable of determining their importance or insignificance in individual cases. Let us contrast this matter with others that are comparable.

STUDY OF HAZARDS OF INDUSTRY AND THEIR EFFECTS,
A DEFINITE TYPE OF WORK

No hospital is capable of giving what is now recognized as good diagnostic or therapeutic service to patients with infectious diseases for example unless it has available the men and the equipment for expert bacteriological work any more than it could give good surgical care without surgical equipment and expert surgeons. Although not a separate science like bacteriology but work based upon various sciences, the study and recognition of the hazards of industry and their effects is a clear-cut and well-defined type of work. Its problems are quite as definite as those of bacteriology and, while they are even more varied and complex, the nature of many of them and the method of attack upon them are clearer and in expert hands more likely to be successful.

The possibility of an industrial origin of health disturbances and the need of determining this point comes up too in the great bulk of the hospital clientele; in fact, its possible importance needs to be considered in a far larger number of cases than does any other health factor. In the first year that our industrial clinic at the Massachusetts General Hospital was so organized that it received the greater part at least of those patients who might be suffering from effects of industry and in whom this needed to be determined with care and through trained and intelligent inquiry over fifty-one hundred persons were sent to this clinic for investigation; of this number approximately one-tenth showed actual results of their work that were at least of noteworthy and often of dominating importance in explaining their ill health. In most of these instances the question could not have been settled, and in those in which there was a relation the relation would have been overlooked, had the investigation been done in the customary way by persons who had not accumulated interest in and extensive knowledge of the possible relations of the patient's

job to his illness. This is clearly shown in our experience in that time in lead poisoning.

EXPERIENCE IN LEAD POISONING

A special search was made for lead poisoning in all persons in whom careful inquiry showed any exposure to lead. Ordinarily the poisoning is looked for only when either the hazard is obvious and commonly known or the symptoms clearly suggest it. The difference in method had the result that the same number of lead cases were found in one year by special search as were diagnosed in five years by the ordinary methods and this in the same clientele coming from the same general line of industries.

A considerable trial of a special industrial clinic in a general hospital and of other less well-defined methods of attacking the problem of the relation of industry to general medicine has convinced me that no other method than a special clinic goes so far to insure good service to the patients and no other method so stimulates and enlightens the interest of the hospital staff in general in this important health factor. Likewise, by no other means is it possible to group the cases together in such manner that the results of study can be analyzed and made available, and in no other way does there occur such an accumulation and repetition of experience as to make evident and important problems that had been unrecognized or had seemed of little significance.

PAID STAFF NECESSARY

To be really useful and successful several things appear to be necessary. The clinic should be in charge of a physician whose greatest interest is in the work and he should be on sufficient salary to enable him to spend most or all of his time at the work. This is necessary in order that he may properly develop his clinic and may be free to make many visits to factories in order to accumulate constantly increasing knowledge of industrial processes and in order to determine day by day whether in doubtful cases seen in the clinic the work really explains a part or the whole of the effect upon health. Much of his time will be needed also in making studies in the clinic, in factories, and in the laboratory of the problems that are frequently suggested, and in this he will have many opportunities to keep occupied voluntary or paid assistants. Another essential element in the clinic's success will be a trained social worker who is familiar with factory conditions and industrial processes as well as with general social conditions. Through her, will be best handled many of the social details of the records and she will be able to investigate both home conditions and factory conditions in order to provide the essential knowledge of the relative bearing of the home and the factory upon the health of the patients. Such a small paid staff is necessary for success. From this it may easily be enlarged with voluntary or paid workers as occasion demands. Furthermore a method must be adopted which will make sure that all cases with interesting or suggestive industrial relations get to the clinic. It will not suffice to depend upon those in the medical, surgical, or other clinics for sufficient

interest to refer cases either spontaneously or upon request. They usually do not recognize the hazard or its relation to the patient and in the pressure of their work they frequently forget to send any that they do recognize.

We have with some success adopted the plan of having a social worker, who is sufficiently instructed in industrial hazards to serve in this way, stamp the cards of all new patients as they enter, if their occupations come within a list furnished her or if they otherwise seem interesting. Whatever other clinics they go to, they must when so designated go also to the industrial clinic before leaving. The other social workers in the various clinics are also instructed to send to the industrial clinic any cases showing points of interest in relation to industry. Cases that are primarily of industrial interest, especially certain groups that are being particularly studied in the industrial clinic, are transferred to that clinic for regular care; others are simply referred for diagnostic, therapeutic, or preventive advice while their management is continued in the other clinics.

Carried out consistently in this way the clinic will, in any large outpatient department, have abundance of material both to provide wide experience in industrial effects upon health and also for study of the problems that local industrial activities furnish. Some of these problems will be already known; some will become apparent from time to time as a large number of people pass through the clinic and the possible relation of a job to a disorder becomes emphasized by repeatedly meeting the possibility.

PRIMARY VALUE OF INDUSTRIAL CLINIC

The primary value of such a clinic has been, in my mind, the better care of the patients. Equally obvious are the opportunities for furnishing new knowledge and thus improving conditions through carefully planned studies and through accumulation of records and analysis of these.

Likewise important to a hospital that has relations with a medical school is the opportunity to train all students into an appreciation of the relations between varied industries and medicine, and to give special and detailed training to undergraduates or graduates who wish to become especially qualified in the medical service of industry. The latter students can be given thorough knowledge of a limited number of hazards through serving temporarily in one or more plants. In no other way, however, than in such a clinic, so far as I know, can they so well be given a comprehension of the extremely numerous and varied things they should be prepared for and then have opportunity to observe in factories a considerable number of types of these and the methods of controlling them. By serving with the staff in the industrial clinic, and in the factory visits that the work there leads the staff to, they get a wide general training in elementary knowledge of these things that would be otherwise obtained only slowly, laboriously, and unsystematically.

Beyond those mentioned, however, we have found other not unexpected sources of interest and helpfulness arising through the clinic.

Diagnoses made in individual cases or advice given to the patient have often been transmitted to the employer with the result that he has thereby first recognized the existence of that hazard in his plant or first seen how it may be controlled. Employers have frequently extended the advice to cover all those exposed, or have investigated conditions not previously studied, or have sought further advice from us or from others. This has been especially true of the small employer who has but slight or no health service in his establishment, but it has repeatedly occurred with large plants.

Labor unions have also at times come to us for health advice through some of their members having been in the clinic. Fairly and tactfully carried out, the relations with labor unions may be made very useful in furthering industrial health, among other reasons because a clinic in a general hospital is obviously not subject to the suspicion that the unions unhappily often have toward the health service in their own industry.

COÖPERATIVE STUDIES OF INDUSTRIAL HAZARDS

The largest possibilities of useful development lie, however, in the research that can be carried out if the clinic acts as a center for coördinating the problems that are unearthed in it with the health and technical departments of the industries on the one hand and the men and facilities on the other that are found in medical schools and hospitals. There are all told among these two groups and their equipment the possibilities of attacking all sorts of problems and not infrequently of solving them. Research developments that will control or do away with hazards are of course in the long run far more important than the diagnosis and treatment of a group of cases, important as the latter is. In the past several years coöperative studies of blood problems, problems in pure physiology, problems in metabolism or in biochemical matters, toxicologic problems, problems of general hygiene and sanitation, and others have appeared desirable as a consequence of observations in the hospital clinic. Some of these have been carried out with our colleagues in the medical school and hospital in spite of the heavy pressure of war conditions. Studies have also been made in co-operation with physicians in charge of large plants and several corporations, some of them very large, have offered the coöperation of any portion of their research departments in working out the technical industrial end or the engineering aspect of some hazard that observations in the clinic suggested the existence of. In this way as in most others our clinic as well as our whole method of attack upon industrial medicine, from the hospital or the academic standpoint, is really in its infancy but progress thus far seems to open a vista of real public service if the varied departments of hospitals and medical schools can develop cordial coöperative relations with the health departments and technical departments of industries. Unlimited possibilities of good results with satisfaction and credit to both sides seem open and the problems and the opportunities for interesting and serviceable work grow constantly as one studies the matter.

CHAIRMAN LAUFFER: It is unnecessary to introduce the next speaker Dr. Evans of Chicago who has previously addressed National Safety Council audiences. I take great pleasure in welcoming him to us.

HEALTH EDUCATION IN INDUSTRY

DR. W. A. EVANS, CHICAGO

In the fight against premature death and disablement due to accident, injury, and illness, progress is being made in certain directions but not in others. The bacterial diseases with the exception of pneumonia, bronchitis, and influenza have been very greatly decreased. The death rate of infant and older children from all causes has been greatly decreased. These two decreases have been considerable enough to lower greatly the death rate. Heart disease, Bright's disease, apoplexy, and diabetes have very materially increased.

We attempt to make a distinction between diseases due to habits and those due to customs. For instance, the bacterial diseases in the main are spread by community customs. The habits of the individual are of lesser importance than the mass habits called customs. On the other hand, in the case of diabetes the larger factor is the habit of the individual. While many flaws can be picked with this classification in the main it serves to make a useful distinction with a reasonable degree of accuracy.

Applying the rule we find that in the main the diseases which are on the increase are those due to faulty habit. Another line of division would be on the basis of organized effort at prevention. Applying this rule broadly we find that the improvements have been in that group where preventive effort has been made and the lack of improvement has been in those where there has been neglect.

When we come to study accident rates we find that there has been a tendency upward for fifty years. The fatal death rates from all external causes by decades in Chicago since 1867 have been:

1867-76	93.2	1897-06	106.3
1876-86	90.6	1907-16	120.8
1887-96	122.6		

The rates for 1917 and 1918 were 118.1 and 99.8 respectively.

SUGGESTED CHANGES IN CLASSIFICATION OF ACCIDENTS

In an effort to analyze these figures I have come to this conclusion. In the rearrangement of the classification of the causes of death it would be wise to divide external causes into those where there is intent to injure and those without intent. The former are not related to carelessness. In this group there should go suicides, homicides, and legal executions—Numbers 155, 155a, 155b, 155c, 155d, 156, 157, 158, 159, 160, 161, 162, 163, 177, 182, 183, 184, 186a—18 causes in the Bertillon classification responsible for more than one-quarter of the deaths due to external causes.

I suggest that when the next revision of the Bertillon classification is

being considered you be represented and that you endeavor to bring about such revisions in the nomenclature and classifications as will make it easier to marshal the facts relative to accidents. Also that you have proper governmental agencies collect and tabulate non-fatal accidents.

And now returning after the digression. We find that the tendency of rates for deaths from all causes to rise is due to a rise in the rates for homicides, suicides, and what have been termed public accidents, and that this rise has been enough or more than enough to compensate for the decrease in industrial accidents.

Between 1913 and 1917 the number of fatal accidents in industry fell from 25,000 to 22,000—an improvement of 12 per cent, and the number of serious accidents from 700,000 to 500,000, and the number of accidents serious enough to keep a man from work six weeks or more from 300,000 to 26,000—a fall of 26 per cent. This improvement was due to education of both employer and employee and the use of safer types of machinery.

During the last seven years the employer class has become greatly interested in accident prevention, the employee class moderately so, but the interest of the general public has lagged far behind. In 1917 of the 77,000 fatal accidents in the U. S. registration area 55,000 were outside of industrial plants. Of the 510 fatal accidents in St. Louis in 1917, 400 were outside of industry. Of the total death rate from all causes in the registration area of about 14 a little more than 1 or one-fourteenth of the whole is due to violence. In 1901-5 the violence rate was 101.7; in 1906-1910 it was 1.07. Since 1910 it has been: 1911, 1.04; 1912, 1.04; 1913, 1.08; 1914, 1.02; 1915, .99; 1916, 1.05.

Table showing number of employees' death rates from all causes, death rates from disease, and death rates from external causes among the employees of the Panama Canal Zone, 1906-1917 inclusive:

Year	Number of Employees	Death rate	Disease death rate	Death rate External Causes
1906.....	26,547	41.73	39.66	2.07
1907.....	39,238	28.74	25.44	4.30
1908.....	43,891	13.01	8.68	4.33
1909.....	47,167	10.64	7.55	3.09
1910.....	50,892	10.98	7.5	3.48
1911.....	48,876	11.02	7.65	3.38
1912.....	51,852	9.26	6.36	2.81
1913.....	56,654	8.35	5.24	3.11
1914.....	44,329	7.04	4.40	2.64
1915.....	34,785	5.77	4.05	1.72
1916.....	33,176	6.03	4.58	1.45
1917.....	32,589	7.09	5.74	1.35

Note the following points—

1. The personnel referred to were almost all adult males.
2. Negroes predominated.
3. The work was done largely out of doors with heavy machinery. The climate was unhealthy but the efforts to control disease were ex-

ceptional. (In none of the reports is there any stress put on accident prevention.)

4. The fatal accident rates of 1908 (4.33) and 1907 (4.30) were higher than the disease death rate of 1915 (4.05) and only 1.44 per 1,000 less than the death rate from all causes in 1916.
5. The death rate from disease after 1911 was exceedingly low.
6. The death rate from accidents was very high every year.
7. The improvement in the death rate from disease is far greater than the improvement in the fatal accident rate.
8. Dr. Gorgas explains that the very high death rate from disease in 1906 was due in greater part to an epidemic of pneumonia.
9. The rapid rise in the death rate due to external causes in 1907 he explains is due to more blasting and railroad work.
10. In 1906 he says there were 35 deaths among the white employees, of which 19 were from disease and 16 from violence.

As a side light showing the importance of fatal accidents in determining the total death rate I call your attention to the attached table. This table shows the death rates per 1,000 from disease and from accidents in the Canal Zone among employees between 1906 and 1917 and compares them with the fatal accident rate in the registration area in the United States. At one time the fatal accident rate in Panama was four and one-half times that in the United States. It is even yet one-third higher. The death rate from disease fell from a maximum of 40.5, thanks to intelligent, well supported effort. The very high fatal accident rate fell only from 4.52 to 1.35 minimum. I hope when we come to build another canal we will have an accident prevention policy comparable to the disease prevention policy employed when the Panama Canal was being dug.

After showing the steady decline of accidents in industry between 1913 and 1919 Payne says, "There is another story for public accidents or accidents occurring in the home, on the street, and generally outside of industrial establishments. There has been a marked growth in the number of this type of accidents in the past few years. The reason for this rapid increase in the number of public accidents while the industrial accidents have as rapidly declined is that industrial managers are thoroughly aroused to the necessity of accident prevention in their plants but the public in general is still unconscious of the significance of safety."

To bring about the desired ends it is not enough to inform and instruct. That does not go far enough. The habits of the people must be changed. Each person must not only know what practices are safe and what hazardous but he must apply it to himself. In the back of his head he must carry the thought constantly. While his mind runs in its proper grooves and his muscles are doing their customary work there must be a subconscious realization of hazards and an instantaneous response to stimuli of danger. It may be that a tendency to go about in an absentminded trance must be corrected or that a naturally poor incoordination and clumsiness must be overcome. This is the problem. How can it be solved? The solution when found is to be applied to the employer group including general managers, superintendents, and all bosses;

the employee group including all who feel no responsibility for others, and the general public. The employer group are very well informed but many are indifferent for one reason or another. At least many do not act at all and others act somewhat thoughtlessly. The employee group are less well informed and less interested. The general public are most in need of information and of interest.

Recently a great professor in a great university wrote as follows of personal hygiene, "Personal hygiene is not a subject that can be advanced by public meetings. It has to be worked out by (or with) each person individually." A good answer to this opinion appeared in the headlines of a daily paper issued about the time this letter was received. It read, "Dress designers call for larger hips this season. Checks and stripes and lots of yellows appear to be favorites."

When fashion decrees that hips are to be larger hips will be larger, or that checks, stripes, and lots of yellow are to be worn, you can bet they will be worn. It will scarcely be denied that fashion determines wearing apparel, clothes, shoes, the shape of the feet, in great measure the food and the methods of its preparation, and in some measure hours of sleep. Now no one will contend that fashion is worked out by or with each person individually. An impulse, and not infrequently a convention of the interested issues a decree and forthwith the civilized world obeys it. There is no other field where there is so little individuality, so little work by or with the individual.

All of the items specified in the above paragraph—clothes, shoes, food, sleeping hours—are matters of personal hygiene. Now personal hygiene is a matter of good habits on the one hand or bad ones on the other and so is safety work when viewed from the standpoint of the general public. Personal hygiene and accident prevention are cut from the same cloth. What I have said about personal hygiene applies to accident prevention. If there is no field for any but individual effort in personal hygiene the same holds true of accident prevention. On the other hand, if public work pronouncements, feats, discussions, newspaper articles, publicity can affect changes in matters of personal hygiene they can be effective in accident prevention.

I agree that the most effective method of education is by personal individual work. I am for it as strong as any one. But it has limitations which make it impossible as a solution of our difficulties. It is tedious, expensive, and requires too much machinery to be practicable as a means of meeting the whole situation. There are great possibilities for the group method even in educating adults. I propose to discuss some phases of some of the group methods.

EDUCATION OF ADULTS

Moving Pictures. This method of education is so well understood by you that I need not say much about it. Let me offer you this suggestion. Try one short run of lessons in a program of lighter stuff. When Health Commissioner of Chicago twelve years ago I found that evenings devoted to health talks and health pictures lost their pulling power, whereupon I

gest that in these articles suggestions of control and compulsion be minimized.

Speakers. Since so many foreign speaking people do not read, it might be well to employ some pensioners and disabled men as conversers, talkers—a functionary corresponding somewhat to the Jewish schnorrer. Go among the men and subtly talk the harmfulness of accidents. But the larger field for personal and oral presentation will be lectures and demonstrations. Many of you have made very efficient use of lectures illustrated and non-illustrated. Let me suggest that you vary your method occasionally by introducing a brief lecture unexpectedly into a program arranged on a basis of entertainment solely. Thus you will secure a little of the time and thought of the indifferent. Such a lecturer remembering the lack of interest of most of his audience will do well to speak briefly, epigrammatically, making use of catchy, easily-remembered phrases.

Still Life Pictures. On the market there are now several automatic projection machines. These can be used to advantage if their pictures and texts are frequently freshened and if the location of the machines are changed occasionally.

Talking Machines. Occasionally advantageous use can be made of talking machines. For instance, short talks by Judge Gary, Mr. Rockefeller, Lloyd George, President Wilson and the presidents of great corporations would prove effective.

Expositions, Museums, and Kindred Methods are of service in educating employers as museums of safety and other permanent exhibits such as the display in the rooms of the Illinois Labor Bureau. Hazardous machines with dangerous parts advantageously set in rest rooms.

So much for the education of adults—always a difficult thing to do, expensive and wasteful.

EDUCATION OF CHILDREN

The education of children is a far more satisfactory field. I have read with interest *Education in Accident Prevention* prepared by Dr. E. G. Payne upon request of the National Safety Council. It is a guide book for teachers. In other words it may be considered an excellent work for the education of teachers in the teaching of accident prevention. The U. S. Public Health Service and various state boards of health have prepared text-books on health subjects to take the place of ordinary readers. As I understand it none of these have ever come into very wide use. Teachers have explained to me that they must use the adopted text-books and no book agents ever attend the meeting of the adoption boards to secure the adoption of these free health readers. If you go into the text-book field there is but one way to do and that is to play the game as it is played. It might be advisable for you to consider coöperation with the health people in the production of readers, spellers, and other texts making use of such stories as you could furnish as material for the books.

There is a general agreement among teachers that teaching should deal more with the experiences of the day. Even first and second readers would be more interesting if they carried some experiences from the work

shop and the home rather than many of the stilted, far-away stories now carried. But when you get into this field, if you do, play the game as it is played.

Payne says while industrial accidents are limited very largely to adults, the same is not true of public accidents. In 1916, 10,534 children under 10 years of age in the registration area were killed by accidents with perhaps 250,000 others severely injured.

Discipline.—This is a good place to say that discipline is a most potent factor in the prevention of accidents. Childhood is the time to teach discipline.

Workmen's Compensation. Far and away the most potent educational influence of accident prevention was the passage of the workmen's compensation laws. The placing of accidents on an economic basis was directly responsible for much of the result. A great part of its effect came through creating a background for the National Safety Council and its superb educational work. Thus indirectly and directly workmen's compensation was responsible for the Safety First movement. Personally I would like to see the application of the same principle to prevention of accidents in fields other than in industry and the general prevention of disease.

CHAIRMAN LAUFFER: We will next be favored with an address by Dr. C. E. Ford of the General Chemical Company on "The Coördination of Industrial and Community Health Activities."

COORDINATION OF INDUSTRIAL AND COMMUNITY HEALTH ACTIVITIES

DR. C. E. FORD GENERAL CHEMICAL COMPANY, NEW YORK CITY

In the early history of medical work in industry the employment of a physician in a plant was considered an evidence of a benevolent attitude on the part of the employer. The protection secured against excessive costs resulting from accident and injury, the shortening of the period of disability, the relation of the doctor to relief agencies, and the doctor's value as an intermediary in industrial relations established more or less the value of the plant physician as a member of the Operating staff; and as a result of really meritorious work on the part of a few pioneers in the field, it became evident that pre-employment examinations, as well as periodic re-examinations, prolonged the usefulness of the employed, both to the industry and the individual, his family and therefore to society.

Probably the greatest opportunity for the promotion of the public health has arisen through the rapid development in industry of medical departments—manned as these departments should be by medical men giving their full time and thought to the conservation of human lives.

In the discussion of our subject, a review of the relationship of the public health department and the medical profession and through them the latter, the public, would seem, perhaps, profitable.

"Public Health" is a field which embraces sociology, engineering, chem-

istry, and bacteriology, as well as medicine, and the man with administrative gifts may have qualified for his post through any one of these allied sciences. The fact of a man being a competent physician does not make him a qualified health officer. Public health is a science and art in itself and peculiar to itself, the essential being that the official should have studied and practiced this science and art. If he be a medical man, his position, with the present professional view point, is strengthened with his profession and the public.

FUNCTIONS OF A HEALTH DEPARTMENT

A health department, in performing the functions imposed upon it by law, must reach, more or less directly, every person within its jurisdiction. The past generation has witnessed radical changes in the theory of preventive medicine. Officials are no longer permitted merely to meet emergencies as they arise. "Health promotion" has become more important than "disease prevention," and "disease prevention" has come to be more regarded than "disease suppression." The archaic policy of acting only in the development of emergency, of merely being ready to make the best of a bad situation in repairing damage after it has occurred, has been relegated to a less enlightened day. In carrying out its work of prevention, a health department must endeavor to arouse the interest and attention of individuals rather than of the masses or classes.

It has become axiomatic that the Government relation can only be as strong as the individuals who constitute it; but it must be borne in mind that public health is a matter for the state and the nation—not merely individual towns or cities, and the war experiences demonstrated that disability, preventable in character, is far more prevalent than we have been conscious or willing to admit.

IMPORTANCE OF PUBLICITY

An aggressive health department employs every possible means of publicity—the public press, as well as the other agencies of which I shall speak later—in an effort to maintain a personal contact. Unfortunately public health publicity costs money and to be obtained, must be paid for. The controllers of the public purse strings have not yet arisen to the importance of this function, and, excepting in the few instances in which private funds are available for the promotion and support of publicity, the endeavor has failed. The success or failure of any endeavor for the betterment of public health depends, to a great extent, upon the attitude of the medical profession. In the main, that attitude is sympathetic and encouraging. However, there have been measures of very decided public value involving principles of social and economic worth that have been so strongly opposed that their worth has been lost to the community. The canons and ethics of the medical profession provide that the first duty of the physician is to the individual, whereas in preventing diseases, the first duty is to the public.

Throughout a relatively brief but active relation with the medical profession it has been observed that the individual doctor has been so

occupied with the specific case that he has all too frequently permitted others to direct the social, economic, and professional adjustments that modern progress has made necessary. This notwithstanding that the professional interests and those of the public are identical and should be solved and applied only by a socially-minded medical leadership.

The present day is intolerant of isolation from affairs. With others the doctor must become active and not only support and direct actively but create those remedies for the ills of society with which he is or should be familiar. Unless medicine does this and makes apparent its group strength before the people, the people will all too frequently be victimized by the various cults and pseudo-medical interests that quickly grasp the importance of public control and especially with legislative and governmental interests.

Science has developed facts that have afforded remarkable opportunity for progress, but, in so doing, serious obligations have been imposed upon the doctor. Changes in health administration have, at times, been radical, perhaps revolutionary, but no more radical and no more revolutionary than the changes that have come to our scientific thought.

The modern health administration, in asking much is likewise giving much to the physician. The individualization of health work, instead of threatening the material interest of the doctor, actually benefits him in many ways. The more intimately the individual doctor becomes acquainted with the aims and purposes and underlying motives of the modern health department, the more valuable his influence becomes to the people of his community and the more useful the department becomes to him in the pursuit of his practice.

PERIODICAL PHYSICAL EXAMINATIONS

Health officials are now urging periodical physical examinations for all persons, as the means of detecting insidious organic diseases in their incipient and easily curable stages and while the medical profession may be called upon at certain times to render service gratuitous, or with small direct return, in such examinations for the purpose of education and demonstration, it is true that the establishment of this excellent custom is not only likely to save or prolong the lives of thousands, but in the ultimate brings largely increased returns to the physician. The more people think health and talk health, the more generally they seek medical counsel and guidance, consequently the more generally the physician is employed.

It is invariably true, whenever there are established anti-tuberculosis leagues, with their dispensaries, medical nursing service, together with the educational and publicity campaigns essential to their success, those medical men specializing in tuberculosis, as well as the general practitioner, have an increased clientele among those actually suffering from tuberculosis and seeking treatment for it, as well as those who came to think seriously of their own physical condition on account of the agitation of the subject. This is similarly true in communities in which campaigns against venereal diseases have been undertaken. In such communities the venereal specialist and general practitioner report an in-

creased demand for this service and, of course, this means that the uninformed have not sought the advice of the advertising or itinerant quack. This well illustrates the fact that that which is best for the people of the community and that which may be over-insistently urged upon them—redound, to the material advancement of the reputable physician.

The physical examination of school children with the discovery of the enormous amount of the heretofore regarded relatively harmless defects of the upper-air passages of the ears and mouth, have conferred enormous physical benefit to the community as well as the financial support of the medical man. This same helpful attitude is maintained by the diagnostic laboratory in their relation with the medical profession. While these laboratories are maintained for the benefit of the people as a whole, the service of the laboratory is rendered almost wholly through physicians.

Occasional specimens are received from laymen but the name of the attending physician always accompanies the specimen, and a report sent to the physician, and in practically every instance it is found that such specimens are sent with the advice of the doctor. In the case of Wassermann tests, it is doubtful if the laboratory ever received a specimen, except from the physician. This is similarly true of specimens from patients suspected to be suffering from diphtheria, typhoid, and the other communicable diseases.

In actual practice the laboratory is maintained wholly for the convenience of the medical man, saving the individual hours of labor and no inconsiderable outlay of money and if one may judge by the increasing demand for laboratory service, this convenience is becoming generally appreciated. On the other hand, the more general the medical profession engages in modern health activities in their own community, the more quickly they utilize the service of the staff of the several divisions of the department, the more constantly they employ the services of the laboratory for the exact diagnoses, the greater assistance they are rendering the Government in meeting its obligations to the people.

The closest possible relation should exist between the private or industrial physician and the public health official. Public health departments heretofore have been limited in their relations with individuals for the purpose of teaching personal hygiene.

THE INDUSTRIAL HEALTH DEPARTMENT

The industrial health department can be made the new and strong arm of the public health department in bringing about precaution in matters of health.

Morbidity statistics ~~not~~ now available may be secured, as well as organized assistance in times of epidemic.

The demand for this sort of service by the far-seeing executive, unappreciative of the necessary qualifications of a medical director capable of undertaking the responsibility, has led many medical men, the recent graduate, the unsuccessful or moderately so, into the field of industrial medicine; but until qualified men are created by university training or long and varied experience, the cause of industrial medicine, and in turn industry itself, will not obtain the largest measure of benefit.

It no longer suffices for an industrial organization of any size to employ a part-time physician who utilizes his job to pay office rent or automobile upkeep. The physician who considers accident work or casualty surgery as a mere "pot boiler" or "stop gap" for a period of financial stress will hardly prove ornamental to his profession.

To meet the present-day requirement of a medical director it seems that the following qualifications, in addition to a medical degree, are essential:

At least five years of general practice—in that a knowledge of man and his foibles may be acquired. During this period it is necessary that the future industrial physician should maintain a connection with the public health agencies, such as the city health department with its various dispensaries, the general dispensary, and other public medical service, in order to develop the social viewpoint as well as to broaden professional skill.

The industrial physician should have a knowledge of practice, not necessarily profound, of the fundamentals of industrial relations and these include—applied preventive medicine, medical and psychopathic medical investigation, recreation, accident prevention, and the methods leading thereto.

Knowledge of the special problems relating to the employment of women and children: some knowledge of pensions and insurance, including liability, group, and social; some knowledge of plant organization, which is likely to prove effective in dealing with the problems of labor.

Knowledge of employment methods; some notion of job analysis, physical and mental tests, to determine the fitness of applicants; knowledge of race problems, knowledge of industrial training, apprenticeship, continuation schools for training in particular jobs; at least some knowledge in relation to the cost of living according to local standards.

Knowledge of the hours of work in relation to fatigue and output; knowledge of shift systems, rest periods, regularity, absenteeism, etc.

At least a superficial knowledge of the security and continuity of employment in slack seasons, while convalescing from accident or disease, in case of labor-saving improvements, as well as with the advent of old age.

He should have a general knowledge of physical working conditions, safeguards, disagreeable gases and dusts; heating, lighting, ventilation, locker rooms, wash rooms, rest rooms, restaurants, hospitals, laundries, toilets, showers, plant beautification, drinking water. Of course he should be responsible for the physical examination of applicants and the periodic re-examination of employees, as well as the medical attention to families of employees when such is supplied.

He should have a very definite knowledge of housing, transportation, recreational and educational facilities; the transfer and replacement of misfits, or as has been said, "fitting the square peg to the round hole."

He should be familiar with the follow-up work, especially among new employees—with absenteeism and the injured: the replacements of injured and crippled employees.

He should have at least some knowledge of the athletic and social

activities, company stores, commissaries, the type of house suitable for economic administration and housing problems generally.

He should be familiar with labor turnover and its cost; designs and data for the construction and operation of hospitals, lunch rooms, neighborhood and community houses; general education and Americanization, together with a knowledge of broad methods of raising the standard of employees' living conditions and ideals.

In the foregoing I have perhaps wandered far afield with the object however of indicating that the medical man with a broad view and such knowledge, however general, will be of such great value to the organization and every person in it as to command the highest respect, wield a constant influence, find his post seeking him, and incidentally name his own salary.

With the broadening of concept a few plant service departments have extended this field by supplementing a series of lectures, or by other means, bringing attention to the various phases of preventive medicine, emphasizing their social and economic value.

That which has made America great in industry is her faculty of bringing together energies hitherto rambling and misdirected into a rounded concrete whole with largely amplified production.

The mainspring of production or success is individual action and not state action. Success is nothing more or less than opportunity for the individual. The enlightened business man of today sees clearly that the measure of his success is almost directly in proportion to the degree of opportunity his operation creates for others. But of what value is opportunity lacking its essential adjuvant?—the individual in good health.

In the U. S. there are 1,500,000 people constantly sick with preventable diseases, and 8,000,000 men between the ages of 18 and 45 are physically or mentally subnormal.

While most of us are born with good health we have but a brief existence before we carry within us, or are exposed without to the agency of our destruction.

COST OF PREVENTABLE ILLNESS

From a recent report by Irving Fisher of Yale we are informed that there are approximately 3,000,000 persons in the United States suffering from some form of sickness of whom 1,100,000 are in the working or productive period of life—three-fourth being actual workers who must lose at least \$700 per year, which aggregates \$550,000,000. The expense of medicine, medical attention, hospitals, extra food, etc., at least equals this amount. Thus we have a total cost of illness amounting to \$1,100,000—at least one-half of which is preventable.

The sick man is a burden to the community, while the well man is an asset.

Out of every hundred who are twenty-five years old today 36 will be dead at 65, 53 dependent upon relatives and charity, 6 self-supporting and only 5 well off.

It has been shown that of families dependent upon charity 77 per cent of the members were physically unfit.

A most effective method of reaching the employee and his family is through the house organ, which, if well edited, is a welcome visitor to the domestic circle of each employee. It is well, of course, that the printed column should be supplemented by presentations by the medical staff of the organization, who should reach groups of employees orally or directly as opportunity may offer by means of the stereopticon or the motion picture.

It has been my practice in lecturing to groups of employees and their families to discuss industrial medicine in accordance with the following scheme, closing the course by discussing problems and hazards peculiar to our own industry:

Physical examinations—their immediate and remote value; likening the human body to some well-known machine or device in the plant and demonstrating the analogy between the wornout and exhausted parts and the organs of the human body, emphasizing the vital importance of maintenance and repair.

This method can be readily applied to such organs as the kidneys, lungs, liver, circulatory apparatus, etc. The acute and chronic infections, whether of industrial or general origin, and their importance are pointed out.

The subject of personal hygiene is simply presented, utilizing the diseases or defects that have come to recent attention in the plant as a basis for illustration.

The subject of sanitation is presented systematically by following the plan of organization of modern health departments and their various divisions; for instance, the department of sanitation. The discussion includes the nuisances—sewerage and sewage disposal; garbage, its collection and disposal—domestic animals, flies, mosquitoes, etc., together with the importance of good housing and the effects of bad housing, and lodging houses.

The spot maps made by health departments indicating the highest tubercular, the highest communicable disease rates—excepting perhaps typhoid fever—the greatest juvenile delinquency, crime, drunkenness, and so on through the entire category of social ills, match exactly the spot maps indicating the greatest housing congestion.

RELATION OF CONGESTION TO DISEASE

Some years ago the Department of Health of this city, through Miss Chadsey, made a study of two districts, one being in the old crowded section of the city and the other in an outlying section—Newburgh way, which is composed largely of employees of the steel mills. Rents were practically the same.

In the first district in 1907 to 1914, there were 908 cases of tuberculosis recorded—52 per 1,000 of population. In the second there were 450 cases, or 28 per 1,000 of population.

In the first district, in 1912, there were 665 cases of communicable diseases, or 3 per 1,000. In the second, 286 cases, or 1.29 per 1,000 of population.

From the foregoing, little computation is required to definitely fix in dollars and cents the higher value of life in the uncongested section.

It must be borne in mind that a house is not a mere place for shelter. It must provide that which will promote efficiency in labor and strength of character and citizenship. The house connotes the family; the family and not the individual is the unit of our civic structure.

It is now well recognized that in the modern factory at least the employee is in better environment than in his own home. It seems the height of folly for industry to expend many times the per capita cost of health administration on the maintenance of healthful surroundings in the factory and permit the ostensible beneficiary to return to a home environment carrying the elements potent with destruction to the individual worker, his children, and posterity.

Under the head of communicable diseases—prevention, treatment, and a simple discussion of antitoxine, vaccines, their manufacture and use, the length and importance of quarantine, etc. Venereal infections and their effects are discussed freely, as they have come to be recognized as the most important of communicable diseases, heretofore shrouded in mystery and crime and not discussed with candor and intelligence. This subject almost always enlists and holds the attention of an audience. It is amazing that the average individual knows so little or nothing of the remote effects of venereal infection.

Tuberculosis presents a wide and interesting field. Its relation to housing, overcrowding, foods, hours of labor, fatigue, rest, sleep, etc. are pointed out.

In connection with child hygiene in addition to the child itself, prenatal care, reference to obstetrics, obstetrical procedure and infant feeding are discussed. The value of the medical examination of children is emphasized.

Industrial hygiene is intimately related to child hygiene, yet when children leave school and enter active life the health authorities lose sight of them. Industrial hygiene is an important feature in public health work and it is plainly the duty of some authority to supervise these young men and women during the early period of their industrial activity.

Under the heading of food and dairy inspection—the production, cooling, handling, shipping, storage and delivery of milk, together with the food value, the importance of bovine tuberculosis and the dangers of the insanitary market, together with the handling of food in the home, are referred to.

In connection with vital statistics, birth registration, and their importance, invariably attracts attention.

The laboratory affords opportunity for a simple discussion of culture taking and examination of diphtheria, typhoid, gonorrhea, syphilis, etc. These subjects always enlist the closest attention of an audience.

A description of the examination of water and its importance is also interesting.

These and other health-department activities presented even with haste

hold the attention of an audience for half to three-quarters of an hour and bring forth questions indicating not a little grasp of the subjects discussed.

Supplementing the lectures it is advisable to offer a motion picture show. Stereopticon and motion pictures appeal to shop employees and their families and large and appreciative audiences are readily obtained either in the shop or at meetings under the management of Employees' Associations which now exist among larger industries. Films are available from many sources. Our Government, in coöperation with other Governments, together with educational and industrial institutions, maintains at Washington a Bureau of Commercial Economics, which has a large series of films on most of the subjects of personal and public welfare. The various state and municipal Health Departments and practically all of the state and national organizations for promoting health have series of pictures presenting strongly dramatic appeals on the subjects having their attention.

The American Child Hygiene Association, the Social Hygiene Association, The National Tuberculosis Association, The American Medical Association, The National Housing Association, and others supply for a very modest cost sufficient material for a season of bi-weekly or monthly lectures.

A satisfactory series of lectures by the Works' physician is difficult for the reason that most of our present-day industrial surgeons in small plants are part-time employees having neither the disposition, qualifications, nor time to discuss community problems. Unfortunately again the physician is trained to individualism, seeing only the case and not viewing disease in its community aspect. His services are usually limited to advice to individual patients, and if interested and conscientious this service is of course valuable and to him is due the highest credit for the discharge of this responsibility. That there is an opportunity for the industrial physician to make a great contribution to the advancement of public health cannot be gainsaid. The work is clearly desirable; but at what cost and how shall it be brought about?

COST OF HEALTH SUPERVISION IN INDUSTRY

In 1916 the National Industrial Conference Board surveyed 99 leading industries in an endeavor to ascertain the cost of health supervision in industry. It was disclosed that the cost incident to the care of 495,544 employees was \$1,238,485 or \$2.50 per capita. The budget of the N. Y. Health Department is \$2,957,202.15, or in round figures, \$4,000,000. The population according to the Bureau of Census July 1, 1918, is 5,872,143, or roundly, 6,000,000. Hence it is that the per capita expenditure is about 67 cents.

The population of Cleveland in the same year was 810,306 and its Health Department expenditure slightly less than \$250,000, or somewhat over 30 cents per capita.

This lack of expenditure does not include however the maintenance of hospitals. If industry sees its way clear to make an outlay of \$2.50 per

employee, surely it is possible for the community to make a somewhat larger output and obtain returns wholly out of proportion to the sum expended by industry and that from the public funds.

It is clear, therefore, that there is an overlapping of effort with no inconsiderable waste of money. Experience has shown that there are three stages to the development of social movements: a period of agitation, a period of organization, and a period of final incorporation of the desired order of things.

CENTRALIZATION OF PUBLIC HEALTH EDUCATION

It is obviously the time for beginning an agitation having for its object the centralization of public health education and control in some centralized governmental authority. This organization might well stand sponsor for such a movement. It is unfortunate that the present scope of function of the U. S. Public Health Service could not include the Administration of Compensation Funds and other forms of social insurance likely to eventuate, which in accord with the claims of their advocates will react to the prevention of disease.

It is perhaps more courageous than discreet to suggest that business in its present attitude toward Government control, complete or partial, of social or economic function, pool its interest in a small group of the community with that of the community as a whole. Nevertheless, with the advantage demonstrated, executives are quick to respond to the demands of the period.

It would seem entirely feasible to consolidate the function of Compensation Commissions with that of National, state or municipal departments of health, or, if the principle of States rights interferes, it would be workable to bring about cooperation between the agencies with the point of contact resting upon the state department to the end that their respective functions be applied to a single or at least correlated effort that would make its impress on the whole community in the better understanding of the purpose and value of preventive medicine.

CHAIRMAN LAUFFER: This brings us to the consideration of the papers which we have been hearing this afternoon.

DISCUSSION

MR. S. D. HUMARD (Department of Health, New York City): In discussing the paper of Dr. Selby I wish to call particular attention to the opposition regarding physical examinations which exists in the ranks of labor. I understand that one of the planks in the platform of the steel strike relates specifically to the matter of physical examination. In the city of New York, owing to the compulsory requirements of the physical examination of bakers and the arbitrary exclusion of bakers from their occupation when the presence of a communicable disease is found such as tuberculosis or syphilis, it has reacted in a very unpleasant and unhappy manner. There is at present being put into effect a scheme of re-vocationalizing these individuals. Even in the tubercular cases, an open

air bakery is being contemplated. So that we will try to work a less degree of hardship, but I do believe that this organization should put itself as in favor of physical examinations, not with the idea of excluding a man from his chosen vocation, but of practically showing him how he can work to better advantage for himself, his family, his employer, to say nothing of the community.

MR. ROBINSON (California & Hawaii Sugar Refining Company): I would like to ask Dr. Selby what he considers a fair remuneration to a physician for making physical examination of employees—that is in the case of a plant which does not employ a physician regularly. Our employees are examined by a local physician, and at present our examination is very simple. It does not go into the details of a thorough examination by any means, and I have in contemplation the request for a more complete physical examination of employees, and in regard to that I would like to get an idea of what this examination is worth to the average physician. We employ an average of about 1400 men.

MR. J. S. KLOBBER (State Medical Board, Washington): The industries which have taken the van in this movement of physical examinations are skimming the cream. They are getting the physically fit men in their employment and they are profiting by it; but if this movement continues we shall have universal examination for employment, and just as sure as you live you are going to have a discard, a discard that is just as inevitable as the discard in a poker game, and those industries which are forced to draw from this discard will not think very much of that which they will draw.

A condition of the physical examination which places on record that condition of the man when he enters industry is one thing. There is a permanent partial disability in industry due to the breaking down of the constitution of the man just as clear as there is a permanent partial disability to industry by reason of the fact that dropping a man down an elevator shaft or chewing him up in some piece of machinery or doing the thousands of other things that he receives compensation for. If that man or that woman is broken down in the occupation incident to his employment the world says, "It is too bad;" the doctor says, "A case of nervous breakdown." We who view that subject from its intimate relation are regretful. The general public says, "Well, another one gone." But there is a liability attached to it on the part of industry, that condition which created that physical disability, and that must be met and made a component part of your examination.

DR. C. D. SELBY: I think there were two or three points brought up in connection with physical examination. One is the attitude of labor. I realize full well that labor is antagonistic to the physical examination, not the theory of physical examination but the way it is applied. They are not opposed to the physical examination for the purpose of determining the condition of their bodies and the use of the information so secured to their betterment, not at all. If they have any advantage coming to them because of the physical examination they accept it willingly and gladly. I maintain that the physical examination and the subsequent

supervision and assistance in the maintenance of health instruction, etc., is a right which labor has the privilege of demanding, and I think labor should demand it. As I said the examination is basic to industrial medicine. Industrial physicians cannot act intelligently in the supervision of health conditions and working conditions unless they have a knowledge of the facts as they exist in the bodies of the men working in those plants, and the only way that they can secure that information is by making the physical examination, but if that information is not used for those purposes, if it is used only for the purpose of rejecting unfit applicants for employment, certainly the physical examination is going to get into disrepute. I visited a number of large institutions during the war. Several of them gave up the physical examination. "Why, did you give up physical examination?" I asked them. "Because the only evident result that we saw from it was the exclusion of workers and we want workers." That was the only effect that those manufacturers saw from the physical examination. Now Ladies and Gentlemen, that was the fault of the medical profession. I say that the theory of examination is all right and it is acceptable to labor. If labor has not accepted it, it is the fault of the medical profession in applying the principle of physical examination—nothing else.

As to what a physician should be paid for his services in making physical examinations, that is a matter for the physician himself to determine. I cannot suggest anything further.

MR. M. C. GOODSPEED (General Electric Company, Erie, Pa.): I would like to comment on this question of rejection. You must reject for certain positions in order to protect a man against himself and to protect his fellow workmen against the man. You couldn't put a man subject to epileptic fits up into the air. You must protect him and the men underneath him. You must reject him for certain jobs but you can give him a job somewhere else.

CHAIRMAN LAUFFER: As this concludes the discussions, we will stand adjourned.

Adjournment.

SATURDAY MORNING SESSION

THE meeting was called to order at 10:00 A. M., Dr. Chas. A. Lauffer, Chairman, presiding.

CHAIRMAN LAUFFER: First in order of business, we will ask for the report of the Nominating Committee. Dr. Davis of Cleveland, Chairman:

REPORT OF NOMINATING COMMITTEE

DR. DAVIS: Your nominating committee has agreed upon the following names as officers of the Health Service Section:

Dr. W. I. Clark of the Norton Company, Worcester, Massachusetts, as Chairman.

Dr. A. W. Colcord, Carnegie Steel Company, as Vice Chairman.

Dr. William A. Sawyer, Eastman Kodak Company, as Secretary.

(On motion the report was accepted and the candidates elected.)

CHAIRMAN LAUFFER: Another item of business before the meeting concerns advance work along technical lines for the ensuing year. The gentleman who read the excellent paper on "Industrial Dermatoses" yesterday, suggested that a motion be passed by this section to the effect that a technical man, a specialist in skin diseases, be put on the committee at the home office of the National Safety Council, and that work along constructive lines be organized through industrial physicians and members of the American Medical Association, to the effect that something in the way of prevention and treatment be arranged for the reduction of industrial dermatoses. We have the assurance that members of the Dermatological Section of the Medical Association will assist us with their records and in every way enable us to find out what has been done in the way of protective coverings for the skin; what has been done in the way of rendering gloves impervious to chemicals by the use of protective measures so that what a committee of this sort would have to do would be largely to visit and coöperate with men in this special field.

The United States Department of Health has done a great deal of work along these lines but there are some things that have not been covered. One year devoted to a constructive program along this line, and another year to a constructive program along some other line, would be highly advantageous to industrial medicine. I think the matter is an important one, and I would like to hear from Dr. Clark.

REGARDING COMMITTEE ON INDUSTRIAL DERMATOSES

DR. CLARK: It would be extremely valuable for us to take things up in just this way. This is a real constructive piece of work which can be done. We all have experiences with dermatoses. I don't think there is any industry that hasn't at least the danger of furunculosis in its work and we go from that to various definite forms of poisoning which occur in special industries.

Now to be able to have some definite ideas along these lines, to be able to call on some central body for information and advice when we run into some definite problem, it seems to me would be of the greatest value to every one. I would like to see such a committee appointed and I would like to see an appropriation for such a committee to carry on its work where it would be in contact with men who would be able to give the best advice possible, and where you or I, or any one else can send in and get information and advice in regard to any perplexing problem along the dermatological line which may arise.

I have been very much interested in the question of cutting oils. We have had practically no trouble in the way of infection in hands and arms, except in a very few individuals who apparently do have a lowered resistance and do have these infections. About a year ago, I established a conference with my nurses and each nurse reports once a week in this conference the number of infections which we have had in clean wounds, and we haven't had any. But, we do have a certain number of these skin

infections around the forearms and hands which we can't say are due to the cutting oil, but may be due to other causes. Now the problem which arises is, how are we going to get the best way of finding out quickly whether our cutting oil is infected? What is the simplest method of finding that out? What should we do if we find the cutting oil is infected? What is the best method, the best and cheapest method of protecting our workers' hands and arms in case there may be some infection in the cutting oil? That simply gives an experience which we are all bound to have, and we can readily see how important the problem is.

THE CHAIRMAN: Could we hear from Mr. Williams of the National Safety Council staff?

MR. SIDNEY J. WILLIAMS: The Council does not want to start competition with any medical organization. Most of you remember the discussion about a year ago in Chicago about a combination of health organizations. We don't want to run counter to that. On the other hand, if this section thinks the line of inquiry which you would like to carry out would be a contribution in the general field of medical and health development, certainly the Council is very glad to have you do anything along that line that you wish. The sections in the Council have always been almost entirely self-governing. I don't clearly understand whether you have in mind principally the appointment of a paid man to work on this subject, or the appointment of a committee from among your own men best qualified on the subject, or both. Is it both, Dr. Clark?

DR. CLARK: My idea, sir, was to have a central individual, or group of individuals, as the case might be necessary, to whom any one could write any dermatological problem and who would be in position to answer him thoroughly, just as you would write to the Public Health Service, but they would probably not give you as good and clear information without special investigation. This man would be able to give you a quicker answer.

MR. WILLIAMS: Would that involve the addition of a man with medical education to the National Safety Council's staff to take care of this work?

DR. CLARK: I don't think it would be necessary to have a man; we could send that matter in to the National Safety Council and let them handle it as they saw fit, and, if there is enough work to justify hiring a man to take care of it, all right. If there isn't, they can handle it as they see fit.

MR. WILLIAMS: So far we haven't had any one on our staff with any medical training whatever. The health bulletins have been prepared by officers of the section, and we have simply issued them. I am sure I can say for the Council and the Executive Committee that they would look with great satisfaction on the appointment by you of a special committee on this subject, because that would be quite along the line of our general policy of collecting and disseminating information in connection with safety and health and allied problems in industry. I am sure also, that the head office will give at least some time, on the part of someone on its staff, to carrying out the detail, routine work outlined by that committee, in the way of writing for information and so on.

I am not sure that we could at this time appoint a full time man on the staff, because just at present we are spending every cent of our income. It is possible you might find some of the younger medical men in industry in Chicago that might be paid a couple of hundred dollars a year for a few hours of work a week.

Dr. Davis makes the very practical suggestion that this committee which you may appoint, should be able to meet in Chicago one or more times during the year, inasmuch as most of you are connected with industries and could make a trip like that occasionally. You could meet at our headquarters, and then we could make such arrangements as seem necessary to take care of the detail work. Dr. Clark as Chairman of the Section is ex-officio a member of our general Executive Committee and will attend its meetings as often as possible and represent the section.

DR. HARVEY (Crane Company, Chicago): I take it from the speaker yesterday that this plan didn't contemplate the hiring of a full time man; neither did it contemplate putting the National Safety Council to any great expense. It was merely to bring out the fact that there was a need of collecting data on the broad subject of industrial dermatoses, and, while it wouldn't be feasible to have joint committees from the National Safety Council and the American Medical Association and the American Association of Industrial Physicians, because they wouldn't do any work, still, as Mr. Williams said, a committee would take hold of the work and get in touch with these experts in skin diseases who would be glad to go over the data and analyze it and get out some good information for physicians in the industrial field. I can't see that there would be any great expense and it doesn't contemplate a physician and surgeon to be added to the staff.

CHAIRMAN LAUFFER: In order to bring it before the meeting will you recommend that the incoming president appoint a committee of three, with power to act?

DR. HARVEY: I make a motion that the incoming chairman of this section be instructed, and requested rather, to appoint a committee of three or five, to handle this broad subject of industrial dermatoses, co-operating with the Executive Committee of the National Safety Council, and other organizations interested in this subject, and report back, if possible, at the next annual meeting.

(The motion was seconded and carried.)

CHAIRMAN LAUFFER: Our first paper on "Malingering" will be presented by Dr. Judson C. Fisher of New York—Dr. Fisher.

MALINGERING—INVOLVING THE PROBLEM OF GETTING THE SICK OR INJURED EMPLOYEE BACK TO WORK

DR. JUDSON C. FISHER, SPECIALIST IN INDUSTRIAL INSURANCE,
NEW YORK CITY

Malingering may be defined as the conscious and deliberate feigning of illness or injury, or as the exaggeration of symptoms. Some comparative Zoölogists, after studying the animal kingdom, say that malingering is a

form of self preservation—an offshoot of fear. In the animals it is called instinct. If one stops to analyze the cases of malingering in respect to nationality, physiognomy, and mentality, there are evidences that this "instinct," as it were, is a real thing and a trait which supports Darwin's Theory of Evolution. History and Literature have recognized malingerers since the beginning of the world. The earliest instance known is recorded in Genesis, Chapter 31, Verse 35, where Rachel, in 1056 B. C. malingered in order to secrete the stolen idols of Laban. What boy in our day hasn't malingered in order to attend the ball game, carry water for the elephants, go fishing, or escape an unprepared lesson? While the problem is old, yet in these fast-moving days of industrial activity there are new aspects which must be considered. The various methods of malingering, the tests for its detection, and the training of the doctors for this special branch are food for other papers.

That admirable legislation known as the Workmen's Compensation Act, now operating in the majority of the states, has given us an opportunity to study closely the injured employee, and, where occupational diseases are included, has stimulated interest in the sick employee.

In justice to the workmen in general, I believe malingerers to be in the minority. The ideas brought out in this paper are for the purpose of detecting and curing an ulcer which causes the innocent to suffer, and by its cure will cause the honestly-disabled employee to receive all the honor, sympathy, and consideration due him.

The malingering employees may be roughly classed as:

- A. Dishonest employees who say little.
- B. Exaggerating employees who are less experienced and therefore voluble to make the most of their injuries.

"FAKIRS"

The dishonest employees or "fakirs" are those who have a slight or no accident or illness. They report an injury and become immediately disabled. The doctor finds little or nothing upon physical examination, but, willing to be always fair, gives the employee the benefit of the doubt and sends him home. His disability becomes total, and on account of "pain" he says he cannot work. If he has a slight cold he reports sick and says the pain in his chest keeps him from work. A physical examination shows no evidence of illness.

Where settlements are permitted, as among stevedores and longshoremen under the Admiralty Law, foreign labor is urged and often assisted to mangle by the "Tunners" or "shysters." Within the last three months I have seen the following malingering cases of this class:

1. B. C. age 38, Italian, married, was lightly hit by a draft of boxes and was supposed to have injured his left shoulder. He went to a doctor, who treated him every day. Physical examination three weeks from date of accident for the purpose of determining the extent of disability, showed marked inability to raise the left arm and, upon palpitation, a very tender shoulder joint. After various tests, no signs of fracture or changes in or about the joints were

discovered. There was a mottled blue area of skin about 4 inches in circumference over the shoulder. The "bruises" were superficial and not deep. Investigation confirmed the suspicion that these "bruises" were caused by some one sucking the skin of the shoulder, and making what the boys call "fox bite." Had the man had a real injury the settlement would have been in proportion and the "runner" would have had a larger fee. In this case the employee was dishonest and the "runner" tried to assist him to be more dishonest with the hope for greater benefits.

2. P. Q. age 46, Hebrew, married, claimed to be walking along a warehouse when he slipped on a banana peel. In trying to catch himself he bent backward and hit his head and the middle of his back upon some crates standing near. No one saw the accident, but a doctor strapped his back. When examined there was a blistered area of skin across the small of the back, which proved to have been made by a hot poker in order to fool the examining doctor. While his back was being examined, his clothes were dropped down about his ankles, and his hat placed upon the floor. During the examination he claimed inability to bend forward. Upon being left alone he was seen, through a peek slit from another room, to bend over, pull up his clothes and pick up his hat.

At present, in the investigation of the State Insurance Fund of New York, a regular school has been discovered where employees of the Fund coached injured employees to malingering so that they received higher awards than they were entitled to receive.

Flagrant malingering where the claimant is dishonest, unassisted, is seen as in the following cases:

1. M. N. German born, age 22, draughtsman, was injured in Niagara Falls. He claimed that while lifting one end of a drawing board he felt pain in both groins. Physical examination showed a large indirect inguinal hernia on both sides. He claimed never to have had a lump on either side before. He insisted upon operation by his New York family doctor and not the Insurance Company's doctor. His doctor used carbolic acid in mistake for novocaine, burned the skin from the boy's navel to his knees and he became sterile by the contraction of the scar tissue over the cords. Investigation showed that the drawing board weighed 12 pounds and his end, therefore, weighed 6 pounds. His could not have been a traumatic hernia. This malingering caused loss of services and money to the employer and much suffering with permanent disability for the malingerer.
2. M. M. was led in by a young girl. He stated he was 51, married, family in Italy, and had been burned in both eyes by live steam. He claimed to be able to distinguish light and dark only. External physical examination seemed to bear this out, except for the fact that his eyes quickly followed the dropping of a ring to where it rolled. While he was faced toward the window his coat was put on another chair, his hat hung in a darkened corner of the room,

and his glasses changed to another position of the desk and partially hid by a paper. His ability and agility in finding these objects while talking about compensation led to his claim being rejected.

3. A young man, formerly an acrobat, age 28, married, sprained his ankles while carrying a heavy chain. He returned to work in three weeks, compensation was paid and the case evidently closed. He apparently did the same and heavier work for nine months. Then he laid off and asked for a rehearing. Physical examination was negative, x-ray was negative, yet he held his feet almost rigid. Several doctors, including the Chief Surgeon of an Accident Board, could find no cause for his complaint that "the pain in his ankles was so bad he couldn't work." I couldn't elicit the usual evidences of pain, and finally had him kneel in a chair facing the back. His feet hung rigidly. Tapping the achilles tendons caused an unexpected free extension of the feet. This movement was not painful. This was one of the very few cases where I felt justified in testifying "this man has no pain." Despite the negative evidence the Board awarded compensation. Leaving the building the employee said to me "I guess I didn't talk up to them enough. S. told me that he talked up and was given \$3000 and I got less than \$1000." After the settlement he had no further need for his cane.

EXAGGERATION OF SYMPTOMS

The second class is composed of employees who have been ill or injured so that the evidences are present upon physical examination, and yet who claim to be unable to return to work. In these cases the physical examination shows exaggeration of symptoms. The men decide not to return to work until they are as "fit as the day they quit." This class may be divided into (1) those who are in the age group 25 to 40, and (2) those who are in the age group 55 to 75.

The age group from 25 to 40 contains many malingerers who desire time off because when idle they make more money as follows: J. C. belongs to several Lodges or Mutual Benefit Societies, whereby the total weekly benefits, including compensation, exceed the average weekly wage. His wife may also be working and adding her mite. In these days of high wages and comparatively low compensation benefits this class has fallen off in numbers, but in ordinary times these employees we always have with us. The men find it much easier to have free medical attention, to have high weekly benefits, and to be able to sit around and talk or read, than to have to work in order to earn the amount sufficient for their needs. This is especially so when the earning power is less productive than the benefits.

The age group from 55 to 75 years—the winter season of life—usually contains men who own a little property purchased with their savings, and have rent practically free. They have children who are married, and any at home usually contribute, so that the income from Compensation Boards, Lodges, and members of the family with an occasional

gratuity from the employer is more than sufficient to feed and clothe the family. These men are satisfied to sit around and talk and do the chores, but when it comes to work they claim inability of all sorts. A good example of this class resides in the city of Buffalo. His history is as follows:

K. K. age 62, married, no children, while working for his brother as a carpenter, fell a distance of 10 feet and landed on both heels. He fractured both heel bones. The injuries were promptly and properly treated. The slight swelling of the legs, common to inactive men of his age, appeared occasionally, and there was a slight deformity due to callous formation in the left heel. He was fitted with proper arch supports and shoes, baked and massaged, and after a period of total disability for 52 weeks, was told to return to work. The brother-employer was approached concerning re-employment of K. K. He said he thought K. K. should rest, and thereby prolonged the disability, because K. K. would "work for nobody but his brother." K. K. claimed pain in the muscles of his leg after standing a while, and pain in the bones of his feet at night. He refused to try to do anything. Five years after the accident the examination revealed nothing more than the usual results of this type of fracture. Investigation proved that he owned his home, did the chores, cut the grass, cared for his garden, hoed the potatoes, and yet exaggerated his symptoms, so that the Insurance Carrier has paid him \$15.00 per week for five years, with the prospect of paying him as long as he lives, and the chance of supporting the widow afterwards.

Statistics show that more employees malingering who are injured than those who are ill. This is probably due to the legal liability feature, therefore, we will deal with our problem of returning the employee to work, with a tendency toward the accident feature. Necessarily this will involve problems of workingmen's compensation administration.

If Health Insurance ever becomes law in this country the American people will be astonished at the days lost through illness in comparison with the days lost now. The curve will increase each year. This was demonstrated in Workmen's Compensation. The first year the law went into effect the insurance companies made money because the benefits were not understood. The next year the days lost increased and have been increasing in numbers each year.

PROBLEM OF RETURNING A MALINGERER TO WORK

The problem of returning the injured or sick malingerer should be attacked as the medical profession attacks diseases. The premise is that the disease is present. To treat it properly there must be a knowledge of the causes, the symptoms and signs of the illness itself, and the cure by (1) preventative measures, so that others will not be afflicted, and (2) the treatment of the diseased one by eradication of the symptoms.

A. As to the premise there is no argument. No sane person doubts its existence.

B. The causes of malingering:

These are many, and because of their importance in treatment they should be mentioned in order.

1. *The Employee.*

Starting with the malingeringer himself we must consider him as to his

Among foreign elements all ages tend to exaggerate and malingering. ability to endure would result in a far less malingering in proportion especially the Latin races. The American youth, except in rare instances, wants to be back at work as soon as possible. His future is before him. About 50 years of age man begins to consider work as a means of existence and takes pride in his past achievements. He begins to feel that society owes him a rest and a pension, and exaggerates accordingly. Some older men, with the pride of years of service behind them, will drag themselves to work if possible that their record may not be broken. Men with such spirit are the real heroes of labor. Unfortunately human nature seeks rest as the sun of life sinks.

The influx of women workers during the world war has been too recent for reliable statistics. It would seem, however, that their ambition and ability to endure would result in far less malingering in proportion than among the male sex.

The less educated, the lazier men become. Conversely, as the mind improves its status so does the malingering become lessened. There seems to arise an ambition which refuses to be downed by ill luck. Therefore, lack of education is recognized as a cause of malingering.

The mental attitude of the employee is interesting on account of the motives discovered. (a) He may be revengeful and feel that his employer owes him more than the law provides, or that the prolongation of disability will tend to get even with the employer for some real or fancied wrongs. (b) He may be ambitious for attention, sympathy, and alms. All clinics have those who make regular rounds year after year. The Hospital Charity Organization Societies, Churches, Lodges, and various benevolent societies know this type well. (c) He may be defective mentally, and that type includes the fanatics, the convulsionists, the hystericals, imitators, and manic-depressive cases.

2. *The Employer.*

Employers may be divided into two classes for our purpose. (a) One class is composed of those who are too generous. They pay full wages for time lost irrespective of compensation laws. In some few cases this would be extremely gracious and well deserved, but the temptation of nature to prolong disability is too strong in the vast majority of cases. (b) The other class is just as close and indifferent as possible. While I was trying to induce a president of a large concern to introduce a sanitary lunch room, hospital, and first-aid organization, he said "Why should I try to make it pleasant and safe for those fellows aside from my question of rate? The whole 5000 would walk out tomorrow and not think about me if an agitator trumped up some fancied wrong." Had he paid more attention to the men's comforts, organized safety-first units, learned a few men's names, dropped a smile or word of commendation

here and there, or built up a brotherhood among the employees, there would be little economic loss through malingering. Personal interest properly exercised breeds loyalty among employees that even instinct can't abuse very much. Keeping the employees informed as to statistics of work in past years for comparison, and accident frequency with loss in terms of sick or injured days, will go far to arouse an unbeatable pride in the workmen's heart. A lack of interest on the part of the employer means a lack of proper follow-up methods and does much to favor malingering.

3. *The Industrial Accident Boards.*

These foster malingering by (a) having no facilities for quick hearings in malingering cases as soon as detected. In some states it takes from 2 to 6 weeks to have a case appear on the calendar after application for hearing has been made. If detected, the malingerer knows he will be given consideration at least to the date of the hearings, which gives him added weeks of benefits, which he otherwise would not receive. (b) Urging legislation, raising the amount of compensation indiscriminately. The man with a sore finger can do work of some kind where the man with a broken leg could not get out to look for it. The helplessness of the latter requires greater expenditures and should have a higher rate. In other words, a scale depending upon the degree of disability should be chosen. The simpler the injury, or the undue prolongation of an accident in like proportion, calls for less in benefits. The most worthy should be entitled to the maximum benefits. Malingering is fostered by high benefits. (c) Mixing politics and sentiment with business. Very few appearing before various state boards have not seen an elaborate staging of a case with relatives for supporting parts, in order to sway the Board, and the subsequent sympathy cause a ruling not upheld by the higher courts. Many have seen union cards and political affiliations worked to the limit, because the Law says that the Board shall be the sole judge of fact. With proper "introductions" the malingerer is confident that the Board may be generous. (d) Failure to prosecute perjurers or malingerers when so proven. This freedom from prosecution is a source of comfort to the malingerer. What has he to lose? (e) Failure to have a competent medical member of the Commission, whose duty would be to arbitrate all medical cases. He would weigh the opinion of the Chief Medical Examiner against the testimony of the Insurance Company's doctor, or the claimant's doctor. Malingerers could not then trust to the ignorance of a lay mind concerning the importance of the medical problems involved, or the symptoms presented.

4. *The Medical Profession, sad to relate, contributes much toward malingering.*

(a) Family doctors depend upon the families and their friends for their practice. They feel they can't afford to get on the wrong side of any fence, consequently the malingerer preys on them for certificates of extended disability which the doctor can later usually back up with some kind of opinion. (b) Lodge and Society doctors are in the same class and their reappointment the following year depends on the vote of the

Lodge. These doctors rarely perjure themselves for a few dollars, but they will stretch the truth. Malingerers get certificates comparatively easy from such men. (c) The shyster doctor, as well as lawyer, we have with us. To such the truth means nothing and they trust to their personality to convince lay Board members of a fearful and wonderful condition in the claimant. This type of doctor has his "price." (d) Incompetent doctors treating all manner of cases prolong and sometimes provoke disability unduly, and discourage the injured or sick. Thus they encourage malingering.

5. *The "Third Party."*

The so-called friendly enemy or runner who learns a few symptoms of disability and how to produce them artificially in some cases. This party, plus a natural malingerer, makes a hard combination to beat. The runner is after his percentage and the higher the cost to the employer, the greater his profits.

C. The detection and methods of detection of the signs and symptoms of malingering will be left to the Industrial Surgeon or Specialist in malingering. Suffice to say that the diseases having been proven present, we next consider the

D. Treatment.

1. *Prevention or prophylaxis.*

This consists chiefly in correcting or removing the causes.

As for the employee; pension the faithful employees before they are added to the industrial scrap heap, stimulate pride in men to outdo the women in stick-to-it-iveness. Educate them at least to an awakening interest; determine the mental attitude by physical and social examination before employment and eliminate the mentally unfit. The moral and physical hazard of those employees in daily contact would be greatly increased if defectives were allowed on duty.

The employer should be kind, gentle, courteous, and jolly, but firm and not unwisely generous. He should make the employees feel it is their business also, and each man is a spoke in the wheel which will not run smoothly if a spoke is missing. He should advocate employees' clubs, comforts, and organizations, and encourage them with his occasional personal supervision.

The Industrial Boards should have one-day emergency calendars presided over by a commissioner who is a competent surgeon and specialist in malingering; a fair scale of benefits so that the worthy receive their due; a high sense of honor as custodians of hundreds of thousands of dollars of employers' moneys; an understanding that politics and sentiment must be minimized in relation to business and the law, and the prosecution or assisting the district attorney to prosecute all malingerers and perjurers so proven.

The Medical Profession will from now on contain trained industrial surgeons. Progressive colleges are beginning the courses. These should supplant the family, lodge, society, shyster or incompetent doctor. These surgeons should be supported by industry but not subservient to it.

The Boards and Employers should refuse to discuss a case wherein there was a runner or shyster lawyer. These vultures prey upon the

laborer's ignorance of his rights under the law and demand a percentage of that to which the Law says he is entitled. There is no need for the runner and he should be eliminated.

2. *The active treatment of Malingering.*

The problem resolves itself into the fact that these employees are lingering and loitering on the threshold of industry. How best to encourage their voluntary return?

(a) Starting at the beginning of employment the application blank should have these questions on it:

- (1) Have you had any previous accidents? Explain.
- (2) Have you had any previous illnesses? Explain.
- (3) Are you now in good health?

A malingerer is not necessarily a *good* liar, for a good liar remembers his previous story.

(b) There should be a careful physical examination before employment. Defects can be noted so that minor injuries cannot be amplified.

(c) Accidents or illnesses must be reported by some one within 12 to 24 hours after occurrence or they cannot be considered. Employers should be protected by the law in this. A physician makes an immediate examination and controls the case, then a smashed finger at home can't be charged to industry; a gonorrhoeal joint can't be referred to a strain two weeks previous; lumbago can't be called sprain at work. Of course where eye particles give trouble next day, or infection sets in three days after a scratch there are definite signs of presumptive injury while at work.

(d) *Proper Organization.*

- (1) Chief Surgeon. A trained industrial surgeon who has specialized in malingering. He should have a pleasant and forceful manner, be a business man and well read. He must have a convincing manner on the stand and have tact.
- (2) Assistants, as many as necessary, to treat all injured men immediately upon report of accident or illness, and to make thorough examinations before employment and at any time where necessary.
- (3) Nurses who can pleasantly jolly a malingerer, and if possible shame him into going back to work.
- (4) One or more social service nurses, male or female, to check up and investigate any suspicious actions or questionable testimony. These nurses should have a claim training so that they know a few details which they could attend to when necessary.

(e) *Proper System.*

A system to lessen malingering could be used as follows:—

As soon as an employee reports ill or injured he has prompt attention by a doctor. The doctor's report, estimate of disability and history of the case seen the previous day, is filed every morning. The employment card is attached to his history and physical examination card and becomes

part of it. These cards or files go to a doctor for comparison. If the case looks legitimate the treatment continues until disability from that illness or injury ceases. The file then is placed back in the filing system and the case closed. If the case looks questionable the facts are investigated by the social service department and action taken accordingly.

If the claimant later tries to reopen his case claiming all sorts of symptoms, he can be confronted with his previous well-kept record.

If disability lasts over four weeks the case automatically goes out of the assistant's hands until the Chief Surgeon shall have made an examination and report. The Chief's word is final—the man goes to work or receives further treatment—general, operative, or reconstructive. This gives also the advantage of the Chief Surgeon being able to watch the work of his assistants. At any time an employee is thought to be malingering the report should be made confidentially to the Chief Surgeon.

The scheme may be expanded into the realms of state medicine. It may also grow into a clearing house for information concerning dishonest employees, such as the life and accident and health companies support. When an employee is dishonest to the point of malingering he should be known, that the honest employees be not made to suffer by his actions. This would reduce the number of so-called "traumatic hernias" alone, so that the saving in this one type would pay for the bureau.

This scheme is also applicable to any group of employers or insurance carriers in any one city where the individual system might be too expensive for any one employer.

(f) Proper punishment.

A firm hand by the Industrial Boards in dealing with malingerers is essential. It matters not whether benefits are cut off on the date the employee should have shown his good will and attempted to resume some work upon the physician's advice, or the knowledge that detection of malingering will certainly be punished by the Boards or Courts—the employee who is faking will fear the consequences. Fear goes a great way to keep people straight who otherwise might be intentional malingerers. This fraud is the meanest of all and should be severely dealt with.

(g) Expert Diagnosticians.

This group would include a well-paid Medical Commissioner, skilled in industrial medicine and surgery and in the detection of malingering, and well-paid Chief Medical Examiners.

Employees may have their own opinions, but they cannot seem to learn that working, after certain disabilities, will do more for them than medicines or treatment in hastening a cure. The difference between the patient visiting his own doctor and being examined by the Commission's Expert is that in the former case the patient seeks advice, while in the latter case the patient squeezes symptoms to fit the condition. The former doctor is perhaps biased. The Expert is unbiased, and while giving the employee the benefit of the doubt, he is an administrator of justice to all, especially that great class of honest employees who say "I don't want anything for myself. I want a good body and to get back on the job."

The Expert should be acquainted with industrial conditions so that his judgment as to a finger injury would be fair to a tailor, or watch-

maker, while the same injury would be less disabling to a foreman or driver, and the return to work order should accordingly be influenced.

The Expert should study the individual and know character. He should know when to agree with dishonest complaints and when not to agree.

He should have a fair knowledge of decisions of State Boards and Courts in various types of cases, as his questions and the answers thereto may prove of great value to the Commission in legally interpreting a malingerer's statement.

Finally, he should have a thorough knowledge of pathology. This is essential to account for many of the symptoms alleged by a malingerer. It is of untold value in the hundreds of tests to check malingerers. That is something of which the malingerer knows nothing. This will stop the testimony of unscrupulous doctors concerning a wonderful pathological condition, purely invented in the hope that the lay members of the Board will give the patient the benefits.

CONCLUSIONS

In attempting to recognize the disease, investigate the causes, and treat the condition, there has been one point in view—that of returning the sick or injured employees who tend to mangle, to work in the shortest time consistent with good recovery. This saves an economic loss to the employer and protects the honestly-disabled employee, who by reason of his honesty should profit in proportion as the malingerer should suffer. The American spirit is justice for all. Stress has been laid on well-trained industrial surgeons. This is because in my opinion few mistakes could be more serious or do more real harm than to stigmatize an honest man a malingerer. It is possible by proper methods to prove malingering. At the point of doubt the Medical Commissioner is essential and his opinion should prevail on all medical questions. A number of malingerers get surprisingly well before they will be examined by the Chief Surgeon or, Medical Commissioner.

The malingerers cause the medical profession making impartial examinations to view any case with suspicion until proven innocent. If we can minimize the number of malingerers we shall have done much for the honest sufferer. We shall also save the toiler from moral degradation which follows misspent time and unearned income. The detection of malingering is a highly specialized branch of medicine. for by it society pays its just debts, fraudulent claims against innocent parties are prevented, and industry receives back the men as useful members instead of their being leeches on society.

CHAIRMAN LAUFFER: In the absence of Dr. Hambrecht, Chairman of the Industrial Commission of Wisconsin, who was to open the discussion. Dr. H. F. Kollenberger, of East St. Louis, who has given a great deal of attention to the element of play in restoring the unconscious malingerer, will address us. Is Dr. Kollenberger present?

Dr. Kollenberger has done work in connection with the Y. M. C. A. and the Army, and has found that men playing ball, and doing various exercises, mere play, have unconsciously exercised the joints of their

backs and enabled themselves to bend and execute movements that they had before thought impossible. A person can do often as a matter of play, what he is unwilling or unable to do as a matter of work.

Dr. Kollenberger is not here. I would be very glad to hear from somebody on the subject of malingering. The question has been admirably opened for discussion.

DISCUSSION

DR. HOLTZ (Pittsburgh): I hesitate to comment on Dr. Fisher's admirable paper, however, he made one or two points which I would like to discuss. There is one point I would like to challenge rather mildly, that is reference to the greater amount of malingering being found in the foreign born, or the persons of low mentality. It has been my experience, in a few cases of malingering I have run across, that the malingerers have been of rather high mentality and shrewd. I don't believe that the successful malingerer can be classed among those of low mentality.

In the matter of getting injured employees back to work as quickly as possible, I have found that carrying into civil industry the practices of some of the things we did in the army are very beneficial. Such, for example, as those severe hospital cases that have been disabled for a number of months. Heretofore it was our experience, and it is possibly rather common, that the severely injured employee easily becomes hospitalized and forgets how to work. Quite recently we have had some pleasing results in applying the modified methods of vocational training or education, if we call it that. These cases in the hospital, if they can't use their hands, we try to have them use their feet. If they can't use their feet we try to have them use their hands. We try to have them do something that occupies their mind and we find at the end of their convalescence they haven't forgotten how to work, and we get them back on the job much more easily than we did before.

CHAIRMAN LAUFFER: Dr. Kollenberger has just come in. Might we hear from you about your work, Doctor?

DR. KOLLENBERGER: In the army, in dealing with the wounded soldiers, we found that the men who came back to us wounded needed many times mental treatment. We found also some of them, if there is such a thing as unconscious malingering, could do things if they would. So, we try to supplement the work of the surgeons in the treatment. We did our work rather through play activities for these wounded men.

I will be just as brief as possible because I know you are crowded here. We found this, and I think you will recognize the point, that when a man is being massaged and is given the various types of treatment his mind is focused on his injury and the poor fellow is wondering if he is ever going to get well. He knows the thing we call "hero stuff" is soon over, and he is up against it. So, we started a plan of play activities so it would give them the exact exercise needed with his mind focused off his injury.

For instance, playing ball. I happen to have this glove with me. Here is a simple glove, with straps to flex each finger and here is a man who

has been shot in the arm, or who has an injured elbow. Men have come to us who have had their arms in casts for six months; the elbow rigid, the fingers stiff. Now what can be done with that man to get his mind focused on some recreation? Well, we got a glove like this. The arms of some of these men were so weak they couldn't hold them up, and they would have to grasp the wrist with the other hand to punch a bag. In a few weeks' time we could put a tennis racket in the man's hand, strapped it on and then have another man opposite him with a tether ball. A tether ball is a ball attached to a string and a stick on the other end of the string. The injured man would try to hit that ball, he had forgotten all about his wrist and his injury, and he would hit that ball and try to wind the thing up on the other fellow. He would play for probably ten or fifteen minutes. You can readily see what would happen, the range of motion would be increased, he unconsciously contracted those muscles in there. If there is any break in the continuity of the nervous system they would not contract.

There was one man put this glove on his hand for the first time and played for about ten minutes, and the glove was taken off. It was quite warm and sweaty and he started to close his fingers, and as he closed them his eyes bulged, because he had never been able to close his fingers as much as that before, and in fifteen minutes he was able to move his fingers.

The thing is this, I have in mind that while there are a great number of tests to discover unconscious malingerers they sometimes discover themselves. They will stoop for a ball, or drop their crutches without thinking. If we can do this for the men who have been injured in our armies, isn't there a great possibility to serve these men who have been injured in our industries? It is a new field and I wish I had time to tell you of our other experiences, they all open up new ways of helping our men.

CHAIRMAN LAUFFER: The next paper is "The Treatment of Burns," by Dr. Clark.

DR. W. I. CLARK: I have a great deal of hesitation in reading this paper. When I was asked by the Chairman to read a paper on burns, I felt a good deal of reluctance in accepting because some of the men in industrial medicine see a great many more burns than I do. I think really a paper on burns should be read by a man who is in one of the steel industries, or some industry where the burn hazard is a very large one. However, from my small experience in burns I have worked out a few ideas, a sort of resumé of the whole subject which I hope will lead to a very active discussion. It is simply to provoke this discussion that I am reading this paper. It is a short one, so you will have plenty of time for discussion.

TREATMENT OF BURNS

DR. W. I. CLARK, JR., NORTON COMPANY, WORCESTER, MASS.

Moorhead, in his *Traumatic Surgery*,¹ published in 1917, writing of burns says: "Practically speaking, they should all be regarded and treated as infected wounds due to heat."

¹Morehead, John J., *Traumatic Surgery*, 1917, p. 616.

Colcord² in a most careful discussion of burns and their treatment says of a visit to a hospital where there were many burned cases: "Every burned surface was covered with pus and the smell was disgusting. Many writers speak of the absorption of pus from suppurating burns as a frequent cause of death."

Why is it that burns tend to run a septic course? The heat which is sufficient to kill the cells of the skin layers in a third degree burn should certainly be strong enough to destroy microorganisms upon this skin and it undoubtedly does. Thus a burn is an injury to one or more layers of the skin resulting in death of the exposed tissues and readily infected either direct from without or from the neighboring unburned skin.

Therefore if we can keep a burn sterile it should, after the separation of the slough, become a clean granulating wound and follow the same course as other wounds of this type.

While epithelium will grow on an infected surface its growth is slow and unsatisfactory as compared with its growth over a sterile surface.

It is exceedingly difficult to maintain sterility in a burn of any magnitude. Even with the greatest care any wound which is frequently dressed becomes infected and this is particularly likely to occur when a mass of dead and partially devitalized tissue is the type being treated.

In considering the treatment of a burn we have to consider two things, the treatment of the burned individual and the treatment of the local condition, the part burned.

The treatment first should be directly for the burned individual. The conditions to be combatted are shock and nephritis. Secondary conditions such as fever and pulse rise with meningeal symptoms, vomiting and diarrhoea, and sometimes symptoms of gastric or duodenal ulcer may appear as a result of thrombosis and toxic absorption from the local burned area. These must be met as they arise.

The order of treatment is as follows:

1. Put the patient to bed in a warm room with hot water bags to feet
 2. In removing the clothes, cut around burned areas being careful not to tear the clothes from the skin and cause additional trauma and avenues for infection.
 3. Protect the burned areas thus exposed by covering with sterile towels or sheets.
 4. Give patient $\frac{1}{4}$ gr. morphine with 1/100 gr. atrophine by hypo. Repeat with caution if necessary.
- Morphine is a stimulating narcotic and if used carefully can be employed to combat the shock without risk.
5. As soon as possible start a Murphy drip in order to combat shock and supply fluids to the kidneys.
 6. When patient's condition begins to improve start treatment of the local burned area.

The local treatment of a burn is practically the same for first degree, second degree, and third degree burns. One or all types may occur in any case.

²Colcord, A. W., *International Journal, Surgery*, May, 1919.

FIRST DEGREE BURN

The first degree burn involves only the outer layer of the skin, there are no blebs following and no scarring results. The first, last, and only treatment needed in this type of burn is to powder freely with powdered stearate of zinc. When this type merges into second or third degree burns in the neighborhood the whole area had best be treated with a solution dressing. Before this is applied, however, a careful cleansing of the skin with a mild antiseptic is carried out. This must be done thoroughly, but gently, especially around the burned areas. For the skin three or four inches from the burn, benzene applied with cotton mops and followed by 3½ per cent Tinct. of Iodine is probably the most satisfactory method of sterilization. As we approach the burn ether should be substituted as it is less irritating. It is applied with cotton mops. The doctor should wear sterile gloves, use sterile instruments, and if he opens blebs should first sterilize the area with 3½ per cent Tinct. of Iodine. Moorehead recommends puncturing the bleb aseptically at the junction between the sound and unsound skin.

After the surrounding skin has been prepared and the blebs attended to, the burned area should be covered with a suitable sterile dressing. There are three types of dressing now in use.

1. Wet Solutions of which the most favored are 1 per cent Sol. of Picric acid and Saturated Sol. of Bicarbonate of Soda.

2. Ointments of which the most used are Boric Acid and Soda Bicarbonate 3 per cent. There have been a number of special burn ointments developed, two of which have been so thoroughly tried out that their formulæ will be given.

First Ointment. Used by Dr. A. W. Colcord in the treatment of 8,000 burns.

℞
 Carbolic Acid
 Thymol
 Menthol
 Camphor of each gr. 5
 Ichthyol
 Balsam of Peru of each gr. 10
 Zinc Oxide
 Starch of each 1½ drachms
 Petrolatum to make one ounce. Mix well.

Doctor Colcord uses this ointment in 1/6 strength from the start. Applied daily with aseptic precautions.

Second Ointment. Used at La Panne,¹ Belgium, during the war.

℞
 Vaseline20
 Lanoline20
 Antipyrine60

¹Dr. René Sand, Belgium, personal communication.

Boric Acid	60
Salol	20
Iodol or Iodoform	20
Phenol	20
Bichloride of Mercury	02

This ointment gave extremely good results and was used with aseptic caution.

The third type of primary dressing is warm wax. This method started with the proprietary substance Ambrein, but it has been found that the action is only mechanical so that there are a number of mixtures of paraffin and resin now on the market which are quite satisfactory. One used at the American Steel and Wire Company and Norton Company at Worcester consists of

Paraffin	70
White Wax	20
Resin	10

All of the combinations are dispensed in solid form and must be melted before using.

METHOD OF APPLYING WAX

The method of applying the wax is first to dry the skin thoroughly using an electric blower such as is used in barber shops for drying the hair. After the area to be treated is thoroughly dried the wax is either sprayed or painted on. Spraying is wholly painless, painting nearly so. The wax must be just liquid before being applied and can best be melted down in a double boiler. When the wax is painted on, sterile cotton swabs on applicators are the best instruments to use. The warm liquid wax should be dabbed on not "painted." The wax hardens almost at once forming a smooth coating extending over the sound skin for a short distance on all sides of the burned area. Upon this thin hardening, wax layer sterile sheet wadding which has been dipped in the wax is laid and over this another layer of sheet wadding. The whole dressing is held in place by a bandage. The advantage of using wax is the immediate covering of the burned area with a smooth sterile protecting surface with splinting of the injured part.

The wax is removed daily coming off en bloc with the sheet wadding. The secretions underlying it are washed off with normal Saline, the area dried with hot air, and a fresh wax dressing applied.

It seems to make little difference which method is used if the work is done carefully and absolute aseptic technique maintained throughout. Personally the author prefers a sterile saturated solution of soda bicarbonate for the first few dressings. It is easy to apply, gives considerable relief to the patient and requires less technique and handling of the injured area than the ointment or wax. It should be applied by saturating a piece of old sterile sheeting in the solution and wrapping this loosely about the burned area. The moisture is maintained by surrounding the

wet linen with oiled silk. The dressing can be moistened from time to time by lifting a corner of the silk and carefully adding the solution.

If there is little sloughing the ointment or wax treatment can be instituted but if much sloughing is present a moist dressing will be needed. The disadvantage of continuing the soda is that if any infection is present it is liable to flourish in the alkaline medium unless the medium is distinctly antiseptic. For this reason it is well to stop the soda dressing after 24 hours and use alum acetate solution.

R
Alumpts. 5
Lead Acetatepts. 25
Waterpts. 500
Dissolve separately and mix.
Do not filter.
Shake before using.

This solution is mild, non-irritating and antiseptic. It has a white precipitate which seems to have a very soothing effect upon the skin. The solution has been used largely at the Worcester City Hospital and elsewhere for burns.

After the slough has separated and granulations begun the burn may be considered a granulating wound.

Three things must now be considered,—encouragement of Epitheliation, care of the granulations, prevention of a deforming scar.

Epithelium forms from the germinal layer of the skin and its down pocketings, and it is from this layer that fresh epithelium is formed. Three things seem to assist epitheliation greatly; first a sterile granulation tissue to grow over, second a smooth surface to grow under, third pressure.

The difficulty of preserving sterile granulation tissue has been mentioned. If it can be preserved, wax provides probably the best type of surface to grow under. Its chief advantage is the ease with which it can be removed without injury to the new formed epithelial cells. At the Ambrein Hospital in Paris a thin layer of sterile zinc oxid ointment is applied along the epithelial edge further to protect the cells especially when the hot wax is applied. The cleansing of the wound after the removal of the wax is easy as compared with the cleansing of a wound covered with ointment. However where there is any tendency to infection of the granulating surface the ointment is probably somewhat preferable because of its antiseptic properties. The importance of pressure in the healing of granulating wounds was first noted by the author when examining a series of burns in the Worcester City Hospital. Burns of the back were in all cases progressing better than burns of the chest or extremity, and it was concluded that pressure was an accelerating factor. It seems to make little difference as to the type of covering which is employed provided it is smooth. Thus sterile adhesive plaster has been used by many, and the author has obtained good results with gutta percha tissue, if there are no wrinkles or air spaces.

INFECTION

Granulation tissue once infected is almost impossible to sterilize as those who worked in France know only too well, therefore the basic principle in the treatment of burns as in all surgery is to keep asepsis of the wound if possible and if in spite of all care it becomes septic endeavor in every way to render it again aseptic.

In burns involving a large area the burned area always becomes infected. This has been strikingly brought out by Fauntleroy and Hoaglund in their recent paper in the *Annals of Surgery*. In cases of this type it is obviously impossible to expect to obtain sterility. The method used in treating these very extensive and difficult burns employed by these authors and also favored by Moorehead is the open-air treatment without any dressing at all. Massive crusts form over the burned areas and beneath these pus forms plentifully. Cases seem to do a little better if the crusts are not removed, but gently lifted when absolutely necessary to give drainage.

The crust forms a dressing very similar to paraffin. Fauntleroy and Hoaglund, in discussing the treatment of these crusts say, "There seemed to be two separate, distinct periods, at which time two distinct results occurred simultaneously in all cases. The first period in which removal was continuously followed by the same heaping up process. The second period in which following a week's period of non-interference, removal, at this juncture, of the crust with the application of a thin smear of boric ointment on lint was followed by a quick bridging over of the raw surface with new skin and complete healing with no scar formation in a few days' time."

To sum up: while it should be possible to maintain sterility in burns, this is difficult and where large areas are involved almost impossible.

In treatment the individual should be treated first, the burn second.

The treatment of the burned area may be divided into the primary treatment which consists of cleansing and the application of a moist dressing, and the secondary or more permanent treatment when open air, special ointments, solutions, or wax may be indicated.

Experience tends to show that absolute standardization of treatment is impossible in the secondary treatment as burns react in different ways. It would be advisable, however, to restrict the drugs and ointments to a minimum number and study each one carefully in order that a certain type of standardization may be obtained.

Emphasis should always be laid upon strict aseptic technique without which good results cannot be obtained.

CHAIRMAN LAUFFER: We are now ready for the opening of the discussion of Dr. Clark's excellent paper. Dr. Colcord, who was to open the discussion, is unable to be present, but his paper will be printed in the "Proceedings."

¹Fauntleroy, A. M., and Hoaglund, A. W., *Annals of Surgery*, June, 1919, Vol LXIX, No. 6, p. 589.

DISCUSSION

DR. A. W. COLCORD (Carnegie Steel Company, Clairton, Pa.): Dr. Clark has given us a splendid paper. He is up to date without being faddish—and conservative without being a back number.

His remarks about treating a burn with the same surgical cleanliness we do any wound cannot be commended too highly. His statements that every third degree burn must in the course of granulation and healing become infected is open to serious question. Much depends upon what we mean by an infected wound. Of course there will be pus germs and pus cells in the discharges. Lexer found in his Vienna clinic sixty pus germs per square m.m. in his cleanest made operating wounds. It takes more than the presence of pus germs, pus cells, and a visible discharge to make an infected wound. Sloughing flesh will have odor and will contain germs of putrefication. But this does not mean infection.

Infection is a disease of *living* tissue and there must be the clinical signs of the reaction—inflammation if you like—heat, redness, pain, and swelling—Nature's effort to repel the invader. The burns where the slough comes away kindly—where there is no marked rise in temperature, where the tissue about the slough show no clinical signs of infection I do not call infected. Much of the tissue must come away in the liquid form and during the coming away of a large slough there may be some rise of temperature.

I must insist that our burns in the Clairton Hospital are not infected as I understand infection. My nurses, assistants, visiting surgeons, and patients themselves all agree with me.

I have seen many infected burns during the past few years in our hospital. They are all from three sources:

SOURCES OF INFECTED BURNS

1. Delayed cases that came with an infection already started.
2. A certain percentage of our Ambrine series—say 25 per cent.
3. A few cases of slight infection of burns where skin meets mucous membrane about eyes, nose, mouth, or anus.

All other cases now reaching far into the thousands run a uniformly clean course and heal with a minimum of pain and scarring under the use of our burn ointment.

This ointment is a powerful local anaesthetic, a deodorizer, a germicide. It comes as nearly to sterilizing the surrounding skin as anything I have seen. It is with slight exceptions, non-poisonous and non-irritating. It can be put on full strength for first dressings, where skin is not broken, spread well beyond the burned area. The surrounding skin has been carefully cleansed with ether. As epidermis begins to shed we change to one-sixth strength, diluting with five per cent boric ointment. In an occasional case of what I call irritable burn (possibly one per cent of second degree burns) it is necessary to use the five per cent boric alone. I have never seen any unpleasant constitutional effects and the only local ill effects have been those with a Balsam Peru idiosyncrasy—say one case in five hundred. Here it or anything else containing even a small amount of Balsam Peru causes a dermatitis. It stimulates granulation and epi-

dermis formation, making the healing more rapid than by any other method I have seen.

Twice I have discontinued the use of this ointment for a time—once to treat a series of thirty cases with picric acid; once to treat several hundred cases with ambrine. In both instances the old employees who were familiar with the ointment treatment were loud in their demands that we return to it as they worked in greater comfort.

The open-air treatment as brought forward by Moore of Minneapolis in 1905 was a great advance over most methods then used. It was used for some years in a number of Pittsburgh hospitals. Dr. Clark is right in saying that the burned area gets covered with crusts and pus. This is infection and means pain and absorption of pus with a higher mortality in extensive burns. It means injured kidneys and the other long train of results of prolonged sepsis.

It means delayed recovery, greater destruction of tissue and more scarring.

I cannot say too emphatically that in my opinion there is no excuse for infection in the average burn. The days of "laudable pus" are gone, let us hope, forever. The same attention to cleanliness we pay in our appendicitis operations and leg amputations will yield as good results in burns.

Dr. Clark asks, "Why is it that burns tend to run a septic course" since the heat sterilizes the burned tissues. Many things happen to "unsterilize" the burned area—probably most are infected during the first few minutes after the injury—clothing dragging over the burned area; a blanket thrown over the patient and touching the burn; attempts to wash the surrounding skin; temporary dressing of cream, oil, butter, vaseline, or various home ointments, none of them sterile. Probably the most constant source of infection is the surrounding skin. Every hair follicle, sweat gland, oil gland, and the whole skin surface of the average working man are filled with pus germs. Here is the weak point in the Ambrine treatment: It does not provide for the sterilization of surrounding skin nor does it absorb the discharges from the burn—just holds them against the burned surface and surrounding skin affording perfect culture conditions for germ multiplication and pus manufacture. The only wonder is that more than 25 per cent of Ambrine cases do not become badly infected. Some advocates of the paraffin treatment advise the changing to Dakin's solution when the burn becomes very septic. But why let them get septic? Why not use a method that keeps them clean from the start?

When an infected burn comes to me I often use two or three days' constant wet dressings with Ochsner's fluid—then as pus disappears change to the ointment.

I also use the Ochsner's during the sloughing stage of deep large third degree burns. I have made a trial of a number of the wet dressings for burns, boric acid, soda bicarb., normal salt, but prefer borax 80 grs. to a pint or Ochsner's fluid for above named purposes.

SKIN GRAFTING

Dr. Clark makes no mention of skin grafting. To skin graft a granulating surface it must be fairly clean. I can readily see how a burn with

the open method or by the Ambrine treatment would be too dirty to skin graft. With the alum and lead solution I have had no experience. I usually use two or three days of wet dressings before skin grafting. Have used both Reverdin and Thiersch grafts with about equal success. Skin grafting should be done in every extensive third degree burn and as early as possible before much scar tissue forms. Young of Glasgow reports some splendid results with the whole skin grafts of Wolfe, Krause, and Matas.

I wish most heartily to endorse every word Dr. Clark says about the use of morphine and atropine as soon as a severe burn is seen. This followed by the constitutional treatment he outlines is, in my opinion, the most important thing in his paper.

His method of cleansing the surrounding skin sounds good. I have not tried it. Washing the surrounding skin or doing anything that may get dirt into the burned area is to be condemned.

On the whole it seems to me we are indebted to Dr. Clark for his bringing the subject of burns up to date. His endorsement of the Ambrine treatment and of the Open-air method has the backing of some of the best surgeons on both sides of the water. I have given my own personal opinions and the results of my experience frankly. It is only by this honesty and fearlessness that we can arrive at the truth.

DR. C. M. HARPSTER (Cleveland): I don't believe I have ever heard as fair a representation of the subject. Of course, we all have certain modifications of our own, but I agree thoroughly with the point brought out so strikingly by Dr. Clark that the large burned areas are almost always becoming infected. I suppose we all use the method of putting on paraffin wax, and I agree on the surgical principle of painting the infected area and sealing up with wax. Now we have made a simple modification in the treatment of our cases in the use of paraffin method of treatment. The paraffin is spread on fairly heavy paper impregnated with Balsam of Peru, a paper of six or eight thicknesses placed over the burned area. That is the primary treatment for uninfected wounds. If the wound becomes infected we continue throughout the case with applications of the paraffin and paper impregnated with Balsam of Peru and we have found we have had splendid results. I recommended this method of treatment in a large chemical works, and special Government industries where a large number of burns occur, and I have received reports from the military surgeons that they have been able to turn men back to work much quicker by the use of this method of treating burns than they did before.

You can also impregnate your gauze with the wax, or mosquito bar or anything like that. Once the wound has become infected, and we have treated cases where there have been extensive burns from the knees up purely with paraffin paper, but once it has become infected I believe the application of bi-carbonate of soda or some simple treatment of that kind is the proper way to handle a burn.

DR. AUGUST F. KNOEFEL (Terre Haute, Indiana): I am perhaps more careless in my technique than most men, but I have yet to see an extensive burn that has never become infected. We work in a coal mining district and the miner is burnt as a result of an explosion of gas, or coal dust. Most of these men work with canvas trousers and cotton shirts

and practically all the burns extend from the waistline up, that includes the two upper extremities, the face, head, neck, and ears, and as I say, I have yet to see one which didn't finally become infected. It is not the type of infection that is accompanied by any high temperature, more of a saprophytic infection. The former treatment was the application of salol ointment, but in the last two years the treatment adopted is to cover the patient's burns with a wet picric acid gauze. This dressing remains in position for two days, then the para-wax (we use the plain para-wax without any addition of medicament whatsoever) is applied, we use both the atomizer and the brush, the camel's-hair brush. We find that with the camel's-hair brush we can cover the body much quicker than we can with a cotton swab. A cotton swab, no matter how it may be prepared, or how it is manufactured will give perhaps half an inch covering with one swipe. With a camel's-hair brush three inches wide, we get three inches wide when we apply it, therefore, we expose our patient much less than if we used a small applicator. It works best at a temperature of 165, although I have seen it run up to 190. As you make the swipe with the brush the patient says, "Ouch" or something like that. But the pain does not persist.

With reference to the remarks read from the paper, that there is a time when there should be a change in treatment, if you continue your paraffin until the wound has entirely healed over, that is, skin epithelium has formed, you will delay that time by continuing the paraffin. There is a time when you are compelled to stop your paraffin dressing and expose it to the air and it will heal much quicker. We still use the old time stimulation method on the small areas that seem in spite of all treatment to fail to heal, and that is, the use of silver nitrate.

CHAIRMAN LAUFFER: Any further discussion on the subject of burns?

I believe Dr. Clark, that would be a good subject for a questionnaire, and if you will get the addresses of all the doctors here and other industrial surgeons by the questionnaire method, the committee that could be appointed could help in the solution of some of these interesting questions that we as industrial surgeons are much concerned in. The sooner we have a man ready to go back to work the less work we have on our hands, and it is to our interest to study the quicker methods of getting the injured back to work.

DR. BLOOMGOOD (Baltimore): I have had very little experience in burns. But in cases of burns where the healing process is very slow, no one will question the statement that a burn that destroys the entire epithelium must heal from the edge. The burn in which there is some epithelium left is different from the one where there is no epithelium left. We meet a stage in which we find it not only difficult to keep the tissues aseptic, but difficult to keep the granulated tissue from forming. But the danger of granulation exists: the greater with the excessive tissue as the base. That excessive tissue ultimately forms and you get edema as you would anywhere where the vessels are contracted because edema is most marked on the return vessels, the venus type not arterial.

The only thing I want to ask is this, I find that in some burns they reach a stage where skin grafting should be employed. That will shorten

the period of disability very much. I will not go into the very important thing which he spoke of, but it ought to be emphasized whenever you speak of a burn that throughout the entire course of the burn you feel you are responsible there is no contraction. Contractions in burns are in the hands of those who dress them. They can be prevented.

In skin grafting, when the patient has sufficient skin from which to take the graft the problem of skin grafting is simple. With a tissue graft I have demonstrated at the end of three weeks you can take another skin graft before you take the tissue, or cut a little pinch graft, and unless you are familiar with the technique you will look upon it as a very difficult thing. The pinch graft you can do every day, one, or two, or three. The pinch graft has an advantage in skin grafting on areas that you can't disinfect. The tissue graft, as a rule, rarely takes, unless you cut out the granulation tissue, or you make it aseptic. It apparently has a stimulating effect upon the granulation tissue.

Now we have learned from work in the war that when an injured man hasn't enough skin for his own graft, we can get successful graft from individuals whose blood matches, from individuals from whom you take blood transfusions. I have had most satisfactory results with grafts from individuals on burns. I have had no experience yet in matching up graft on persons whose blood matches. In the past our grafts have been very satisfactory, but perhaps you have found skin grafting unnecessary. The reason I have had a large experience in skin grafting is due to the fact industrial surgeons have not first treated the burns.

CHAIRMAN LAUFFER: Dr. Sloan, who will take Dr. Crile's place on the program is here, and will now read Dr. Crile's paper.

WHAT THE WAR HAS TAUGHT US IN SURGERY

DR. GEORGE W. CRILE, CLEVELAND, OHIO

The great contribution of the war to surgery was not the production of hitherto unrecognized methods of treatment, but rather the accumulation of masses of evidence regarding the comparative value of various methods.

There is no fundamental distinction between the war patient and the civilian patient. The soldier coming for treatment is in a greater or less degree of exhaustion from the conditions of his environment, the civilian patient is in a greater or less degree of exhaustion from the condition from which he seeks relief. Further exhaustion from the trauma of the operation, hemorrhage, and infection are the prime dangers in each case.

In the army the outstanding requirement is to return every possible man to active service in the shortest possible period of time consistent with a permanent cure. Efficiency in civilian surgery should demand the same.

It is to this end that the lessons learned in the field are being studied anew in their relation to the civilian patient.

"SURGERY LIVED YEARS IN DAYS"

In the service in the field many lessons were learned. Every theory was tested in the crucible of practical application on a vast scale. We

were dealing with hundreds of thousands of patients as we deal with hundreds here. Surgery lived years in days. The combined experience of thousands of surgeons was immediately available for comparison and for study by the individual surgeon; by the surgical staffs of hospitals; by the consultants; by the Red Cross Research Society; by the Interallied Conference; all of which were seeking to discard the false—to find and to hold fast to the true. All questions pertaining to the care of the sick or wounded soldier were thus studied in detail and in the mass by the nations at war; and finally in Paris at a conference of those chosen by their respective governments to make up a consensus of opinion, conclusions from this great mass of evidence were scrupulously drawn.

One fact stands preëminent among the many elicited by this vast experience; i. e., that the prime problems of war surgery as of civilian surgery are shock, anemia resulting from hemorrhage, and infection. Whatever the lesion of the patient, whether it result from war missiles or from disease, provided the lesions are anatomically operable, he will recover if these three menaces can be obviated or successfully treated.

INFECTION

The mere fact that man is surrounded, covered, and penetrated by an infinite number of bacteria, and lives, is a proof that the human body has within itself adequate defense against bacteria. This defense we may be sure was attained through struggle and survival—that is, through biologic adaptation—and is the bulwark of the treatment of infection.

An interesting proof of this biologic adaptation is the fact that the various parts of the body have varying powers of defense against infection, the most efficient defense in general being possessed by those parts most exposed to infection from injury, such as the external soft parts or those which lie in infected areas, such as the intestines.

On the other hand, the inner protected parts—such as bone, especially deeply-placed bone, the deep muscles and encased organs and tissues, such as the heart, the brain, the spinal cord, and the retroperitoneal tissue—have had less opportunity to make a selective struggle, hence in these parts weaker defenses against infection have been evolved. What does the tissue of the foot possess that is not possessed by the mediastinum, or by the femur? What does the peritoneum possess that is not possessed by the dura, what endows the skin and the peritoneum with a better defense against infection? That part whose defense is weakest usually possesses a limited blood supply, as compared with parts whose defense is stronger. There is apparently no other difference as striking, nor as marked as the difference in blood supply. We may then infer that a rich blood supply is the key to the defense against infection. The face and scalp, the external parts of the body, the abdomen, have a rich blood supply as compared with the deep lumbar muscles, the bones, the spinal cord, the retroperitoneal tissue. Not only is the normal blood supply less in these poorly defended regions, but the local vaso-motor mechanism is less developed, hence there is less reaction to the invading bacteria. For the most efficient defense there must be not only abundant blood, but normal blood. As Sir Almroth Wright has shown, the blood must not

be acidosed, as when blood pressure is low, for saprophytes flourish in such a medium. The bones, the deep tissue planes, the mediastinum, the spinal cord, the brain, the retroperitoneal space, are all hazardous regions for infection. In the mind of the surgeon the body should be charted like the sea, and he should direct his course according to this chart. One region requires one plan of action, another, such as the scalp or the face, no special plan. Face wounds heal almost equally well with good surgery, with poor surgery, with no surgery. The infected mediastinum heals almost equally badly with no surgery, with poor surgery, with good surgery. A pulseless patient becomes a universal mediastinum. A limb, anemic as from a neglected tourniquet or from the severing of the arterial supply, becomes as helpless as the meninges; the war patient in exhaustion from cold and wet and exposure, from loss of sleep and from fighting, and the starved civilian with cancer of the stomach or with perforating ulcers, alike have a universally weak defense. Patients prostrated by shock or by hemorrhage have low resistance. As a rule, defeated, dejected troops have less resistance than victorious troops. The defense, then, in the normal soldier varies with the several parts of the body, the frontiers of the organism being best defended. The defense, even at the frontiers of the organism, is lowered by interference with the local blood supply, whether of an entire limb, or of the devitalized bloodless tissue along the injured track of the missile; it is weakened by low blood pressure from shock, with its secondary acidosis; or by hemorrhage; it is weakened when the entire individual is in exhaustion. The defense, in turn, is augmented by rest, by sleep, by fluids, by the revision of wounds; by restoration of the local and general blood supply.

In addition to these measures which augment the resistance of the organism as a whole, it is essential to increase the local resistance as well. Whether we are dealing with a war or a surgical wound, this may be secured by vitalization of the part attacked; by physiologic rest, by destruction of contaminating bacteria, by the application of heat.

In war wounds vitalization is accomplished by the excision of every particle of devitalized soft tissue and bone; by removing every particle of foreign material—clothing, mud, missiles—in such a manner that there is no added surgical devitalization from goading retractors or rough handling of fractures. Vitalization is promoted also by making sure there is no interference with the blood supply, by employing a minimum of foreign material for treatment, such as tubes, etc.

The wound may be further vitalized by moist or by radiant heat. The vitality may be maintained by overcoming infection; by preventing pooling of wound secretions. Therefore in recessed wounds the Carrel-Dakin treatment does best. The deeper and the more recessed the wound, the greater the indication for Carrel-Dakin. It must always be borne in mind that the operation must be done lightly and sharply; for if there be rough handling, needless moving of compound fractures, if piercing hooked retractors tear the flesh, and if intermittent muscular contractions grind tissues between the ends of ragged bone fragments, then the net result of the operation is the substitution of surgically devitalized tissue for the devitalized tissues of battle casualty.

Physiologic Rest. Physiologic rest includes more than mere muscular and psychic rest: it implies equally *cellular rest*. Living cells are disturbed by air; by desiccation; by physical contact of dressings; by many chemical antiseptics; by bacterial toxins. These points have been strongly emphasized by Sir Almroth Wright whose teaching has placed a renewed emphasis on the importance of the *cellular protection* of wounds, to ensure cellular physiologic rest.

To secure physiologic rest in the case of a fracture, an even adequate continuous extension must be made—an extension sufficient to prevent the goading of soft tissues by sharp bone, and to prevent bony fragments from grinding each other. Physiologic rest of the soft parts means mass quiet by means of supports—such as splints, slings, swings, and extension suspensions; it means for compound fractures and for injuries of the soft parts no tight bandages, no tight stitches, no accumulation of wound secretions—blood, serum, etc. For open wounds it means that antiseptics must not be *damaging*; that dressings must be painless; it means elevation of extremities for comfort and the prevention of swelling. For visceral injuries it means absolute rest, low diet, freedom from excitation, associated environment.

Destruction of Contaminating Bacteria. The first and most dependable agency for the destruction of contaminating bacteria is the bactericidal power of tissue. This normal defense of tissue against bacteria is present only in living tissues: and the ability of living tissue to overcome infection depends on its vitality. Normal living tissue has strong bactericidal power. As vitality is impaired down to the death point, so is the bactericidal power impaired to the zero point. Moreover, when infection begins, the infecting agent itself has the power of diminishing the vitality in advance of the infection through chemical injury, tension and swelling. Thus as Kenneth Taylor, Cuthbert Wallace, Bashford, and others have shown, many anaerobes cannot live at all in normal tissue, but only in damaged tissue. The anaerobic invasion is made possible only by injury through chemical action, through shell injury, through swelling or anemia, or shock and exhaustion whereby the resistance of the tissue is lowered. Therefore in a compound fracture that is settling down, one goading by a sharp fragment of bone will devitalize a small area, and in consequence an area of infection with the advancing tissue damage will be established. Therefore we may say that the whole wound is defensively only as strong as its weakest point. If the defense line is broken at one point, the entire line of defense may give way.

Antiseptics. As for the relative value of the various methods of antiseptics it is difficult to choose among them. Perhaps the method which has proved most universally useful, excepting under battle conditions, is the Carrel-Dakin. This is of value in wounds with necrotic tissue, in empyema, in recessed wounds with a tendency to pooling of the wound discharge, and as a general method. Carrel and Dakin have made an outstanding contribution to surgery. Dichloramin-T, flavine, bip, and Wright's hypertonic solution, each has its value under certain conditions. Perhaps the most useful of all in civilian surgery after Carrel-Dakin is flavine

which is non-toxic and can be used for days without ill effect. It is of special value in multiple stage operations in which it is necessary to keep the wound in *statu quo* for a limited period, as in certain cases of exophthalmic goiter. It should be noted that it should not be used in contact with silk sutures as it dissolves them.

Heat. The therapeutic value of heat has been sanctioned by the experience of physicians and of the laity since the dawn of medical history. The therapeutic place of no other agency is as secure. Moist heat, dry heat, radiant heat, electric light, sunlight—all influence the infections favorably.

In what way may heat exert its beneficent influence? Granting the premise that the natural defense of the organism against infection is made through the agency of phagocytosis and the chemical antagonism of the blood plasma, it becomes evident that in either case the defense is chemical. The fact that the defense is chemical gives at once a clue to the mechanism by which heat assists the defense against bacteria. It is probably because with the rise of each degree in temperature in any system—inorganic or biologic—the chemical activity is increased ten per cent and the electric conductance two and one-half per cent. The increased chemical activity increases the chemical defense: the increased electric conductance increases the metabolism. Therefore, we may suppose that heat accelerates the chemical defense so far as it involves the metabolism of the phagocyte, and so far as it involves chemical defense of the blood plasma, and that heat also aids by increasing the total amount of blood in the inflamed part, thereby increasing the number of phagocytes. Moreover heat assuages pain.

ANALOGY BETWEEN APPENDICITIS AND THE WAR WOUND

In this discussion of infection an interesting analogy between appendicitis and the war wound suggests itself.

In a case of acute appendicitis, if the dead appendix is removed before the infection has invaded normal tissue, then the wound is closed immediately, primary union follows, and the vast possibilities of the inflammation of the great abdominal cavity will be averted. Likewise, if the dead tissue in the track of a war wound is excised, before living tissues are invaded, the inflammation of a great mass of soft tissue will be averted.

In appendicitis even after the infection has penetrated the wall of the appendix and invaded the peritoneum, excision of the dead appendix will facilitate recovery. In war wounds, even after the infection has passed beyond the devitalized tissue, excision of the devitalized tissue will facilitate recovery.
