When an appendicitis has developed into a localized abscess with an organized wall of granulations, the surgeon deals with the abscess as such. When the infection in a war wound has developed into an abscess with new tissue organization, no debridement is done, but the abscess is treated as such.

In the war wound the stage of contamination of dead tissue—the period before infection develops—corresponds to the period before infection from

a dead appendix penetrates the wall. In this period if the dead appendix is excised cleanly, the case recovers; if the dead tissue of the war wound is excised cleanly the case recovers.

Appendicitis and war wound infection develop through identical phases—localized infection, spreading infection, abscess.

If an appendix abscess is roughly handled, spreading peritonitis, phlebitis, bacteriemia, etc. may result. Comparable results follow when an infected war wound is roughly handled.

Appendicitis was not mastered until the surgeon had learned to forecast its future accurately, and today—in other words until he took the initiative away from the disease and attacked instead of defended. In like manner the military surgeon discovered that in the case of the war wound, as long as he left the initiative to the infection, he could not achieve mastery. To wait in the case of a devitalized war wound until the infection had spread widely—until there were pain, swelling, redness, and tenderness, was to court defeat. Like the tomorrow of the appendix, the tomorrow of the war wound must be read today—and action taken today.

An antiseptic does not cure appendicitis—it does not cure the war wound.

There is no difference in principle or in practice between the treatment of appendicitis and the treatment of war wounds. The time factor is equally vital; the treatment is comparable; the natural defense is identical.

SHOCK AND HEMORRHAGE

The consensus of opinion of the Interallied Surgical Congress and the British and American surgeons in military service generally may be summed up in the following brief dictum: *The best treatment of hemorrhage and shock is rest, warmth, fluids, morphin for pain, and blood transfusion.*

Civilian surgery and war surgery in their relation to shock present one important difference. The depleted civilian patient may be in a "pre-shock" state when he comes under the surgeon's care; the wounded soldier is often in shock. Nevertheless identical methods will prevent the development of shock in the first case and will successfully combat the present shock in the latter.

Physiologic Rest. Physiologic rest includes mental and psychic, as well as physical rest. It means reassurance; it means an atmosphere of quiet and confidence: it means optimism as well as skill. Physiologic rest can be achieved only by the cooperation of surgeon and intern, nurse and orderly.

Warmth. The loss of power to create body heat is one of the damaging effects of shock, for the organism is much injured by a subnormal temperature. The application of heat, therefore, is one of the essentials of the treatment and of the prevention of shock. The most readily applied form of heat is hot air under blankets. Under war conditions, hot-water bottles and other forms of direct heat are not useful, because of the time required for application, and because of the danger of producing burns.

Morphin. If the patient has pain, if he is restless, and if the pain and

restlessness cannot be otherwise relieved, then give morphin in one-sixth grain doses until the pain and restlessness is overcome; and there is evidence that morphin in still larger doses is specifically useful.

Oxygen. If there is a wound of the chest interfering with the supply of oxygen, then give oxygen. If available, all cyanosed, all gray-blue patients, all shallow-breathing patients should have oxygen. A nitrous oxid machine for giving anesthetics is an excellent means of administering oxygen under pressure.

Fluids. Water in some form should be given, preferably by the mucous membranes. Sodium bicarbonate in a five per cent solution and combined with five per cent glucose is most effective. But in acute, grave cases from 2,000 to 4,000 c. c. of fluid should be given each twenty-four hours. Water intravenously is rapidly eliminated from the body. Water absorbed through membranes or tissues is retained in much larger amounts. Water to be most useful should have a biologic pass.

Prevent and Overcome the Damaging Effect of Low Blood Pressure: (a) by elevating the foot of the bed; (b) by early transfusion, the Bayliss solution of gum acacia may be used. It has the advantage of being more readily available than blood. Under war conditions, donors for blood transfusion are usually numerous among the lightly wounded patients.

One of the greatest errors is to allow a patient to remain in a state of low blood pressure in the hope that he will improve through his own resources, reserving a blood transfusion to be used as a last resort after it has become obvious that the patient is going to die. This is the same faulty logic that was once used in dealing with appendicitis. When the indication for operation in appendicitis was supposed to be a clammy, pulseless state, when the patient was dying, surgical treatment became almost discredited. It is equally illogical to wait for impending dissolution in shock before improving the circulation. Treatment should not be deferred until the inaugural state of death is established. There is another method of treating shock which is not generally applicable to war conditions, that is narcotization with morphin—giving morphin on the same scale as in the Alonzo Clark treatment of peritonitis, i. e., keeping the patient under morphin so completely that the respirations are cut down to about twelve to fifteen per minute and the patient is deeply asleep. During this time one should give between 2,000 to 3,000 c. c. of normal saline infusion subcutaneously. When properly carried out excellent results may be obtained by this method which, however, should never be employed if there is cyanosis, and never routinely, and always under expert supervision.

THE OPERATION

The Interallied Surgical Conference adopted as one of its conclusions that in the treatment of wounded soldiers *the anesthetic of choice is nitrous oxid-oxygen combined with local anesthesia.* Among the evidence offered in support of this tenet Surgeon-General Sir Anthony Bowlby presented the work of one of the most brilliant British military surgeons, Captain Douglas C. Taylor, and the work of the Chief of the Anesthetic Service of the British Army, Captain Gregory Marshall. The experience

The essential points in the associated treatment of abdominal infection, therefore, are the following:

1. Nitrous oxid-oxygen.
2. Anesthetized incision.
3. Accurate, clean-cut operation to diminish both infection and shock.
4. Adequate drainage.
5. Fowler's posture.
6. Vast hot packs over the entire abdomen, spreading well down over the sides.
7. Five per cent sodium bicarbonate, with five per cent glucose by rectal tap, continued as long as it is tolerated.
8. Primary lavage of the stomach, repeated only if indicated. (It will rarely be indicated if *anociation* is complete.)
9. From 2,500 to 3,000 c. c. of normal saline subcutaneously every 24 hours until the period of danger is past.
10. Morphine hypodermically until the respiratory rate is reduced to from 10 to 14 per minute, and held to this rate until danger is past.

Under this combination of the association of peritonitis with the associated operation, my associate, Dr. W. E. Lower, and I have performed 499 consecutive operations for acute appendicitis, with or without generalized peritonitis, without a death.

THE GOOD SURGEON

The surgeons and the pathologists who for four years have intensively studied war wounds, have formulated many theories of treatment—many apparently contradictory theories. Thus there have been presented the claims of the value of various chemical agents against those of no chemical agent; of moist dressings against dry; of heat against cold; of frequent dressings against infrequent, and of no dressings against both; of sunlight and of electric light against occlusion; of immersion against hot air; of bacteriological control against clinical judgment; of vaccines, toxins, and foreign proteins against normal reaction; of wound inoculation with harmless organisms against wound sterilization; of isotonic against hypertonic solutions; paste has competed with paste; bip with ip; sap with both; and chromic pastes with all.

Does not this intensive study of infection in war wounds for this comparatively short period equal and recapitulate the more leisurely study of infection during the thirty years since Lister first proposed the carbolic spray? And is there *not* slowly emerging from the present conflict of opinions the same fact as that which emerged from the post-Listerian period—that the one agent of successful surgery, whether war surgery or civil surgery, is *the good surgeon*?

In civil surgery here in America, by what agency was mastery achieved over appendicitis, over cholecystitis, over tubal infection, over adenitis? What agent has contributed the most to the success of resection of the intestines and of the stomach; of gastroenterostomy; of treatment of suppurating stone in the kidney; of the treatment of infection of subcutaneous tissue? What agencies have achieved survival? One and but one

—*the sound surgeon*, who always creates opportunity. Is it possible that in these four intense years of war surgery, in which more experience in traumatic surgery has been accumulated than during the past 30 years, we have traveled around the same circle as in civil surgery and have again found the same *surgeon*?

By sound surgery we mean the assumption of complete inclusive responsibility for every item that enters into the result; the consideration of the wound as well as the patient; the development of an ability to read the wound as well as the man aright. Sound surgery means quick, innocuous, timely intervention; it means seeing clearly the tomorrow of the wound; it means no intervention unless there is to be a net gain; it means a sharp knife, a good anesthetic, a painless innocuous dressing; it means as much respect for the tissues of the anesthetized man as those of the unanesthetized man; it means a training in judgment that unerringly tells when to cut, how far to cut, when to quit cutting. It plays all the defenses and reparative forces of the patient. Good surgery is the exponent of no single method. It recognizes the anatomical and environmental situations in which chemical and physical agencies are useful. Good surgery exploits physiologic rest and fluids and sleep; it gives little pain. Good surgery evokes confidence; and confidence begets restoration. Good surgery, then, makes use of antiseptics and physical forces, just as it uses incisions, counter-drainage, revisions, skin-grafting, blood transfusion. Good surgery does not substitute an easy formula for its principles; above all, it always is dissatisfied with its work and always is open to suggestion.

What could the good surgeon accomplish with the wounds of war, with good opportunity but no antiseptics? Without antiseptics he could close by primary union a higher percentage of contaminated wounds than with antiseptics; he was able to remove damaged tissue with such accuracy that the natural defenses of the revised wound became its best antiseptic; he closed penetrated knee joints more securely without than with antiseptics; he closed penetrated skulls without, better than with, antiseptics; he cleared up foul and infected superficial wounds as well without as with antiseptics; he met gas gangrene with the timely use of the knife as well without as with chemical agents. He closed healthy superficial wounds with early suture tied lightly; healthy wounds that could not be closed by suture he closed by skin-grafting, both as a healing and as a bacteriocidal policy; he closed fecal and urinary fistulæ without antiseptics.

On the other hand, he realized equally that in compound fractures with or without bone infection, in deep, recessed wounds, in pyocyanous infection in many other types of wound that antiseptics might have great advantages, and he used them and used them well. In certain phases of a wound, he would use Carrel-Dakin; in another, acetic acid; in another, hot pack; in another, incision—a physiologic incision today to avoid the tissue tension of tomorrow; in another transfusion; in another, sunlight or electric light; in another, continuous alcohol to make a scar covering.

In the rush of a great battle, he incised for drainage, and in addition

he made "physiologic incisions" to avoid the tension that is sure to follow the next day from the inevitable infection.

But in quiet times, he dissected out every atom of devitalized tissue. He read accurately not only the wound, but the patient; not only the patient, but the military situation; not only the military situation, but the condition of the infecting soil, the state of transport, his surgical assistance, and the type of nursing care—that is, he weighed accurately his chances for success. Therefore, the army medical service and the wounded man pinned their hope and their faith first, last, and always to the one agency of wound treatment that in civilian surgery emerged clearly from the confusion of the Listerian period; emerged clearly from the confusion of the four years of military surgery—the sane, sound surgeon.

CHAIRMAN LAUFFER: In opening the discussion of this paper, in the absence of Dr. Moorhead (whose paper will be published in the proceedings) I would like to call on Dr. Bloodgood.

DR. BLOODGOOD: I hope this paper will be published, and I believe I can say this summary is the best that he has done. Perhaps there are some surgeons who don't realize these little details because in civil surgery as a rule the tissue of an individual will stand a great deal of insult. It will heal in spite of everything. When you are called upon to treat an individual whose resistance is lowered, or a particular type of wound where the resistance is lowered, the results depend upon these details. But, unfortunately when you have an individual of that kind, a wound of that kind, and don't get recovery or don't get a good healing of the wound you can always place that individual in the group that should have died any way, so that your mistake is covered. It is a very difficult thing to compare the additional recovery and the lowered mortality in the group in which this detailed knowledge, and the action on that detailed knowledge, is required for the reduction of mortality and improving results.

A great many good surgeons think these points are more or less dreams, but there are some of us who know absolutely that these are essential to a certain group. Now the only way to develop that technique is by routine. You might say it is unnecessary, but the treatment must be in routine. Unless you have made it routine, you, your assistants, and your entire team will not be equal to applying the treatment the way it should be. I believe if we could corral all operations for exophthalmic goiter in this country the mortality would tell you the teams that have developed this technique in their lowered mortality.

CHAIRMAN LAUFFER: This very excellent paper will be published in the report of this Safety Council, whether it will have any publicity through the medical press or not, I don't know. But I believe it is worthy of publication in one of the surgical journals. It was certainly a very excellent paper and I hope arrangements can be made to have it put very extensively before industrial surgeons.

I would like to ask Dr. Bloodgood what is the most successful form of dressing to be used with the small pinch graft? I have used a large number of them and I would like to know what you have found, Doctor, has been the most successful dressing.

DR. BROODGOOD: I think all your questions will be answered in Davis' book on Plastic Surgery. I don't know of any surgeon in this country who spends more time on that subject. I wish that some of my associates were here because they do all the grafting now, but they taught me how to use the pinch graft. My experience in grafting has been excising a granulating wound, and we reached a point of one hundred per cent., we excised the area and cut it out in grafting. That is the ideal way, but after your area reaches a certain point you can't do it. The pinch graft we have been using, they just wipe the little granulated wound they have tried to keep clean, put the graft on, and no dressing. After that you can go back to whatever dressing you want.

I have had very little experience with the treatment of burns, but I believe Dr. Crile's statement in regard to good surgeons applies here. I have treated burns in children's hospitals, and I can see all those cases and I have never had any better results and that was a period when I had more time to treat a burn than any other time since. It is the essential feature of the treatment. You know, you can go all the way through the treatment but if you are dirty, no form of dressing that you can apply will be good enough to counteract your dirt. The cleansing of that wound is one of the important things, the daily dressing of that wound in which it is given a bath just as you give a young baby a bath. The skin must be clean. The burned area of the body must be clean, and Gentlemen, the best thing I find after a certain stage is soap and water. Soap and water, and it takes time. I believe that it doesn't make any difference what you put on your burn if you are clean. I have found just as good results with boric acid, but the burn after a time meets the stage that it needs some other food than boric acid, or any other treatment. Exercise of the individual is important and sunlight, but I think there is a stage when grafting should be done.

DISCUSSION

DR. J. J. MOORHEAD (Interborough Traction Company, New York City): Colonel Crile has very adequately stressed the importance of infection and the value of some of the antiseptics, notably Dakin's solution used by the Carrel technic. Unfortunately, this solution is difficult to prepare, it is unstable, it is not well suited for emergency treatment except in large hospitals. In addition to this, the application of the Carrel technic needs special training, it is time-consuming, in effect making each dressing an aseptic operation. For these reasons this valuable method of combating infection can have but limited application in the ordinary accidents of industry. One of the very valuable war lessons in this connection was the demonstration that thorough cleansing of a wound within twelve hours of its receipt was the best preventive of infection. This cleansing aimed sparingly to cut away all bruised or damaged tissue from the wound for the reason that the organisms of infection thrive on just that sort of soil. By this process (called debridement by the French) the vast major-

¹Dr. Moorhead was not present at the session and his discussion of Dr. Crile's paper was not read, but was later sent in to be included in the proceedings.

ity of wounds could be immediately sutured so that primary union would be attained. In the ordinary wounds of industrial warfare, it is not often necessary thus to debride the injured area as the same effect can often be obtained by vigorous scrubbing and mopping with soap suds. The part is then cleansed with sterile water, liberally swabbed with 3 per cent tincture of iodine, loosely sutured and provisionally drained for 24-48 hours. If then no evidences of infection are present the drain is removed. In wounds already infected we must resort to antiseptics, as Colonel Crile has stated. Once the process is under control and we have demonstrated the absence of streptococci, we may proceed to suture this class also, thus cutting short the period of healing. This plan of *primary suture* for cases seen within the first 12-24 hours, and *secondary suture* for cases seen later, is one of the great advances in traumatic surgery.

Shock and hemorrhage usually co-exist in the traumas of industry and Colonel Crile has had unusual opportunities before and during the war to demonstrate the value of transfusion. Likewise he calls attention to the safety of nitrous-oxid and oxygen as the anesthetic in this group. Of all anesthetics, chloroform seems particularly dangerous in traumatic cases and it should never be used. In the absence of nitrous-oxid, ether by the drop method on the open mask is the safest. For short operations, the French surgeons converted me to the use of Ethyl chloride and I have many times used it for cases not requiring more than fifteen minutes. It should be given on a mask and is valuable also to induce anesthesia preliminary to ether. Local anesthesia, intra-neurally or intra-spinally has also a place, notably in certain amputations.

After all is said, as Colonel Crile has so well indicated, the capacity of the surgeon is the big factor in the result, irrespective of the antiseptic, procedure, or apparatus employed. The routine of treatment can be learned by the novice; but the teaching of experience makes the sane, sound surgeon.

One other war lesson is that relating to the treatment of fractures. The conversion of a compound into a simple fracture by the process of debridement is a real gain. In well muscled parts, like the thigh and arm, this procedure should be used with extreme care. The Thomas splint and the modifications of it should have a wide application. The methods of direct traction such as the Beseley tongs and the Finochietto-Chutro stirrup have a place of great usefulness in fractures of the lower extremity.

Another important lesson is the procedure of early mobilization of injured joints. We learned in the war to keep an injured and even an infected joint active and not passive. Likewise we did not splint joints adjacent to fractures for nearly so long a period as was our former practice. Function is dependent upon activity and in future we will less often permit joints to remain long inactive.

CHAIRMAN LAUFFER: If our discussions are at an end, I wish to ask on behalf of the incoming chairman, that the courtesy extended to me during the past year be extended to him. I invite you all to the National Safety Council in Philadelphia next year, providing it is held there.

We stand adjourned.

Metals Section

October 2-4, 1919

J. A. OARTEL, Chairman

Director of Safety, Carnegie Steel Company, Pittsburgh, Pa.

HOMER J. WEEKS, Vice-Chairman

American Steel and Wire Company, Cleveland, Ohio

W. E. WATTERS, Secretary

National Malleable Castings Company, Melrose Park, Illinois

THURSDAY MORNING SESSION

CHAIRMAN OARTEL: As you know, at the last session of the Congress, Mr. Frank E. Morris of the American Rolling Mill Company was elected Chairman of the Metals Section, and he served until he was appointed Field Secretary for the National Safety Council, at which time the job was wished on me, so I have served only part of the year.

Because of this change in the officers of the section, the best work has not been done, but we have tried to do what we could.

The year that has passed has been a remarkable year in the reduction of accidents in the iron and steel industry. I suppose you are all familiar with the figures contained in a recent letter written by Dr. Frederick L. Hoffman, Third Vice President and Statistician of the Prudential Life Insurance Company, to Mr. C. L. Close, Manager of the Bureau of Safety, Sanitation, and Welfare of the United States Steel Corporation.

In that letter the Doctor tells of the remarkable reductions in life insurance premiums that have been given to men working in the iron and steel industry wholly because of the safety work that has been done. I think that is one of the biggest contributions that has ever been made to safety, the fact that a conservative life insurance company that does not do things hastily has, after a thorough investigation, decided that our safety work has brought such results that they can consistently lower premiums on life insurance. And so, I think it may be said that this is one of the big contributions to safety that has been made in the last year.

There have been some remarkable accident reductions by a number of companies, but I won't take the time to tell you of them.

I will now call on Mr. Watters, our Secretary, to give his report.

REPORT OF THE SECRETARY

Your executive committee had their first meeting in Chicago, on October 15, 1918, and their work for the coming year was planned. There were present: F. E. Morris, Chairman; Homer J. Weeks, Vice Chairman; W. H. Cameron, S. J. Williams and R. H. Guerrant of the National Safety Council staff. The Secretary was absent on account of illness.

Metal Section activities for the year 1918-19 were taken up in detail and it was agreed that each of the standing committees should be continued, and that the work of the section should be carried on along the same general lines as heretofore.

The advisability of having a special committee to disseminate information among the members of our section was discussed and it was decided that this work should be done by including this information in the monthly news letter.

BULLETIN AND SAFE PRACTICES COMMITTEE

After thoroughly canvassing the field, Mr. J. A. Oartel, Director of Safety, Carnegie Steel Company, was chosen as Chairman, of the Bulletin and Safe Practices Committee.

A report was obtained from Mr. Lamont, as to the amount of bulletin material on hand and it was learned that there was enough to run until the first of December.

It was suggested by Mr. Williams that many bulletins from other sections are applicable to the industries of the Metals Section, and that the scheme of leaving it to the headquarters staff to decide on material for the bulletins for all the sections would avoid any duplication of effort.

The different departments of the Iron, Steel, and Foundry Industries were outlined so that Mr. Guerrant would have a guide to work from, and it was agreed that the sectional members present would send several scenarios in to the Council headquarters so that the various principal hazards common to the section would be covered. A machine-shop bulletin would be of interest to all Metals Section members in view of the fact that every industry in our Section has a machine shop.

Therefore, it was decided that for the year twenty-six of our bulletins should be General Metal Working bulletins such as would be useful in any machine shop, and that twenty-six should be special bulletins applying strictly to the hazards of Iron, Steel, and Foundry members. The bulletins for the past year then have followed this plan, the Metal Working ones being issued on alternate weeks with those which were strictly sectional.

SAFE PRACTICES PAMPHLETS

The pamphlet on "Cleaning and Finishing Rooms in Foundries" which was prepared by Mr. Guerrant for the Metals Section, was carefully reviewed and was issued to members of the Section last Fall. The second Safe Practices pamphlet for the Section, that on "Blast Furnaces," is almost ready for the printer, and will likely be issued within the next three or four weeks.

NEWS LETTERS

Rather than depend on a general appeal for material for our monthly news letter it was decided to make a specific appeal to a limited number of members whose interest in the work of the Section is assured.

OTHER COMMITTEES

The selection of the other committees was postponed until the next meeting.

NEXT MEETING

It was decided to hold the next meeting in Pittsburgh, November 20. The meeting adjourned at 5:30 P. M.

THE SECOND MEETING

The second meeting of your Executive Committee was held in Pittsburgh on November 18. Those present were: F. E. Morris, H. A. Weeks, J. A. Oartel, J. A. Northwood, W. R. Rasmussen, W. E. Watters.

Each of the different committees reported much progress. The program for the next Congress was laid out more in detail.

There were two more meetings of your executive committee held, one in Pittsburgh in May, and one in Cleveland in June, for the purpose of completing the draft of the Safe Practice pamphlet on "Blast Furnaces."

Mr. John A. Oartel, Director of Safety, Carnegie Steel Company, succeeded Mr. Frank Morris, as chairman of the Metals Section, Mr. Morris being appointed District Field Secretary of the National Safety Council.

Since our last Congress the Metals Section has received 41 new members.

We have also had 31 members cancel their membership, the cause in a big percentage of the cases being the plants closing down.

(On motion the report was accepted.)

CHAIRMAN OARTEL: I think perhaps I should report for the Bulletin and Safe Practices Leaflet Committee, although Mr. Watters has touched on that in his report. I was getting along fairly well when I was made Chairman of this section and because of that, the work did not go along quite so well, but we have tried to do what we could and have been able to produce some very good bulletins.

I think, perhaps, I should also report for the Program Committee, of which Mr. J. A. Northwood of the Cambria Steel Company was Chairman. Mr. Northwood is unable to be present today, but I think the program we have for this Section, if not the best, is the most practical that we have ever had at a Congress. Of course, you will pass your judgment on that at the close of the sessions.

I think it would be in order now to appoint a Nominating Committee to nominate a Chairman, a Vice Chairman, and a Secretary for the ensuing term. I will appoint on that committee Mr. C. E. Pettibone, of the Pickands Mather Company; Fred Bennett, of the Buckeye Steel Castings Company; and H. E. Steinmetz, of the Midvale Steel and Ordnance Company. Will this committee please be prepared to hand in their report on Saturday morning?

The first address on our program this morning is by Mr. H. L. Church.

ACCIDENT PREVENTION IN A MALLEABLE IRON FOUNDRY

H. L. CHURCH, DIRECTOR OF EMPLOYMENT SERVICE, ROCKFORD MALLEABLE
IRON WORKS, ROCKFORD, ILL.

There are, broadly speaking, two angles from which one must view the question of accident prevention in industry—the physical and the human. By physical, I refer to the matter of safe equipment and the responsibility of keeping that equipment safe at all times. The other is the human element, and has to do with the habits of the men and the manner in which they perform their work. Owing to the fact that the amount of power-driven machinery in a foundry is comparatively limited, we are of the opinion that the vital matters in promoting safety in the malleable foundry are largely concerned with the human element and the various activities that grow directly or indirectly out of it. This is particularly the case when we are dealing with prevention of accidents distinctly characteristic of the malleable business, and are not considering such cases as are common to all branches of industry.

There are two factors that conspire to make work in a malleable foundry especially dangerous, if proper care is not exercised. These factors are *the work itself and the men who do it.*

FOUNDRY WORK MUST BE MADE SAFER AND MORE ATTRACTIVE TO HOLD THE MEN

In the first place, the handling of molten iron—especially of malleable—is fraught with danger. Malleable cools very quickly, hence a molder must work rapidly to pour off a ladle full. The fatigue attendant on carrying ladle after ladle of iron, the heat always in evidence, which produces an enervating effect, and the mental strain one is under at the time, combine to present a field of activity that is not very attractive. One often finds seasoned foundry men who for some reason or other get away from the molding trade, and who are with difficulty induced to return. One man told me some weeks ago that he had spent the best years of his life in a foundry and he was a blamed fool for so doing. He is now watching a machine in one of our large plants, not making as much money as he did while molding, but he says he is better satisfied. I do not wish to pose as a crape hanger, but we must face the fact that men, in northern Illinois at least, are leaving the molders' trade, and we are concerned as to where our future molders are to come from. This is preëminently a problem for the employment executive, but the safety engineer also has his role to play. We are of the conviction that foundry work must be made more attractive and more safe if we are to hold the men we already have, and that is part of the safety man's job.

The second reason grows out of the first condition I have outlined. As foundry work is not desirable and appealing, it does not attract the class of men who fit into organizations where the more skilled operatives are called for. Consequently, the foundry employment man usually has to take practically the lowest class of workers available. As a rule, these

are foreigners who understand little, if any, English, and read but indifferently their own language. Most if not all of these never have received in their own country even the most elementary notion of safety and sanitation. Put these men into a malleable foundry where working conditions are unpleasant and hard for even the fellow above par, and you have a combination that keeps the foundry safety engineer guessing most of the time. More than this, the employment service tries to develop and Americanize these men, and then is obliged to see many of them slip away into more enticing fields of industrial activity, conditioned, of course, by their ability to expand. This is true especially of the present generation which is characterized by apparent unwillingness to tie oneself down to a trade, and is not applicable to men of the older generation, among whom are the mainstays of present-day industry. However, the personal service director who has a broad outlook on life will not complain about this fact, but will face it gracefully, and feel that he is doing his part to develop and unify to a certain extent the heterogeneous elements that fall into our national melting pot.

The net result of these two conditions outlined, the nature of the work, and the kind of men who must do it, is that the problem of safety in the foundry is preëminently one for the employment department, as a large part of the labor turnover in a malleable foundry is due to this peculiar maladjustment of the man and the job.

FOUNDRY BURNS

Our organized safety movement dates back to the spring of 1917, when we installed a first-aid hospital. A few weeks later, our employment department was inaugurated. One of the first lines of research work we undertook was to study the accidents reported during 1916 and the first half of 1917. Interesting information was gathered from this study. We learned that a large percentage of foundry burns, which formed the most distressing and costly of our accident cases, were suffered by men comparatively new in the business. Our experience has revealed the fact that molders who have been following the trade for years, and helpers who have become seasoned to the hazards of foundry life, are almost negligible as far as the human element in accident prevention is concerned. Not so, however, the half-baked molder or transient gangway dancer. These fellows, we found, suffered by far the greater number of burns. This brought us face to face with our problem: to reduce the number of burns among the inexperienced foundry workmen, which constituted our most serious hazard. Insistence on the use of safety shoes, goggles, leggings, and gloves prevents a great many burns, but we believe one must go deeper than that to get at the heart of the matter.

I remember reading a number of years ago a humorous sketch entitled "Curtailing the Liquor Traffic." One old timer suggested that the traffic be curtailed by cutting off half of its tail. Another maintained that two-thirds of the tail should be amputated. Still another thought that the whole tail might be spared. Finally, a radical grapejuice advocate suggested "cutting off the cur's tail right behind the ears." We feel some-

what the same way, at least as far as curtailing the number of foundry burns is concerned. We believe that the best results are to be obtained by getting right at the men themselves. In other words, we can control such externalities as safe equipment, preventives, sanitary surroundings, etc., but we cannot control the inexperienced human element. This we must educate. To substantiate this, permit me to say that an analysis of the accidents during 1917 showed that 57.8 per cent were due to the carelessness of the injured man, and 17.1 per cent to the carelessness of a fellow employee. The remaining 25.1 per cent were accidents which occurred under such circumstances that no particular blame could be placed. During 1918, 38.4 per cent were apparently unavoidable, as against 25.1 per cent the year before. This, of course, reduces the number of accidents due to some one's carelessness, showing a gain over the preceding year. This year, to the first of September, has made even a better showing. We have had 38 accidents within this period, and just 50 per cent have been unavoidable; the other half being traced to negligence. I might add that a large number of the accidents referred to the company physician this year are eye cases, with no disability involved.

We have just said that the experienced foundry man does not cause us any concern as regards avoidable accidents, but we are especially concerned with novices. For this reason when we take on a man who is new to the malleable game, no matter whether he is an apprentice molder, a skilled molder who has worked only grey iron, or a laborer, we tell him how to do his work with the maximum of safety to himself and his fellow workers.

REQUIRE MEN TO WEAR MOLDERS' SHOES

Among other things, we explain our reasons for requiring all men who work in the foundry during the heats to wear molders' shoes. These we supply at cost. We further tell the new man that his feet are under inspection at all times, and we expect him to keep his shoes in such condition that they afford the necessary protection. If the new man is to carry iron, we warn him against damp ladles and explain the danger of dumping drops in damp places. We also explain that the rights of others must be respected, and that he must await his turn at the furnace spout. In order to enforce these rules, we provide a watcher at each furnace during the time that the heat is taken off.

The location and purpose of the first-aid hospital is told the newcomer, and we try to impress on him the necessity of reporting to his foreman immediately even the slightest scratch or abrasion. Often it is discouraging to find out that men who ought to know better sometimes pay no attention to a slight wound, but neglect it until it becomes painful. On the other hand, it is very gratifying to see a new man come to the hospital immediately.

GOOD PICTURES NEEDED FOR FOUNDRY BULLETIN BOARDS

I have already alluded to the fact that the average foundry laborer is unlettered, either in English or his native tongue. For this reason, we do not believe that bulletin boards have any particular value. Pictures.

however, speak every language, and he who does not read at all can profit by them. I wish there were more good pictures suitable for the foundry industry. Machine shops, railroads, electrical, and construction trades are well represented, but the library of pictures illustrating the distinctive hazards of the foundry industry make a relatively small showing.

We have developed one branch of activity at our plant which may have contributed somewhat to the reduction of accidents during the past two years. We have a man in our organization who speaks several languages fluently, and a few others in a passable manner. One of this man's duties is to spend some time in the foundry each day, and as opportunity presents itself, to talk to the men along the lines of safety and accident prevention, as well as other propaganda that occasionally seems advisable. More men of the untutored classes can be reached by occasional chats in their native language than can be appealed to by high-brow pay envelope stuffers, well written bulletins, etc. These are all right in their place, but their place is not the malleable iron foundry.

FIRST-AID WORK

Every foundry should have a first-aid hospital. In plants where the payroll runs up into the thousands, and where there are many accidents every day, a trained nurse or experienced first-aid attendant is necessary. In smaller shops, where it does not seem advisable to secure the exclusive services of an expert, there can usually be found two or three men with level heads and steady nerves, who can be easily trained in first-aid work, and any of whom can be available when needed. This reduces the cost of operating the hospital to a low point, and in small shops this is the only way to handle the matter.

So well has our first-aid hospital been handled that in the twenty-seven months of its existence, only two cases of blood-poisoning have developed from an injury or burn. In both of these cases, injuries were not reported until too late to stop infection. It might be interesting to add that one of these cases was the first-aid attendant himself, who scratched his hand on a rusty nail, and did not take the trouble to disinfect it. His penalty for not practicing what he preached was that he was tied up for two or three weeks and had a merry time keeping the blood-poisoning within check.

There is another problem connected with handling first aid in accident cases. The average workman is prone to neglect an accident for several days, until it becomes serious. One may follow up the policy I have outlined, and he may think he is getting the matter pretty well in hand, when some fine day, Tony or Mike or Pete lays off, and later we learn of an accident of a week ago that he neglected to report, and that has now become painful and of grave concern to him and to us.

We have developed a method of handling this situation which cannot fail to succeed if faithfully followed up. Every morning a list of absentees is made up and every man whose reason for absence is not known either to his foreman or to the employment office, is visited at his home and the reason for his absence is learned. We are doing this primarily

Metals Section

October 2-4, 1919

J. A. OARTEL, Chairman

Director of Safety, Carnegie Steel Company, Pittsburgh, Pa.

HOMER J. WEEKS, Vice-Chairman

American Steel and Wire Company, Cleveland, Ohio

W. E. WATTERS, Secretary

National Malleable Castings Company, Melrose Park, Illinois

THURSDAY MORNING SESSION

CHAIRMAN OARTEL: As you know, at the last session of the Congress, Mr. Frank E. Morris of the American Rolling Mill Company was elected Chairman of the Metals Section, and he served until he was appointed Field Secretary for the National Safety Council, at which time the job was wished on me, so I have served only part of the year.

Because of this change in the officers of the section, the best work has not been done, but we have tried to do what we could.

The year that has passed has been a remarkable year in the reduction of accidents in the iron and steel industry. I suppose you are all familiar with the figures contained in a recent letter written by Dr. Frederick L. Hoffman, Third Vice President and Statistician of the Prudential Life Insurance Company, to Mr. C. L. Close, Manager of the Bureau of Safety, Sanitation, and Welfare of the United States Steel Corporation.

In that letter the Doctor tells of the remarkable reductions in life insurance premiums that have been given to men working in the iron and steel industry wholly because of the safety work that has been done. I think that is one of the biggest contributions that has ever been made to safety, the fact that a conservative life insurance company that does not do things hastily has, after a thorough investigation, decided that our safety work has brought such results that they can consistently lower premiums on life insurance. And so, I think it may be said that this is one of the big contributions to safety that has been made in the last year.

There have been some remarkable accident reductions by a number of companies, but I won't take the time to tell you of them.

I will now call on Mr. Watters, our Secretary, to give his report.

REPORT OF THE SECRETARY

Your executive committee had their first meeting in Chicago, on October 15, 1918, and their work for the coming year was planned. There were present: F. E. Morris, Chairman; Homer J. Weeks, Vice Chairman; W. H. Cameron, S. J. Williams and R. H. Guerrant of the National Safety Council staff. The Secretary was absent on account of illness.

Metal Section activities for the year 1918-19 were taken up in detail and it was agreed that each of the standing committees should be continued, and that the work of the section should be carried on along the same general lines as heretofore.

The advisability of having a special committee to disseminate information among the members of our section was discussed and it was decided that this work should be done by including this information in the monthly news letter.

BULLETIN AND SAFE PRACTICES COMMITTEE

After thoroughly canvassing the field, Mr. J. A. Oartel, Director of Safety, Carnegie Steel Company, was chosen as Chairman, of the Bulletin and Safe Practices Committee.

A report was obtained from Mr. Lamont, as to the amount of bulletin material on hand and it was learned that there was enough to run until the first of December.

It was suggested by Mr. Williams that many bulletins from other sections are applicable to the industries of the Metals Section, and that the scheme of leaving it to the headquarters staff to decide on material for the bulletins for all the sections would avoid any duplication of effort.

The different departments of the Iron, Steel, and Foundry Industries were outlined so that Mr. Guerrant would have a guide to work from, and it was agreed that the sectional members present would send several scenarios in to the Council headquarters so that the various principal hazards common to the section would be covered. A machine-shop bulletin would be of interest to all Metals Section members in view of the fact that every industry in our Section has a machine shop.

Therefore, it was decided that for the year twenty-six of our bulletins should be General Metal Working bulletins such as would be useful in any machine shop, and that twenty-six should be special bulletins applying strictly to the hazards of Iron, Steel, and Foundry members. The bulletins for the past year then have followed this plan, the Metal Working ones being issued on alternate weeks with those which were strictly sectional.

SAFE PRACTICES PAMPHLETS

The pamphlet on "Cleaning and Finishing Rooms in Foundries" which was prepared by Mr. Guerrant for the Metals Section, was carefully reviewed and was issued to members of the Section last Fall. The second Safe Practices pamphlet for the Section, that on "Blast Furnaces," is almost ready for the printer, and will likely be issued within the next three or four weeks.

NEWS LETTERS

Rather than depend on a general appeal for material for our monthly news letter it was decided to make a specific appeal to a limited number of members whose interest in the work of the Section is assured.

OTHER COMMITTEES

The selection of the other committees was postponed until the next meeting.

NEXT MEETING

It was decided to hold the next meeting in Pittsburgh, November 20. The meeting adjourned at 5:30 P. M.

THE SECOND MEETING

The second meeting of your Executive Committee was held in Pittsburgh on November 18. Those present were: F. E. Morris, H. A. Weeks, J. A. Oartel, J. A. Northwood, W. R. Rasmussen, W. E. Watters.

Each of the different committees reported much progress. The program for the next Congress was laid out more in detail.

There were two more meetings of your executive committee held, one in Pittsburgh in May, and one in Cleveland in June, for the purpose of completing the draft of the Safe Practice pamphlet on "Blast Furnaces."

Mr. John A. Oartel, Director of Safety, Carnegie Steel Company, succeeded Mr. Frank Morris, as chairman of the Metals Section, Mr. Morris being appointed District Field Secretary of the National Safety Council.

Since our last Congress the Metals Section has received 41 new members.

We have also had 31 members cancel their membership, the cause in a big percentage of the cases being the plants closing down.

(On motion the report was accepted.)

CHAIRMAN OARTEL: I think perhaps I should report for the Bulletin and Safe Practices Leaflet Committee, although Mr. Watters has touched on that in his report. I was getting along fairly well when I was made Chairman of this section and because of that, the work did not go along quite so well, but we have tried to do what we could and have been able to produce some very good bulletins.

I think, perhaps, I should also report for the Program Committee, of which Mr. J. A. Northwood of the Cambria Steel Company was Chairman. Mr. Northwood is unable to be present today, but I think the program we have for this Section, if not the best, is the most practical that we have ever had at a Congress. Of course, you will pass your judgment on that at the close of the sessions.

I think it would be in order now to appoint a Nominating Committee to nominate a Chairman, a Vice Chairman, and a Secretary for the ensuing term. I will appoint on that committee Mr. C. E. Pettibone, of the Pickands Mather Company; Fred Bennett, of the Buckeye Steel Castings Company; and H. E. Steinmetz, of the Midvale Steel and Ordnance Company. Will this committee please be prepared to hand in their report on Saturday morning?

The first address on our program this morning is by Mr. H. L. Church.

ACCIDENT PREVENTION IN A MALLEABLE IRON FOUNDRY

H. L. CHURCH, DIRECTOR OF EMPLOYMENT SERVICE, ROCKFORD MALLEABLE
IRON WORKS, ROCKFORD, ILL.

There are, broadly speaking, two angles from which one must view the question of accident prevention in industry—the physical and the human. By physical, I refer to the matter of safe equipment and the responsibility of keeping that equipment safe at all times. The other is the human element, and has to do with the habits of the men and the manner in which they perform their work. Owing to the fact that the amount of power-driven machinery in a foundry is comparatively limited, we are of the opinion that the vital matters in promoting safety in the malleable foundry are largely concerned with the human element and the various activities that grow directly or indirectly out of it. This is particularly the case when we are dealing with prevention of accidents distinctly characteristic of the malleable business, and are not considering such cases as are common to all branches of industry.

There are two factors that conspire to make work in a malleable foundry especially dangerous, if proper care is not exercised. These factors are *the work itself* and *the men who do it*.

FOUNDRY WORK MUST BE MADE SAFER AND MORE ATTRACTIVE TO HOLD THE MEN

In the first place, the handling of molten iron—especially of malleable—is fraught with danger. Malleable cools very quickly, hence a molder must work rapidly to pour off a ladle full. The fatigue attendant on carrying ladle after ladle of iron, the heat always in evidence, which produces an enervating effect, and the mental strain one is under at the time, combine to present a field of activity that is not very attractive. One often finds seasoned foundry men who for some reason or other get away from the molding trade, and who are with difficulty induced to return. One man told me some weeks ago that he had spent the best years of his life in a foundry and he was a blamed fool for so doing. He is now watching a machine in one of our large plants, not making as much money as he did while molding, but he says he is better satisfied. I do not wish to pose as a crape hanger, but we must face the fact that men, in northern Illinois at least, are leaving the molders' trade, and we are concerned as to where our future molders are to come from. This is preëminently a problem for the employment executive, but the safety engineer also has his role to play. We are of the conviction that foundry work must be made more attractive and more safe if we are to hold the men we already have, and that is part of the safety man's job.

The second reason grows out of the first condition I have outlined. As foundry work is not desirable and appealing, it does not attract the class of men who fit into organizations where the more skilled operatives are called for. Consequently, the foundry employment man usually has to take practically the lowest class of workers available. As a rule, these

are foreigners who understand little, if any, English, and read but indifferently their own language. Most if not all of these never have received in their own country even the most elementary notion of safety and sanitation. Put these men into a malleable foundry where working conditions are unpleasant and hard for even the fellow above par, and you have a combination that keeps the foundry safety engineer guessing most of the time. More than this, the employment service tries to develop and Americanize these men, and then is obliged to see many of them slip away into more enticing fields of industrial activity, conditioned, of course, by their ability to expand. This is true especially of the present generation which is characterized by apparent unwillingness to tie oneself down to a trade, and is not applicable to men of the older generation, among whom are the mainstays of present-day industry. However, the personal service director who has a broad outlook on life will not complain about this fact, but will face it gracefully, and feel that he is doing his part to develop and unify to a certain extent the heterogeneous elements that fall into our national melting pot.

The net result of these two conditions outlined, the nature of the work, and the kind of men who must do it, is that the problem of safety in the foundry is preëminently one for the employment department, as a large part of the labor turnover in a malleable foundry is due to this peculiar maladjustment of the man and the job.

FOUNDRY BURNS

Our organized safety movement dates back to the spring of 1917, when we installed a first-aid hospital. A few weeks later, our employment department was inaugurated. One of the first lines of research work we undertook was to study the accidents reported during 1916 and the first half of 1917. Interesting information was gathered from this study. We learned that a large percentage of foundry burns, which formed the most distressing and costly of our accident cases, were suffered by men comparatively new in the business. Our experience has revealed the fact that molders who have been following the trade for years, and helpers who have become seasoned to the hazards of foundry life, are almost negligible as far as the human element in accident prevention is concerned. Not so, however, the half-baked molder or transient gangway dancer. These fellows, we found, suffered by far the greater number of burns. This brought us face to face with our problem: to reduce the number of burns among the inexperienced foundry workmen, which constituted our most serious hazard. Insistence on the use of safety shoes, goggles, leggings, and gloves prevents a great many burns, but we believe one must go deeper than that to get at the heart of the matter.

I remember reading a number of years ago a humorous sketch entitled "Curtailling the Liquor Traffic." One old timer suggested that the traffic be curtailed by cutting off half of its tail. Another maintained that two-thirds of the tail should be amputated. Still another thought that the whole tail might be spared. Finally, a radical grapejuice advocate suggested "cutting off the cur's tail right behind the ears." We feel some-

what the same way, at least as far as curtailing the number of foundry burns is concerned. We believe that the best results are to be obtained by getting right at the men themselves. In other words, we can control such externalities as safe equipment, preventives, sanitary surroundings, etc., but we cannot control the inexperienced human element. This we must educate. To substantiate this, permit me to say that an analysis of the accidents during 1917 showed that 57.8 per cent were due to the carelessness of the injured man, and 17.1 per cent to the carelessness of a fellow employee. The remaining 25.1 per cent were accidents which occurred under such circumstances that no particular blame could be placed. During 1918, 38.5 per cent were apparently unavoidable, as against 25.1 per cent the year before. This, of course, reduces the number of accidents due to some one's carelessness, showing a gain over the preceding year. This year, to the first of September, has made even a better showing. We have had 38 accidents within this period, and just 50 per cent have been unavoidable, the other half being traced to negligence. I might add that a large number of the accidents referred to the company physician this year are eye cases, with no disability involved.

We have just said that the experienced foundry man does not cause us any concern as regards avoidable accidents, but we are especially concerned with novices. For this reason when we take on a man who is new to the malleable game, no matter whether he is an apprentice molder, a skilled molder who has worked only grey iron, or a laborer, we tell him how to do his work with the maximum of safety to himself and his fellow workers.

REQUIRE MEN TO WEAR MOLDERS' SHOES

Among other things, we explain our reasons for requiring all men who work in the foundry during the heats to wear molders' shoes. These we supply at cost. We further tell the new man that his feet are under inspection at all times, and we expect him to keep his shoes in such condition that they afford the necessary protection. If the new man is to carry iron, we warn him against damp ladles and explain the danger of dumping drops in damp places. We also explain that the rights of others must be respected, and that he must await his turn at the furnace spout. In order to enforce these rules, we provide a watcher at each furnace during the time that the heat is taken off.

The location and purpose of the first-aid hospital is told the newcomer, and we try to impress on him the necessity of reporting to his foreman immediately even the slightest scratch or abrasion. Often it is discouraging to find out that men who ought to know better sometimes pay no attention to a slight wound, but neglect it until it becomes painful. On the other hand, it is very gratifying to see a new man come to the hospital immediately.

GOOD PICTURES NEEDED FOR FOUNDRY BULLETIN BOARDS

I have already alluded to the fact that the average foundry laborer is unlettered, either in English or his native tongue. For this reason, we do not believe that bulletin boards have any particular value. Pictures.

however, speak every language, and he who does not read at all can profit by them. I wish there were more good pictures suitable for the foundry industry. Machine shops, railroads, electrical, and construction trades are well represented, but the library of pictures illustrating the distinctive hazards of the foundry industry make a relatively small showing.

We have developed one branch of activity at our plant which may have contributed somewhat to the reduction of accidents during the past two years. We have a man in our organization who speaks several languages fluently, and a few others in a passable manner. One of this man's duties is to spend some time in the foundry each day, and as opportunity presents itself, to talk to the men along the lines of safety and accident prevention, as well as other propaganda that occasionally seems advisable. More men of the untutored classes can be reached by occasional chats in their native language than can be appealed to by high-brow pay envelope stuffers, well written bulletins, etc. These are all right in their place, but their place is not the malleable iron foundry.

FIRST-AID WORK

Every foundry should have a first-aid hospital. In plants where the payroll runs up into the thousands, and where there are many accidents every day, a trained nurse or experienced first-aid attendant is necessary. In smaller shops, where it does not seem advisable to secure the exclusive services of an expert, there can usually be found two or three men with level heads and steady nerves, who can be easily trained in first-aid work, and any of whom can be available when needed. This reduces the cost of operating the hospital to a low point, and in small shops this is the only way to handle the matter.

So well has our first-aid hospital been handled that in the twenty-seven months of its existence, only two cases of blood-poisoning have developed from an injury or burn. In both of these cases, injuries were not reported until too late to stop infection. It might be interesting to add that one of these cases was the first-aid attendant himself, who scratched his hand on a rusty nail, and did not take the trouble to disinfect it. His penalty for not practicing what he preached was that he was tied up for two or three weeks and had a merry time keeping the blood-poisoning within check.

There is another problem connected with handling first aid in accident cases. The average workman is prone to neglect an accident for several days, until it becomes serious. One may follow up the policy I have outlined, and he may think he is getting the matter pretty well in hand, when some fine day, Tony or Mike or Pete lays off, and later we learn of an accident of a week ago that he neglected to report, and that has now become painful and of grave concern to him and to us.

We have developed a method of handling this situation which cannot fail to succeed if faithfully followed up. Every morning a list of absentees is made up and every man whose reason for absence is not known either to his foreman or to the employment office, is visited at his home and the reason for his absence is learned. We are doing this primarily

to secure information that will help us to work along the lines of stabilizing our working force. However, a valuable by-product of this plan is the help it brings to the first-aid department. If a man has been injured and he has neglected to report it until it became painful and compelled him to lay off, we get at the fact the first day he is off duty. If it looks like a case that may be critical, we get the matter before the company physician. If it seems likely that the first-aid department can handle the case, and that a few days off is the maximum, we take the man back to the factory where the first-aid department takes care of his case. We then take him home if necessary. We follow him up and see that he gets the necessary care until he is able to resume work.

This, in the main, is the outline of our efforts and experience along the lines of accident prevention in the malleable iron foundry. No plans, however clever or well laid, will succeed without persistent, honest endeavor. No system is better than the man or men who operates it. Whether we have succeeded in reducing accidents by activities along the lines we have outlined is of course debatable. We may have been simply fortunate. Possibly so. Our records do show, however, that our accidents have been reduced in number, and if we have been simply fortunate, that fortune at least coincides chronologically with our organized efforts.

REDUCTION IN ACCIDENTS

Permit me at this time to present a few statistics. During the second half of 1917, which was the first half-year of our organized effort, we had one foundry burn to every twelve men employed. During the first half of 1918, we had one burn for every 30 men, and the same ratio obtained during the last half of the year. The first six months of this year was somewhat better, with a showing of only one burn to 44 men. Since the first of July to date, we have had only one burn that necessitated a man laying off. We are especially gratified at this result in view of the comparatively large number of apprentice molders we have been obliged to take on, owing to a serious shortage of skilled molders.

To judge from our own experience, we do not hesitate to say that every malleable iron foundry, no matter how small, should be equipped with a safety organization somewhat along the lines we have tried out. It may not be possible to have one who devotes all his time to this work, especially in the smaller plants. In view of the peculiar employment problems that confront foundries at present, we believe that every malleable shop should have an employment service department, part of whose functions is the safety-first propaganda. These two branches can be combined very successfully if plant conditions do not warrant an exclusive safety engineer.

EXTENDING SAFETY AND SANITATION TO THE HOMES

I have already alluded to the fact that the malleable foundry usually has to take practically the least desirable class of workers available and try to develop them. This affords the opportunity of the malleable foundry to serve society, if there exists any altruistic sense at all, and I for one, believe that there should be. We must take these men as we find

them, many of them hardly above the ten-year-old in mentality, and give them their first instructions in safety and sanitation. If we can do so without becoming manifestly paternalistic, we might extend the scope of our operations to reach them in their home life. The average man spends about nine or ten hours under influences created and maintained by his employer. The remainder of his time, not devoted to sleep, is with his family and acquaintances. If, under these circumstances, the employer cannot inculcate the principles of safety, who will? If it is inadvisable to extend our safety work to the men in their homes, we can at least hope that they will apply in their home life what we are trying to teach them in the shop. If we can impress the men with proper conceptions of safety and sanitation in such a way that they become not merely a formal observance of shop practice, but a rule of life, vital and dominating, we are contributing our share to the development of those elements of society that come under the sphere of our influence.

CHAIRMAN OARTEL: Mr. Church, I am very sure I express the sentiment of the entire Metals Section when I voice my appreciation for your very practical paper.

Gentlemen, we have two or three minutes left for discussion. Are there any questions any of you want to ask Mr. Church? Is there anything you want to add to his paper?

DISCUSSION

MR. WILLIAM RANDALL (Valley Mould and Iron Company, Sharpsville, Pa.): I would like to ask Mr. Church if he compels or demands his employees to wear leggings and safety shoes.

SAFETY SHOES

MR. H. L. CHURCH: We compel them to wear safety shoes. We have not compelled them to wear leggings as yet but are inducing them to do it by moral suasion. We expect to do so in the near future.

MR. WILLIAM RANDALL: If you can't obtain that result, what do you do, discharge them?

MR. H. L. CHURCH: We haven't had much trouble in compelling them because we furnish the shoes.

MR. WILLIAM RANDALL: Does your company furnish all the shoes?

MR. H. L. CHURCH: Yes. We furnish the shoes.

THE SECRETARY: Do you make any charge for the shoes?

MR. H. L. CHURCH: We handle them absolutely at cost. We had one spell several months ago when the fellows were complaining about the high cost of shoes. We discontinued the shoes and told them to buy them up town. In about a week there was an awful holler about it, and we went back to our old practice.

MR. H. N. YATES (Rogers-Brown Iron Company, Buffalo, N. Y.): What kind of shoes do you mean by moulders shoes, congress or lace shoes?

MR. H. L. CHURCH: Congress shoes.

MR. H. N. YATES: We find great difficulty in getting the men to adopt

those shoes. I would like to ask what the duties of your Service Department are.

MR. H. L. CHURCH: The employment service is intended as a clearing house of labor methods. We call the Employment Manager the Employment Service Director. He investigates discharges, secures new help, takes care of the personal relations of the men in the shop. He is the same as the Employment Manager in most concerns.

CHAIRMAN ORTELL: There is a request that Mr. Vanderpool say something on leggings and shoes.

MR. VANDERPOOL: At the National Malleable Castings Company we have no trouble in getting men to wear leggings. We furnish the leggings, making an initial charge. Their money is refunded if they leave us. We go around daily and inspect the leggings, and those in need of repairs we pick up and at the same time hand the man a new legging. We haven't had any trouble in getting them worn.

MR. J. D. JAMES (New Jersey Zinc Company): We have had quite a number of foot burns by metal. Very often we had as high as two or three a week. But, in the last few years we have eliminated burns altogether.

First of all, we tried leggings, but the men complained that in the summer months they could not wear them because they were too warm. So, we kept experimenting on a kind of footguard. We don't have any trouble in getting them to wear the spats, as we call them, and have eliminated foot burns altogether. I have a pair at the desk and if you would like to examine them, I will be glad to show them to you. We don't charge anything for them and we have no trouble in getting the men to wear them.

CHAIRMAN ORTELL: Let us leave the inspection of those spats until the close of the meeting. I am sure we shall all be glad to see them because this is so vital a point in our industry.

The next address was to have been delivered by Mr. M. F. Gartland of the Marion Gray Iron Foundry Company, Marion, Indiana, but Mr. Gartland is detailed on account of illness, and the paper will be read by Mr. T. W. Vanderpool of the National Malleable Castings Company.

THE PERSONAL ELEMENT IN A SAFETY PROGRAM FOR THE FOUNDRY

M. F. GARTLAND, MARION GRAY IRON FOUNDRY, MARION, IND.

We state a fact and we don't need to prove it when we say that the foundry can never be made as safe as a parlor. We may have the most expensive and most modern machinery and equipment that money can buy, our buildings may be models of perfection so far as light and ventilation and general arrangement are concerned, we may coerce our men in the matter of wearing molders' shoes, leggings, and goggles, but the fact remains that a splash of hot iron will still cause a burn when it comes into contact with the human body. A casting or a piece of pig iron will still mash a foot or break a toe if it drops at the right spot at the right time.

Our high grade equipment will do a great deal to eliminate the

splashes and other accidents due to machinery but beyond that there is yet another element. Improved methods of handling the product will eliminate a great deal of the danger that arises from this source but no piece of machinery or equipment has ever been made that is entirely fool proof. We must seek yet further for the final analysis of our safety problem. We shall still have our accidents in spite of all these good things.

If we could operate a foundry by machinery from the pig iron yard to the shipping platform without the touch of a human hand we should have no foundry accidents. But we can't do that, we must have men. Our foundries must be alive with men through every part of every working day. Again, if we had the men of our foundries engaged in the task of making mud pies by hand we should have no foundry accidents. The element of danger that lies in the nature of our product would be eliminated. But we are not in the mud pie business and we are not making and shipping castings by machinery. We are making our product from pig iron and scrap. To put it on the market we must have men. Men must unload the iron, the coal, and the sand. Men must charge the furnaces and heave in the coal to heat them. Other men must draw off the molten charge and pour it into the moulds, and still other men must dump the castings from the moulds and follow them step by step through the finishing processes and then put them on board the cars for their destination. In each of these operations from beginning to end there is a certain element of danger from the very nature of the materials and because of the fact that human hands must direct each one of them. This element of danger or hazard can be lessened but never eliminated entirely by the installation and use of more modern equipment.

THREE ELEMENTS OF HAZARD

We have, then, three elements of hazard with which to contend even in the best of our foundries: our equipment, our product, and our men. The safety engineer and the foundry expert have done a great deal to eliminate the danger in the manufacturing process and they will yet do a great deal more. Let them do it. That is their job but let us give them our best coöperation. They each have their field, and each is important to our organization. They have dealt primarily with machinery and mechanical processes and in the course of time may hope to arrive at something near perfection, so far as safe machines may be concerned. The greatest hazard yet remains and here is a job for the human engineer. While the safety engineer is dealing with machines the human engineer is dealing with a problem far more complex than any machine can ever be. He must deal with human nature and all of us know enough about human nature to know that we know very little. We don't know ourselves so very well so, of course, we cannot hope to know fully any one else.

THE HUMAN ELEMENT

It is the purpose of this paper to direct your attention to certain phases of the work of the human engineer. For the sake of clearness the sub-

ject will be presented as though his work were to be entirely divorced from that of the safety engineer. It will be so presented but with full knowledge of the fact that the two types of work are very closely related to each other and that the safety engineer is very often a human engineer as well.

We are asked to discuss today the strides that have been made in the progress of safety work for foundries. Perhaps the greatest stride possible has been made when we recognize the true nature of our problem and put our hands to the task of its solution. We may say with confidence that the foundries of the country have recognized the problem and that they have set about solving it. We may find conclusive evidence of this fact in every new safety device that is installed and in every piece of so-called welfare work that is being undertaken for the workers in our plants. Owners and managers everywhere are beginning to recognize the human element that enters into their safety problem and they are all striking out, some of them blindly, perhaps, to find its solution. We have housing plans. We have gardens by the thousands for our employees. We have clubs and classes. We have entertainments and socials. We have free clinics and visiting nurses and social service workers. We have bonus systems and plans of profit sharing and a score of other lines of welfare work all trying for the one goal of making the worker a more efficient and better satisfied man. All of these things are good and should have a great deal more of our attention. They should be encouraged among our workmen and should be given larger appropriations of money. We have but to look into our own lives to see how easily men are thrown off their guard. We know that a night without proper rest is fatal to our highest efficiency on the day following, and we know that a long stretch of hard work without periods of proper relaxation and recreation will bring about a break down in our better judgments. We may not suffer a broken foot from a falling pig of iron or a burned ankle from a splash of molten metal but we have accidents in our mental processes which are just as painful and a great deal more costly in dollars and cents. Perhaps we should have a great deal more serious accidents than the foundry laborer has if we carried our load and worked where he works and under the same conditions.

We know that everything we do in our leisure time has its effect upon our lives while we are at work. The thing that is true of the executive who works in ideal surroundings is still more true of the man who labors with his hands and earns his living in the heat and smoke and confusion of our foundries. To a very large extent he is made or unmade by the things which happen to him outside of his work-day life. So then we may say that a divorce suit in a local court may be more dangerous to the man involved than an open pit near his work bench. A threatening landlord may produce more injuries in our foundry than our worst hazard of equipment. In other words, the man whose mind is ill at ease or who isn't properly housed and fed may make our plant more unsafe than it would be if we removed every safety device in the whole place. The man who was just born careless and never outgrew it is more dangerous to our plant when he is in there at work than he would be if he stood off

at a safe distance on the outside and hurled firebrands into it three times a day.

THE MISFIT

Now let us look at some of these men of ours who are so prone to injury. Let us make up our minds to help them if we can. The effort will pay for itself in many ways. First there is the man who is a misfit. We didn't know there was such an animal a few years ago but we are beginning to recognize him now. There are men in all of our foundries who ought not to be there. They have been drawn into our employ through a chain of circumstances and it is hard for them to break away. They belong there just about as much as the members of the National Safety Council belong in the business of deep-sea diving. They have about as much sympathy for our business as the average safety engineer has for the business of the steeple jack. Not having interest in their work they lack the incentive to become efficient workmen. They drag through the day without enthusiasm and leave when the whistle blows with a full quota of accidents piled up behind them. These are the men who make our State Industrial Commissions keep one eye on our accident charts. It is because of such men as these that we have a high rate of industrial insurance for our foundries of all types.

But they are there. Our foreman can point out half a dozen of them any time we ask him. We know they are there but what are we going to do with them? That question is easier to ask than it is to answer. Perhaps the easiest thing would be to give such a man the opportunity to find work somewhere else. We would have done that in the old days but we hesitate to do it now; not that we love the man any more than we did but it is not so easy to replace him with a better man. Another and better solution is to give him his opportunity in some other part of our own plant if possible. We know this plan will work because we can all call up a great number of individual cases where it has worked. The trouble is that very few if any of us have adopted it as a principle for every day application. The consistent application of this principle will eliminate a great many of our misfits. It will make careful and efficient workmen out of a great many of our accident makers and will often be the means of keeping a valuable man on our pay-roll. Of course we can't do this by merely saying that it will be done. If we believe it we must work it day after day, week in and week out. It will call for a closer cooperation between our different production departments and between all foremen and the employment department.

We cannot lay down any rules for the application of this principle. Each case must be handled in its own way. We cannot say how long a man should be kept on trial. Some men respond much more quickly than others, and we cannot say that the principle will work in every case because we know it won't. There are some men who are misfits no matter where you place them and for such as these there is no hope in the foundry. The sooner we start them on their way out the better off we shall be. All that we can give to the plan is patience and perseverance and good common sense will not produce perfect results but we can accom-

plish something that is very much worth while. We shall understand our men better, at the very least, our men will understand us better and in this we shall have more of their loyalty and devotion.

THE MAN WITH PERSONAL TROUBLE

The next man who is a great maker of accidents is the man whose mind is ill at ease. He is not so easy to recognize and not so easy to deal with when we do find him. He may be troubled about any one of a score of things and very often there seems to be a combination of nearly all of them. He may be, under ordinary conditions, a very careful and loyal workman but when "troubles a ton" fall upon him he loses his sense of proportions and all thought of safety for himself or others is crowded out of his mind. The secret of his trouble is that his mind is focused on his own personal problem, so, of course, it cannot be focused on his work. When a man works without thinking we may be sure that he will soon make trouble for himself or for some one who works near him. When we meet with a case of this kind we must have a specific remedy. A prescription of the "shot gun variety" has no value to this man. He is not interested in generalities. His own personal problems must be met and solved. Every plant needs a squad of sharpshooters who can hit the spot every time. Call them what you will: visiting nurses, social service workers or what not but first find your men and women who have common sense and good judgment and then turn them loose with authority enough to ride over every precedent and break every rule of the plant if this be necessary to supply the one and only remedy for the worker who is in trouble. A dozen troublesome cases for which real remedies have been found and applied are worth more to a plant as a business asset than to have entertained the whole working force in most royal style. These personal contacts with the individuals of our work forces are just about as important and should be carried out just as systematically as our contacts with our best customers.

Now we shall have failures in dealing with this group just as we have failures in dealing with the misfit. Cases will be found where it will be impossible even to establish a friendly relation. It will be more than impossible to be of help but the effort, if honestly made, will not be lost entirely. On the other hand we shall find that the help we are able to give to those who do receive us, in many cases, is a real God-send to their lives.

THE CARELESS MAN

The next man who makes us lie awake at nights wondering what is going to happen next is the careless man. He was born that way or his life has been such that he has grown that way. Nearly all of us are careless to a certain degree but we find men in all walks of life who are dangerously and criminally careless. They are more dangerous to the plant than a box of dynamite. We can be sure that the dynamite will explode under certain conditions but we never can tell when the careless man will let go. He usually does so without warning and in a moment of time may put the whole works out of harmony for a month or two. If such men

bore the complete result of their own folly we might well say "Good enough for them" but they don't. The innocent must always suffer with the guilty and the careless man is more dangerous to his companions than he is to himself. We have all known men who continually keep others in trouble on account of their carelessness but who seem to live under a lucky star and never get hurt themselves.

The fortunate thing about the careless man is that we can educate him both as an individual and as a worker. We must appeal to him on the basis of loyalty to his family and the welfare of those who work with him. The careless men of our plant can be helped with the "heart-to-heart prescription" in the form of safety bulletins and messages about educational activities. A downward curve in the production report after the matter of pride to them. The most effective means we have may become the most careful if he should suffer a serious injury as the result of his folly or if he should inflict an injury upon a fellow worker. It should be said, however, that he probably will not rise to his new degree of efficiency on his own account, but that he may be led there after a heart-to-heart talk with some member of the executive staff. After all the safety meeting and the safety bulletin very often fail because most of us are prone to think that a safety message is a fine thing for the other fellow. The heart-to-heart talk will place the responsibility on the individual where it belongs. Here again the personal contact is the thing that is most effective in gaining the desired end.

As we shall find some misfits who cannot be "fitted" and some personal problems we cannot solve so we shall find some careless men we cannot cure. Carelessness is born in selfishness and where selfishness has taken deep root in the life of a man it is hard to lift it out. There are some men to whom no appeal can be made. When we find a man like this, the best gift we can bestow is the pay-off slip. We owe it to ourselves, we owe it to our careful workmen, and we owe it to our incurables of every kind to give them the opportunity to work where there is less that is hazardous. Our business has in it so many unavoidable hazards that we cannot afford to be hampered by the man who will not help us to make it as safe as possible.

ENVIRONMENT

There are two other elements in a safety program which should have consideration here. They are not entirely personal but they are so closely related that it would be a mistake not to mention them in passing. The first of these is the element of environment. Environment is directly related to efficiency and efficiency is a half-brother to safety. The man who works at a rate of speed which is normal to him as an individual will have fewer accidents than he would if he worked a great deal faster or a great deal slower. The piece worker, who, naturally, is interested in maintaining a high degree of personal efficiency, will have fewer accidents than the day worker who takes occasion to kill a block of time now and then. The one is keyed up to his normal pace with mind alert and with attention centered in his task while the other takes the pace that will keep him out of trouble with the foreman. His mind may be

a blank and his attention may be focused anywhere but on his work. It is not difficult to see the relation that exists between each of these men and the accident record of the plant where they work.

We may say with confidence that everything which has a bearing on the productive labor of our men has also a bearing upon our accident experience. Everything which takes the attention of our men from their work will be reflected in the number of accidents we have and everything we do to improve working conditions will mean not only a higher rate of production but also a lower rate of injury. Even the buildings where men work have their bearing on this personal problem of safety. A building so constructed that men can constantly watch the street outside is a menace to the safety of the plant. When men watch the street they do not watch their work and nothing is more productive of injury. We should have our buildings well lighted, to be sure, but the light should come from windows well above the level of the average workman's eyes.

Responsibility for the environment of the plant does not rest upon the management alone. All who work in the plant have their share in this. The foreman who keeps his department as neat and clean as possible will produce more and better castings than the foreman who allows his men to work in a place that is constantly out of order. Just as the executive will do better work in a well appointed office that is kept clear of rubbish so will the molder and laborer do better work if they are not compelled to climb over miscellaneous piles of slip boxes, bottom boards, and broken ladles every time they move about the shop.

The second thing which should have special mention here is that of proper instruction for the man newly hired. This is a more personal matter than that of environment. A man may be a good workman even a master of his trade but if he does not know *our* methods of doing work in *our* foundry he may cause any number of accidents to himself and others before he learns. No man should be turned loose alone on a job until he has learned all he can be taught about it. He should know all of its hazards and should be shown how his work is to be related to other work throughout the plant. He will work with more understanding and with a more sympathetic attitude of mind. These have a direct bearing on the question of his making a safe and efficient workman for us. That we believe in this is evidenced by the fact that we all say "we do it the best we can" but we are not thorough about it. We go about it in a haphazard way. One foreman will tell a new man this thing and that thing and the other thing and then some one else will tell him two or three other things and we suppose he has been instructed in all he needs to know. What the man needs is a comprehensive view of the whole organization. The task of giving him this information should be assigned to a definite group of qualified men and the new man's acknowledgment of having received such instruction should be made a part of his employment record.

The time allotted to this paper and its discussion will not permit us to go into this subject as deeply as we might wish. Let it be said that this is just one more of the loose ends that fly about all of our plants. If we

had the vision and the power to gather them all up and weave them into the fabric of our organization we should have organizations so strong that we need have little fear of the ordinary troubles that come to us.

INDUSTRIAL RELATIONS

All of these problems were greatly minimized in the old days when the workman lived in the home of his employer. The complexities of modern life will never permit us to return to this condition but we must approach the ideal of the constant personal contact with our workmen if we would seek to minimize the problems of this our present day.

That there is nothing that is entirely new or original in the subject matter of this paper is well known to the writer. It is only hoped that by bringing these same things to our attention again and again we can be brought to see anew our obligation to those who work for us and with us. There is nothing new to be brought forward in this problem. It is the old problem of the relation between men. We have not entered into any new obligation to our men in this new day of great industrial activity. Our obligation is the same if we have one man or a thousand men working for us. It is that we shall give them all we can of ourselves so long as they are faithful and loyal and continue to give us the best that is in them.

If the repetition of these things which are so well known to some of us has enabled any one of us to see our problem and our obligation with a little clearer light the effort has not been in vain. If it helps any one of us to get away from the running of our business as we would run a machine; or if it helps us to understand the personal element that is in our safety problem and helps us to make the solution of the problem a personal matter for our personal attention it will have accomplished its purpose.

In the absence of the Chairman while giving his address before the A, B, C Section, Mr. W. E. Watters, Secretary of the Metals Section, took the Chair.

ACTING CHAIRMAN WATTERS: In the absence of Mr. Gartland, we may be handicapped in the discussion, but if there are any questions Mr. Vanderpool can answer, I am sure he will be glad to do so.

If there are no questions, we will call on Mr. Earl W. Kessler for his paper.

SUGGESTIONS OUTLINING FUNCTIONS OF SAFETY COMMITTEE

E. W. KESSLER, DETROIT STEEL CASTING COMPANY, DETROIT, MICH.

I wish to take a few moments from the allotted time for the reading of my paper, to express my appreciation for the privilege of meeting with such a splendid organization, and also of representing the Detroit Steel Casting Company as a member of the National Safety Council.

The paper I am about to read contains suggestions outlining safety work as applied to steel foundry practice.

The support of the management is absolutely essential in inaugurating safety functions, and should properly recognize the work by giving it a genuine place in the organization, and best to prove its interest it should be willing to cooperate with the members of the Safety Committee in a frank and open manner; also to authorize the adoption of all consistent recommendations that may be offered by the Safety Committee or that may be otherwise properly presented.

The attitude assumed by the management will naturally reflect upon the employees, and should it be one of indifference then only indifferent results can be expected. The work will succeed only in proportion to the amount of conscientious effort put into it and the more support and cooperation given it the more gratifying and lasting the results will be. This is the first step.

The second step is that of organizing a Central Safety Committee, consisting of the foremen in charge of the various departments in the plant; also other high-grade men in whom the management as well as the employees have implicit confidence in their ability to adopt and practice safety methods affecting the departments under their supervision.

The Central Safety Committee should be a permanent one and its duties should be to outline and supervise all safety work, and to receive and act upon all reports, recommendations, and suggestions. It should meet regularly at least every two weeks for general discussion.

We have another committee in our plant, known as the Workmen's Committee, which is made up of men who are actively engaged in different operations. The duty of this Committee is to report to the Secretary any hazardous conditions affecting that class of work or operation, and especially the careless practices of fellow-employees, and less upon the points of danger to be protected by safeguards.

The Central Committee, which acts upon all the suggestions made by the Workmen's Committee, without any desire to disrespect or belittle its work, has found that in several instances it was not advisable to make corrections suggested by the Workmen's Committee.

This, Gentlemen, is the procedure that we inaugurated in the year 1913 and have continued up to the present time. We have during this period equipped our chippers, grinders, break-off men and acetylene welders with goggles. We have also obtained the best possible equipment for our sandblast men and electric welders. All emery wheels are properly guarded and properly set by one of our mechanics, who is held responsible for the placing or setting of the wheels on the arbors, as there is a possibility of the wheels being broken by careless workmen. This eliminates some of the danger of a wheel breaking while in operation. In our No. 2 shop we have a gang of men pouring hot metal. Previous to the time that we insisted upon these men wearing safety shoes, many of them suffered with burns on their feet. However, since our men have been wearing these safety shoes accidents of this nature have materially decreased.

HOOKS AND CHAINS

The question of hooks and chains was called to our attention at one time, and as a matter of fact there is a good deal of danger involved in their use. It was suggested that we have a weekly inspection of hooks and chains, and that we anneal all chains about every three months, also that when chains are found to be in bad condition, they should be scrapped and replaced as there is no economical practice in allowing a chain to be used in a defective condition. All these suggestions were adopted by the Central Safety Committee.

Of course we all realize that the equipment used in a steel foundry is very different from that of an automobile plant, and other manufacturing plants. In many of the large manufacturing plants in Detroit where methods of safety are in force, every machine is well guarded. Our plant has not a large equipment of machinery, but wherever gears are exposed they are properly guarded.

After all is said and done, however, a large percentage of the accidents in a steel foundry (I was tempted to say a majority of them) are of such a nature that they cannot be guarded against by the installation of guards or the use of any mechanical means which the company can reasonably be expected to install. There is always an element of danger where large weights, such as flasks, molds, castings, etc., are being constantly handled irrespective of whether these are handled by foreigners or native-born men. As a nation we are careless, and nowhere are we more careless than in the safeguarding of our own lives and limbs. In all walks of life we are prone to take chances to save us a minute's time, or something even of less value. It is a part of the feverish pace at which we live. The foundry is no exception to this prevailing spirit, and as long as it exists, though safety devices help, they will not eliminate many of the distressing accidents which are all too common.

One of the most important functions of the Safety Committee must therefore be to endeavor to inculcate in the men a greater degree of caution in their work and a feeling which will decrease the number of chances they constantly take.

A short time ago I talked with a safety man who is connected with one of the large concerns in Detroit employing several thousands of men. He stated that in their plant almost everything had been done toward making conditions safe for the employees, and that their big problem was the slight accidents of which I spoke a few moments ago, and he wanted to know how they could be overcome. My answer to his question was, "It is utterly impossible to employ safety devices to overcome them, as it is up to the employee himself." These slight accidents are caused by thoughtlessness, ignorance, and carelessness. Carelessness seems to be lurking in every plant in the United States, and the only way to get it out of the plant is by spreading National Safety propaganda around the plant trying to impress upon the minds of the men that this is a safe shop, where principles of safety are practiced, and they too must think Safety; and if it were not for constant medical attention many of

the slight accidents would probably result in infections and possibly something worse.

ACTING CHAIRMAN WATTERS: Is there any discussion on Mr. Kessler's paper? It was very good and brought out some very interesting subjects.

[Mr. J. D. James comes forward wearing a sample pair of the spats used in his plant, to show them to the members of the Metals Section.]

MR. J. D. JAMES: As I said a moment ago, we had quite a number of foot burns in our foundry so we tried to get the men to buy foundry shoes, but we couldn't compel them to do that. They claimed they couldn't afford to buy those shoes in addition to Sunday shoes.

PREVENTING FOOT BURNS

The next question was how to prevent foot burns. We designed a sort of spat. They didn't work very well; the string would come off. Then we went a step further and tried something in the shape of a legging. They complained against that and said they were entirely too hot. We couldn't compel them to wear the leggings, so we tried the spats you see on me. We have been using them over two years and we have not had one single foot burn during that time. In fact, before we take the metal from the cupola, every man has his spats on. As soon as we do the morning work and the casting, they get into them. The foremen put them on also, and in that way they set a good example for the men in wearing them.

(A discussion on the subject followed and Mr. James also showed the members of the Section a belt he devised for the use of brakemen.

Mr. Oartel resumed the Chair.)

DISCUSSION

CHAIRMAN OARTEL:—Mr. James has brought up a very good point. Hasn't it been true in the past that we have devised things like this and shoved them at the men? I think Mr. James has told us a better way, the way of moral suasion, of reasoning with a man and bringing it up in a friendly manner? I think if we will do that, it won't be long before we get the men on our side.

I have known of many instances where a foreman with tact has taken things up in that way and by the use of tact and friendliness has converted men to the safety idea who have been radically opposed to it.

USE INTERPRETER TO GIVE SAFETY INSTRUCTION

There is a question I would like to ask Mr. Church. I didn't have time after his paper. Mr. Church, you spoke of a man who would go around among the employees occasionally, a man who could speak their various languages and give them instructions and talk safety to them. What does that man do in your plant?

MR. H. L. CHURCH:—He is connected with the employment work.

CHAIRMAN OARTEL:—As an interpreter?

MR. H. L. CHURCH:—He does other work as well. He scouts out after

the men when they are absent and takes care of the first-aid work, as well as the interpreting work.

CHAIRMAN OARTEL: How do the men receive his safety talks and instructions?

MR. H. L. CHURCH: Very kindly, indeed.

CHAIRMAN OARTEL: I have always taken the attitude and insisted upon it wherever I could, that one of the places we are falling down in our accident-prevention work is in our lack of instruction to new men, and I think this idea is a very good one, and that is why I am interested in it.

In our own company we have a certain plant where they do something along that line. It is one of the hazardous departments—the shipping department—where they load billets, bars and plates of steel that have to be handled with cranes and slings. You men who know anything about that know it is very hazardous—the danger of chains breaking, the danger of not getting a good hold on the load and things like that.

They decided to appoint a man similar to the one Mr. Church has told us about who should have for his particular duty the instruction of new employees. The success in this has been wonderful. So, I wonder if we haven't neglected the new man just a little too much. He has come into our plants. We have given him a pick or a shovel or other tool and he has gone to work.

MR. H. L. CHURCH: We utilize that man also in interviewing applicants who don't speak English fluently. Our feeling is that the average foreigner asking for a job is very ill at ease because he cannot handle the English language fluently. So, we interview the man in his native language. We find that when you get a man on the quiet, he will present his better self to you, and the man who knows the other fellow's language, knows his national culture, too—the national viewpoint of the applicant—and he is able to put himself into the other fellow's place. You get at the better side of the men in that way.

We use that man for instructing the men in the American language and interviewing, also for interviewing these men in their homes in case of sickness or any trouble where we think we can help them. He is connected with the Employment Service Department.

CHAIRMAN OARTEL: Another thing that interested me was your mention of a man who looked up what we call "delayed treatment cases". I think that is a very good idea, in getting them before they develop into very serious cases. How long have you had that in operation?

MR. H. L. CHURCH: I think we started that about the first of March. We started that preëminently to keep a close touch on the fellows who quit. We found the labor turnover high. We found that going to see a fellow right after he quit and before he settled in a new job, if he did have a grievance, we could fix things up. In my paper I referred to that as a by-product. It has been working fine. We intend to keep that feature working as long as we do business on the lines we are now working.

CHAIRMAN OARTEL: I imagine most of you are foundrymen. This is the only foundry program we have and I hope that we will make the best of it. We still have about forty-five minutes before twelve o'clock, so if there is anything that lies close to your heart in safety, speak it out.

These are the occasions when we rub against the other fellow and get his ideas and viewpoints and frequently in that way we get a good deal of good, some ideas that we can take back and put into operation in our own individual plant.

There came to my notice in the last year a foundry case where the State Inspector came in and said they needed more light. That was one of the recommendations. Now, you as practical foundrymen know the situation either in an iron or steel foundry. You have the dust from the sand. You have the dust from the castings, and you know how dim it is in a foundry. But, they whitewashed that foundry and the result was nothing short of marvelous in the increase of light. There was a question as to how long it would last. Of course, the foreman and the old-timers said, "What is the use? It will last a day or two and then it will be in the same condition." But, it lasted more than a day or two. So, I give that out as a bit of information—the case of whitewashing this foundry. I have no doubt that it made more cheerful men.

I see our old friend Dr. Chaney is in the room. Dr. Chaney has been working at the safety game for a long time giving us some very valuable statistics and I know of nothing that would be better than to call on Dr. Chaney at this time to give us a few remarks.

DR. LUCIAN W. CHANEY (U. S. Department of Labor): I thought I was here to listen and not to talk, but called on in this fashion, I can hardly refrain from making the most of the opportunity.

NEW REPORT ON STEEL INDUSTRY IN PREPARATION

I have followed with a great deal of interest from year to year the fortunes of the different departments of the iron and steel industry. Now, this gives me the opportunity to advertise my wares. I am to have a new report on the steel industry coming out this next year. I am very sure you will be interested in following the experience which is shown there, and especially the influence of war times.

We have had the most tremendous upheaval, industrially, that has ever occurred and it has affected our whole experience in the matter of accidents as well as in a whole lot of other things. It has unquestionably affected the foundries. Following the experience of certain large companies whose figures I have had from year to year, I find that during the war period they all went up. Their accident rates were higher than they were before. The foundry is rather an irregular proposition. It doesn't vary so much from year to year in the matter of the number of cases that happen but severe cases do often happen.

You will have some years when you have a very high severity and other years when it isn't so much. The thing which is attracting my attention, and making me wonder, is why the foundry runs along so closely to some other divisions of the iron and steel industry which naturally are more hazardous. I think most of you would naturally think the blast furnace was a more hazardous place than a foundry. Now, as a matter of fact, the blast furnace has dropped a great deal faster than the foundry in the severity of their accidents.

Why are you still killing folks in the foundry? Do you have to? Some of you know that I talked about that subject this morning and I have it on my mind—that is, that the deaths in the foundry seem to be more numerous than they need to be. Where do they happen? Almost all of them in the transporting of material. That is the serious thing in the foundry, judging from the figures I have, that is, you pick up a big mould or casting with a crane; in connection with the operation of the heavy material with which you deal, you are having a considerable number of deaths. During the war, you had more. I don't believe I need to explain to you why you had more. If any of you were doing business then, you know why.

It seems to me that with the readjustment of the industrial conditions, which must come now after we have gone through this war period, there is a chance for a very heart-searching inquiry on the part of you foundry-men as to how you can cut down these dangers and get rid of them.

Your foundry accidents have not gone down as satisfactorily (and this does not mean any particular foundry but foundries in general all over the country) and as rapidly as I think they ought to as compared with other departments of the iron and steel industry. Now, I want you, with the reconstruction that is going on, to inquire into the situation more earnestly and more exactly than you have done.

You aren't going to get at the situation unless you adopt, as we have in the Bureau of Labor, statistics, and some of the accident commissions are adopting some method of following the costs.

You can follow your experience by costs per hundred dollars on pay roll per accident. You can tell whether you are better or worse this year than last year. It is a simple thing to do—to follow the cost. But, if you want to know if you are getting along as well as the other fellow, you have to have some other method of procedure.

Now, we have developed a method of investigating accident costs which we call the severity rate, and if you are familiar with that, it will enable you to compare your own experience with foundries in general. If you haven't given that matter attention as to finding some way of following accident costs from year to year, which will not only tell you what you are doing but tell you how you run in comparison with industry as a whole, you ought to know about it. Of course, I have a certain amount of personal interest in this method of procedure because I devised it along with a colleague of mine, but it isn't a point of whether you deal with it according to my method or somebody else's.

Study your costs, or go into them more carefully than you have done. You certainly have a margin of opportunity which will be disclosed to you by a study of that kind, which ought to help the accident severity more than it has.

CHAIRMAN OARTEL: Doctor, I am sure that if you can get them on their toes and send them back home asking "why," they will get results.

TRANSFERRING MATERIAL

Dr. Chaney in his remarks told us that most fatalities in foundries came from transferring material. Now, what does that tell you? There

are two factors in transferring material on an overhead crane. One is the crane man and the other is the man who does the hooking on. Has any one here had any experience along educational lines with those types of men? Have you done anything to educate your crane men or educate your floor men? I would like to hear some discussion along that line. I don't think we can get, either by engineering revision or mechanical safeguards, anything that will protect us from this hazard of transfer in a foundry.

MR. EARL W. KESSLER: I wish to mention several things that happened in our foundry during the past year, in the matter of transferring castings.

We have found it a very good idea to have a chain man. At different times we had chain men and other times we didn't, I presume owing to the fact that the labor situation was rather acute and we tried to get common labor. But, we always manage to have a chain man who will do the hooking on and then while the load is being transferred, this chain man gives the warning to the men. Of course, it is rather hard to carry a load and not pass over any one, so we always use the chain man to warn the fellows.

Then, when they are lowering a flask, they seem to get their hands under the flask, and it seems hard to impress on the foreign element that they should keep their hands from under the flask. Many injuries occur in that way. The chain man is always instructed to warn these men, too.

CHAIRMAN OARTEL: Mr. Vanderpoll has been requested to tell us something about how they transfer castings in his plant.

MR. VANDERPOLL: We have what we call the main man or the leader and he is to go ahead about twenty-five feet of the tray or whatever the crane is handling, and the crane man has a special gong he uses. We aim to keep men from being under overhead loads. It is hard work but we try to have a crane man who will confine the load to the gangway or that place where the men will not be working.

SECRETARY WATTERS: How do you transfer your material at the other plant where you don't have overhead cranes?

MR. VANDERPOLL: With plain, everyday hands.

SECRETARY WATTERS: How about those mules?

MR. VANDERPOLL: We are now installing the electric tractor. We find they are a big help. Nevertheless, it is more or less hand labor in getting loaded up.

It is not so much hauling the load that causes the accidents but getting the load to haul. Where we have our accidents is on the curves, knocking off the castings by striking gates and other objects.

MR. J. D. JAMES: We have decided that the only way to prevent accidents is to see that the slings and hooks are always kept in good order, and that care is exercised by the man who does the hooking. The road must be clear for the crane at all times.

SECRETARY WATTERS: I would like to ask if anybody here has a system of daily inspection on rope slings, either wire or hemp, and what his experiences along that line are.

MR. WILLIAM RANDALL (Valley Mould and Iron Co.): We have a report turned in to the safety director's office every week giving the number of the chain and its condition. They are either O. K.'d or sent to the shop for repairs. We must have that report, positively, every week.

SECRETARY WATTERS: Is there only one man who makes that inspection?

MR. WILLIAM RANDALL: Yes, sir, we have an expert in that line who makes the inspection on the slings and chains.

SECRETARY WATTERS: Have you any idea of the number of chains and slings you have, roughly?

MR. WILLIAM RANDALL: I judge possibly seventy-five to a hundred.

SECRETARY WATTERS: All sizes, I suppose?

MR. WILLIAM RANDALL: Yes.

SECRETARY WATTERS: Do you make a practice of giving a minimum size of rope or chain?

MR. WILLIAM RANDALL: I am not sure what the size is.

SECRETARY WATTERS: Is it as small as half-inch?

MR. WILLIAM RANDALL: Nothing as small as that. I am under the impression that an inch is the smallest in a cable. Of course, we have some very heavy loads in our foundry and you can't run any risks in handling such loads.

CHAIRMAN OARTEL: While we are talking on this subject, I want to call your attention to the fact that one of the topics of tomorrow's session is "Consider the Crane," and I am sure we will all be very much interested in that.

WEEKLY CHAIN INSPECTION FOR CRANES

MR. A. S. PHELPS (Pratt and Letchworth Company, Buffalo, N. Y.): In regard to this weekly chain inspection: about four months ago we started weekly chain inspection and every chain is numbered with the letter indicating the department prefixed, and the office clerk sends out a report to the master mechanic with a special man delegated to make these investigations weekly. He goes around every Monday or Tuesday. The chains are suspended from the crane, every link is inspected, and defects noted on the report. He is provided with red danger tags and if a link or hook is defective, one is attached to the crane, at once putting it out of service.

When the inspection is completed, one report goes to the master mechanic and one to the office, and that chain is not used until the repair is O. K.'d by the master mechanic. When the repair is made, a notation is made on the master mechanic's report which is then sent to the office.

We have a card index. One side shows the detailed construction of the chain, the size and capacity of the hooks, etc. On the reverse side of the card is the detailed report of the defect found and the notation made by the master mechanic of the department.

We hope from this to learn in what department and what class of chains are failing. That is, in one class you may find a hook continually pulling out. We wouldn't notice it otherwise if it wasn't for this report. It really takes a chain record to locate where some particular hazard is.

I haven't any copies of those cards here, but I shall be glad to send them to any one interested.

CHAIRMAN OARTEL: Have you had any result in accident prevention?

MR. PHELPS: The hookers and the foremen of the department are supposed to make a general inspection of the chains each day but the thorough inspection is made by a practical man each week and is recorded as I have told you.

We have noticed in the annealing department that two particular lengths were failing and continually failing. We noticed the notation on the card and it seemed there was a square type of stool where the chain hooked around and since then we have designed that stool on a radius.

CHAIRMAN OARTEL: That is what the Doctor would call engineering revision.

STANDARD SIGNAL FOR MOVEMENT OF THE CRANE

Have any of you had any experience in educating or instructing your crane men or floor men as to what their duties consist of? It has been the experience of all of us that in transferring a load, several men want to give instructions, and that has often resulted disastrously. I know companies that have restricted the giving of orders to one man. It has brought very good results. They have also designed a card of instructions for floor men which they post all along the floor regarding what the duties are in giving signals and illustrating these cards with the signals to be given. A standard signal has been published, gotten out by the American Bridge Company. The U. S. Steel Corporation is using it. The State of Pennsylvania has adopted it and I think a number of other concerns. It gives a standard signal to be given for each movement of the crane.

AMERICAN STEEL & WIRE CO. REPRESENTATIVE: We have safety rules and we hold what are known as departmental safety meetings. Those are held twice a month. The crane men have to learn these instructions by heart, and then they take them, one at a time, into a room and each one of the crane men is supposed to know these rules by heart. He goes through them every once in a while so he is thoroughly acquainted with them.

Whenever a crane man is taken sick or is absent and we need extra men, we take an apprentice from the electrical department, a man familiar with electrical apparatus. We don't get anybody from the mills.

CHAIRMAN OARTEL: Have you those rules published in a booklet?

AMERICAN STEEL & WIRE CO. REPRESENTATIVE: The rules are published in a booklet but I have no authority to say whether I could give them out. If there are any here who would like to get them, I could take their names and take it up with the higher authorities. In regard to signals, we are using the method mentioned and it is very successful.

CHAIRMAN OARTEL: Is there anything else along that line? Is there anything of general interest to foundrymen?

DR. LUCIAN W. CHANEY: I haven't heard any reference to the careful study by Mr. Earl Morgan with regard to chains, which was published by the National Safety Council and afterwards republished in one of our

bulletins. The question of the safety of the chain or sling used seems to me to be still a very serious one. I continue to have in the reports which come to me from year to year evidence that the chains and the slings which are used are not as good as they ought to be. They break too frequently and when they break, serious and even fatal injuries are very apt to result. Anything that will shed light on the way to safeguard the crane operator is worth while.

CHAIRMAN OARTEL: Is there anything else? If there is nothing else, a motion to adjourn will be in order.

Adjournment.

FRIDAY MORNING SESSION

CHAIRMAN OARTEL: The first paper on our program this morning is by Mr. C. C. Rausch. The topic is "Consider the Crane." Now, my experience has been that the crane is one of the live hazards of the metal industry today and I am very sure that Mr. Rausch, from his wealth of experience, will give us some good information along that line.

CONSIDER THE CRANE

CHESTER C. RAUSCH, ASSISTANT DIRECTOR, SAFETY INSTITUTE OF AMERICA,
NEW YORK CITY

Ever since Noah handled lumber while constructing the Ark and the Egyptians stones while building the Pyramids, the problem of handling material has been present in industrial work of whatever sort or kind. It is not improbable that one of the earliest methods of handling material was by the use of some form of rope manufactured of hide or woven barks passed over the limb of a tree. Later some means was found to use parts of trees that had been blown over, or that had in some way been felled, to construct the simpler forms of derricks. As we know them today derricks and cranes are the result of a development extending through centuries and representing the solution of many problems one after another. Of late years various forms of power have placed at the disposal of man a ready means for adapting his machines to types of work that were formerly done by the laborious efforts of man and beast.

In no particular field has greater development been made than in that of handling and conveying materials in connection with the processes of construction, manufacture, and transportation. More recently the fact that electric current furnishes such a flexible source of power has greatly accelerated this development and in the past decade the enormous increase in the use of steel and iron for the fabrication of structures and objects formerly made of wood has called for a further development of machinery to handle the greater unit weights involved. During the last three or four years particularly the production of cranes of all sorts has increased unbelievably and not only is their lifting capacity greater but

their flexibility of operation and their safety of manipulation as well. Where we formerly saw a braced pole derrick superseding a single stick or gin-pole, we now find locomotive cranes, tower derricks, overhead travelling cranes, gantry cranes, floating derricks, wall cranes, gib cranes, and a variety of combinations of these devices that enable almost any conditions where material must be handled to be met by the selection of a type of crane to do the work and that will at the same time, consume the least power, offer the greatest flexibility, and afford the greatest safety during operation.

During the last ten years the writer has had opportunity to observe the operation of cranes of all types used in manufacturing purposes and in construction work, as well as in those fields that generally are considered under the head of transportation. In spite of the developments that have been made, both from the point of efficiency and safety, there appear to be still a large number of hazards that are reproduced repeatedly in the construction of later models or that result from the manner of their installation or the method of using them. It is to call attention to some of these points and to offer some suggestions by which these recurring hazards may be eliminated that the present paper is prepared.

The locomotive crane is coming to be one of the most common types in use, both in shops and in yards. Unlike the overhead travelling crane, it is not confined to definite limits of operation within a building or over a given yard space but, because of its mobility, it operates equally well within a shop or about a yard. This flexibility of operation considerably eliminates the number of times that a piece of equipment must be handled when it is taken from one location to another. Moreover, the boom forming part of its construction enables it to reach places an overhead crane could not approach. This one feature, probably more than any other, has brought about its introduction in many plants to perform a great variety of work formerly done with the use of rollers, skids, and various sorts of lifting tackle. The locomotive crane is a rather recent development and while its hazards are more or less obvious, there are not as many men available who are skilful in handling this type of crane as there are of other types. The greater skill required in their operation, and their mobility, has resulted in a greater number of accidents from their use.

ROAD-BED SHOULD BE KEPT IN BEST CONDITION

One of the main sources of hazard consists in the failure to keep the road-bed over which the crane must travel in the best condition. Frequently, in an effort at economy, light weight or partly decayed sleepers and second-hand, defective or light rails have been used, resulting in an inconvenient and unsafe roadbed. The failure to keep the road-bed properly tamped and drained allows it to settle and become uneven so that the crane does not travel steadily and is far more liable to overturn. The use of improper frogs, crossovers and switches, and the failure to keep them in repair, increase this hazard. Such a road-bed throws nu-

merous strains into the structure of a moving crane by the swinging motion imparted to the load suspended from the boom. This condition sometimes becomes aggravated to a point where collision of the suspended objects may occur with other railroad property or with structures in the yards adjacent to the track upon which the crane travels. This distracts the engineer's attention so that collisions with pedestrians, trucks, and teams are more apt to occur.

When locomotive crane track-ways are placed too near buildings, especially on curves, the entire attention of the engineer is often required to prevent collision with buildings and in cranes that are capable of considerable speed of movement damage is frequent. Where the crane is large, both in lifting capacity and range of boom and the engineer's cab is located some distance above the ground, this hazard is peculiarly acute. The writer recalls a case where a slow-travelling fifty-ton locomotive crane could pass a building only by being turned on its table at the same time it was moving ahead on a portion of a curve. The corner of a building placed beside the curve was entirely demolished and a considerable portion of the roof removed by being struck by the frame. Another time, while making this turn, the engineer was giving his entire attention to avoid collision with the building and failed to notice an automobile truck standing close to the rails. On a straight track it would have cleared the truck, but caused a collision because the crane was turning on its table. The crane which had considerable power of locomotion, forced the truck against the side of the building, demolishing its entire front end.

CRANES FREQUENTLY OVERTURN

Overturnings are frequent with locomotive cranes. In the smaller sizes the wheel base is extremely short and in many cases the boom is swung with loads beyond the safe capacity for any increased angle of elevation and the crane is tipped on its side when this angle is increased ever so little as a result of even slight inequalities in the road-bed. Even when travelling on a straight track under these conditions and with the boom axis parallel to the axis of the track, slight obstructions on the rail are sufficient to cause disaster because the crane is working practically at its ultimate lifting capacity and its point of safe balance. This type of accident occurs in construction work particularly, because the road-bed is nearly always of a temporary nature and poorly laid. Moreover, on such jobs, supervision of crane operators is apt to be less careful and the material handled less standardized in size and weight, so that overloading is easier and more frequent.

Another difficulty is the inability of the operator to maintain a clear view both ahead and behind his crane while travelling. Inability to see toward the rear when the crane is moving forward frequently results in people being injured when the crane is turned on its table and inability to see toward the rear may cause people or objects to be run over when the crane moves in that direction. Reflecting mirrors, similar to those used on automobiles, tend to eliminate this difficulty, provided the mir-

rors are adjusted carefully and are of sufficient size to afford ample view. In some cranes small windows have been placed low down in the rear of the crane and the storage tanks and coal pockets altered to permit the use of peekholes through which the engineer while standing in his usual place and turning his head can see behind the crane. Even when alarm bells or gongs are used the engineer cannot be certain, without seeing, that an accident is not imminent to material or persons on the track.

Whenever any crane overturns, unusual and frequently very considerable strains are placed on the structure of the crane, particularly the boiler and steam piping which, because of the internal pressure in them are already seriously stressed. Engineers, even if they are fortunate enough to escape scalding or injury when the crane overturns, may be penned in and seriously burned unless the doors and windows on such cranes are arranged to open outward and are provided with fasteners operating from both the inside and the outside.

Many times the original structure of the crane, particularly the boom, has been changed: lengthened to increase its range, strengthened to increase its capacity for lifting. Any lengthening of the boom immediately reduces the capacity of the crane to handle safely loads at a given elevation and an increase of the cable size and strength or an increase of the steam pressure to permit the lifting of heavier loads at greater boom elevations introduces strains that frequently cause collapse. The failure of many crane engineers to recognize the tremendous reduction in the safe capacity of the crane due to any change in elevation has resulted in the collapse of many booms. This tendency to lengthen the boom has been greatly increased by a desire to facilitate the placing of work in locations beyond the reach of the boom as originally made. The writer recalls a number of instances where such changes as this have resulted in death to the operator. It is a tendency that most certainly should be corrected.

SPECTACULAR STUNTS GREATLY INCREASE HAZARDS

If the operator of a crane, and particularly of one that has been structurally changed, is given to the performance of spectacular stunts while operating it the limit of damage is beyond estimate. Speeding the crane along the track, rotating the crane upon its turn-table at such speeds that the load is swung far beyond a point directly below the end of the boom, thus virtually increasing its length in addition to creating a considerable side strain and the dropping of load from considerable heights and stopping it just before it reaches the ground, are performances which the cranes were not constructed to stand, even considering all factors of safety used in their design. The combination of two or more of these performances at the same time may introduce strains great enough to overturn the crane, to destroy its structure, and to injure not only the crane but many structures adjacent to it. Where the crane is elevated upon a trestle the hazard is greatly increased because strains are sometimes thrown upon such a structure that it cannot safely with-

stand them. If the crane falls from such a structure it is obvious that the damage is apt to be tremendous. Many operators overload cranes and take a chance that the crane can handle the load. This tendency is fostered by the fact that the crane is never under the observation of a single foreman but moves from place to place in charge of its operator. While such acts are, of course, matters of discipline, there are several devices which have been attached to cranes to indicate when the crane is at the point of overturning and to give audible warning beforehand. The best devices of this sort are placed in the cab of the engineer and are frequently supplemented by an indicator placed on the boom which shows, by means of a pointer, the safe load that may be picked up for any given boom elevation. This indicator may also indicate safe overhead clearances for the boom. The use of the tables of safe boom elevations for given loads frequently placed on plates attached to the frame of the crane or in the cab, cannot be depended upon because they require the exercise of the element of personal estimation of conditions upon the part of the operator.

Whenever cranes approach obscure corners of buildings, door openings, or other points from which traffic or individuals may issue, the engineer should be under obligation either to stop the crane or to have it in such control that a collision could occur only under unusual circumstances and then in a manner to cause only minor injuries.

Locomotive cranes are frequently poorly illuminated even when they perform their work in places where the operator has no adequate opportunity to see clearly the work he is doing. The placing of several storage battery cells aboard such a crane provides current for adequate light in the interior of the cab for firing and for illuminating the gauges and particularly for a spot light that can be controlled by the engineer and thrown upon the objects he is handling. Very frequently a light placed on the tip of the boom, and arranged to throw its rays vertically downward, has been found of great advantage. Whenever such cranes work at night consideration should certainly be given to these points.

The work done by locomotive cranes is nearly always conducted out of doors and little attempt is made to house them or to protect them from the elements. As a result rust, with all its attendant and subtle hazards, attacks the machine in various places—the cables particularly. Proper painting should be given at frequent intervals, adequate lubrication provided, and the boiler should have regular inspection. Improper feed water may introduce trouble enough to put the crane out of commission.

In the operation of such cranes dependence is frequently placed upon lowering the load and swinging the boom to throw an object upon storage piles or into a location that cannot be reached by the crane when in its ultimate safe position for such a load. The element of time is here depended upon to permit the load to swing into its final place before it can tip the crane far enough to cause it to overturn or leave the rails. Any failure of judgment on the part of the operator is fatal.

Another pernicious tendency is sometimes revealed when the crane is

derailed and a leverage action is created by attaching the boom to the track ahead and by the application of power causing it to lift the rear end of the crane so that it may be swung again to the rails. This is done with the boom in an almost horizontal position and has destroyed cranes by introducing the severest strains to which the crane could be subjected. It is obvious that this can only be done where the road-bed is laid in a manner sufficient to permit such a strain. Recognizing this fact and to increase the leverage the operator endeavors to reduce this strain on the track to a minimum by placing the boom in its lowest position. The housing of the hoisting mechanism and the anchorages of the turn-table are very often torn apart in this manner.

OVERHEAD TRAVELLING CRANES

Overhead travelling cranes have probably received as much attention at the hands of designing and safety engineers and inspectors as any other single piece of equipment. This is probably due to the fact that it travels over areas in which are located many workmen and much valuable machinery and material so that a failure of any part of the crane may bring about disastrous results. A locomotive crane necessarily clears its own way before proceeding so that there is not the same proportion of hazard as in the overhead crane which may create dangerous conditions over the heads of many men without their knowledge. One common fault is the failure to keep the rails upon which the overhead crane travels in proper line both for lateral and vertical adjustments. A slight settling of the rails or a slight misalignment sideways as a result of strains introduced by wind, settlement of building foundations, overloading of structural framework, etc., frequently causes the tracks to assume an extremely crooked appearance. The writer knows of a case where as much as fourteen inches of settlement occurred and where there was a lateral displacement of nearly eight inches. On this particular crane-way loads as heavy as twenty tons were being carried and in order for the crane to navigate at all one rail had been practically freed of all anchorage to its supporting girder and had even been greased under the flange to permit it to slide sideways and so follow the movements of the crane. Struts, with nuts on the end, held the rails from falling off the girder. The eccentric strains thrown on the frame of the building by this condition and upon the crane, due to a swinging of the load which was thrown out of equilibrium by such movements, was considerable and several serious accidents resulted. Fortunately a change in management furnished an incentive to eliminate these conditions. In another case a crane repeatedly jumped the runway rails at one end until the wheels were found to be of different diameters and so made one end progress farther than the other.

OVERHEAD CRANES SHOULD HAVE SIGNS INDICATING THEIR SAFE CAPACITY

Far too many overhead cranes are used without adequate signs to indicate their safe capacity. The writer recalls a case in which a load, so

large that the crane could not lift it, was placed under as much lifting strain as the crane could exert and was then dragged down the length of the shop to its location. Such practices, while they are not frequent, indicate a tendency on the part of the operator to take chances—a tendency probably fostered by his lack of adequate information regarding the capacity of the crane or of the dangers which such treatment introduces.

Wherever the space available in a shop will permit, there should be a free aisle-way from one length of the crane-way to another over which loads may be carried without the necessity of passing over more than a few individuals. There are not many old shops where this is possible but there should be some portion of the shop specifically kept as free as possible from men and valuable material and machines to permit the crane operator to carry material over such a space without any more hazard than is necessary. When unusual loads are carried over such spaces every individual should be made to stand from under the load.

There are many excellent installations of the highest quality of cranes operating over inadequately illuminated spaces. The fact that the operator is a considerable distance above the floor where the attachments to the crane hook are being made and that he must see through a haze that sometimes develops in shops from product being manufactured in spite of proper ventilation only aggravates an already bad condition. This hazy atmosphere might be a permanent or only a temporary condition. For example, a foundry is very often badly troubled with this haze during a pour and a machine shop that may be generally clear will become clouded for a portion of the day as a result of a large babbiting operation done inside the shop or from the wafting of smoke or fumes into the shop from other parts of the building or from out-of-doors. On days when natural illumination varies it sometimes happens that the lights are not turned on during the darker periods so that there are periods of comparatively poor illumination from the crane operator's standpoint.

PROPER ILLUMINATION AIDS THE CRANE OPERATOR

In many shops the artificial illumination is not sufficient to afford adequate vision at any time. It may be far too expensive to increase the general illumination for the benefit of a single crane operator and in such cases, and even when illumination is good, excellent results have been obtained by attaching to the crane trolley one or more lights properly covered with a focussing reflector and so arranged that the area immediately about the hook when at its lowest point and near the floor is brightly illuminated. Such illumination tends not only to assist the crane man to observe what is being done on the floor but helps the crane attendant to make proper attachments to the load. Furthermore, when such a load is travelling down the shop the brilliant illumination throws it into bold relief and it serves as an admirable warning of its approach. In many shops the hook of the crane is painted white and kept white in order that it shall attract attention to itself and furnish some measure of indication to the crane operator of its location with

reference to the floor. Where such a hook is illuminated by overhead lights as just suggested, it is very conspicuous.

In many shops lighting fixtures arranged to furnish general illumination of the floor are, from necessity, placed above the travel-way of the crane. If such buildings have wide spans the crane operator, unless properly shielded by an awning to his cab, is confronted in his view up and down and frequently across the shop with many spots of brilliant and glaring light that serve to confuse his vision. In some shops this general illumination from above the crane-way is augmented by lamps having angle reflectors, and too often no reflectors at all, placed just below the crane runway. When operating the trolley on the far side of the shop these lamps throw a steady stream of light into the face of the operator, seriously confusing his action. Such lamps should be shielded from above with reference to any position the load to be observed by the crane operator must assume.

A person making an examination of any considerable number of overhead travelling cranes is impressed by the fact that so many of them have none of the electrical equipment in the cab properly guarded. There are exposed contact points, circuit breakers, knife switches and terminal lugs carrying from 110 to 500 volts or more. Contact with these exposed points may not only kill a crane operator but may temporarily incapacitate him so that his crane continues its motions uncontrolled. The use of the simplest form of shields or guards composed of asbestos, wood, sheet metal or other material are not only easily applied but inexpensive. The possibility of serious accident in the movement of an uncontrolled crane is sufficiently great to require ample protection for the crane man and new equipment should be specified to have only back-connected control panels and inclosed resistance grids.

Many cranes have practically nothing more than a hand rail to keep the operator in the cab. During his slack moments, when he is comfortably stretched on a box, stool or bench, any lapse of consciousness would permit him to shoot under this rail and fall to the floor below. There is no reason why the crane should not be enclosed to a reasonable height with grillage to prevent such an accident and in a manner that need in no way interfere with the craneman's vision or movements.

REPAIR DECK SHOULD BE PROVIDED

Cranes, like all other apparatus, require occasional repairs and continual maintenance. It strikes one as almost criminal to note the lack of any adequate repair deck over which the crane may be housed and from which oiling, adjustments and repairs may be safely performed. There is scarcely a condition in any shop where such a deck cannot be provided in one end or the other for at least a portion of the width of the crane span. Although there are many heavy parts used in the construction of the trolley of a crane, no provision is made for a small wall crane or a travelling chain hoist to assist in this work. Many times repair men are exposed to serious hazards from falling on account of this lack. It is not infrequently the case that the bottom

chords of the roof trusses are used in making repairs and at such times they are subjected to strains which they were never designed to withstand. Workmen are frequently called upon to make crane repairs after dark and to use electric drills or soldering irons in connection with their work. The placing of a few plug receptacles for the attachment of portable extensions to make connections to these tools would greatly assist in this work. Such provisions should be made as parts of a repair deck.

Most cranes are now fitted with an over hoist or over travel stop that automatically arrests the upward travel of the hook and its load if the operator fails to disconnect the power of the hoisting motor as the hook-block approaches the hoisting drum. On large cranes that handle heavy loads the hook travel upward is slow and in many cases the part being hoisted requires a maximum upward travel of the hook. Crane operators have been observed to turn on the power and calmly wait for the load to come into contact with the over travel release, thus disconnecting the motor. The fallacy and danger of such operations are evident and should be matters of strict discipline.

Every crane requires its cable to be lubricated to prevent wear from friction and destruction from rust. While such lubrication accumulates grit and dirt in some shops the advantages of the lubrication tending to give long life to the cable more than offset the damage which this grit may do. The lubrication of the cables is sometimes accomplished by a man standing on the trolley who applies the grease as the cable is wound up. Sometimes the cable is all wound up and the top half of the drum properly greased. The bottom half is then greased after the drum has made a half revolution to bring the ungreased cable into an upward position. The writer recently saw a very clever greasing device which could be temporarily attached to the top of the hoisting block in such a way that an arm holding collar made of soft wicking could project out and surround the cable. This arm was connected with a tank supplying grease in such a way that the cable, by passing through the collar, became properly lubricated throughout its entire length.

PROVIDE MEANS OF ACCESS TO CABS

In view of the present knowledge concerning crane operation it seems rather trite to mention the fact that so many cranes are operated without a safe or convenient means of access to their cabs. The daily exposure of operators to falling, to contact with live wires, or to being overcome by fumes or gases while climbing to their cabs is considerable. It would seem the part of wisdom that not only new structures, but old structures as well, should be equipped with either a properly enclosed ladder or an adequate stairway from which the cab could be reached with a minimum of danger.

Overhead travelling cranes, and locomotive cranes to an increasing extent, are handling material by means of electro-magnetic lifting devices. These are so ruggedly constructed that they will withstand almost unlimited abuse. The only weak link in their safe operation is the cable

connecting them to the source of power or the power supply itself. Usually the source of power is sufficiently reliable to make failure only a remote possibility. The cable, however, is subjected to all manner of rough handling as a result of following the movements of the magnet and from its contact with the ground, material being handled and, sometimes, with the devices that are used to keep the slack of this cable from fouling itself with the boom. One of the best solutions of this difficulty has been the adoption of a cable which can follow the magnet in the same manner that the lifting cable follows it. If this cable passes over a suitably grooved pulley at the tip of the boom, or on the trolley drum of the crane, and is so arranged that a counterweight will carry the slack down the boom or that it will wind up on the drum of the trolley most of the wear can be avoided. Suitable electrical connections can be made by means of contact with a sliding bar or with a rotary collector ring on the trolley winding drum. A proper application of this device will not only result in longer life to the cable but avoid all damage due to kinks, cuts, abrasions, and strains.

One may still find a tendency to overload crane hooks. While the hazards created by the improper use of chains is well known, and may result in careful handling of them on the part of well informed operators, there are still a considerable number of floor men who introduce strains in crane hooks which it is impossible for them to stand without serious deformation or breaking. In handling some objects several chains are used so that the mouth of the hook is filled and attachments are made to the very tip of the hook in such a way that a severe side bending strain is introduced in addition to the lifting strains introduced by the chains hanging at the bottom of the hook.

NEGLECT OF CRANE REPAIR AND UPKEEP

The inconvenience attendant upon work performed on overhead cranes and the failure to provide convenient platforms from which to perform such work, has resulted in much neglect of crane repair and up-keep. One of the most noticeable defects is an increase in the amount of play and back-lash that is allowed to develop in all parts of the structure, particularly in the gears. When this is excessive and the gears pound badly, the starting of the motor or its reversal from a raising to a lowering motion introduces strains on pinions, shafts, keys, and other parts sufficient to cause much damage. This wear is very often due to the fact that adequate lubrication has not been furnished because access to the oil and grease cups has been difficult and the person responsible for maintaining the equipment has neglected to do his work because of the difficulty of getting at the places where it must be performed. In some cases this condition has been helped materially, and even overcome, by the use of oil cups or compression grease cups serving all parts of the crane and so located that they can all be reached from the crane walkway. It then becomes necessary only to go with an adequate amount of grease or oil to the several conveniently located cups to keep bearings adequately lubricated.

Gantry cranes, wall cranes, and other combinations of hoisting apparatus capable of operation in one or more directions, each has its particular problems, but they have been covered by consideration of similar conditions that occur largely in both locomotive and overhead travelling cranes. There is probably no piece of apparatus that does more to facilitate easy and convenient work than do these various types of cranes and it seems strange, when one considers that so much has already been done to make them safe, that there still remain so many obviously dangerous points at which they could be improved, not only to facilitate their speed of operation but to reduce materially the hazard to the operator himself and to those adjacent to the movements of such cranes.

(This paper having been printed in advance, Mr. Rausch with the permission of those present waived its reading and opened the discussion with incidents illustrating statements made in the paper. He said in part:)

STUNTS OF CRANE OPERATORS

MR. RAUSCH: One thing I have noticed is that men operating cranes become obsessed with a psychological reaction of their work. They find there are certain things they can do with the crane. They can allow it to run freely before it is brought to a stop. They can let it take a load up quickly, and so on, and after a time that becomes such an obsession that they endeavor to do stunts, and that has introduced a number of accidents.

I recall one case where a man was severely reprimanded several times in the operation of a tower crane that was handling steel construction plate for ships. You know, most shipyards are exposed to considerable and very high winds, perhaps more so than places where cranes are operated between buildings and the wind does not, therefore, get a large sweep. This man wanted to depend on the swinging aspect of the wind and to control by the force of that wind rather than to take the time and allow guides in the control action in the wind.

Now, a plate four feet wide and from eight to ten feet long presents a considerable area and the wind exerts a considerable force against it. Those of you who have attempted to swing a large barn door know the effect. That man was accustomed to do that. The result was that one day the sling instead of swinging in a uniform way got a gust or pocket of wind and the plate swung in such a way that it freed itself from the clutch. The clutch may or may not have been in good condition, but the plate under the action of that wind apparently swung in such a way that with the lowering effect, it broke loose. That may seem an exaggeration, but I think you men can appreciate that with a rapid lowering of the plate in a sudden gust of wind, the hook was freed and the plate came down. Fortunately, the only damage in that case was to property and not to individuals. That is one illustration.

In another case, an attempt was made to swing the bucket and at the same time carry it over the limit beyond which the crane boom itself could operate. That was done with the knowledge of the construction manager of the particular job because he would not take the time or

expend the money to move the rail over. Subsequently it was necessary to erect a derrick to supplement the action of the crane.

I wonder if anyone in the audience has had a similar experience with motions of cranes, due to winds or to centrifugal swinging or other forces that have caused the cranes to drop the loads or overturn or break in some way so as to cause damage.

— — — — —
LACK OF CONSIDERATION FOR NATURE OF THE WORK

One thing in construction work I would bring to your attention. In many plants the crane is taken off for a portion of a week and put on construction work. It is all perfectly well with a man familiar with cranes under regular condition, but when you take this crane down, you may change its boom length, you may alter it in some way to handle the drums of a boiler or a long piece of shafting or some piece of equipment.

I recall one crane used in a cotton mill to handle tiers. A tier is a big kettle from ten to forty feet in height. They used that crane to handle those tiers and they used their regular operator. The regular operator had very little to do. Practically all he had to do was unload coal and occasionally small loads from flat cars. The rest of the time he spent reading in his cab until called for. This day he was called was following a Saturday of rather strenuous unloading of coal. No one took the trouble to indicate to the crane operator the amount of load he was handling. He was judging the load on the fact that the tiers looked fairly light. They were hollow. They were nothing but a light load from appearance, yet it happened because of the construction and the chemicals used in them, in which case a certain plate had been used, he failed to take into account that the tier was about twice as heavy as it appeared. The result was that when he reached over the hole in the roof, the crane tipped forward until the hook rested on the edge of the roof and the result was one of the tiers was badly damaged.

Practically such accidents are due to the lack of consideration for the nature of the work that the crane was to do.

I recall one time the need for requiring an engineer to make a study of the crane that had been in use. It was presumed that that crane had been examined regularly and frequently. Ample lubrication apparently had been provided. The cables had been renewed. At proper intervals other repairs had been made. I don't know why I had the feeling, it may have been a plain, ordinary hunch, but I felt that the crane should be gone over. The result was the main block was found to have a sheave pin, normally an inch and a quarter in diameter, which, because of improper lubrication, had worn so that the thickness of the sheave pin was less than my little finger: and that was to take about twice the usual lifting load. I don't know what would have resulted if the examination had not been made. It is presumable it might have been taken up a short distance.

That only brings to light this point in operation: it is necessary to make periodical examinations. It is frequently well to have a man not concerned go over it in an unbiased way and check up every point. One would presume a worn sheave pin that had worn down to that extent

would have been observed. It happened that concurrently with the wearing of the sheave, the lip of the sheave had also worn and that had misled the man. There are other parts of the crane vital to the suspending of the load and those frequently are badly worn.

ILLUMINATION IN RELATION TO CRANE OPERATION

Another thing I have noticed in cranes is the failure to consider the crane operator from the point of vision. To place a crane operator in a cab over a load is to presume that he has an excellent opportunity to oversee what is going on when the reverse may be the case. You know, as I mentioned in the paper that it is a custom to provide more brilliant illumination in the shops. It has been a custom to insert in the old receptacles lamps of higher candlepower and much more brilliancy, and very often the crane operator has been the victim. I could mention several plants where that is true. The crane operator is obliged to look into extremely brilliant and high powered sources of light. Those can be shielded ever so little, without reducing the illumination, and give the operator a position from which he can work in comfort and with no trouble whatever.

The most successful arrangement for illuminating the object which the crane is handling that I have seen is one that has been evolved by two of the men of the Brooklyn Navy Yards. I don't know just who was father of the idea. That is to place a concentrated focusing shade with a high-powered light on the trolley of the crane so that it throws a flood of light on the object and on the block itself, thus furnishing illumination as they do on the policeman on the street crossing at night. In that manner, there is an area of brilliant illumination in which space the crane tender is able to operate. That also serves to illuminate the load when it is raised and lowered and serves as a warning when it is moved up and down the shops.

If, on the other hand, the block itself is painted white or black and white stripes, it then serves as a warning, particularly if illuminated in this way. You know, the average shop becomes uniform in color. On the other hand, if the block is properly painted, at day and night as well because frequently you have clouds in the day time, you will have very little difficulty of a block striking objects. That is beneficial to the crane operator. Many shops have planers, boring mills, presses, and other machines so situated that the load must be carried over them. I have in mind an accident where the crane operator gave as the explanation the fact that he could not see with sufficient clearness to distinguish the block from the general tools and walls of the room so as to raise it to clear the equipment.

I could think of a dozen other points along the same line as possible points to which some of you men, although you may be interested, had never had your attention drawn.

MR. G. G. KINGSLEY (Halcomb Steel Company, Syracuse, New York): I would like to ask if the men at the Navy Yards had any experience in regard to the life of the lamp that was focused for direct illumination?

MR. C. C. RAUSCH: I am glad you mentioned that point. It is a point of omission on my part.

It is necessary to so suspend the lamp that the vibration of the trolley as it travels, or in the turning of the drum, will not jar the lamp. The present-day lamps are pretty rugged but they will not stand an undue amount of jarring. It is necessary to make the suspension that the major portion of the shock will be removed by absorption. That can be done by suspending the socket on little piles of felt washers because they will pack down and yet absorb that little extra vibration that destroys the filament.

MR. G. G. KINGSLEY: The reason I asked that is because in our crane illumination in our melting shop where the atmosphere is hazy, we have suspended three lamps fastened to the end of a conduit along under the bridge walkway and it has been our experience that the life of the lamp is very short due to the vibration of the crane. We are just about to install at the end of the conduit a spring and allow the cable to run through. It will be giving the lamp sufficient space to take up that vibration.

MR. C. C. RAUSCH: It is surprising how little absorption in the way of shock absorption is necessary to have the filament in an electric lamp.

Even a single washer will absorb the shock sufficiently to save the filament. Your electrician, if he is aware of that fact can easily provide against it.

Mr. Lewis of the McKinney Steel Company, I believe was to punch the legal holes in my argument.

MR. O. J. LEWIS (McKinney Steel Company): No comment is necessary. I believe on the comprehensive consideration of the crane.

From our classified statistics, we find our crane accidents are more in connection with the appurtenances to cranes, the cables, the slings, and the chains; so, in order to get this under way, just let me touch on points that relate to the operation of the crane in that way, and it will be my experience in a steel plant, the open hearth, the rolling mills, and the shops connected with them.

We found that one of the things causing accidents was the lack of uniformity of signals, and we found that standardizing the signals adopted by the National Safety Council, illustrated in that way and posted throughout the crane cabs, was the starting point of our uniformity of operation.

We found the use of handles on the hook to be one of the most important things we have had. Hooks should not be welded. They should be forged.

We are still waiting for an efficient limit switch. I think the limit switch contributes to our accidents everywhere. We had a case the other day where the limit switch was placed very high. By the very nature of the work the limit switch must be placed high, and in running the switch, the momentum of the crane runs along and causes an accident.

In our analysis of the classification of accidents, classified under the headings of hooking or unhooking, struck by load, falling loads, we find a large percentage due to the process of hooking and unhooking. We have found more effectiveness in the use of uniform signals, avoiding the use of several giving the signals, especially in the changing of loads

where men are ready to lift. The best way to learn the lesson is to travel with the crane operator.

Just one more point: It is rather far-fetched from the operation of the crane and yet it has a bearing on it, especially in view of its serious consequences. It is the wearing of the trunnions on the steel ladle due to the tilting of the ladle. There is a heavy abrasion there that involves the strength of the trunnion and brings about the necessity for closer inspection on what might be considered merely a break or crack. That is deceiving, and should lead to the systematic and efficient inspection of ladle trunnions. That is a point I have had in mind and if any one has a system of scheduled efficient inspection, I would like to have it.

CENTER OF GRAVITY

MR. C. C. RAUSCH: There is one point that has occurred to me, brought about by this suggestion. Crane operators, crane signal men, and floor men are not men who really appreciate just what is conveyed by the idea of center of gravity. I don't want to introduce any technical discussion here but if a crane operator or a crane floor man could for once and for all be absolutely familiar with what is meant by the actual center of gravity, probably 95 per cent of the accidents due to the tipping over of loads would be avoided, and if to that knowledge he could add this fact, I am wondering if it would not be worth while to educate crane men, to take them by themselves, and demonstrate to them by picking up various objects. Show them how to pick up an object when supported by different points. For instance, you can pick up a roll in a sling and you know unless the sling is held perfectly in the middle there is a tendency to slip, or if it is not held by eyes in the hook so it can't turn you know perfectly well it will assume a position so that it finally comes to rest with the center of gravity under the hook which is the point of support.

You can pick up a tank or a crooked piece of structural steel so that the point of the center of gravity of the object is apparently supported without the object. Or, rather, the center of gravity appears not to be in the object, and in fact is not.

A crane man will learn that by experience but if you can take a crane man aside at the beginning and tell him, and illustrate by photographs, then he will eliminate those accidents due to picking up an object and swinging it along the floor rather than carrying the crane to pick up the object directly over its center of gravity, or move the crane in such a way that the object can be picked up without changing its location.

I have photographs in my office of an accident where a man was cut completely in two in a case where a transformer was lying on its side and was picked up by the ears on the side of the case, and at a certain point the friction of the end of the case and the concrete floor was such that the pull on the crane was sufficient to slide the thing against the wall, and the man was caught. I venture to say that every man who has seen a crane in operation has seen that tendency. When once a man gets that firmly in his mind, it is a thing apart from him and unconsciously he will govern his crane and so attach his slings to the load and bring

the crane over the general center mass of that body, that there will be no accident.

Now, that suggestion, if carried out by the man who will take the trouble to get his crane men and floor men and illustrate so fully that it becomes clear to them, will have cleared a point that has caused deaths and a great many accidents and much destruction of property. I am sure that is familiar to you all and only needs to be followed to more logical solution to avoid that sort of trouble.

CHAIRMAN OARTEL: We have overrun our time on this subject, but I think it was worth while, and am sure if I have anything to do with the Metals Section program next year, we will have Mr. Rausch speak on the center of gravity in connection with crane lifts, and perhaps have him illustrate in some way or demonstrate with an operator. Because as a practical mill man, I know how vital that point is.

To carry the point of Mr. Rausch a little further, have we not been preaching theory in our mills and factories when we should have been demonstrating things to our men?

The next paper was to have been given by Mr. H. P. Heyne, Safety Inspector of the United Alloy Steel Corporation, but we have a telegram informing us that Mr. Heyne is ill and unable to be present. So, the paper will be read by Mr. O. N. Toner of the National Malleable Castings Company.

NEW WAYS TO PUT SAFETY ACROSS IN A STEEL PLANT

H. P. HEYNE, SAFETY INSPECTOR, UNITED ALLOY STEEL CORPORATION,
CANTON, OHIO

Each establishment should have its system of shop discipline, but there are ways in which the employees can better inform themselves regarding what is expected of them, through the inauguration of a systematic program for conducting the work.

The new way to put safety across in any plant, is to meet the problems with a better understanding of affairs, and an assurance of fairness between the foremen and the employees, which should furnish the material for erecting the foundation for the coöperative spirit which the coming era is ushering in.

The two factors which bind men together are fellowship and good-will, based on mutual confidence. These are indispensable in attaining unity of purpose on the part of all for the welfare of all.

COÖPERATION

The spirit of coöperation brought about the desired results in the war. It will be found necessary to promote this same spirit in all lines of endeavor, and to direct our efforts toward minimizing the economic loss by teaching the elimination of waste and increasing human efficiency, which may be accomplished through advancing the average man's ability.

We are entering into a new age, and our advancement depends on enthusiasm and coöperation in industrial, social, and spiritual activities.

We must eliminate all forms which may not be in accordance with what is just and of good repute. Not until we can trust each other without being skeptical, shall we have made a great stride in the progress of humanity. A truthful person, one who can be trusted under all circumstances, surely is an asset to any community.

We should unite and maintain the forces of progress as they were united in war, and stand for construction and development of world welfare against demolition and retrogression.

We are living today in a changing era, and tomorrow will bring an advanced period in evolution, which means that more thought and action must be directed to the moral and intellectual side of life. The subject of living on a better and higher plane where all may come to a better understanding, should be taught and discussed, in private and public gatherings, so that the proper seeds may be sown in all directions and our efforts prove productive.

OUR SCHOOLS

We must get encouragement through our schools, for they are the greatest factors in the making of the future. Institutions of learning have devised ways and means for advancing education, through making the studies interesting and teaching as much as possible by facts. Pupils should be taught the right things in the right way, for many fundamentals have been neglected. There are many conditions, today, which might have been prevented had the persons been properly taught. It would not be amiss to direct our efforts to the end that all humans would be better and cleaner, through banishing all evil and destructive habits and customs. We have accomplished much through coöperation, fellowship, and efficiency; but there still remains a large area to be cultivated.

FOREIGNERS IN SAFETY WORK

Let us not disdain nor ignore one another, regardless of our so-called station in life, for we are all members of the universal family, and should assist our less fortunate brothers.

In our several departments where the workmen have little or no knowledge of the English language, we appointed the more enlightened foreigners on the mill safety committees, through an interpreter who explained to them just what was expected of members of the safety committee, and also that the safety committee button was presented to them in recognition of their ability in promoting safety among their fellow employees.

The committee button turned the trick, for the men felt that they were being considered, in assisting us in the work. The number of lost time injuries (those extending beyond balance of the working turn) was reduced 14 per cent for the first half of 1919 as compared with that for 1918 (our reduction in 1918 as compared with 1917 was more than 50 per cent), which was partially accomplished through getting the foreigners more interested in safety work. In other words, these fellows had a greater chest expansion. However, we made it clear that they must approach their fellows in a proper manner, otherwise they would

not obtain their cooperation; and we made them feel that they were safety investigators and were considered a part of the safety organization.

The safety button is a badge of an accident preventionist, and must not be construed by the men as having any authority invested in them, other than to signify to their fellows that they are safety investigators. The button which, of course, was not presented until after the men had an understanding as to what was expected of them, had a good psychological effect.

The personnel of our Workmen's Committees up to June 30, 1919, was composed of foreigners to the extent of 12.6 per cent, and they have shown quite an interest in safety work. (Members on Workmen's Committees, 339 Americans and 49 foreigners.) Why should not the foreigners be considered the same as the Americans, for an injury is an injury, regardless of race, color, or creed? The foreigners are a part of our working force and should receive consideration at least to the point that they are human beings.

ACCIDENT STATISTICS

Accident statistics should consist of simple summaries and charts, which enable the executive, by brief reference, to know the present condition as compared with a preceding period. Without the records, it is difficult to determine the degree of progress.

We maintained records of injuries from different angles; including the classification by departments, occupations, and by foremen. The reports were furnished the foremen so that they could study the conditions and get after the "high spots." The report indicating the injuries to men under the various foremen, shows at a glance the foremen's accident standing, and gives one something to work from when approaching the foremen, by comparing the rates with others who have a better classification.

This scheme created and maintained the competitive spirit among the foremen, and made them talk and practice safety.

THE FOREMEN

One of the important duties of a safety engineer, is that of keeping the foremen interested in accident prevention work, which means the changing of plans from time to time, so that their enthusiasm may be maintained.

The safety engineer should always be on the alert for articles dealing with accident prevention, and to distribute the information among the department heads and on bulletin boards, as the dissemination of the proper kind of information will manifest itself in a manner whereby the safety movement will be further advanced and receive the recognition to which it is entitled.

The service bulletins, issued by the National Safety Council, may be put to good use by distributing the messages among the foremen, as these bulletins may show up some of their weak points, and cause them to think.

We get our foremen to read the bulletins together with other material, by attaching a circular letter to the papers, which they sign and pass on to the one whose name next appears on the list. The file is returned to

the office after having made the rounds. In other words, we have a record of the papers having been read, and the psychological effect which the signing has upon the foremen. In cases of instructions, we give each foreman a copy for his file.

ACCIDENT INVESTIGATIONS

Too much stress cannot be laid on that section of safety engineering which deals with accident investigations, as corrective measures or methods are the outcome of the results of the investigations if they are conducted in a thorough and impartial manner.

Each accident involving lost time should be thoroughly looked into, together with injuries where no time was lost, but which might have been serious.

On the more serious cases, we interview each witness to the accident, so that we may get at the root of the trouble. The witnesses make affidavits to their statements before a notary in our department. The injured employee's statement also is taken, so that we have full information from both sides.

When the statements have been secured, a meeting of the investigating committee is called, which is composed of the department superintendent and foreman of the division where the accident occurred and the members of the safety teams. The information is gone over, whereupon the committee renders an "Investigation Report," which is signed by the members of the committee. The report brings out the results of the investigation as to what or who was to blame for the accident, and makes recommendations with the view to preventing a recurrence.

A copy of the witnesses' statements and the committees' report is forwarded to the General Manager, General Superintendent, and Department Superintendent. A copy also is retained in the permanent files of the Safety Department.

The time consumed in drawing up statements in a business-like form, and attacking the accident from various angles is well spent, in that each case is recorded in a detailed manner for future reference; and the psychological effect, which the investigations have upon the men, in time results in a reduction of injuries, and an economic saving to the employer.

PSYCHOLOGY IN SAFETY WORK

When a proposition is to be offered, it would prove advantageous to take the matter up with the persons concerned and invite their suggestions, for they might have something to offer which would prove practical and beneficial. At the same time their having been consulted would have a good effect on the men, which leads to cooperation in the work.

When a person is having a hard time and comes for sympathy, it is best to recognize his sufferings and find some word of encouragement. Then again, when one approaches with a message of his good fortune, try to share it with him in a sincere manner. This is human engineering, and will assist in a proper understanding and the binding together of individuals with a proper feeling and interest toward each other.

Supervisors should not criticise employees without first having made

an investigation, and then it is not necessary to ride "roughshod" over them, but give them an opportunity for an explanation, as a correct interpretation may clear the situation.

After all, what have we gained by following the method of "Rawhiding"? The men become dissatisfied, which affects their efficiency, and upon the first opportunity they will leave the service of the company; this necessitates the "breaking in" of a new man, which results in a loss of production, with greater liability to accidents, as well as increase in the labor turnover.

Every one desires cooperation in the work, and if the supervisors are considerate but firm, they will be successful in having the men work *with* them instead of working for them.

SAFETY ENGINEERING

Safety engineering might be called the study of human nature, which will be one of the important business principles in the future, and is worthy of serious thought.

One quality which plays an important part in safety engineering is the habit of being courteous, by simply saying "Please" and "Thank You," and bidding the time of the day; just a mixture of good manners and kindness. It produces sunshine on the cloudy days; its presence cheers a person and puts him in a better mood.

We can assist each other by being friendly, and our friendliness will be reflected among our acquaintances, who will become friendly in spite of themselves.

A safety engineer should be an example of good-fellowship,—to the extent where he needs an adding machine when he starts to count up his friends.

Safety first is applied common sense—it is a service of unselfish usefulness—for there can be no efficiency without common sense.

DISCUSSION

CHAIRMAN OARTEL: Is Mr. Darr of the Cambria Steel Company here? As Mr. Darr who was to lead the discussion isn't here, we will throw the matter open for general discussion. I am sure you gentlemen have tried out a few new stunts. You aren't up-to-date Safety Engineers if you haven't because my experience is that we have to keep bringing in new ideas from time to time.

Is Mr. Claude Smith in the audience? We would like to hear from you, Mr. Smith.

MR. SMITH: About the only new stunt we pulled off in the last year was a couple of months ago. We, the same as everybody else, ascertain what departments and what gang have few accidents and in order to reward them, we give them publicity. During the last year we have taken photographs of those gangs (eight by ten, mounted on ten by fourteen-inch cards) and given them to each man. Of course, you cannot get a department of several hundred to swing that stunt.

We get these men together, take their photographs, give them a little

talk on safety, and then publish the photograph in our safety bulletin, which gives them the publicity and honor for their achievement. We then have enough printed, and paste a letter on the back congratulating the men and expressing the hope that they continue their record, and that every one in the photograph will never be injured through neglect or carelessness. The photograph has a value to the men because every man likes to get a picture of the men working with him in the gang. We have found this has been a very popular undertaking for getting the cooperation of the men in connection with accident prevention.

Another stunt we have worked this year in departments where we have had rather a hard struggle in getting a good accident record is to hold a raffle of a gold watch. Of course, every one in the iron and steel industry knows I am strong on prizes. We work new stunts continually. For instance, on our plant number one we had a difficult time to get them down to the right kind of accident record, so we decided to hold a raffle in that department. Our plant interpreter took out cards with printed numbers on them. There was a detachable stub with rules to prevent accidents on the reverse side. Each man in the department was given a stub which entitled him to one chance on the gold watch. In that way the personal element entered into it because we saw each man and gave each man a card. His support was assured because in order for him to have a chance to win he would have to get through the month himself without having a lost-time accident. The department would have to get through without having any accident of more than seven days lost time. This department got through the month with a splendid record and a man from the pit won the gold watch.

When we awarded the watch, the men gathered around and we gave a safety talk. That can best be carried on in only one or two departments in a month.

Another thing we have done is to make use of blackboards on which to draw cartoons on accident prevention. We now have a blackboard about four times as large as the average bulletin board located in each department near the bulletin board. Our inspectors draw pictures on those bulletins twice a week. We draw up the design at the office; they draw them for the boards as they go around the plant. We don't have the same design on all the blackboards, but have a dozen designs ready. That seems to get a message to the men. They go around the blackboard and discuss in their own language what the picture means. That is a good educational stunt.

MR. PHILIP STREMMEL (National Enameling and Stamping Company, Granite City, Illinois): This is a very important subject and there is a great deal of thought in it—"New Ways to Put Safety Across in a Steel Plant." Now, there are a number of ways to put it across but there is only one way to put it across as it should be done.

THE QUESTION OF GIVING PRIZES

I have just heard the gentleman preceding me say something about giving prizes. I object to the giving of prizes to any man for the doing of work in any plant.

I have been a Sunday School Superintendent for twenty years, and I have always taken the position that no child should be rewarded because it is a regular attendant at the Sunday School. Are you educating the child to come to school or to get that which is fundamental in life? So it is in the safety game. Are you giving the safety work to these men, and getting them on these committees, and interesting them for the purpose of securing that prize, or is it for the purpose of interesting them in safety?—

Now, in our plant, the one thing we are trying to do is to impress upon the men of our plant that they have certain responsibilities resting upon them and that they must answer in the affirmative that they are their brothers' keepers, and from that standpoint, Mr. Chairman, we should present our safety program, not for the sake of prizes, or using them as a means to inspire men to become interested in safety, but to make them feel that it is a part of their job to be interested in safety. In the first place, it is for their personal benefit and they are doing the bigger thing. They are doing the humanitarian thing when interested in it in order to protect the other fellow. It is a mutual proposition.

There is nothing new in putting safety over in a plant. It is the old, old story of self-protection, and for the other fellow.

For example, we have meetings in our plant in such a way that the men want to come to these meetings. We have the meetings in a way that the men receive a vision of the responsibilities and the advantages of safety and they do not ask for any prizes.

When I took charge of the safety work, they were offering all sorts of prizes and I immediately cut it out. I want to say to you (I don't say it egotistically or because I have charge of it, either) that we are today accomplishing more along the lines of safety in our plant than ever before. Why? Not because we do it differently today than ever before but because we are constantly, through bulletin boards and other means, keeping before the men that they are their brothers' keeper, that there is a responsibility resting on them and that they have a duty to perform. By that means, from the smallest man up we have been able to put safety across in the plant without awarding any prizes.

In our last meeting we had a group of motor truck boys. One day a boy who does not operate one of these trucks, while it was standing alone, started it up, running into a man and breaking his leg. So, we got this young man and brought him into the safety meeting. We also brought the motor truck boys into the meeting and we discussed the question. After it was over, twelve of the motor truck boys asked if they could be members of the safety committee. We said, "Sure." It is amazing how careful those boys are operating the trucks today. They are not joy riding today as we have previously caught them. We do not caution them any longer because we brought the man whose leg was broken before them and it was an object lesson for them.

If you use the method of demonstration, bringing these things home vividly and constantly, getting them to realize that they are their brothers' keepers, I assure you, you need no prizes, no new fangled things to

put safety across because the average man has intelligence enough and there is a desire in his heart, not only to protect himself but the other fellow and home and loved ones. I think, that while some try this thing this way and that, there is only one way fundamentally.

MR. R. C. SALISBURY (Interstate Iron and Steel Company, Chicago): I do not see the comparison or advantage of comparison between the Sunday School boy and the foreign element, that is, in the teaching of the two. Mr. Stremmel hasn't outlined any specific plan or approved any other medium than the safety prizes.

For nine years we have conducted successful safety campaigns and always through the medium of safety prizes. The men come to learn why those prizes are given and are told by their foreman that the prizes are awarded for a good accident record. It would seem to me that a comparison between Mr. Smith's accident records and Mr. Stremmel's would be the only way of determining which is successful, without prizes or with prizes. I would like to see a comparison of their accident records.

CHAIRMAN OARTEL: That is a good point. I think if that could be kept in mind for next year, it would bring out an interesting discussion.

MR. SMITH: In speaking of new ideas to bring safety across, I don't want to omit the importance of that which Mr. Stremmel has been talking about. I believe in putting safety across from an educational standpoint just as much as anybody. In fact, anybody who has made an analysis of accidents knows about 98 per cent of the accidents occur, even after the plant is safeguarded, due to the human element. Knowing that 98 per cent is up to the human element, then 98 per cent of our efforts should be directed toward the human element. We know that education is the big problem, it is just a question of how you are going to educate your men.

We have a great many bulletin boards and all kinds of meetings; that is all a part of the regular routine work. These stunts which I just mentioned were some of the ideas worked out in conjunction with that work, not interfering with it, not deviating from the regular work in any way because we believe in just those things he believes in; it is fundamental.

A few years ago when rule books first came out, a great many companies issued rule books. They were published at Gary Works when I was there. We had no prizes when those books were given out. We got a good many men in the offices for witnesses. We asked, "Did you read your rule book?"

"No."

"Where is your rule book?"

"Home in the trunk," or "Thrown away."

Well, we commenced to find a way to make the men read their rule books. In a small plant that may be a simple matter, but when it comes to a plant of several thousand men, it is a problem to get every man to read his rule book. So, we got out safety service medals, which were given to any man who worked six months without having lost time on account of accident, and had passed an examination on the safety rules. Now, if that isn't worth while as a prize proposition, I don't know what is

worth while. I think it is very much worth while because we are getting the employees to read the rules.

You give a man a "prize" for producing a certain tonnage in a rolling mill. It is the same proposition in accident prevention. Of course, in some places the superintendents in small departments are able to put this across without the use of prizes. I believe that safety can be put across without prizes, but, prizes make it a little easier. It is just a case of making it easier to accomplish your purpose. If a man is going to receive a watch, belt or knife, or anything else as a prize, it will be an incentive. We found that before we offered prizes for suggestions, we got about one hundred suggestions a year. After we offered prizes, we got about four hundred; that proves it.

From my experience, there is no question but what prizes get some benefit, a whole lot more than they cost.

MR. H. L. CHURCH (Rockford Malleable Iron Works, Rockford, Ill.): The question of prizes seems to me to be based on whether a man is an idealist or a practicalist. If a man is a practicalist, he will take the ground that a child should go to Sunday School on general principles. He will take the position that any man in the mill or machine shop is his brothers' keeper as well as his own. While, the idealist will bribe the child to go to Sunday School. When I was a kid I was bribed to go to Sunday School, and I'm glad I was. If we can bribe these kids of twenty-five and thirty years of age, yet kids in mentality, go ahead and bribe them and then let the information soak in.

CHAIRMAN OARTEL: I am sure that a great deal could be said on both sides of this question, and as Mr. Smith has said, "By their fruits shall you know them," and I am sure I shall suggest this as an item on our program for the next Congress.

Next on our program is a "Practical Demonstration of Investigating Accidents," which will be staged by Mr. H. J. Weeks, Chief Safety Inspector of the American Steel and Wire Company, with a number of the employees of that company. Mr. Weeks' company has gone into that very thoroughly and I am sure we are going to get something good. We will have to ask your indulgence for a few minutes until we set the stage.

PRACTICAL DEMONSTRATION OF INVESTIGATING ACCIDENTS

STAGED BY H. J. WEEKS AND EMPLOYEES OF
AMERICAN STEEL AND WIRE COMPANY

Report of Court of Inquiry held in Accident Case of
Fred Koefig. Check No. 1,000. Carpenter

(Address to audience by Mr. H. J. Weeks.)

It is the practice of the American Steel and Wire Company to make an investigation of all accidents or near-accidents, the object of which is to determine the cause, place responsibility, recommend discipline for the

negligent person, and suggest means for preventing a similar accident. The members of the Court are generally the Works Superintendent or the Assistant Superintendent, the Master Mechanic, the Labor Employment Supervisor, three foremen, and the district and mill safety director. We will now give you a demonstration of our procedure.

MR. G. A. PHILLIPS addressed the Court as follows:

We are gathered here to investigate the accident of Fred Koenig. Koenig had his finger taken off in the Carpenter Shop while ripping boards on the circular saw.

The injured man makes the statement that he was ripping some $\frac{3}{8}$ -inch boards of short length and while pushing the last board through, his hand in some manner came in contact with the saw.

The foreman makes this statement. That the man was ripping some $\frac{3}{8}$ -inch boards 12-inches wide down to 8 inches with the saw guard raised and while doing this, in some manner his fingers came in contact with the saw.

Time of Accident: 2:00 P.M., Tuesday, Sept. 2, 1919.

Nature of Injury: Amputation first finger, right hand.

Length of time off duty: Two to four weeks.

Board: Messrs. H. J. Weeks, Chairman; G. A. Phillips, Assistant Superintendent; A. C. Germain, W. J. Smith, F. Fennell, O. Walker.

EXAMINATION BY THE CHAIRMAN OF O. F. WALKER, EMPLOYMENT SUPERVISOR

Q. Mr. Walker, do you have in your records, Mr. Koenig's employment slip?

A. Yes, sir.

Q. When was he hired?

A. On the fourth of February and started to work on the fifth.

Q. Who hired him, you, or your assistant?

A. I did.

Q. Did you read form No. 3453 to this man, explaining the safety rules?

A. Yes, sir.

Q. Did this man seem to comprehend their meaning?

A. He seemed fully to understand them.

Q. Did he sign one of these cards?

A. Yes.

Q. Who conducted this man to the Carpenter Shop?

A. I did.

Q. What did you do after you arrived there with him?

A. I introduced him to Mr. Kirtland, Carpenter Shop Foreman, who showed him the wood-working machines, safety devices, lockers, etc.

Q. How about the fire escapes?

A. He was also shown those.

Q. Did you stay with Mr. Kirtland while he was doing this, or did you return to the office?

A. I stayed with Mr. Kirtland until he finished.

Q. After you left Koenig that day did you make it your business to return to that department for the purpose of ascertaining whether or not this man was following his instructions?

A. On several occasions I went to the department to see how the man was getting along and as far as I could see he was doing his work in a satisfactory way.

EXAMINATION BY THE CHAIRMAN, OF MR. G. E. KIRTLAND, FOREMAN
CARPENTER SHOP

Q. Mr. Kirtland, tell us what you know about the accident to Fred Koenig.

A. I understand he was ripping some $\frac{7}{8}$ -inch boards for boxes, the boards were 18 inches long and 12 inches wide and he was ripping them down to 8 inches and doing this work with the saw guard up. He was pushing them through, one board following the other, until he came to the last board and then his hand came into contact with the saw.

Q. How do you know this man Koenig had the guard raised?

A. One of the shop men, Chase, told me.

Q. Had this man ever been instructed as to how to use the saw guard and other safety devices in your department?

A. Yes, he was brought in by the employment supervisor and I took him all through the shop and showed him different pieces of machinery, and I asked him if he was a carpenter and he said yes, and I asked him if he ever worked on the machinery such as we had in the shop and he said he was familiar with it. I showed him over the shop, explaining the fire escapes, water pails, fire extinguishers, and took all the pains I could to instruct him on the lines of safety.

Q. After you had your talk with this man you were then satisfied that he was an experienced carpenter and used to handling wood working machinery?

A. Yes.

Q. What was your observation of this man after he had been working there some time, was he careful or inclined to be careless?

A. I thought he was a little careless at times. I was walking through the shop and noticed the saw running with the guard up out of position, and he was preparing boards to put under the saw. I called him and told him it was not permissible under any circumstances to have the saw-guard raised.

Q. Was this the only time you saw him with the guard out of position?

A. I was through another time that I recall, and noticed the guard raised.

Q. Did you again call his attention to this dangerous practice?

A. I did and in a manner I thought he thoroughly understood and told him it would not be permitted under any circumstances.

Q. From that time on up until the time of the accident, did the man do his work in a careful manner?

A. Yes, so far as I know.

Q. Is there anything else you have to say in regard to this accident we have not mentioned: if you have, speak freely?

A. I don't know of anything.

EXAMINATION BY THE CHAIRMAN, OF FRED KOENIG, THE INJURED MAN

Q. Koenig, how is your finger today?

A. I suffered a good deal last night but the doctor said I might go back to work before long.

Q. Fred, tell us as near as you can how you got hurt.

A. I was sawing some $\frac{7}{8}$ -inch boards 12 inches, down to 8 inches in width and in some manner my finger came in contact with the saw.

Q. How long have you been working for the company?

A. Six months.

Q. When you were taken to the Carpenter Shop were you introduced to the foreman and did he in turn take you over the Carpenter Shop explaining the safety devices and rules of that department to you?

A. He did.

Q. Did you thoroughly understand the instructions you received?

A. I think I did.

Q. I understand that you are an experienced carpenter and used to handling wood-working machinery; is that correct?

A. Yes, sir.

Q. How much experience have you had?

A. About six years.

Q. When you were employed did you receive a card on the back of which were a number of safety rules with instructions to follow?

A. Yes.

Q. Have you that card with you?

A. I think I have.

Q. Read the rules on the back of that card.

1. This Company maintains a Safety Organization for the purpose of preventing injuries to employees.
2. Every employee is considered a member of the Safety Organization.
3. Safety instructions and rules must be obeyed.
4. Safety devices installed must be used.
5. Safety guards removed for repairs or adjustment must be replaced before machinery is started.
6. Unsafe conditions or practices are to be reported to the foreman.
7. The Company maintains an emergency hospital for treatment of injured employees, free of cost.
8. All injuries, no matter how slight, must receive immediate attention.
9. Good conduct is expected; horse-play or fooling will not be tolerated.
10. Failure to comply with Safety Rules and Regulations may mean immediate dismissal.

Q. Did the foreman give you other specific rules to follow in regard to the safety devices in your department?

A. He showed me all the workings of the different safety devices in the department and explained to me how to use them.

Q. Was this particular saw on which you were working at the time of the accident, provided with a guard?

A. Yes sir, it was.

Q. Was the guard in place at the time the accident happened?

A. Yes, I think it was.

Q. You are absolutely positive, Fred, you had this guard in place at the time the accident happened?

A. Yes, I think so.

Q. Is there anything else you wish to say in regard to this accident we have not talked about?

A. That is all I know of now.

Q. Have you any suggestions that would make conditions around the saw any safer?

A. No, the guard that is installed on that saw is a good one.

EXAMINATION OF J. ROITZ, CARPENTER. (WITNESS—FOREIGNER.)

(J. Tylicki, Interpreter.)

Q. Joe, do you speak English?

A. (Shrug of shoulders.)

Q. Have you ever attended a Court of Inquiry?

A. He never did.

(Procedure of the Court was here explained to the man by interpreter.)

Q. Joe, tell us what you know about this accident.

A. I was working at my bench and heard a loud conversation between Chase and Koenig. What he had to say I don't know. But as I was coming back I noticed Koenig measuring off a board and he began to rip the board and as he began I started to tell him to lower his guard, but before I reached him the accident happened.

Q. Who is Chase?

A. I don't know, but I know he works there.

Q. Joe, did you ever use a circular saw?

A. Yes, I did.

Q. Did you ever use it with the guard up out of place?

A. I always kept it down because I think too much of my hands.

Q. Joe, as I understand it, when you first turned around you noticed a man attempting to explain to this man, Koenig, that it was dangerous to saw with the guard up. How do you know that this man was telling him to put the guard down?

A. I don't understand the English language, but judging from his motions I thought he told him to lower the guard.

Q. Is there anything else you know about this accident we have not talked about?

A. That is all I know.

EXAMINATION OF W. CHASE, WITNESS

Q. Will, do you work in the Carpenter Shop?

A. Yes sir.

Q. What do you do?

A. General carpenter.

Q. Have you ever attended a Court of Inquiry?

A. Yes, sir.

Q. Did you see Fred Koenig get hurt?

A. No sir, I didn't see him. I was up there just shortly before he got hurt and he was running the saw with the guard up and I cautioned him about this and also told him to put it down, that it was very dangerous and against the rules and saw that he put it down before I left and he also said he had been doing this kind of work for a long time and had never been hurt.

Q. Where did you go after you warned him?

A. I got the board I was looking for and went back down stairs.

Q. You did not actually see the accident?

A. No.

Q. Have you ever used a circular saw?

A. Yes, a good many times.

Q. Do you always make it a practice to use the guard?

A. Yes.

Q. Does this type of saw guard on that saw cause you any inconvenience?

A. None.

Q. Is there anything else you wish to say?

A. Nothing else I can think of.

RE-EXAMINATION OF FRED KOENIG, INJURED MAN

Q. Fred, in your statement a while ago you said you had this guard in place.

A. Yes, I did.

Q. Does this saw-guard cause any inconvenience whatever when you use it?

A. No.

Q. Then Fred, why weren't you using it at the time you were injured?

A. Well, I

Q. Now wait a minute Fred. We are going to be fair with you and expect you to be fair with us. What I can't understand in your statement is this. You know as well as I do that the end of this saw guard protrudes beyond the teeth of the saw at least 4 inches and when down rests on face of the board and if you had the guard in place, explain to me how you could receive that injury.

A. Well I don't know. I think if I had the guard down I wouldn't have got my finger off.

Q. Now Fred, why did you want to tell us you had that guard down when you knew you didn't?

A. I remembered the rules I read and thought that I might be discharged for violating them.

Q. How many times have you read those rules?

A. When I first got the card and then stuck it in my pocket.

Q. What was the length of these boards you were sawing?

A. Seventeen inches.

Q. How were you pushing them through?

A. I took one board and started it through and took the second to follow the first and took the third to follow the second and in that manner kept my fingers away from the saw.

Q. Do you remember rule No. 5?

A. No, I don't remember it.

Q. Take out that card and read it.

A. (Reading the rule.) Safety guards removed for repairs and adjustment must be replaced before machinery is started.

Q. You understood that rule all right, now read No. 4.

A. (Reading the rule.) Safety devices installed must be used.

Q. Now read the last one.

A. (Reading the rule.) Failure to comply with Safety Rules and Regulations may mean immediate dismissal.

Q. Fred, I asked you a while ago if you had any suggestion to offer whereby an accident of this kind could be prevented and you said you had none. Have you any now?

A. None that I know of but I know if I ever get back to work I won't use machinery unless the guards are in the proper position.

Q. You know this guard should be kept down all the time, in fact you remember the rules pretty well. In a case of this kind what do you think we should do?

A. I don't know. I guess I will have to leave it to you gentlemen.

Q. Have you always made it a practice of keeping the guard in place before?

A. Yes, most of the time.

Q. Not always though?

A. No.

Q. Just before you were injured, didn't Chase come over to where you were sawing, when you happened to be sawing with the guard up? Didn't he attempt to put the guard down and caution you against the dangerous practice?

A. Yes, he did.

Q. What did you say to him?

A. Oh, I laughed at him and said I thought I understood my business.

Q. How do you feel about it now?

A. I wish I had taken his advice and I think I would have my finger yet.

Q. You know now just as well as Chase that it is very important that these guards be used, and if used they often prevent suffering. You realize that?

A. Yes.

Q. Now Fred, if you are permitted to go back to the work do you think you will use the guards that are put there for your protection in the future?

A. I won't use any machine unless the guard is in the proper place.

Q. You are absolutely sure about that, are you?

A. I am.

CONCLUSIONS OF THE BOARD

MR. WEEKS: Gentlemen, this concludes the testimony in this case. We will now proceed to work up the summary.

[The following were the questions and decisions reached by the Board.]

Q. What was the injured man doing?

A. Ripping some boards on a circular saw.

Q. How did the accident happen?

A. The saw guard was raised out of position. While in the act of ripping the last board, not having a board to follow and push it through, his hand came in contact with the saw.

Q. What was the exciting cause?

A. (Mr. Fennell). Mr. Weeks, do I understand that the exciting cause is the cause leading up to the accident?

A. Yes, exactly.

In this case I would say the exciting cause was the man sawing boards on a circular saw with the guard raised out of position. (Agreed.)

Q. What was the proximate cause? (Which is the near or exact cause?)

A. His hand coming in contact with the saw.

Q. Who is to blame directly?

A. The injured man.

Q. Who is to blame indirectly?

A. No one.

Q. What can be done to prevent a similar accident? Do you have any suggestions to offer, Mr. Phillips?

A. Well, the testimony shows that the saw guard is sufficient and the only thing we can do, I think, is to insist that our men make use of the guards provided. I might say that we have already called together all of the men who use the machinery and explained to them this accident, impressing upon them the importance of using the guards. Also at our regular departmental safety meeting held each month we review in detail each accident which happened in the previous month, and this accident will be taken up at the next meeting.

Q. Were there any safety rules violated?

A. Yes, rules No. 4 and No. 5.

Q. Were any safe guards involved?

A. Yes, the saw guard.

Q. Mr. Smith, getting back to what can be done to prevent a similar accident: Do you as Master Mechanic have any suggestions whereby that guard can be made any safer by adding some mechanical feature to prevent raising the guard?

A. I think it possible to put a locking device on the guard so a man can only raise it to correspond with the thickness of the board he is working on and lock it in position so it cannot be moved unless the foreman moves it. Make a key and lock it in position.

Q. If I remember that guard correctly, it is provided with a wing

nut which permits shoving out of place. By removing the nut and providing a lock as you say, and giving the foreman the key, this should remedy the situation. Do you think it can be worked out all right?

A. Yes.

Q. Will you try to work up something right away?

A. Yes.

Q. About how long before you can do this?

A. About ten days or two weeks.

Q. What discipline is suggested for the negligent person?

A. (Mr. WALKER, Employment Supervisor): I should think in a case of this kind, the man was properly instructed and cautioned and the safety devices explained to him, he ought to have at least a week off without pay after the doctor releases him.

Mr. PHILLIPS: I don't quite agree with that. That is rather a primitive method. I think we can agree on some other discipline. He will lose three or four weeks now as it is and I happen to know that he has a large family and really can't afford to lose that time. He has suffered a great deal with his finger and realizes it was the result of his own carelessness and will be safer and more careful than he was before and that will be a good example to the rest of the department. I believe, however, he should be disciplined in some way, and my suggestion would be to give him his choice of making a speech to the men in his own department or taking a week off without pay.

Mr. WEEKS: Gentlemen, I think Mr. Phillips' suggestion a very good one. This man has a large family and regardless of the fact that this injury was due to his own carelessness, we should not cause any suffering as a result of his losing time. He needs the money and I hope you will all agree to Mr. Phillips' suggestion. (Agreed.)

(It was suggested that his foreman be delegated to put this proposition up to him in a diplomatic way and try to persuade him to make the speech rather than take the week off without pay.)

Mr. Kirtland, Foreman Carpenter Shop, was called in at this time and addressed as follows by the chairman:

"Mr. Kirtland, from the testimony we have received in this investigation, we are all agreed that this accident was due wholly to Fred's own carelessness. He seems to understand the rules in a general way and with the instructions you had given him previous to the accident at the time he was employed and also cautioned him a couple of times after that, we can't help but feel that he is entirely responsible for the accident. We therefore feel he should in some way be disciplined and it has been suggested that we give this man his choice of taking a week off without pay or let him give a safety talk to the men in his department at the next departmental safety meeting. It is my opinion that Koenig would rather take the week off than give this talk but we want you to try and persuade him to give the talk, and suggest that you put it up to him when he comes in."

Mr. Koenig was then called in and addressed by Mr. Kirtland, his foreman, as follows:

"Well Fred, the Board of Inquiry has investigated this accident very carefully and the testimony of the men in the shop and also your own testimony proves it was gross carelessness on your part and no one to blame but yourself. They feel something should be done to discipline you to bring you to a point of realization that it is your duty to take care of your own person and follow the rules laid down for your protection. They have not entered into this with a spirit of punishment. It is simply done to bring you to the point where you will look out for yourself and follow instructions; and they have recommended that you either take a week off without pay or that you give a talk to the men in your department on safety at the next departmental safety meeting. You are a married man of a family, and it seems to me Fred, you have suffered enough, and more loss of time would bring a hardship on your family. I think under the circumstances if you will give your fellow-workmen a talk on safety it will do them good and won't deprive you of anything and you are certainly in a position now with your finger tied up, to impress upon them their duty to follow instructions and protect themselves. Now Fred, what are you going to do?"

Mr. Koenig's answer:

"Well Gentlemen, you certainly got me in an awful predicament. I don't like to lose the week without pay after losing all this time and I have never made a talk in my life, but I think I had better give my fellow-workmen a talk, so I will decide to give them one."

MR. KOENIG'S SPEECH

(Audience representing his fellow workmen)

Boys, you have guards on the machines. USE them. Don't try to skin out of them the same as I tried. It was my own fault I got hurt.

I tell you, boys, they have a bunch of foremen here in the Works that will get you if you don't. They got me. It is right up to you and up to me where you have the safety appliances, to use them. Don't try to have them sticking up in the air the same as I did, trying to hustle your work. I gained about two minutes, and here I lose three weeks, and suffering nights, getting my wife up at night and her telling me "For God's sake be quiet." I tell you, boys, the Company installed these safety appliances and paid lots of money for them and put them there to keep us from being crippled.

Mike, you remember when the foreman raised hell with you. You were grinding at the emery wheel without goggles. Now don't do that any more, Mike, your eye might have been a goner. Another fellow I saw ripping boards threw one down with a nail sticking up where lots of men pass. I'll tell you one thing, boys, right here: I am going to be for safety first, last, and all the time.

Now, boys, another thing: I used to look at the accident board and laugh at them putting the figures on there, but when it moved from three to four it was I, and believe me, boys, I didn't laugh then. I am going to see every time that clock moves, and I am going to that department

and talk to the fellow and see if I can't convert him to be a "safety first" man.

Don't try to get up in front of these fellows who investigate the accidents and lie like I did, for they will handle you rough. There is no use trying to sneak away, because they got you. If you try and lie out of it they get you cornered. You may as well "come clean", because if you don't you are trapped nine times out of ten. I was, and am ashamed to think how I tried to get out of it.

Now, boys, I want to thank you all for this little attention you have given, and I want to know that every one of you fellows are going to be safety first men. I want you all to preach safety first, last, and all the time.

MR. PHILIP STREMMEL: Mr. Chairman, if I am in order, I want to make a motion that we who are present this morning, who have had the privilege of listening to this Court of Inquiry given so splendidly by these gentlemen, give them a rising vote of thanks for what they have given us this morning.

(The motion was carried unanimously.)

DISCUSSION

CHAIRMAN OARTEL: We have about five minutes for discussion. If you have any questions you would like to ask Mr. Weeks, I am sure he will be very glad to answer them:

MR. R. C. SALISBURY: I would like to ask Mr. Weeks what accidents are conducted in this Court of Inquiry and how he conducts the Court of Inquiry in regard to hospital cases.

MR. F. F. PULSE (American Steel and Wire Company): I have been conducting Courts of Inquiry in the Chicago District for the same company. The accidents on which we hold Courts of Inquiry are those in which it is not obvious where the blame should be placed.

In my district we hold Courts of Inquiry when the facts are such that we don't get the information from the regular investigation. We also hold Courts of Inquiry where they serve as an example, also in case of serious injury, fatality, loss of a limb, or accidents of that kind. We hold them because this Court of Inquiry advertises the fact that when accidents happen in a department, foremen and men involved in the accident have to come before this Court. In these Courts of Inquiry, we make reference to the safety rules that exist in the department. We ask the witnesses if the foreman in his departmental meeting has taught certain safety rules that are involved in the accident. We get the opinion of the men. Sometimes there are a dozen witnesses. They will come in, one after the other, and they will back the foreman's discipline or they won't. They will sometimes say that they haven't heard of that in a safety meeting. Years ago we used to hear, "Nobody told me not to do that" or "Nobody told me to do that."

The publicity is the great advantage of these Courts of Inquiry. The minutes of the inquiry are taken and passed around to the other departments. The foremen know that these go to the highest superintendent,

the manager of the district, the highest officials, and that is one of the greatest restraining influences in this accident-prevention work.

MR. LEWIS: In case of a serious accident, when do you interview the man?

MR. WEEKS: We sometimes wait until he comes back from the hospital. Sometimes we take his deposition and he is asked the same questions that he would be asked at the Court of Inquiry itself. Sometimes it is best to have the Board of Inquiry immediately after the accident while there is still so much interest in the accident.

MR. LEWIS: Would you any time later bring the man into the Court of Inquiry?

MR. WEEKS: No. We would consider that the effect had been obtained by the publication of the Court of Inquiry and not do anything further.

MR. LEWIS: Well, providing there was discipline recommended?

MR. WEEKS: He would be acquainted with the discipline, and might be told in a departmental meeting when he came back.

MR. SMITH: I just want to ask whether these Courts of Inquiry are held privately?

MR. WEEKS: Ordinarily we hold them privately. We generally get more witnesses than are actually required in order to get more men from the department into the thing and thus let them see what happens when they break the rules.

MR. SMITH: It might be a good idea to hold one publicly.

MR. WEEKS: I never thought of that. We could hold it in the department. There would be one disadvantage, because some of them would take up quite a lot of time, and it would hardly be practicable to close a department down for about two hours to conduct a Court of Inquiry.

CHAIRMAN OARTEL: Gentlemen, Mr. Smith of the Inland Steel Company, who has been very active in the Metals Section since its organization, has something to say.

MR. SMITH: During all of the time since the Council has been divided into sections, it has been a difficult matter for the officers of the iron and steel section to secure cooperation from the men out in the field, and to carry on this work in a manner satisfactory to everybody concerned. I think every officer will agree with me on that point, and I think that at this Congress some effort should be made to make the activities of the Metals Section have more value to all members of the Section.

The iron and steel industry is probably the greatest industry of the United States. It is the backbone of all industries. The men here today are the representatives of that industry and while many are not here because of labor conditions at this time, they are as interested as those who are here.

PERMANENT SECRETARY FOR METALS SECTION

Some effort should be made to arrange that the activities of the Section will be of more value to each and every member during the coming year. I think one of the things that should be done is that a permanent Secretary should be appointed for the Metals Section. It is a hard thing for one man to handle all the activity for a Section of this kind. The dues

from the membership of this Section should be sufficient so that the National Safety Council should put some experienced iron and steel Safety Engineer in charge of the secretarial work, the dissemination of information, the gathering of information as to how accidents occur, guarding, special bulletins, anything that may occur in connection with the safety movement. I know that each and every one would be benefited by this.

There are accidents occurring in our plants every day. They may occur in Chicago, Cleveland, or Pittsburgh. If we knew exactly how that accident occurred, we would be able to prevent it in our plant. There are a great many other things that would be of special value in the iron and steel section.

I think this time is the only opportune time for the matter to be discussed and some conclusion reached, and a recommendation made to the Executive Committee of the National Safety Council.

I would like to have some suggestions on that line.

CHAIRMAN OARTEL: Mr. Smith, is it your idea that this permanent Secretary should be financed by the Council without an increase in dues?

MR. SMITH: Absolutely. I think there are enough dues so it should be done by the National Council.

CHAIRMAN OARTEL: I think the proper way would be by a motion instructing your Chairman of the Metals Section to bring it before the Executive Committee.

MR. SMITH: I will make such a motion.

(The motion was seconded.)

CHAIRMAN OARTEL: The motion is that a paid Secretary, who is a trained Safety Engineer having experience in the Iron and Steel Industry, be appointed for the Metals Section, the salary of said Secretary to be paid by the Council without an increase of dues to the Metals Section. Is there any discussion?

MR. F. G. BENNETT (The Buckeye Steel Castings Company, Columbus, Ohio): Would you want that taken up with the Executive Committee at once?

CHAIRMAN OARTEL: I think it would come at the regular Executive Committee meeting.

MR. SMITH: This has nothing to do with election of officers for this Section. This man would occupy the same position with the Metals Section as Mr. Price does with the National Safety Council. This man would not conflict with any officer of this Section. I am not trying to take care of any election of officers or anything like that.

My idea is that there should be some man (you might call him Executive Secretary, Safety Engineer of the Iron and Steel Section, or something else) to act as safety engineer for the entire iron and steel industry of the country. He should travel all around and study the systems that are in effect in different plants, then go to the other fellow and tell him how the others are doing it, giving advice as to what can be done, what is successfully carried out in other plants and what gives results. I think a man experienced in the iron and steel industry will undoubtedly be able to do that and accomplish a good deal.

CHAIRMAN OARTEL: I would like to postpone the question a little. Mr. Guerrant of the National Safety Council staff is here. He has been doing some work in the Metals Section in the preparation of Safe Practices pamphlets. I would like to hear from him on what the Mining Section is doing along this line.

MR. R. H. GUERRANT: I know that many of the sections want additional service from the Council. One man of our staff can't give any one section his entire attention. For instance, I have five sections in addition to preparing the general Safe Practices pamphlets.

The Mining Section for three or four years have wanted an experienced mining engineer to be of the same service to them as the man Mr. Smith has in mind would be to this Section, and today I think they are taking up at their meeting the advisability of appointing that man. They have been authorized, I believe, by the Executive Committee to take this matter up, but they intend to raise an additional eight thousand dollars a year. That man will be a mining engineer and will devote all of his time to the members, in the gathering of bulletin material, writing sectional pamphlets, visiting properties of the members, and helping them organize for safety. They expect to raise eight thousand dollars additional (to their dues) from the members for this service.

MR. SMITH: Do you intimate that the Executive Committee have informed the Mining Section that they are unable to finance that?

MR. GUERRANT: Yes.

MR. SMITH: If that is true, I don't think there would be any difficulty in raising at least ten thousand dollars in the iron and steel industry.

MR. GUERRANT: The iron and steel is the largest section, and, of course, ten thousand dollars divided among the members would not be a great deal for each one.

MR. SMITH: Why wouldn't it be better to change that motion if that is the opinion of the Executive Committee and raise ten thousand dollars? I move that we raise ten thousand dollars; that our new officers be given the authority to raise that amount among the iron and steel members and that they select and employ a trained iron and steel Safety Engineer for this position. This to be done under the auspices of the National Safety Council.

CHAIRMAN OARTEL: Do you wish to substitute that?

MR. SMITH: Yes.

MR. SALISBURY: I would like to ask how a plan of this kind will affect the proposed plan of the permanent Secretaries that the National Safety Council have under way?

CHAIRMAN OARTEL: What do you mean?

MR. SALISBURY: I understand the St. Louis and Pittsburgh districts have a permanent Secretary, and I think there is a plan of that kind in a tentative form now for a permanent Secretary in all big cities if they can finance it.

CHAIRMAN OARTEL: I think I can answer that question. I am from Pittsburgh. I know the St. Louis, the Cleveland, and Rochester plans. It means an increase of at least double the amount of dues you are paying.

That is, if you are living in a district where there is a permanent Local Secretary and you joined that Local Council, it means you pay possibly twice as much dues. This proposed secretary would be in addition to that.

MR. SMITH: In regard to the permanent Local Secretary, I don't think he would be as valuable to our Section as having a man in the iron and steel industry for this industry alone. The Local Council Secretaries are good for the membership, but in so far as taking care of the iron and steel industry, it doesn't answer the purpose.

MR. SALISBURY: It would occur to me that one of the two systems would have to be eliminated to keep down the cost of dues in order to make one of the two plans a success.

MR. SMITH: How many members are there in the Section?

MR. GUERRANT: There are over two hundred members, I believe. The dues paid are based upon the number of employees. Suppose your dues are a hundred dollars a year. You might have to pay twenty-five dollars a year more for a man to give you this service.

Just one more word, I think the plan proposed by the Mining Section, that this man be associated directly with the Chicago office is a good one. The Council will print all the literature as they do now for the Section, but this man will devote all his time to the Mining Section duties.

MR. SMITH: The mining proposition is about like the iron and steel. They have peculiar problems. They really need a man just as we do. They feel that need and I think we feel it in this Section. I think we are both following along the same line.

MR. PHILIP STREMMEL: I would like to say that so far as we are concerned, I think we would meet with some objection from our company for this reason: We have a tri-city, local council, a Mississippi Valley division of the National Safety Council. We support the tri-city, then we have the St. Louis, Mississippi Valley division, with a permanent secretary, then the National Sheet Association also have a man who is acting in a similar capacity, so that taking it altogether, with another additional Secretary, I doubt seriously whether our men would consider it.

CHAIRMAN OARTEL: Are there any other remarks on this very vital subject?

MR. LEWIS: It seems to me it would be observing better form if the matter is presented as in the original motion, that it be submitted to the Executive Committee.

CHAIRMAN OARTEL: I think I can answer for the Executive Committee that the Council would be perfectly agreeable if we could raise the money.

MR. SALISBURY: It seems to me that on account of the small attendance here at this time, it would be better to take this matter up at the meeting tomorrow morning and then we can get a full expression on it.

CHAIRMAN OARTEL: There is only one trouble and that is it would injure our full program. Why not have the Council send out letters saying, "Do you want this service and if so, do you want to pay for it by paying more dues?"

MR. SMITH: You could in that case advise them about what the dues would be in each instance.

MR. PHILIP STREMMEL: I think that would be the better plan.

MR. SMITH: I have no intention of forcing the issue. This was only an idea of service. I think everybody who has served as an officer of this Section the last four or five years has realized the difficulty in getting out bulletins. The benefit would be worth all the money it cost to any one who has any accident problem at all. But, in a large operation where they are having accidents continuously, there is no question but what the small amount of money it may cost would be many times regained by the service rendered.

There is no question about it but what the members in this room would like to get about four times as many bulletins as they do. If we could get real iron and steel bulletins more often, if we could get ideas on statistics, on safety, on rule books, on Courts of Inquiry such as held here this morning, and on a good many other things, the amount paid by each company would be small in comparison with the benefits derived.

MR. SALISBURY: I move the matter be laid over until tomorrow.

CHAIRMAN OARTEL: Do you offer that as an amendment?

MR. SMITH: I am satisfied.

(Seconded. Carried.)

CHAIRMAN OARTEL: The matter is on the table until tomorrow morning.
Adjournment.

SATURDAY MORNING SESSION

THE meeting convened at 9:30, Mr. J. A. Oartel presiding.

CHAIRMAN OARTEL: We have a matter that was held over from yesterday morning in regard to a permanent paid Secretary for the Metals Section. It seems that we don't have a copy of the resolution here. Mr. Bennett, will you state it?

MR. BENNETT: That we take up with the Executive Committee of the National Safety Council the matter of having a paid, permanent Secretary or Manager for this section.

CHAIRMAN OARTEL: This matter was laid on the table until today, so now it is open for discussion. Mr. Smith, who suggested the matter yesterday, went home last night. Do you wish to have any discussion? I will make this explanation for the benefit of any who were not here yesterday.

REGARDING A PAID PERMANENT SECRETARY

The idea is to have a man employed by the Council who shall look after and direct the work of the Metals Section. Heretofore the work has been done voluntarily by the elected officers of the Section. They, as you know, are employed elsewhere and cannot give much time to this matter.

The Section has grown so large, the development has been so great, that we think we have come to the place where a man should be employed to give his entire time to the Metals Section. So, the idea is that your Chairman, whoever he may be next year, shall bring this matter to the attention of the Executive Committee of the Council. To employ

such a permanent secretary would necessitate an increase in dues, or a fund to be made up in some way to pay his salary. It might run up as high as ten thousand dollars. Do the members of the Metals Section want to pay more dues?

Yesterday a thought was brought before us about membership in the Local Councils, which means an increase of dues wherever there is a paid Local Council Secretary.

A sectional paid secretary would mean an increase in addition to that. Do you want to take that step at this time?

I suggested yesterday that if this matter met the approval of the Executive Committee, that the National Council send out a circular letter to all the members to get their opinion about it.

Do you wish to have any discussion on this matter this morning before we put the motion? We have the motion before us. All we need to do is to vote upon it. Are you ready for the question?

(The motion was carried.)

CHAIRMAN CARTER: The first address will be "The Testing of Goggles for Protection Against Radiant Energy", by Mr. Charles E. Oakes, Associate Electric Engineer, United States Bureau of Standards, Washington.

THE TESTING OF GOGGLES FOR PROTECTION AGAINST RADIANT ENERGY

CHARLES E. OAKES, ASSOCIATE ELECTRICAL ENGINEER, U. S. BUREAU OF
STANDARDS, WASHINGTON, D. C.

The injurious effects to the eye of ultra-violet radiant energy which occur as a result of many operations in industry, for example electric arc welding, steel making, etc., have been known for many years but in spite of the fact that scientists have studied these phenomena, until recently no quantitative data, comprehensive in scope, have been available in such form that the engineer can use them for the purpose of writing specifications for glass.

Before entering into a detailed discussion of the methods of testing glass designed for protection from radiant energy, it might be well to explain the relation of the particular form of radiant energy with which we are concerned to the many other forms of radiant energy which manifest themselves in many well-known ways, some of which are applied commercially at the present time.

Radiation is a form of energy and can therefore be transformed into other forms of energy. Radiation in general is a transverse wave motion with a speed in space 3×10^{10} cm. per sec., but with frequencies and wavelength varying over an extremely wide range. The form of radiant energy which is most well known to us is light and this subject received the first consideration from scientists years ago. Radiation is visible, as light, only when having wave-lengths of about 76×10^{-6} cm. to 39×10^{-6} cm. Only radiant energy of these frequencies can be observed by the eye.

Alternating current waves, electric waves used in wireless telegraphy.

As will be noted, the total range of radiation is extremely great, the electric waves consuming the greater part of the radiation spectrum and a much greater part than the visible radiation.

[illegible]

means of a tuned circuit which contains inductance and capacity in the proper ratio and connected to a suitable indicating instrument such as a telephone receiver, a thermo galvanometer, a bolometer, etc.

In nearly every case where we want to measure quantitatively energy it is first necessary to change its form so that it can be recorded or detected. I may cite an example. The wireless sending apparatus propagates through space radiant energy in the form of electric waves. These waves impinging on a receiving circuit properly tuned convert the radiant energy into electrical energy. This electrical energy is dissipated as heat energy and in order to measure it a part of it is localized in a bolometer or thermocouple or thermo-galvanometer, or telephone receiver. The

localized heat energy is transformed into electrical energy, whose magnetic effect is used to turn a coil of a galvanometer against the resistance of a mechanical force such as a spring. The galvanometer visualizes the result by means of a mirror and a scale or by a pointer passing over a scale. We thus make use of the visible radiant energy of the sun or an artificial light to picture for us the relative position of the scale and pointer. By these few examples it can be seen it is necessary to make many transformations of energy before the final result can be visualized. The same general method is followed in measuring radiation in any part of the spectrum.

However, there is one important difference between electric radiation and light radiation. Electric radiation is usually, although not necessarily of one frequency while light radiations usually are a mixture of waves of an infinite number of frequencies. The infra-red and ultra-violet radiations are always present, although the worker is unconscious of the fact, and if present in considerable amounts. These invisible radiations are known to injure various parts of the eye. For these reasons the eyes must be protected especially where radiation of high power is encountered. Since light radiation is usually made up of waves of an infinite number of frequencies, it becomes necessary to separate them if measurements on a particular wave length are to be made. These waves do not travel through media such as glass with the same velocity as they do through space. Not only is the velocity usually decreased but the reduction in speed depends on the frequency. If the radiant energy of different wave lengths is passed through a transparent prism—transparent as far as the wave lengths under consideration are concerned—this difference in velocity results in the direction being changed and this affords a method of separating the waves. By focusing the radiant energy after passing through a prism on a screen a spectrum is formed. To the eye there can be perceived only the colors of the spectrum. That there is radiant energy of other wave lengths present but not visible can be proven by holding a sensitive heat measuring device in the path of radiant energy in the infra-red portion of the spectrum. If a photograph be taken of the spectrum, wave lengths shorter than those of the visible spectrum will be recorded and we thus have evidences of ultra-violet radiations. A heat measuring device will also detect ultra-violet radiation. An ordinary prism made of a material transparent to the radiant energy of those wave lengths to be studied is all that is necessary to separate the individual waves enough to conduct whatever experiments are necessary.

In the detection of the presence of radiant energy of different wave lengths a multiplicity of methods may be used. The eye can detect the wave lengths exhibited by the visible spectrum because the eye is particularly sensitive to these. The photographic plate can be used for the visible spectrum and it will record also radiant energy in the ultra-violet and beyond, even through the x-ray portion of the spectrum. A standard method of detecting the presence of radiation and obtaining a quantitative result is by making use of a heat-measuring device. All radiant energy if intercepted and absorbed disappears as radiation by conversion

With this general explanation of the methods of measuring radiant energy, which has been given in order to picture the whole field of radiant energy and the relations of the various forms one to the other, we now pass to the particular field in which we are especially interested, the portion

FIG. 2. CURVE SHOWING SENSITIVITY OF THE EYE

The safety man is interested in a glass that will transmit as little of the ultra-violet and infra-red as possible. But why is he interested in the transmission of glass? Because the reduction of the energy in the infra-red and ultra-violet to a degree which will not be injurious will give us the required safety.

The lack of sensitivity of the eye to radiations outside the visible is a

secondary reason why the presence of these radiations is dangerous. The man does not realize their presence.

Fig. 2. For the same amount of power expended the physiological effect on the eye, that is the amount of illumination evidenced, is a maximum near the middle of the visible spectrum and decreases on each side from there to zero at the end of the visible range. The ultra-violet and infra-red radiations on entering the eye are transformed into chemical energy or heat energy and produce harmful effects. This is particularly true of the ultra violet portion of the spectrum, the action on the tissues being chemical while that of the infra-red seems to manifest itself as a heat effect. That there is a permanent injurious effect from the infra-red radiation has not been proven, but there is no doubt that it may cause

FIG. 2. SPECTROSCOPE SET UP FOR TESTING THE TRANSMISSION OF GLASS

serious temporary injury. It is, therefore, necessary to absorb as much as possible of these radiations before they reach the eye.

It becomes necessary to know the properties of the glass in order to insure adequate protection. This is done by tests and by buying on specifications based on these tests, protection is assured.

The apparatus used for testing such glass is simple in principle, although skill and experience in using it are necessary in order to obtain accurate results. The essential requirements are (1) a spectroscope for dispersing the radiant energy into a spectrum which will extend over the ultra-violet, visible and infra-red; and (2) a radiometer for measuring the spectral intensities of the light transmitted by the glass under test.

In Fig. 3 is shown the spectroscope with slit 4, 8; lenses (or silvered

mirrors) 5, 7; and prism 6 of glass fluorite or quartz. The radiometer 9, is placed at the narrow exit slit 8, through which passes a narrow strip of the spectrum. The radiometer may be a bolometer, a thermopile, a photometer, or a photographic plate. The bolometer or thermopile acts through a galvanometer.

The spectrum is formed at 8, and narrow portions pass out through the slit for measurement of intensity. The source of light, 1. (and infra-red and ultra-violet rays) is a gas-filled tungsten lamp placed in front of the spectroscopy slit. There is a shutter, 2, to exclude the light when desired. The glass under test, 3, is usually placed close in front of the entrance slit 4.

Suppose we wish to determine the transmission of a certain glass, for

FIG. 4. TRANSMISSION CURVES

the red (or yellow). The spectroscopy arm is rotated so that red light passes out through the exit slit, 8, and falls upon the bolometer or thermopile (or other radiometer). The intensity (galvanometer deflection) of the light is noted first with the glass in front of the slit and second when no glass is in front of the slit. The ratio of these intensities gives the per cent transmission. For example, suppose that, with the glass in place before the slit the light from the lamp warms the thermopile sufficiently to cause a galvanometer scale deflection of 50 mm. and when the glass is removed, the galvanometer deflection is 100 mm. The ratio is 50/100 i. e., the glass transmits 50 per cent of the incident light.

In this manner the whole spectrum is explored step by step and the transmission of the glass is determined. In order to show the result

obtained by this test I shall choose two glasses which have been tested at the Bureau. One is not suitable for electric arc welders' goggles and the other will give full protection.

Curve 1 is the transmission curve of a blue-green glass and curve 2 of a yellow-green glass. In curve 1 a high transmission in the ultra-violet, an average of about 16 per cent transmission in the visible which is predominant in the blue and green and a high transmission in the infra-red is shown. On the other hand curve 2 shows that the glass transmits no ultra-violet, the transmission in the visible is about 1 per cent and that in the infra-red about 2 per cent, the transmission being very low in the region of the infra-red adjacent to the visible. The test proves

FIG. 5. REPRESENTATIVE CURVES

that the yellow-green glass will give complete protection. Data on a large number of glasses (the data being given under their trade names) can be found in Bureau of Standards Technologic Papers Nos. 93 by W. W. Coblentz and W. B. Emerson, and 119 by K. S. Gibson and H. T. McNichols.

Tests on a large number of glasses together with a knowledge of the glasses that have given good service in practice should give us sufficient data to construct a practical specification for glasses to be used in different processes. This has been done in the draft of the Safety Code for the Protection of the Head and Eyes, which has been prepared by the Bureau.

What are the essentials which should enter into a specification for glass for welders, for example? The intensity of the radiant energy from these sources is extremely high and is rich in ultra-violet. It has defi-

nitely been proven that ultra-violet radiant energy is harmful. Therefore it should be eliminated. It is, therefore, justifiable to place a limit on the per cent transmission of wave lengths less than 360 millimicrons, which is near the beginning of the visible. However, a much more satisfactory test can be made at a wave length of 406 millimicrons because the spectrum of a mercury lamp shows a sharp and distinct line at this wave length, and hence a test of great accuracy can be made. Further it has been found by test that all glasses have a transmission curve which either slopes up or down beyond this point, Fig. 5. If then a limit is placed on the transmission at this wave length, an accurate test can be made at this point and a rough confirmatory test made somewhere in the ultra-violet to show that the trend of the curve is not upward.

Although it has not been definitely proven that infra-red rays cause permanent injury to the eye, the protection against them is so easy of accomplishment that it should be furnished. However, it is not desirable to set a fixed limit on the transmission of all wave lengths in the infra-red, but rather to set a maximum total transmission for arc welders' goggles together with a limitation of the transmission in the visible. The specification for welders' goggles as proposed for the Safety Code for Head and Eye Protection is as follows:

Helmet windows shall transmit not more than 1 per cent of the radiant energy of any wave length less than 406 millimicrons, not more than 1 per cent of the light and not more than 10 per cent of the total radiant energy from a 200-watt, 110-volt, gas-filled tungsten-filament electric incandescent lamp operating as commercially rated (approximately 0.86 watt per spherical candle).

A similar specification has been written for oxy-acetylene welders and cutters' goggles. The light source in this work is not as intense as in arc-welding and the worker must be able to see his work clearly. These criteria must be taken care of in writing the specification for these lenses. Ultra-violet rays are present, however, and, therefore must be dealt with as in arc-welders' goggles. The visible and infra-red are limited by prescribing a maximum total radiant energy. The rule for oxy-acetylene welders' and furnace workers' goggles is as follows:

Lenses or helmet windows shall transmit not more than 1 per cent of radiant energy of any wave length less than 406 millimicrons and not more than 50 per cent of the total radiant energy from a 200-watt, 110-volt, gas-filled tungsten-filament, electric incandescent lamp operating as commercially rated (approximately 0.86 watt per spherical candle).

Protection may be obtained by the use of a single glass which has the proper transmission for the various parts of the spectrum or a number of glasses may be used providing the transmission through the combination is properly limited.

DISCUSSION

CHAIRMAN OARTEL: Gentlemen, while I will admit this was a little over my head and perhaps over the heads of some of you, yet it is a mighty good thing, this work that the Bureau of Standards has been developing. The practical end is that they are going to tell us just whether a goggle

will injure a man's eye or not. I am very sure Mr. Oakes will be glad to answer any questions you may have to answer.

MR. OAKES: Those papers I referred to are part of the regular publication of the Bureau of Standards, and you can get them by writing to the Bureau.

MR. HOMER J. WEEKS (American Steel and Wire Company, Cleveland, Ohio): I would like to ask Mr. Oakes if he has run any tests on "Crookes' " glass?

MR. C. E. OAKES: I haven't, but the Optical Section has. They have made a very elaborate test which is described in that publication.

MR. HOMER J. WEEKS: Can you tell me what per cent of the light is cut out by this glass and what per cent of the ultra-violet rays?

MR. C. E. OAKES: I can find it here shortly.

(Mr. Oakes referred Mr. Weeks to the pamphlet he mentioned in his paper.)

CHAIRMAN OAKEL: Are there any other questions?

MR. KINGSLEY (Syracuse, N. Y.): I have taken from what Mr. Oakes has said that the ordinary "Pug" glass will not eliminate very much of the ultra-violet rays.

We do a lot of melting steel electrically. The head of the department says that in fixing the slag of the furnace, the men do not look at the arc, they just look at the slag they are fixing. The arc is there and the rays hit the eyes. I want to know whether looking at the rays will affect the eye.

MR. TOLMAN (National Lead Company): I would like to know what the unit of area is in testing these lenses for admittance of radiation.

MR. C. E. OAKES: The unit of area isn't limited at all. You can use a piece of glass an inch in diameter, usually a piece of two inches by two inches.

MR. TOLMAN: What are the specifications in terms of the amount of light that would pass?

MR. OAKES: Just what do you mean?

MR. TOLMAN: I mean the thickness, the area through which the light passes.

MR. OAKES: If the lens represented four square inches and allowed fifty per cent to go through, the intensity would be one-fourth as great. It doesn't make any difference if you have it larger—

MR. TOLMAN: What I am getting at is that the eye is using at any one time a certain standard area of that glass and, for example, in exposing to arc welding, there is a very small area of that glass used at any one moment, and it is the density of that glass that interests us. It is specific density and not the density of an undetermined area. It seems the area must be defined on the test.

MR. OAKES: The only thing that controls it is the thickness and the quality of the glass itself.

For instance, I can take a high intensity source, and as I explained by the curve, the amount of light as detected by the arc, there is a physiological effect which varies somewhat with the density of the source, but not

enough to make those specifications in it practical, for they are now subject to much alteration.

MR. TOLMAN: There is one other thing, the question of lenses of varied thickness, that is, a lens with a dense spot in the center, with a tapering density, reducing resistance to the rays from that spot out—that protects the man's eye from the arc itself and yet enables him to see in the area around the dense spot. It avoids introducing a tripping or falling hazard at the time you are protecting his eyes from the light.

The lense that is dense all the way over is practically so thick that a man cannot see the moment he turns away from the light, and he is very likely to trip over some hazard on the floor. Has that subject been given any attention?

MR. OAKES: The thickness of the glass does have a slight effect on the transmission but the effect is so small that when you are considering arc welders' glass, it is almost negligible. We have to reduce it to such a low minimum transmission that the thickness is almost a negligible quantity. The ratio of the transmission varies.

CHAIRMAN OARTEL: If there are no other questions, we will proceed with the rest of the program.

This is a very valuable subject and it might be a good idea to continue the subject next year, because there will be more developments by that time.

I will now call for the report of the Nominating Committee.

REPORT OF NOMINATING COMMITTEE

MR. BENNETT: Mr. Chairman, the Nominating Committee offers the following nominations: for Chairman, the present Chairman. Mr. J. A. Oartel; for Vice-Chairman, Mr. W. E. Watters, the present Secretary for the Section; and for Secretary, Mr. H. E. Steinmetz of the Midvale Steel and Ordnance Company.

(These men were elected.)

CHAIRMAN OARTEL: I appreciate the confidence you impose in me in electing me Chairman of the Metals Section, one of the largest sections of the National Safety Council.

I have tried to do what I could in the term of my office, which was only a part of a year, and I want to assure you that I will do what I can for the promotion of safety in the Metals Section in the great steel and iron business of the country.

MR. W. E. WATTERS: I appreciate this honor, and I will give you everything I have and be as faithful in the coming year as in the past. It has taken a great deal of my time but I have given it with all my heart, and I will do the same the coming year. I thank you.

MR. H. E. STEINMETZ: I have nothing interesting to offer to the Section. I wish merely to thank the members of the Metals Section for having elected me to the office of Secretary, and I will try to carry on the work which Mr. Watters has so ably handled during the past year.

CHAIRMAN OARTEL: Gentlemen, I take delight in partially returning the compliments a certain gentleman has been paying me for a long time.

So, without preliminaries, I want to introduce to you a real man. I think that is perhaps the best thing I can say about him. It was my privilege to go to St. Louis in April to address the Safety Engineers' School which is being carried on there by the Mississippi Valley Division, and the audience was composed of 330 men—foremen, superintendents, safety engineers, and such people, interested in safety there to learn. That was the impressive thing, and they were there because Mr. Stremmel was at the head of the thing and kept it going. So, Mr. Stremmel has made a big contribution to safety in the Mississippi Valley during the past year, and I am sure his influence is going to become wider as the days and weeks go by. I take pleasure in introducing Mr. Philip Stremmel, who will speak on "Humanizing a Steel Plant."

MR. PHILIP STREMMEL: I do not know why this subject was assigned to me. To my mind it is the most important subject before this convention. It is a subject in which we are all vitally interested. It seems to me that there are men in attendance at this convention who are far better qualified to handle this most important subject than I am, but it has been assigned to me and I have done the best I could.

HUMANIZING A STEEL PLANT

PHILIP STREMMEL, SUPERINTENDENT, HOT MILLS, NATIONAL ENAMELING AND STAMPING COMPANY, GRANITE CITY, ILL.

The World War, through which we have just passed, and the innumerable problems growing out of it, challenge Capital as it has never been challenged in all history. The world, in respect to labor, wages, hours of labor, management, etc., is practically chaotic. No one knows what a day may bring forth. We do know, however, that underneath this seething volcano of unrest there are certain unmistakable facts. The part Labor has played in the great world struggle has rejuvenated her. The working men are not only awake, but they are conscious of exerting a tremendous power. They are also determined that the fruits of the awakening shall not be lost. They look back on the old days and wonder how they could ever have submitted to that regime, and now Capital and Labor must settle the issues so clearly raised. The issues being joined, we must candidly and intelligently set them forth and abide the arbitrament of Reason and the dictates of Justice.

How, then, can we Humanize the Steel Industry? And how do our share in solving the fearful problems of world reconstruction?

CONFIDENCE MUST BE RESTORED

First: If the steel industry is to be humanized, confidence must be restored between the employer and employee. The whole history of the steel industry has been one of struggle. The employees have believed that their rights could only be secured and maintained by organization. They must organize or they were helpless. On the other hand the em-

ployer fought organization, because he was convinced that it was an invasion of his rights. The truth is, both were partly right and both were partly wrong.

The employer and employee must come to a state of mutual understanding, and in the realization of that fact a great step forward shall have been taken. The employer must not limit his interest in his employee merely to his power to produce. He must also see his family; their educational, social, and spiritual needs must express themselves in the pay roll. Not merely an employee is to be dealt with, but his family also. The employer must have vision enough to see that he must not think only in terms of profit and production but he must also think in terms of his responsibility to the community growing out of his plant.

So when Capital, keeping pace with sociological thought as well as with modern methods and machinery, sets itself to see man as a man as well as a worker the old dissatisfaction and distrust will disappear. The basis of confidence, therefore, is self-respect. Without respect, mutual respect between employer and employee, there can only be struggle to the bitter end, which will ruin both.

The employer can no longer camouflage the employee. He can no longer get up in large conventions, make speeches about the rights of the laboring man, that labor is not a commodity, that labor has the right to organize, that wages must not be reduced, that there must be a fair system of collective bargaining, that there shall be no baron and serf, then return to his respective plant and permit the very thing to come to pass that he had spoken against and received much praise and publicity about.

But if we respect the employee's rights, concede that many of his demands are incontrovertibly just, he, in turn, will come to respect us and the basis of confidence becomes an established fact. This is basic. No enterprise, however great or strong or essential, can abide the troublesome days ahead, that does not seek to build upon the foundation of fundamental social needs. This matter of self-respect involves the freedom to think and to act on one's conviction. The employer cannot have the confidence of his employees if he discharges men because they believe in organization or belong to a radical political party. We have condemned wanton acts of destruction and did not realize that the employer's methods of repression, lack of fair play, had much to do in making their employees the prey of conscienceless agitators. To restore confidence means that the agitator will be a fact of history. In the new order of justice, honorable dealing, respect, there will be no place for the agitator who doubtlessly has prejudiced Labor's cause on many a field of battle.

COÖPERATION BETWEEN EMPLOYER AND EMPLOYEE

Second: If the steel industry is to be humanized there must also be coöperation between the employer and employee. The employer and the employee have certain definite interests in common, and the one lesson that all concerned must learn is coöperation. It means success anywhere. It must always be remembered that the steel plant is only a cog in this great progressive movement, and that our work must be viewed, there-

fore, from the standpoint of the world. Coöperation then would mean a united effort in attempting a solution of our present difficulties as well as the matter of increasing efficiency and production. If jealousy, suspicion, distrust, covetousness, are permitted to fatten in the minds of the employees, what can the employer expect but war? It will be war, day in and day out, as long as men are moved by such motives. Production will be curtailed; the men will grumble; the atmosphere will become anarchistic, and in the end both Capital and Labor must pay the cost. A way out can be found. It will be found. We have faith in our business and we must acquire faith in man, faith in movements, and look forward to the gradual elimination of the problems that at first seem insuperable. Coöperation is the outstanding lesson of the great war. As long as England, France, Russia, Italy, Belgium, Serbia, fought alone, Germany went from victory to victory. America upon entering the war insisted upon a unified command. General Foch then became Commander-in-Chief of the Allied Armies. Now France did not fight as France, nor England as England, nor did any other nation fight alone, but each and all, from then on, fought as a single Army in a Common cause. Political and racial consideration were left behind, and the splendid coöperation began by the Americans at Chateau Thierry, drove the German back and farther back until finally he begged for Peace. England, alone, would have failed; so would France, so any other allied nation. American resources saved the world; not in ourselves alone, but because we saw that the cause was one, and that coöperation on all fronts, all pulling together for the one great purpose of victory would make it an actuality. Labor and Capital must learn this lesson. The way is not clear, but the fog is lifting, and if there be a way out, coöperation will find it. Capital and Labor must see that no lasting victory can come to either side, if it come out of jealousy, envy, hatred, distrust. But all pulling together, a just wage, fair conditions, and shorter hours can be had; and all involved enjoy their rights and privileges as men and as citizens as we march onward to the triumph of right, of justice, of truth, or brotherhood—the day when dreams come true.

EVOLUTION OR REVOLUTION

In the third place, the steel industry must be humanized to save itself from industrial revolution. The old days are gone, and it is no longer a question of returning to pre-war conditions, which is unthinkable; but it is a question of working out the demands, the ideals of Labor, in an orderly process. It is either evolution or revolution; strikes, lockouts, will seem small matters as we face the deadly struggle of Capital and Labor growing out of the world upheaval.

Labor is organized, and is organizing more intensely and determinedly every day. Workmen mean to maintain the new standards of living and they will work out the pressing, if not distressing problems peaceably if properly approached, and in time. They have had to fight every inch of the way, and the laboring man, the world over, is in a fighting mood today and means to win. Labor, then, must be approached in the spirit

of the times. Capital will simply invite destruction if it attempts to maintain the old order. We must see the world as it now is and deal with the new conditions in a spirit of justice and of utter unselfishness. This does not mean that every demand made by Labor can be granted, but it does mean that in the granting of some of their demands that we propose thoroughly to face the issues, exhibiting a spirit of fairness, of willingness to do all that is within our power to give Labor her due and also keep our business upon a paying basis. Our profits may not be so large as formerly, but the confidence, the harmony, shall have made our investment trebly secure, because out of the readjustment will come not only respect, but love for law and order. There is no other way that is so full of promise: and in view of the unprecedented economic upheavals shall we not follow the path that leads to peace and security? If we still doubt and hesitate let us turn our eyes toward Russia. Do we want such an economic revolution in our land, and shall we, by sheer resistance, continue to feed the flames of hate between rich and poor, that when the revolution comes a man and his family shall be killed simply because he has money? The war did not cause Bolshevism, it only gave the Bolshevist-minded a chance to rally the oppressed peasants by promises of economic freedom. To understand Bolshevism we must know the history of Russia, and how the nobility—the class of wealth—by the abuse of their power, their utter selfishness, the lack of vision and of faith, made possible the most tragic spectacle of the modern world. We have judged Bolshevism by its atrocities, its cruelties, its vices, but we must also see an oppressed Russia—a Russia of economic slaves. They, the masses, have suffered long centuries, and finally maddened by the very inhumanity of their condition, Trotsky and Lenine make wealth or its possession the crime of crimes. Death and starvation stalk abroad in that once powerful empire, and the whole world shudders as her Bolshevistic doctrine threatens the very heart of civilization itself. Russia, ignorant Russia, is feared by the whole world. But America is not ignorant, and the American laborer has a leadership today that for brains, for penetration, for acuteness, for perspicacity, will compare favorably with leadership of any of the great corporations of the land.

Our Universities have made a scientific study of our social life. Sociology cries out that these conditions can be changed, that they must be changed, and the conscience of the country is behind these movements and preachments. Sociology is not socialism. Let us not confuse the issue. Sociologists on the whole are sane and are making an invaluable contribution to our social life. They are not prejudiced usually, but they are the prophets of a better day. These leaders of thought want the new day to come by evolutionary processes. They do not plead for confiscation of property, but they do plead for the admitted rights of men. These are some of the forces that are leavening the new order, and the world's greatest Prophet challenges Capital by the mightiest words of history, saying: "Whosoever loseth his life shall save it; and whosoever saveth his life shall lose it." So Capital can only save itself by losing itself, and in the losing of itself makes for Democracy, the brotherhood of the world.

shall be glad to answer them while I proceed to connect up the regulators to the gas cylinders.

The first question is, which regulator to connect to each acetylene cylinder. The manufacturers have arranged these so that there can be no mistake. You will notice that the oxygen regulations are usually painted red and the acetylene black, and the connections will not fit the wrong cylinder. The cylinders are made with connections that look as if they would fit, but generally one has a male connection and the other has a female connection.

The first thing to do is to look in all your valves and see that there is no dirt or oil. In charging these cylinders, some one may take off the cap, leave it undone, and some one else may drop oil in there. One drop of oil would mean that the man would go to the graveyard.

The next thing is connecting up the hose. Hose for oxygen is either white or red and for acetylene black. Both are tested to stand 300 pounds pressure to the square inch, but it is a good plan to use hose on one gas only, because in changing about one may take up one hose and connect it on the other connection and cause trouble, especially in acetylene and hydrogen. It causes bad results to change hose.

QUESTION: Do you use any filler on your thread?

MR. SCHLEICHER: No, sir. There is no filler, oil or grease of any kind used on the connections. Several government departments specify one quarter inch iron pipe thread connections so that any change of the hose will fit.

You will notice that there is a clamp supplied with each hose that prevents leaking at the connection. This clamp surrounds the hose completely. In tightening, there is no slipping of the hose to cause a leak. A spark on the man's clothing might ignite and cause fire.

QUESTION: Is there any danger of using glycerine?

MR. SCHLEICHER: Glycerine and graphite are the only lubricants safe to use.

QUESTION: What type torch is that?

MR. SCHLEICHER: This is manufactured by the Alexander Milburn Company. It is designed for cutting, and can be used for emergency welding.

Where a man has foundry work or any kind of light work, you use it for cutting and occasionally, when there is a necessity, you may use it for welding. You can use the same tips that are designed for this welding torch. You notice that one torch is heavier.

QUESTION: Where does the mixture take place?

MR. SCHLEICHER: The mixture takes place in the tip.

The mixture in the torch has been done away with, for the simple reason that the fire from the ignition of gas will always go back to the point of mixture, and we found this a good practice: by eliminating the mixture in the torch, overheating is done away with, and the possibility of burning the operators' hands.

QUESTION: Is that torch guaranteed from backfire?

MR. SCHLEICHER: Yes. The tips are so designed that there is no back-firing. The gases are mixed after they pass the seat and there is an ex-

pansion chamber in the tip. The chances are if the tip did get overheated, the fire would go back to that expansion chamber, but no farther.

QUESTION: What is your tip made of?

MR. SCHLEICHER: It is made of a special composition of an alloy of bronze.

After connecting up the hose, the next thing is to see that there are no leaks.

On all torches, the oxygen, as a rule, is the top connection, marked OXY. Some manufacturers mark them with an "O." All are made with the gases at the bottom marked "A." With this torch, on cutting, you could not use one gas or the other with improper connections, but in welding, if you did connect the oxygen on the acetylene connection, it would make no difference because there are no mixed gases in the torch. The tips are designed to take care of either connection.

Now that we have connected up, the next operation is to turn on the gas. Don't stand in front of regulator. The practice has been to stand in front while opening the valve. That has caused accidents. First see that the regulating screw is released, no matter what regulator you use. By having it screwed in with the tension on the spring, and the valve open, there is 1,800 pounds pressure released from the initial pressure side to the delivered pressure side of regulator.

Now, with the regulating screw released, open the valve. This cylinder has a stuffing box at the top and it is best to open it all the way, if there should be any leak, it is made tight by the steam inside. There are other cylinders that do not have the feature, but should there be any leak, they are arranged to shut off the supply immediately. Take the cap off and fasten the stuffing box that holds the pressure in.

The next thing is to get the pressure desired to the torch. Then it is well to find if there is any leakage. Shut off gas and try your connections. Now if the indicator stays in the position that it is set to, you know there is no leak. The acetylene gas is the same thing.

Next see that your regulating screws are released and then open up your torch valve. Always stand back of a regulator when you open up the valve. Don't stand in front because there may be something inside of the regulator to cause it to blow out.

The acetylene cylinders are charged at the stations to three hundred pounds pressure. They are then allowed to set, and the pressure drops to about two hundred twenty-five or two hundred fifty pounds. This bottle, and all cylinders of acetylene are filled with a porous substance that is saturated with acetone to absorb the acetylene gas. Free acetylene gas in a cylinder, if compressed to over eighteen to thirty pounds pressure, would be dangerous, but compressed into the cylinder charged with acetone is safe, the acetone acts as a sponge and absorbs the gas and keeps it from exploding from hard knocks. You could fire a bullet into that cylinder and it would not explode.

It is important to handle them carefully, especially oxygen cylinders. They are tested to 3,000 pounds pressure, but if you knocked that cylinder down, or stood it near heat, it might open up some bad spot not

shown in the test. It should not shatter in fragments but open in seams; whereas, the soft plug in the oxygen cylinder is immediately behind the valve.

Now, if this oxygen cylinder is set out in the sun it would raise the pressure, and if it gets in the neighborhood of 2,000 or 3,000 pounds, the soft plug would give way.

QUESTION: What temperature is dangerous in the sun?

MR. SCHLEICHER: Whenever they are set in the sun, it is a good idea to cover them. I have seen them blow out at less than twenty-six hundred pounds.

The acetylene cylinders have two safety plugs in the top and two in the bottom, so if there was any fire in the building, it would release and the acetylene gas would burn out as at a torch tip. The fire would not get into the cylinder unless there was a mixture of air. It is mixture of air that causes explosions.

QUESTION: I have known of two instances where the soft plugs did not blow out.

MR. SCHLEICHER: Did the bottle burst?

QUESTION: Both cases were identical. There were seventeen tanks in each case—sixteen worked all right and the seventeenth failed.

MR. SCHLEICHER: That was likely due to the oxygen producers or the bottle may have had a bad defect. They should be tested about every nine months, at any rate within a year.

QUESTION: What is the method of the test, a hydraulic test?

MR. SCHLEICHER: The cylinders are set into water and pressure of three thousand pounds put into the cylinders. The pressure is registered on a chart. You know that any pressure will make the bottle expand; that raises the water in the register column one quarter of an inch and if it doesn't come back as pressure is released the bottle is rejected. The working pressure is 1,500 pounds at seventy degrees Fahrenheit.

Now proceed with acetylene gas. This cylinder now registers 270 pounds. That is a little higher than usual. Probably this bottle might have been sitting in the sun and thus the pressure rose.

The ordinary operator may use but one size tip for general work. That is all right in his way of thinking, but it is not all right in the matter of gas saving. Each manufacturer gives a chart of the size tips to use on special work. This tip is number four. The chart shows what size work a number four tip will do. It is designed to cut metal from one inch up to six, and the pressures are two pounds for the acetylene, and six for the six inches material, and twenty to fifty for the oxygen. That is the correct amount of oxygen to operate this tip normally.

You will notice that below two pounds the cutting tip will be ineffective on one inch metal. Now, you can use a pound or so higher, but it is not necessary. You perhaps have noticed that some operators will screw the regulator in, getting ten or fifteen pounds, and try to cut one inch material. He is not only wasting gas but interfering with the proper mixture. It doesn't matter with the ordinary cutting but it does where you want a clean cut or want to keep from oxidizing the metal.

That is where you get your hard surfaces—by having too lean a mixture or too fat a mixture.

The number two tip will be used for this half inch material, with two pounds on the acetylene regulators and five pounds on the oxygen.

QUESTION: Does it make any difference the way you have the tip placed?

MR. SCHLEICHER: The principle of that is to work in a straight line, to have your holes one following the other so that the first hole is pre-heating the metal at the top surface and the back hole will take care of the sides, the center doing the cutting.

Some men say, "I can do cutting with a welding torch." Some can if they get the piece hot and are steady enough to hold it and continue to cut by shutting off the acetylene gas and by using oxygen alone. Any metal except cast iron, will burn under the action of oxygen. But the pre-heating is to do away with the lost time in trying to be steady.

QUESTION: Is there any trouble in starting a cut on a round, or circular surface?

MR. SCHLEICHER: In starting a cut on a round shaft, do not try immediately on top. I have seen a number of operators do that—try to cut on top and bore through. It is bad practice. It will give a bad cut and freeze up in the cut.

The best practice is to get about one quarter from the bottom of the round and work up. That keeps the bottom of the cut clear, whereas if you start on the top, it will freeze and cause the oxide to flow around the shaft, and before you get through, you will be cutting the oxide, also the iron.

That is on shafts up to eight, ten or twelve inches. In pieces of twenty-nine or thirty inches or larger, the manufacturers have a straight head torch. We have a straight head torch but this is the angle head torch.

In making shafts for steamers, they forge them out in two sections with a large flange in the center.

(Mr. Schleicher drew a diagram on the blackboard.)

They vary from twenty-four to thirty inches in diameter. The torch is fastened in a fixed position and the shaft is set on rollers and revolved toward the torch. This keeps the cut clear. You would cut in, say eight or ten inches, or as far as you can until the center ranges from twelve to fourteen inches. Then by getting a long tip and bringing in your torch, you can finish the cut through. With a machine held rigid, you can do that readily.

In connecting up the tip, it is always a good principle to make sure, no matter what seat or torch you are using, that both seating surfaces are clear. Oftentimes torches lying in a box or somewhere in the shop will get some dirt, oil or particle of iron on either seat which will cause a leak, and a leak is bad both for the operator and torch.

I will set the tip in position to cut a half inch thick on straight cutting and adjust the pressures for same, two pounds on the acetylene and ten pounds on the oxygen. Now oxygen in itself will not burn. The fuel in this case is acetylene. If you use a match, do not hold it in your hand because the flame might burn your glove or hand. If you have no

lighter, lay match on a surface and then turn the tip to it.

It is much cheaper to buy a friction lighter than to heal a burned hand. In lighting a torch put your thumb on the turned part of your lighter and use your friction lighter in the right hand and your torch in the left hand. Then if the gas does strike your lighter, it will not strike your hand.

Are there any questions you would like to ask? You may have something in mind.

QUESTION: At about what distance are the eyes, not protected by goggles, subject to injury?

MR. SCHLEICHER: There is no set distance that would be a good rule for the simple reason that one person could stand there all day and it would not affect his eyes, and another may be affected in a few minutes. With oxy-acetylene the ill results are not nearly so quick as with electric, if you look at an electric arc with the naked eye it is sometimes disastrous.

It is always a good principle to see that the goggles you are using are suited for your eyes. It is not good practice to get just any pair of goggles. We give all operators three or four pairs of goggles to try. We let them work with them for a while to see which are suitable. You may be using a light pair of glasses when a dark pair would be better for you.

Now, (demonstrating) there is the neutral flame; it is neither in excess of oxygen or acetylene. There is a second cone; there is a particle of dirt. Now, notice that flame is very blue, indicating an excess of oxygen. You could cut with that flame but it would be very much slower than the proper neutral flame. Notice the difference in color when I turn off and on. There is the excess of oxygen and there is the neutral flame. Can you see that extra stream of oxygen through there, in the center? That is what does the cutting—that stream of oxygen, the metal oxidizes or is cut away.

Now, the principle in cutting is to hold your flame so, (demonstrating distance from metal), as the greatest heat is at the end of the white cone. The heat there at the apex of that white cone ranges from sixty-one to sixty-three hundred degrees Fahr. If you hold it down hard on the metal, you will be smothering it. Then, if you hold it up too high, it won't cut well. The general rule is about one quarter inch. With this tip a quarter of an inch would be all right.

The first thing is to get your flame down to the metal which is about a quarter of an inch at the apex of that cone to tip end. The metal heats very readily. Do not turn in your oxygen until you can see the metal in a molten condition. If you do, you will have the metal thrown up in your face.

In general practice there are frequent calls for cutting holes in metal. The principle is to hold torch in right position, touching the metal with flame to heat it. Be very slow when you start in such a position and you won't have an excess of sparks flying.

If there are any questions you would like to ask, or if you would like to (Informal discussion followed.) try the torches and regulators, you can.

Adjournment:

Mining Section

October 2, 3, and 4, 1919

B. F. TILLSON, Chairman

Assistant Superintendent, New Jersey Zinc Company, Franklin, N. J.

H. G. DAVIS, Vice-Chairman

Lehigh and Wilkes-Barre Coal Company, Wilkes-Barre, Pa.

W. H. SHEARMAN, Secretary

New Jersey Zinc Company, New York City

THURSDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M. by the Chairman, Mr. B. F. Tillson.

DELEGATES ATTENDING

Arthur, P. M., American Zinc Company of Tenn., Mascot, Tenn.
Bach, E. E., Chief, Americanization Bureau, State of Pa., Philadelphia, Pa.
Baker, D. J., "Coal Age," Pittsburgh, Pa.
Balck, Carl, Prudential Insurance Company of America, Newark, N. J.
Bennett, Charles B., U. S. Metals Refining Company, Chrome, N. J.
Betz, John A., Lytle Coal Company, Minersville, Pa.
Boardman, John L., Anaconda Copper Mining Company, Butte, Mont.
Bowyer, C. B., Stonega Coke and Coal Company, Stonega, Va.
Brissenden, P. F., U. S. Dept. Labor, Bureau of Statistics, Washington, D. C.
Budeller, William, North Butte Mining Company, Butte, Mont.
Carpenter, T. J., Semet-Solvay Company, Ensley, Ala.
Chase, W. C., Woodward Iron Company, Woodward, Ala.
Concannon, John, Anaconda Copper Mining Co., Butte, Mont.
Davis, E. K., The B. F. Goodrich Company, Akron, Ohio.
Davis, H. G., Delaware, Lackawanna & Western Coal Co., Wilkes-Barre, Pa.
DeBlois, L. A., E. I. du Pont de Nemours & Co., Wilmington, Del.
Dingman, Oscar A., East Butte Copper Mining Co., Butte, Mont.
Durkee, J. O., "The Coal Industry," Pittsburgh, Pa.
Dwight, Arthur S., American Institute Mining & Metallurgical Engineers, New York City.

Fay, A. H., U. S. Bureau of Mines, Washington, D. C.
 Flyzik, Martin J., State Safety Board, Olympia, Wash.
 Gidley, W. W., Phelps-Dodge Corporation, Bisbee, Ariz.
 Goodale, C. W., Anaconda Copper Mining Co., Butte, Mont.
 Green, C. L., Consolidation Coal Co., Fairmont, W. Va.
 Guerrant, R. H., National Safety Council, Chicago, Ill.
 Hall, R. Dawson, "Coal Age," New York City.
 Hamilton, Alice, U. S. Dept. Labor, Bureau of Statistics, Washington, D. C.
 Hubbell, N. D., W. J. Rainey Coal Co., Uniontown, Pa.
 Hunter, E. R., Dr., American Red Cross, Washington, D. C.
 Kerr, James L., E. I. du Pont de Nemours & Co., Wilmington, Del.
 Knoefel, A. F., Dr., Bureau of Mines, Terre Haute, Ind.
 Kurtz, R. H., Miller Rubber Company, Akron, Ohio.
 Lewis, T. D., Lehigh Coal & Navigation Co., Lansford, Pa.
 Lockney, I. L., Chief Safety Engineer, State Safety Board, Olympia, Wash.
 Luckenbach, G. A., Koehler Safety Co., Scranton, Pa.
 Lunt, Horace F., State Bureau of Mines, Denver, Colo.
 McLeod, Angus, Butte & Superior Mining Co., Butte, Mont.
 McMorris, Ed., Union Carbide Co., Sault Ste. Marie, Mich.
 Moore, P. W., Ohio State Mine-Rescue Car, Columbus, Ohio.
 Morris, F. F., American Atmos Corporation, Pittsburgh, Pa.
 Murphy, M. E., Pickands, Mather & Co., Cleveland, Ohio.
 Myers, Fred W., New Jersey Zinc Co., Franklin, N. J.
 Oda, Fumio, Kyushu Imperial University, Japan.
 Osborne, Fred, Somet-Solvay Co., Holt, Ala.
 Purcell, C. A., American Atmos Corporation, Wilkesburg, Pa.
 Quayle, S. E., W. A. Hanna & Co., Virginia, Minn.
 Randall, W. I., E. I. du Pont de Nemours & Co., Wilmington, Del.
 Raymond, R. M., Columbia University, New York City.
 Reed, Joseph W., Consolidation Coal Co., Fairmont, W. Va.
 Rellis, J. F., Union Carbide Co., Sault Ste. Marie, Mich.
 Roach, L. R., Wisconsin Steel Company, Benham, Ky.
 Roberts, J. C., Colorado School of Mines, Golden, Colo.
 Riggs, George W., Mine Safety Appliances Co., Pittsburgh, Pa.
 Richards, R. C., President, National Safety Council, Chicago, Ill.
 Schofield, W. D., Inspiration Consolidated Copper Co., Miami, Ariz.
 Seip, R. H., New Jersey Zinc Co., Franklin, N. J.
 Shearman, W. H., New Jersey Zinc Co., New York City.
 Shove, Byron D., Oliver Iron Mining Co., Ironwood, Mich.
 Sinn, F. P., New Jersey Zinc Co., New York City.
 Smith, E. W., Deputy, State Mining Dept., Byesville, Ohio.
 Southward, G. B., West Virginia Coal & Coke Co., Elkins, W. Va.
 Sperr, F. W., Michigan College of Mines, Houghton, Mich.
 Sullivan, W. W., Oliver Iron Mining Co., Hibbing, Mich.
 Swan, George, Davis Daly Copper Co., Butte, Mont.
 Tillson, B. F., New Jersey Zinc Co., Franklin, N. J.
 Trestrail, A. H., Pickands, Mather & Co., Palatka, Mich.
 Van Schaack, David, Aetna Life Insurance Co., Hartford, Conn.

Watson, Joseph E., Timber Butte Milling Co., Butte, Mont.

Williams, S. J., National Safety Council, Chicago, Ill.

Wilson, C. H., Utah Copper Co., Garfield, Utah.

Wilson, T. D., American Atmos Corporation, Pittsburgh, Pa.

Woodburn, Orr, Globe-Miami District First Aid Assn., Globe, Ariz.

CHAIRMAN TILLSON: Gentlemen, it is a pleasure for me to welcome you all to the fifth annual meeting of the Mining Section of the National Safety Council. In view of the fact that your Chairman has a paper at the last session on Saturday morning which, in part, deals with the past activities, as well as proposed new activities, he believes that time can be economized by not burdening you with any historical resumé of what has been taking place during the past year, as that will be covered to a general degree in that paper.

In addition to the papers we have listed on the program, we have arranged, if we have time, to consider several other subjects. The National Safety Council prepared Safe Practices pamphlets on "Manila Rope" and "Mine Car Haulage"; the former is a subject close to the hearts of mining members, which has been discussed at times in the past and on which a special committee has served since the inception of the Mining Section.

A few copies of this pamphlet will be accessible to us, and it is desirable, if any recommendations are to be made on the points not included in the pamphlet, that those things should be made record of.

Mr. Guarrant, Safety Engineer, of the National Safety Council, this year made a tour to some of the mining properties to start a Safe Practices pamphlet on Mine Cars and Haulage, which was a subject upon which strong opinion was expressed at the last Congress, and recommended as a subject first to be covered by a Safe Practices pamphlet devoted to the specific needs of the Mining Section alone. We may be well pleased to know that this new departure has been shared by only two other sections in the National Safety Council.

Instead of distributing the pamphlet previous to our meeting, it was deemed advisable to hold it in mimeographed form until we had the advantage of all the opinions of the members who would meet at this annual Congress in revising the suggestions which were made and giving the benefit of their experience, in adding new information and new cuts which might well illustrate it.

There is another paper not on the program which, when the time seems auspicious, will be brought up for discussion in the Section.

In the regular order of business, the reports of our committees are in line, and first I believe it is the proper thing for the Chairman to appoint a Nominating Committee to consider the officers of your Section for the coming year, and submit a slate at our final session on Saturday upon which slate you can vote or nominate any other men from the floor for the offices in question. It is merely the function of the Nominating Committee to see that at least the procedure is co-ordinated so that there will be some nominees for the positions. I take great pleasure in requesting Mr. R. Dawson Hall to act as Chairman of the Committee and for him to be assisted by Mr. C. W. Goodale and Mr. J. C. Roberts, to

gather together as they find time and consider a slate of officers for your Section for the coming year.

The Chairman of the Standardization Committee is absent. Mr. Mitke was Chairman of that Committee and he was called away for some work in Mexico. He has not forwarded any report and in due justice to him, I may say that his appointment was late and I know of no particular activities which the Committee has performed this year.

Mr. R. Dawson Hall, the Chairman of the Membership and Publicity Committee, is with us, and I will ask him for his report.

REPORT OF MEMBERSHIP AND PUBLICITY COMMITTEE

MR. R. DAWSON HALL ("Coal Age"): I am afraid that during the year I have been obliged to leave much of the work to the headquarters of the National Safety Council. All the information I have at this time is that the membership of the two sections, the Metal and Coal Mining sections, amounts to 253, of which 165 are of coal mining companies and 88 metal. They have paid in dues \$6,532.50 and \$7,877, making a total of \$14,409.50. I think we have a pretty good membership and I think the feeling is good with regard to our Bulletins and that there is a general feeling of satisfaction, the only trouble being with those who are particularly anxious for more first-aid activity. I feel that is a matter that will be taken care of during the coming year, and I think then we shall be able to overcome all the difficulties which may be in the air.

I believe everybody is very well satisfied with the Mining Section of the National Safety Council and the prospects are very good for the coming year.

(The report was accepted.)

CHAIRMAN TILLSON: The Chairman of the Mine Rescue and First-aid Contest Committee unfortunately resigned from his office, due to the stress of work which had kept him from performing his duties. Dr. Shoudy had first accepted that position, but he found that he was unable to continue, as he was greatly tied up with other duties, and it was not found possible to replace him with a man of the same caliber, and due to the late season there is now no active chairman.

The Chairman of the Accident Statistics Committee is Mr. A. H. Fay. We will now hear from him.

REPORT OF ACCIDENT STATISTICS COMMITTEE

MR. A. H. FAY (Statistician, U. S. Bureau of Mines): I am afraid, as Chairman of the Accident Statistics Committee, I have been rather remiss. We have not had any meeting. About all I have been able to do is suggest a number of topics which might be brought up at this meeting. These were accepted.

I also suggested the names of some men who might be able to handle some of the particular subjects.

I might also say in connection with my regular work in Washington, I am supplying statistics for all of you, anyway.

(The report was accepted.)

CHAIRMAN TILLSON: Dr. A. J. Lanza, Chairman of Mine Hygiene and Sanitation Committee, I do not see present, so I presume he has no report.

Mr. O. P. Hood, Chairman of the Committee on Ropes and Safety Devices in Hoisting and Haulage, has sent in no report.

Mr. John Lloyd, Efficiency Engineer, Lehigh Valley Coal Company, Chairman Mine Fire Prevention and Fighting Committee, is not here yet.

Lt.-Col. C. H. Connor, Chairman of the Committee on Standardization of First-Aid Methods and Rules for Conducting and Judging First-Aid Contests, is not here. I understood that he was going to be represented by Dr. Hunter. Dr. Hunter is not here, so we will pass his report.

D. J. Parker, Chairman, Standardization of Mine Rescue Training Committee, is detained at Pittsburgh, and will be here tomorrow, when he will deliver his paper.

The first paper we have is that by Mr. A. H. Fay.

¹MINE ACCIDENTS: ENGLISH SPEAKING VS. NON-ENGLISH SPEAKING EMPLOYEES

ALBERT H. FAY, ENGINEER, U. S. BUREAU OF MINES,
WASHINGTON, D. C.

The employment of non-English speaking labor in American mines has been brought about by reason of the rapid expansion of the mining industry, beginning in the early eighties. The Americanization of this great body of labor, and its relation to accidents in the mining industry, are two problems of prime importance,—the first as affecting citizenship and the growth of this Republic, and the second as an economic problem in mining costs. The former exerts an influence upon the latter, for the former implies education, social welfare, civic pride, and a general uplift to the ideals that America stands for. Ignorance, dirty and filthy living conditions, ill-health, disregard for law and order, discontent and lack of civic interest, lead to indifference and carelessness, perhaps the greatest of all accident causes. Eliminate carelessness and at least 50 per cent of the accidents will disappear from industries.

IMMIGRATION TO AMERICAN MINES

During the decade previous to the year 1880 (as well as in earlier years), the greater part of the employees in the coal and metal mines were Americans or representatives of the English, Scotch, Welsh, German, and Irish races. The majority of the men of foreign birth had been in this country for some years previous to the great expansion of the mining industry which began about this time. English-speaking miners continued to immigrate and to find employment in the mines in large numbers until about 1890. Since that year comparatively few immigrants from Germany

¹A large part of the data in this paper was abstracted from "Immigrants in Industries," a report of the Immigration Commission, 1911. Senate document, 663, 61st Congress, Second Session, Vols. 6, 7 and 16, which are devoted exclusively to the mining industry. It is a report based on an exhaustive study of the question, and should be studied by every one interested in the Americanization of the miner.—A. H. F.

and Great Britain have entered the industry, although Swedes and other Scandinavians have been constantly employed since the early eighties.

The employment, in the mining industry, of immigrants from Southern and Eastern Europe began about 1880. The Slovaks were the first arrivals and immigrated in considerable numbers. They were followed within a year or two by a few Magyars, and the number of immigrants of this race gradually increased each year. The Polish immigration began about 1890, although individual members of the race had been coming for a period of nine or ten years. After the year 1890 Poles and Slovaks arrived in great numbers. A few Italians were employed before the year 1895, but the immigration of this race did not begin upon a large scale until about 1900. They were at first engaged in railroad construction and maintenance-of-way work and gradually drifted into the mines. Croats were employed in some sections before 1890, and Servians began to arrive in small numbers in the early nineties. The great bulk of all the immigration from Southern and Eastern Europe, however, has occurred within the past eighteen years. Russians, Bulgarians, Roumanians, Ruthenians, Syrians, Armenians, Macedonians, Croats, Servians, as well as Poles, Magyars, Slovaks, and Italians, have been among the recent arrivals. The races of Southern and Eastern Europe have continued, up to the time of the war, to find employment in the mines in increasing numbers in almost every important mining district in the Eastern States, and the Lake district. Many of these recent immigrants have found their way to the Central and Western states. As a result of the rapid expansion of the mining industry, many mining communities have been founded, the population of which is largely made up of immigrants who have arrived during recent years.

The pioneer American, English, Irish, German, Scotch, and Welsh miners are thus outnumbered and their positions filled by the more recent immigrants. It is not difficult to account for this racial change which is still going on. The former operatives and their descendants had opportunities to secure more congenial and safer work in other industries. Many of them advanced in the industrial scale, becoming foremen and attaining other responsible positions. A large number have abandoned the occupation of miner for positions as day or shift men. Many also migrated and located in the Middle West and Western states. Many of the former miners who left the industry entirely because of change in mining methods or the employment of immigrants entered mercantile, clerical, mechanical, and more pleasant work of other kinds. Many of the business and professional men in the mining towns were formerly mine workers. Their places were filled without difficulty with recent immigrants who were content with the wages and working conditions which prevailed in the mines. The wages paid in American mines seem very attractive to the recent arrivals of agricultural laborers from Southern Europe.

FAILURE OF NATIVE-BORN TO ENTER THE INDUSTRY

Another noteworthy tendency is seen in the fact that the racial displacement has occurred not only through the departure from the industry

of the former employees, but also through the refusal of their children to enter the industry and the attitude of the parents themselves, who frequently discourage it. Of the total native-born, of fathers who were miners, a large percentage enter occupations other than mining. The conclusion from the limited data at hand, therefore, seems to be that while the foreign-born males of more than 16 years of age, whenever employed, work in the mines, the persons native-born of native father, together with the second-generation immigrants, are entering the mines only to a limited extent. This inference bears out in a large measure the experience of the mine operators, who state that the native-born and the second-generation immigrants are not entering the mines in the same numbers as formerly and that the industry is receiving a constantly decreasing number of employees of these classes.

There exists a prejudice against recent immigrants, which also operates to an important extent in the displacement of former employees. Many Americans, English, Germans, Scotch, Irish, and Welsh did not and do not desire to be associated in the mines with the recent immigrant, and the feeling has become prevalent that a sort of reproach attaches to an intimate working relation with the foreigner. The races of former immigration have, therefore, left the industry and have entered other work which they feel is more dignified and congenial.

The relatively small number of American miners who remain in the industry must work side by side with the recent immigrant. To a greater or less degree the standard of safety in the mine is set by the demands of the ignorant and inexperienced immigrant, not by the more intelligent American, and the standard of life is decided, to a larger extent, by those conditions which will be accepted by the same recent immigrant. In short, in order to work in the coal mining industry, the Americans must compete with the recent immigrant, who, as a rule, is not very particular as to the living and working conditions. These conditions, however, are in most cases far better than in factory towns where congestion prevails.

Another effect of recent immigration from Central and Southern Europe has been the preventing of the English, Irish, Scotch, and German immigrant entering the mining industry. As already noted, these Western European races were coming to the industry in large numbers prior to the early eighties, but began to decline toward the end of the decade and practically stopped about 1893 or 1894. There can be no question but that the immigration of the Slovaks, Poles, Magyars, and other races operated to prevent the further coming of these older immigrants to the industry, precisely as it operated to drive out of the industry those already employed together with the native Americans. There is, therefore, no incentive for the English or German miner to migrate to the mining regions and compete with the Slovaks, Croatians, and Italians, etc.

CITIZENSHIP

A point of general interest is the tendency on the part of the different races of foreign birth working in the mining industry to acquire citizenship, and their general interest in public and civic affairs. The recent im-

migrant manifests little real or intelligent civic interest. This may be ascribed to his ignorance of our political methods, his inability to read or speak English, the social and political aloofness of these races in the more or less remote mining villages, and their desire to avoid taxation. Those who reside in or near the cities seem to exhibit more interest than do those of the isolated communities. It seems that the Bohemians and Moravians, 94 per cent of whom can read some language, take a much more active part in civic affairs than any other race of recent immigration in the bituminous districts of Pennsylvania. Among the other Slavic races, the Slovaks (82 per cent read) and Poles (77 per cent read) lead in this regard, while the Croatsians (67 per cent read) make the poorest showing. It is almost the universal statement that this latter race shows but little civic interest, and that very few become naturalized. The Italians (81 per cent read) both North and South, are more active than the Slavic races in their efforts to become citizens, and appear to take a more active part in civic affairs. In cases where there seems to be encouraging civic activity it is nearly always due, not to their own intelligent efforts to attain citizenship and exercise its privileges, but to the influence of interested politicians, who in many cases may be leaders of their own race; for example, an intelligent banker and steamship ticket agent. It seems true of all the later immigrating races that they take far less interest in civic affairs than did the German (97 per cent read) and English (98.5 per cent read) immigrants.

The foreigner should be taught that the laws of America were made to protect, and not harass, every good citizen, rich and poor alike, and it is the duty of well-informed Americans to make this understood. If well-meaning foreigners, the making of good citizens, are left entirely to their own devices, they fall an easy prey to the designing I. W. W. and the Bolsheviki. Somebody who understands their language fully, and in whom they have confidence, should explain to them that they are being deceived so long as they listen to anti-American propaganda.

RELIGIOUS ORGANIZATIONS AND THE IMMIGRANT

The association between the native Americans and the Southern and Eastern European immigrants is limited. The general attitude of many members of the native churches toward the immigrants is one of indifference and there is a strong inclination in many communities to shun association with the immigrant in religious activities. In many cases where missionary efforts are made, services for the immigrants are frequently held in barns, stores, or other unattractive places, thereby lessening the interest in them. The races from the Southern European countries, which compose a large portion of the mining population have been reared where there is no social caste in religious organizations, and have worshipped in buildings which are unsurpassed in beauty and grandeur. When these people are offered services held in stores, barns, and similar buildings, their interest in the services naturally is less and they become indifferent. Lack of interest in religious affairs tends to decrease activities in civic affairs. The various religious organizations can be important agents in

teaching these immigrants the rudiments of the English language and pointing out to them their duties as American citizens.

LACK OF MINING EXPERIENCE ON THE PART OF RECENT IMMIGRANTS

Men of the races of the old immigration (Western Europe) have been employed in the mines of the United States for many years. As a result of their experience both in this country and abroad, they are far better qualified as miners than are the Southern and Southeastern Europeans.

The older immigrants speak English either as their native tongue, or, as in the case of the Germans and Scandinavians, because of long residence in this country. They may be treated in almost every respect upon the same basis as the American miners.

The employees of the races of the recent immigration, on the other hand, have been in the United States for so short a period of time that even though it be assumed that they have been employed in mining ever since their arrival, they must have had but a brief experience at most of the mines of this country. The data further show that very few of their num-

ber had mining experience abroad. The accompanying chart, based on Table 1, shows that, for example, over 80 per cent of the Scotch and English miners had mining experience in their native country before entering the American mines, while for the south Italian and Croatian less than 5 per cent have had mining experience. Most of the latter were farm laborers in their native countries as indicated by Table 1 and the chart. Upon coming to the United States they decided to follow the occupation of mining because the work was better paid than any other obtainable, although many of them had been here only a few months and many more but a year or two. Under these circumstances it is not surprising that they know little or nothing of rock formations, of fire damp, of the properties of coal dust, and of the handling of explosives,—matters about which every coal miner should be thoroughly informed. To determine whether a piece of slate or roof is or is not likely to fall, often requires a considerable degree of experience, and the majority of the Slavs, Magyars, and Italians have not this experience.

IMMIGRATION IN ITS RELATION TO MINING ACCIDENTS

The mines are presumably less safe than they would be with native American, English, Irish, Scotch, Welsh, or German labor, because recent immigrants often accept more dangerous working conditions than the first-named employees. Furthermore, the later immigrants are ignorant and untrained, and are a source of danger to themselves and to the other workmen. Among the older mine workers the feeling is strong that the employment of non-English-speaking races has complicated the problem of safety in the mines. They assert that carelessness on the part of recent immigrants, and the ignorance of those who are suspected of having obtained their places without having had the required experience as miners, have tended to render the mines less safe and thus increase accidents.

A large proportion of the deaths and injuries reported for the coal mines of the United States occur among the non-English speaking miners. The employees consisting of the races of Southern and Eastern Europe, having had little experience in mining either in this country or abroad, are particularly liable to accidents, and as the responsibility for accidents rests in many cases with the men injured, to say that they are particularly liable to accidents is in effect to say that they are responsible for a considerable proportion of all the accidents occurring in the mines.

The mine accidents for which the workmen are themselves responsible fall naturally into two classes—those due to carelessness and those due to ignorance. As regards the first of these, it is probable that the foreigner is no greater offender than the person of native birth. Many of the Americans and other English-speaking miners are undoubtedly reckless, and a very large proportion of all the accidents occurring among their number seem to be due to this cause. Grave risks are often incurred for the sake of avoiding a little extra labor. Props are left unplaced, open lamps are used instead of closed lamps, cars are driven in a careless manner, explosives are handled recklessly—all in defiance of the most elementary rules prepared by men of long experience in the industry.

Among the recent immigrants, on the other hand, many of the accidents

are unquestionably due to ignorance, for by reason of their lack of experience, they do not see nor realize the dangers that confront them; nor do they readily comprehend the necessary precautions that must be taken to make their working places safe.

Lack of experience in the mines has a marked effect upon the high accident rate as indicated by a study of accidents among the immigrants whose experience in mines, before coming to this country, was known. The fatal, serious, and non-fatal injury rates in the coal mines of Pennsylvania and West Virginia are approximately 14.5 per 1,000, for those of whom 10 per cent had mining experience prior to coming to the United States. The accident rate for those of whom 10 to 20 per cent had mining experience is about 12 per 1,000, showing a rapid decrease as mining experience increases. It would seem from this while experience is limited, these immigrants soon gain sufficient knowledge to use a certain amount of caution thus giving a decline in accident rate.

As contrasted with the decrease in accident rates among those of whom 5 to 30 per cent have had mining experience, the accident rate based on similar data for those of whom 50 to 60 per cent have had mining experience prior to coming to this country is 10.5, whereas the rate is 12 for those of whom 80 to 90 per cent have had experience in the mines. A marked increase with the extra experience. This is largely due to the tendency of those with considerable experience to become more or less careless or reckless and to think that they can slight certain features of work without an accident. A new man entering the mine would not consider for a moment crimping a cap with his teeth, whereas many of the men who have been in the mines for 8 to 10 years would not hesitate and do not hesitate to crimp caps with their teeth. Other instances of carelessness might be cited. The available data, therefore, seem to indicate that inexperience is responsible for many accidents, and that a little experience begets much caution on the part of the recent or new employee. As indicated above, there is thus a tendency toward a rapid reduction in accident rates to a point where between 30 to 40 per cent of the employees have had mining experience. Beyond this percentage, caution wanes and is replaced by carelessness with a resultant increase. The green miner may be over cautious but he lacks experience. The worn-out miner has the experience, but too often caution is replaced by carelessness. Caution combined with experience will go far toward accident reduction.

Another element of danger is contributed by the fact that few of the recent immigrants speak or understand English (Table 2), while almost none are able to read or write the English language, and placards of warning do not reach them. It is probable that the instructions of the mine bosses and inspectors are, because of this fact, frequently misunderstood. An inspector, for example, tells an immigrant miner, in English, of course, that his roof needs propping. The miner seems to understand, but does not, and a fall results. In some mines printed signs are used to indicate the presence of gas or other peril. These signs are quite unintelligible to most of the foreigners. A common language is absolutely necessary in every safety-first campaign. Accident rates are much lower in England, France, Belgium, Germany, Austria, and Japan than in

the United States. In these countries but few foreigners are employed, a common language being used in each country. The difference in fatality rates cannot be entirely attributed to the lack of mixed languages, but certainly a large percentage of the accident reduction may be attributed to the "common language" mines.

*This table includes only races with 40 or more males reporting. The totals, however, are for all races.

Note: Compiled from "Immigrants in Industries," a report of the Immigration Commission, 1911. Senate Document No. 663, 61st Congress, Second Session, Vols. 6, 7 and 16.

A comparison of accident rates with the ability of the miner to read some language or to speak the English language, shows that the ability to read, although it may not be English, has a greater influence on accident reduction than the ability to speak English. This may be accounted for by the fact that ability to read develops a higher degree of intelligence and places the employee in a better position to realize dangers more readily than one who cannot read. Furthermore, if he is able to read, he is more likely to heed danger signs put up in certain places.

The recent immigrant, because of his lack of experience, his inability to speak English, and his keenness for earning money, is often willing to work in places where more experienced or more intelligent men would refuse to work. For the same reasons he will frequently be satisfied with and accept mine equipment too defective for safety.

OCCUPATION OF ENGLISH SPEAKING AND NON-ENGLISH SPEAKING RACES

TABLE No. 6

Percentage of employees by occupation and English speaking and non-English speaking races.*

Occupations	Americans and Western Europeans		Southeastern Europeans	
	Number	Per cent	Number	Per cent
Superintendents	10	.78		
Foremen	14	1.10		
Bosses	76	5.96	6	.28
Inspectors	10	.78	15	.70
Engineers and Motormen	50	3.92	12	.56
Firemen	29	2.27	10	.47
Electricians and Helpers	12	.94	7	.33
Blacksmiths and Machinists	33	2.59	13	.61
Carpenters and Masons	46	3.61	9	.42
Track and Roadmen	64	5.02	21	.97

Pick Miners	428	33.57	1,107	51.61
Loaders and Scrapers	45	3.53	379	17.67
Trappers	16	1.26	20	.93
Pipe and Pumpmen	20	1.57	7	.33
Laborers	176	13.80	271	12.82
Total	1,275	100.00	2,141	100.00

*Represents ten typical bituminous coal mining companies of Pennsylvania.

Table 6 shows comparative figures by occupations, based on the payroll of 10 typical coal-mining companies in Pennsylvania. These figures show that about 33 per cent of the English-speaking employees are employed as pick miners as compared with about 52 per cent for the Southeastern Europeans. As a matter of fact, from trackman to loader, the English-speaking employees represent about 61 per cent of the total, as compared with 82 per cent for the Southeastern Europeans. These figures, therefore, indicate that the non-English speaking foreigner is employed in the most hazardous of the mine occupations, hence one reason for the higher accident rate.

ACCIDENTS BY NATIONALITY, IN PENNSYLVANIA AND WEST VIRGINIA

For comparison of accident rates between the two groups of employees, the figures given in Table 2 are representative. In the Pennsylvania anthracite mines 43 per cent of the employees are English-speaking and this number is charged with only 28.8 per cent of the fatalities, whereas the other 56 per cent (representative of continental Europe) sustained 71 per cent of the fatalities. Likewise in the Pennsylvania bituminous mines the English-speaking employees represent 35 per cent of the total and are charged with 27 per cent of the fatalities, whereas the other 65 per cent (representative of continental Europe) are charged with 72 per cent of the fatalities. As regards the figures for West Virginia the English speaking employees represent 67 per cent, and notwithstanding the fact that this includes 17 per cent of colored employees, only 53 per cent of the fatalities are charged to the English-speaking employees, whereas the other 33 per cent sustained 47 per cent of the fatalities. Almost the same ratio holds for non-fatal injuries in the three groups of mines cited.

Had the fatality and injury rate for the English-speaking American been maintained throughout the three groups of mines, there would have been a saving of 716 fatalities and 900 very serious injuries, a strong argument for Americanization and education of the miner.

CHAIRMAN TILSON: Mr. Fay has added a valuable paper to his former valuable contributions to this Section, and I am sure it is a subject which is of considerable interest to all of us. We will now consider any discussion in regard to Mr. Fay's paper.

DISCUSSION

MR. N. D. HUBBELL. (W. J. Rainey, Uniontown, Pa.): Mr. Fay touched on one subject that has hit us in the bituminous coal region so hard that it is stirring up a lot of comment around the region. I don't know whether it will get outside the region or not. We are, like everybody else, feeling very much the scarcity of diggers. We get in the mine the second generation of foreigners. We probably have a higher percentage in the mines than Mr. Fay's figures show, but they do not go in as diggers. They start as haulers, trackmen, and many of them are taking the examination for fire bosses and assistants.

The officials of our company have raised this question, Is the state law, which limits the age to eighteen years, turning men away from the occupation of digging? They have cited many instances of boys who would go in the mine when they are sixteen years old with their fathers and dig, and by the time they are seventeen or eighteen, would probably be as good diggers as their fathers. Some of the officials of our company have made the statement that at that age I was just as good a digger as my Dad. However, if those boys wait until they are eighteen, they get a bigger, broader view of life and they won't go into the mine at all, and I doubt if two or three per cent of those who go in are willing to dig.

Would it be fair to ask for opinions of some one else on the question of whether or not the eighteen-year limit is really affecting our available material for making diggers?

CHAIRMAN TILLSON: Mr. Hubbell, I think that we can discuss that in one of our round-table discussions, which will be open for various subjects.

MR. MARTIN J. FLYZIK (Member State Safety Board, Olympia, Wash.): I would like to ask Mr. Fay a question. Where does the Bureau of Mines find the greater percentage of accidents per one thousand men employed or one hundred thousand tons of coal mined, in the bituminous region or in the anthracite region of the United States?

MR. FAY: I haven't the figures at my finger's ends. In Pennsylvania, bituminous is lower than anthracite. I am inclined to think the bituminous is lower.

MR. FLYZIK: For fifteen years we have tried to place on the statute books in the bituminous region, from Pennsylvania west, extending even into the Northwest of Wyoming and Washington, laws that would require at least two years of experience before a man could qualify for mining coal at the face. In all this campaign, we are always met with the opposition from the management, that we are trying to monopolize labor.

Many years ago I arrived at the conclusion that in order to minimize accidents in the coal mines of the United States, it will be necessary to make our laws more stringent, particularly so with the foreign labor in the mines. I am glad Mr. Fay has presented a paper on that subject. I have made a short study of the subject myself and I believe that the reason for many of our accidents in the coal mines in the State of Washington can be attributed largely to the bringing of foreigners from the factories and the agricultural fields of Europe right in to the face, permitting them to dig coal without any experience whatsoever.

MR. CARL BALCK (Prudential Insurance Company, Newark, N. J.): Our latest chart exhibited in the Armory shows the mortality of accidents, and the curve gradually goes up to age 30 and then goes down. I would like to know your opinion of the reason for it. I think that the young fellows do not take care, do not know the business well and also the foreigners do not know their business well.

MR. FAY: Part of the answer is that there are more young men employed in the mines than older men, and you will not get the true accidents nor will you get a true accident rate until you know how many men over thirty years of age are employed in the mine.

MR. BALCK: This is by age.

MR. FAY: Do you know how many are employed by age?

MR. BALCK: I think so.

MR. FAY: Unless you have the number of men employed in a certain age group, thirty to thirty-five, forty to forty-five, fifty to fifty-five, etc., and the number of men killed or injured within those groups, you have no way of measuring accurately the number of accidents.

Suppose you employ one Italian and he is killed. That will be at the rate of one thousand per thousand because there was only one man, and he was killed. If you have a thousand and only one is injured or killed, it would be one per thousand, although in either case only one man was

killed. The figures are not what they should be. You don't get a true conception of the hazard. There are more men employed in mines between twenty and thirty than any other group.

MR. BALCK: Don't you think the number killed, according to the figures, would be higher among the younger men?

MR. FAY: I would suspect it would be lower than among the older miners. It is only a theory on my part that the extended experience begets carelessness, and then too, when a man is forty, forty-five or fifty, he is not so active as he was when younger.

If you insurance people can get figures showing the number of men employed in age groups that are reliable, it will be of great value. I know you can get the number killed and injured, but it is the employees you don't get.

MR. JOHN L. BOARDMAN (Anaconda Copper Mining Company, Butte, Mont.): I would like to discuss some of Mr. Flyzik's remarks in regard to developing men in the mine. Mr. Flyzik wants the men prohibited from working at the face until they have had two years' experience. That, obviously, is not the duty of the state, for the simple reason that the state can't furnish the men. As soon as the state prohibits the man from working at the face until he has had two years' experience, you are in truth shutting off your source of supply. It is not the duty of the employers undoubtedly. It is up to the employers to keep the mine running. Here is the point:

LABOR UNION CONTRACTS

The labor unions are demanding this. Then it is up to the labor unions to provide a way for supplying men to fill the positions. The labor union, when it makes a contract with an employer, should guarantee its service, should guarantee that the contract shall be fulfilled, and they have closed shop agreements with almost all mining people in the United States. Therefore, they have the tools by which they can force the issue if they want it forced. All they have to do is to require that a man must have had this experience before he becomes a full-fledged member of their union. They can take care of his education in some way or other, because they have absolutely entire control over the entire business. In some cases, a man can't work for a mining company unless he is a member of the union. All they have to do is to guarantee that the man is qualified.

MR. H. G. DAVIS (D. L. & W. Coal Co., Wilkes-Barre, Pa.): Relative to the service clause of the mines, Mr. Fay referred to the stopping of immigration from England, Scotland, Ireland, and such places, and fixed the date at 1890.

In 1889 the Pennsylvania Assembly passed a law requiring the service of men in the mines as laborers for two years before they could qualify as miners. I don't know whether you can notice the connection or not. News of this law soon spread all over the European continent, with the result that the English-speaking men, particularly, stopped immigrating to the northeastern Pennsylvania coal fields. Nobody would come here

except those who had committed murder, or robbed somebody, and had to get out. The rest stayed there, for the simple reason that the men who were born and brought up on the top of a coal pit didn't want to come here and load coal for a couple of years. What was the result?

Some came and immediately returned to their homes or went on to western Pennsylvania, where no services were required before they could become qualified miners.

We have for thirty years been trying to have that law repealed or amended to this extent: Put a service clause in, if you please, of three months.

The D. L. & W. Coal Company had an Austrian come to us for employment. He showed me by a certain series of certificates that he had qualified in his own country to become a miner, and I want to say this, that the service rendered by that man proved that he was a miner in reality. Although he wasn't able to speak the English language, he was able to cut coal and do it well.

I do think that when a man who is born and brought up in a coal-mining country or state goes to another state, credit should be given him for his knowledge. Why can't he be a miner in Illinois if he is a miner in Pennsylvania?

I hope that the states of this country will never pass a law that will require more than three months' service, if they pass any, if a man can show that he is from a state or country where mining is in vogue and that he has had experience there.

MR. R. DAWSON HALL ("Coal Age"): I would like to question Mr. Fay's statement as regards the dangers of mining being so much greater than other work around mines. There are certain little things like driving, etc., which do not cause as many deaths as mining, but do in proportion to the number of men engaged in that occupation.

MR. FAY: The word mining, as I used it, meant everything below the collar of the shaft.

MR. HALL: Is the foreigner in a more dangerous occupation?

MR. FAY: I had 80 per cent of them. I picked five different groups. I not only took the miners, but the trammer, the muckers (in the metal mines), or loaders (in coal mines), and the man who is driving the team and the hauling man. In the five groups all the occupations go, and about 75 per cent were foreigners and about 25 per cent Americans.

MR. T. D. LEWIS (Lehigh Coal & Navigation Co., Lansford, Pa.): For two or three years we have conducted classes, and have specialized on a class in Americanization or naturalization. Our effort there has been to cause all these men to want to be good Americans, to instill in them a desire for citizenship, and that has worked out very well. Those men have come in bunches and taken a keen interest in attending the school for one or two years. We have started a great number of them on the road to first and second papers. In that class we made a specialty of instructing them in things they ought to know in the mine. We don't teach them the English language by giving them the A, B, C's. We try to teach the words and danger signs and the things they need most when

they get into the mine. That has done a good deal to reduce our accident ratio among the men who don't speak English.

FAILURE TO OBEY LAWS

Mr. J. C. ROBERTS (Colorado School of Mines, Golden, Colo.): Mr. Fay spoke of the fact that it was not so much disobedience as misunderstanding of orders or instructions that is to blame for the accidents. I believe that a great many of our accidents are due to the fact of disobedience to orders; that is, failure of men themselves to carry out the orders or to obey law and order, and it is not the fault of a foreigner so much as the fault of the American.

A few years ago I was in Chicago with a friend of mine. We were watching the traffic as it went one way and the other. After the traffic cop blew his whistle, a man whipped up his horse and went across the street. This friend of mine remarked, "In London the cop blows his whistle and the people involuntarily stop. Why? Because he is the law, and as such they respect him. It doesn't matter in what regard they may hold that man personally, he is the exponent of the law and they respect him because he is the law."

"In Berlin, on the other hand, the cop blows his whistle, and the people involuntarily stop because he is the law and they fear him."

I said, "Yes, old man, but we neither fear nor respect that law. Every man wants to be a law unto himself and do as he pleases."

I would say this to my men, "If you don't like the law and the rules and regulations laid down by the company or the concern for which you are working, move on. We don't want you. Go some place where they haven't those laws. As long as those laws are on the statute books, as long as those laws and rules exist in the mine or territory or state and county in which you live, obey them."

If the foreigner comes and sees you and me, American citizens, disregarding and disobeying the law, sees us saying, "To — with the law," what does he do? He goes us one better, and he takes liberty for license and does as he pleases. That, I think, is the cause of a great deal of the trouble in our country.

One other thing: We were speaking about the loaders. There was a mine in Montana—the Great Northern Coal Company's mine, which is not in existence now—Mr. Pierson was the manager. Several years ago he told me he hadn't had a fatal accident in his mine for over three years and not a serious one for over two years. He did it by regulating his labor. He only had a few skilled laborers in his mine. He had one class of men do the timbering; another, the track-laying; another to cut the coal; another to bore the holes; another gang of men to come along and shoot that coal. Then the loaders came around under a shift boss and loaded that coal.

The coal digger, as we know him, had no responsibility except to shovel that coal and leave the result of his brawn and muscle.

That man produced cheaper coal than any mine in Montana and had fewer accidents

CHAIRMAN TILLSON: Gentlemen, if we can find the time, and if the rest of you desire to continue some of this discussion in blanket towards the end, we will do so. I feel that I must call for the next paper, "The Management and Training of Men," by W. W. Gidley.

MR. W. W. GIDLEY (Phelps-Dodge Corporation, Bisbee): I was asked by Mr. Price to write a paper to be presented before this body on the "Organization of Committees as Conducted by the Phelps-Dodge Corporation in Its Operations," but owing to the fact that I was absent the entire summer, I was unable to get this paper together. However, I have had for some time some ideas which I should like to present to you. They have come from my own experience. I have had quite a varied experience in the handling of men and it is unquestionably true that today the training of men in safety, efficiency, economy, and in all the various phases of industry, stands vividly foremost in the present trend of affairs along industrial lines.

I believe that up to the present time we have failed to give the great faculty, human nature, the proper attention, and so I have written a brief paper along those lines and I trust that I have brought out, or will bring out, some features that will prove of interest to you.

THE MANAGEMENT AND TRAINING OF MEN

W. W. GIDLEY, SAFETY INSPECTOR, PHELPS DODGE CORPORATION
COPPER QUEEN BRANCH, BISBEE, ARIZ.

No factor in the industrial world today presents to the employer a problem of such extreme complexity as the training and managing of men. It has been proven repeatedly that wholesale discharging by those in authority, in order to procure the right man for the place, is a dismal failure. It is therefore expedient that a system be developed whereby this weakness may be properly analyzed and a correct solution applied.

The time has arrived when men who supervise labor must know the meaning of morale and how it is developed. The heads of various departments in any industry must be interested in safety, efficiency, and democracy, and understand how these features may be linked together with proper discipline.

There are three fundamentals in our subject which we will endeavor to discuss in their relative importance: design, management, and training.

DESIGN

Let us look at Humanity's general design and then consider it under the aspects of management and training, defining its province, explaining its duties, and pointing out some errors prevalent in these several departments of its action.

The simple preservation and continuance of the race is a fundamental design of Humanity. In his infancy, man is the most helpless of all creatures, the most narrowly endowed with instinct, and the most feebly furnished with strength; and hence demanding the most untiring atten-

tion to develop his physical system to a healthy maturity. It is to meet this early necessity that the family has been designed and instituted; and like all arrangements of this kind. It is self-acting and self-adjusting, working out its ends with a simplicity and perfection unknown to any human institution.

One of the great difficulties experienced with labor in industry today is due to the abandonment of training, as the young man reaches the age of maturity, in the several essentials designed to meet the necessities of manhood. We see thousands of young men growing up with no provision to meet later requirements of life. It is this class who usually become an easy prey for those filled with skeptical and socialistic philosophy; they begin to see only those things which are pessimistic and so many manifestations that vex and disgust them, that they eventually become incased in ideas un-American, with tendencies that remove the finer sensibilities. It is here that a counteracting agency is needed to oppose these influences in order to keep the better emotions in play. This is found by following up the early design of training, with changes necessarily expedient to prepare for the later callings in life. The individual who has received vocational training at the proper period is not apt to be susceptible to skeptical influences. He naturally becomes imbued with a desire to improve and perfect various methods connected with his vocation, has a broader vision and develops the faculty of perceiving a future.

Another design is the social culture and consequent happiness in life. It is in this fact that we probably find a reason for the protracted infancy of man. Were he designed, like the lower animal, he would be earlier fitted to shift for himself. But the continuity of training influences are essential to mould and perpetuate certain human elements requisite for social betterment. Many of the larger corporations throughout the country have proven to their own satisfaction that provision for social culture among their employees is a profitable investment.

MANAGEMENT

The management or government of men in industry is a problem requiring utmost scrutiny in working out its details. Human nature in its mature development of reason and experience demands the restraint of government of state; so it is in industry. Hence, right reason unites with reiterated declaration that successful industrial organizations must embody good government. Let us look at the points involved in this aspect of it. The governing power of industry is lodged in its executives. The authority of a department head is usually restricted to the sphere of certain rights and duties. Although the authority of the executives is not co-equal, yet it should always be co-incident, especially in the enactment and execution of the rules of the organization.

Every industrial organization should have its rules. These rules should be formed with utmost care and consultation. As there may be too much legislation in the state, so there may be in any industrial organization; but in both the greater danger consists, not as much in

undue as in unsteady legislation. A few plain rules steadily enforced will be worth more than the most minute attention to trivial details. These rules should be the expression of the united will of the industrial executives. They should, however, as far as possible, be such as would commend themselves to the employee and convince him that they are based on fairness and mutual principles. The moment the employee suspects deception on the part of the foreman, the authority of the latter is weakened and the respect of the worker is impaired. It is absolutely necessary that in every case the worker should thoroughly understand the reason for the rules governing the conditions under which he is employed: thus confidence in decisions by those in authority will be greatly strengthened by perceiving the propriety of these rules. This will enlist both reason and conscience on both sides and create mutual understanding.

The execution of rules is another problem. It is here that failures are most frequent and disastrous. The cause of these failures will be more fully presented when we speak of the mistakes usually committed in management. The rules of industry should be enforced gently and yet with inflexible firmness. Here there should be an absolute oneness in the governing organization. If the foreman of any department shield employees under his supervision from certain penalties for violating the rules of the organization, he creates a tendency that will be surely practiced on himself with redoubled effect. The grand agent in executing rules is mutuality. This, to be properly effective, should manifest itself in words and actions. The boss whose repulsive attitude represses all interest of the worker not only misrepresents his employer, but builds a wall between himself and his men which cannot be penetrated. One great mistake in management of men is that the boss is prone to censure but fails to commend them when work well-performed merits approval. As long as the nature of man remains what it is, it will demand reward for faithful service. It is not necessary or proper to show favoritism to any particular employee, but simply to enable him to feel that the path of his daily vocation is not entirely obstructed with dissension. The want of proper management is the greatest defect in industry: it acts at the very root of the organization and is felt in all its departments. The growing amount of delinquency among employees is, in a great measure, due to lack of proper discipline and control. Why are there so many complaints about inefficiency and such difficulty in securing improvement? Chiefly because of the neglect by those in authority to exercise good management by precept and example. The perception of unscientific management may be easier than the discovery or application of the remedy. That remedy will be found by correcting the errors into which the executives fall and training the employee in efficient methods.

Let us then consider in brief terms some common mistakes in management. Partiality is a very great error in the management of men and one that deserves specially to be guarded against, for it injures alike the favored and the slighted employee and the former more often than the latter. But to treat all dispositions alike is equally erroneous. There are marked differences of character in manhood. Some

natures are constitutionally tractable, others the reverse. and to treat both alike would be like trying to work wax and iron in the same manner. The first duty of the boss then is to study the character of the man and adapt his discipline to that character, in order that he may receive the training his respective nature demands. Again, it is wrong to raise an issue with an employee when it can possibly be avoided. This will seldom occur if men are properly trained. But if an issue is distinctly made obedience to the rules of the organization must necessarily be the point obtained. Extreme care should here be exercised, the employee must be convinced, not by criticism or ridicule, or by argument with tendencies to belittle his opinion, but by calm deliberation and persuasion in order to retain his respect and perpetuate mutual interests, thus avoiding disastrous after-effects.

Constant fault-finding is another common error and is pernicious. There are many minor faults in men that are like the branches and sprays of a large bough, all of which will be removed by the removal of the main stem. To be continually carping at these secondary faults, while the primary causes are neglected, only tends to disorganize and disinterest the employee. Instruction demands many words, management but a few; and these few closely connected with prompt, decisive acts, or they will be mere empty air.

It is often difficult in managing men, especially those of variable temperament, to preserve that uniform bearing that is requisite. But special effort should be made to do so. To allow certain working rules of the organization to be violated today, when tomorrow, because of a change of humor, we rebuke the same liberties, is to injure all good management. Uniform governing of men will do more to secure efficiency than the most strict severity alternated with seasons of laxity.

TRAINING

The philosophy of human nature is not only a most engaging study, as belonging to the highest department of knowledge, but is a most practical and necessary attainment.

All persons engaged in the supervision of labor should be familiar with it, at least with its general principles, just as an agriculturist ought to possess a general knowledge of the laws of vegetation, the order of nature in the seasons, and the powers of the soil with which he is called to labor.

Vocational training is a real science. We cannot easily over-estimate it. Surely a science which embodies the necessary attainment to develop the aptitude whereby a man's earning power is designated should take the highest rank.

The present phase of industrial development demands that the supervision of men requires the faculty of training ability, consequently all executives, regardless of the magnitude of their sphere of duties, are called to study and practice this important science. Like all other sciences, the science of vocational training rests on truths and facts. Most of these are now understood and established. A wise executive cannot safely overlook them.

dispositions and habits will secure success in life against many disadvantages; while the want of them will neutralize the most important advantages in external circumstances.

To be successful in educating the employee, the teacher must of necessity be a student himself. He may possess all the qualifications to direct and promote efficient methods but must reckon with the human element. He must assume the task of patiently seeking to develop all the faculties which requires constant study of the master-faculty, "Human Nature."

CHAIRMAN THILSON: Mr. Gidley, in thanking you for this presentation, I wonder whether it would seem to you suitable, if your voice isn't tired, to take up, before discussion, Mr. Willis' paper, which is on a kindred subject.

INDUSTRIAL RELATIONS IN THE MINING INDUSTRY

CHARLES F. WILLIS, CONSULTING SUPERVISOR, DEPARTMENT OF INDUSTRIAL RELATIONS, PHILIPS DOWGE CORPORATION, BISBEE, ARIZONA

Industrial relationship problems involve the more or less intangible recognition of labor as a group of men and women and not as a commodity; it recognizes men and women employed in industry as human beings subject to precisely the same desires, the same longings, and the same ambitions as the employers. The practical side of the problem, however, has been the creating of conditions which will give the employees the same opportunities in the enjoyment and pursuit of happiness as those employing them. It has come then to mean concrete things, industrial democracy designed to give workers a voice in the conditions under which they work, housing plans which will give them an opportunity to better their standard of living, educational plans which will open a road to promotion, health insurance plans proposed to remove the loss to labor due to ill health, and so on through innumerable so-called welfare activities.

CONDITIONS IN MINING INDUSTRY PECULIAR

The major part of industry is factory industry, many employees under one roof, living close by their work, in communities where there are other factories. Industry has naturally gathered itself into groups, those manufacturing similar products being segregated in districts. While the solution of industrial relationship problems are with each business, there is a good deal of similarity in conditions which render the experiments of one place valuable to another, but mining stands apart on account of great differences; even individual mines cannot solve the same problems in the same manner.

The individuality and psychology of the worker in a mine is no different from that of the worker in any other industry, but the natural conditions under which a mine operates are so different from those of factory operation that the things which have proven successful and efficient in

smoothing the difficulties between the employee and the employer in other industry often cannot possibly be applied to mining, and other solutions can be applied only with difficulty.

The fact is well known and appreciated that both factory and mine workers are restless, that there is industrial unrest which causes a general dissatisfaction with everything, but few of the workers have given any considerable thought as to the cause of this restlessness. Without giving any deep thought to the mental agitation in industry today, its causes, effects, and remedies, workers as a whole are prone to grasp anything new as a possible solution. The growth of Bolshevism is not due to the fact that so many men believe in the wanton destruction of capital and in the various other destructive doctrines of the sect, but rather that they believe that something is wrong and are grasping upon that in the hope that it may be the solution of their difficulties.

PSYCHOLOGY OF THE MINER

It is a fallacy to assume that the psychology of the worker is different from the psychology of any other human being. Without a doubt, much difficulty is caused by the fact that capital and management have often assumed that the worker has a different mental state than their own. John D. Rockefeller, Jr., in an issue of the Atlantic Monthly in 1916 said "In spite of the development of big business, human nature has remained the same, with all its cravings and with all of its tendencies toward sympathy when it has knowledge, and all of its prejudice when it does not understand. The fact is that the growth of organization in industry has proceeded faster than the adjustment of the interrelations of men engaged in industry."

More and more in the development of big business organizations has the worker gone to routine work, without expression of individuality and without recognition or distinction, and these are the normal desires of all men. Human nature is made up of fundamental instincts, and every man, whether mucker or capitalist, has the same desires. Industrial relationship work today consists in supplying concrete physical outlets for these natural cravings; each part of the work is in some way related to the expression, on the part of the worker, of those primary desires.

There is first the instinct of self-preservation, that desire to keep and retain health, to provide satisfactorily for himself and family, and to prevent accidents. There is normally in every man an instinct of workmanship, a real desire to do the best he can in every job that he undertakes and, if that desire is not smothered by a "what's-the-use" attitude on the part of the man, it will come to the front. The lack of opportunity for self-expression and initiative often suppresses the normal desires of a man to do his best in a job. Self-respect is present in every man, the desire to do, think, and act so that he may feel the equal of any man. The balanced life and the instinct of play demand recreation, to provide a safety valve for the inevitably repressed instincts—not frivolity or dissipation but wholesome recreation.

While there are many other normal instincts, they are of little consequence in this discussion except the natural desire of a normal man for a satisfactory and happy family life. The inability of the worker to use and develop his normal instincts are the real causes of unrest, and an analysis by the worker will often cause him to seek and find the remedy without groping in the dark for some industrial revolutionary change, which will not in the least change his desires or cravings. Psychologists call these cravings repressed desires or balked dispositions, and while all persons have some which are not satisfied, it is only an accumulation that causes unrest.

HOW THE INDUSTRY TREATS THE WORKER'S DESIRE FOR SELF-DEVELOPMENT

Let us see then how mining has promoted or defeated the desires of the workman for individuality, recognition or distinction, self preservation, workmanship, self-expression, recreation, and home loving. It is not so many years since mines were comparatively small affairs, when a miner knew mining, when he could drill as well as use a shovel, when he could timber, lay pipe lines, dress steel, and perform all of the functions that a miner is called upon to do in a small organization. The growth of large organizations, however, has limited him to an individual task, shoveling, car pushing, or drifting. It has segregated different types of drilling and has differentiated stopes, shafts, raises, and drifts. Tool sharpening has been further segregated, so that it now takes several men to sharpen steel where formerly one did the whole operation. The result has been a depreciation in the skill necessary to perform the various functions of mining and a natural depreciation of the knowledge of the men filling the positions. The old-time all-round miner is almost obsolete now, and he resents the lack of skill necessary to be a miner today.

In spite of the standardization of work around a large mine today, however, there is still the work for the all-round man. Miscellaneous jobs are constantly coming up which require real mining skill, and which, in most cases, involve additional hazards, and it is the old-time miner who is called upon to do them. Because of this he feels that he is penalized, that he is required to do difficult and dangerous jobs, jobs that any man could have done at the time he learned mining.

While at no time has the miner been able to do the whole of the work of producing metal, in small organizations he was often able to see each part, realize the dependence placed upon his work, and appreciate that the work and livelihood of other men depended upon his work. Today, however, the absence at work of fifteen, twenty or even a hundred men makes little difference in the progress of the industry. A few years ago a man expressed himself directly to the boss and would often see the results of his self-expression; today there is a multiplicity of steps to reach the boss, and even though he may ultimately see the results of his suggestion, the workman has had his desire for self-expression curbed.

Recognition is always difficult to give in large organizations, for it is

hard to measure a man's right to it. In the routine of a day's work, a man does little to distinguish his work from that of thousands of others. The opportunity for distinction is small, and promotion as an evidence of recognition of services can *only come to a few*, as compared with the days of small organizations. The saying "there is always room at the top" is hardly true in the growth of large organizations, for there are getting to be fewer and fewer top places, and a lessened opportunity for recognition.

While there is as much, if not more, opportunity for recreation in the communities of large organizations, it is of a different nature. The recreation of a small mining camp was not ready-made recreation, obtained only for the admission fee; it was initiated by the worker himself, developed and carried out by him. If it was a show, he was with it all the way through its rehearsals and performances, not merely seeing the finished product. Where the worker used to receive hours of diversion in self-made recreation in small mining camps, he now receives minutes. It is true that there are many more opportunities for recreation today, but it needs much more to make up for the loss of the community initiative and development which marked the recreation of small mining camps of a few years ago. The tendency of the recreation of today is toward frivolity, which does not tend toward the balanced life, as it does not use the facilities of a man that are dormant during his daily work.

While mining operations have gone to extremes to get safe and healthful conditions, the instinct of self-preservation has been repressed, due to the decreased lack of skill of the individual miner. Progress in safety work in mines has been such as to decrease the total accident roll by a large percentage, but the decreased skill of the individual miner has made him less able to take care of himself and recognize unsafe conditions. In no other industry does the safety of a man so depend upon his fellow workers as in mining. While this does not show up prominently in the accident statistics, the feeling exists among the men—particularly the feeling of dependency upon the fellow worker as a factor over which the workman himself has no control.

The opportunity for the development of home life has been the one instinct that has been promoted by the growth of large organizations. Mining was formerly done by single men, men with a roving disposition, who made up for a lack of recreational facilities by moving often and getting a variety of them. Housing plans, home building associations, good schools, etc., have made it possible for the miner to have a family and stay in one place. More important than this is the fact that large organizations have stabilized the industry; it has gotten away from the conditions of working today and shutting down tomorrow, and provides a security of employment which was formerly lacking. The miner used to feel that he could not have a home and family because of his uncertain livelihood, but that condition has entirely changed. Large mining organizations are not only continuous, but a man half way trying to do the right thing can remain in employment year in and

happen. Men and houses are needed. Everything is needed at once. The bosses are so engrossed with production possibilities that they have no time for civic problems, for the equal and consistent development of the community along with the mine. Everything is needed quickly; instead of houses, shacks are built; instead of streets one finds alleys and trails; instead of sewers, there are latrines; and instead of decent and civilized recreation, the red light district and the saloon.

In many instances, community problems are given some consideration and thought, but the operators are at a loss to know what to do. They cannot know at that time that the camp is to be a permanent and paying one; they know nothing as to the size and extent of the community necessary, they know nothing of the possible life for which the community must be built. As a rule, they do not realize that money spent in the development of the town is in any way related to the success of the mine. It is not until some pressure is brought to bear that the operator begins to understand that he is not only developing a mine but a city as well, and somewhat reluctantly, he begins to provide a few of the things necessary to a well-organized community.

It is usually during this period that labor troubles have their inception. Living conditions as a rule are bad, and working conditions not as good as they might be. The camp is unhealthful. Then, too, the mine is not yet on a paying basis; money is all going out and nothing coming in; wages are low and the management is slow to spend money not directly related to immediate production. Troubles are consequently frequent, grievances numerous and often real, and from this time on the feeling grows that the camp is operated for the company only. Workmen become disgusted and leave; often, they do not return but continue to spread stories of the treatment of labor at this camp and in this way the community gets a bad reputation in the mining world which is difficult to overcome.

It matters little whether or not these grievances are later corrected. The reputation remains and often will remain for a generation. Traditions are hard to live down. Even in the present day, one hears occasionally in camps of the West: "Don't go there, they have typhoid epidemics regularly." This is in spite of the fact that the conditions causing typhoid have been removed for many years, and that the disease is now almost unknown in the camp. It may be one of the cleanest, most healthful camps in the country, and yet occasionally this feeling against it, which is purely a traditional one, remains.

STABILITY OF PRODUCTION CONDUCTIVE TO CIVIC IMPROVEMENT

The next stage in the life of a mine is that of stable production and consistent profits. Mining operators have now become so systematized that attention may be given to town problems. Many times the sudden realization of the needs, accompanied by the fact that the mine is now in position to supply them, brings about a bad condition of hastily-thought-out and poorly-devised remedies, which in some cases are worse than the original conditions. The normal procedure is the slow and

laborious development of the community, a process often much more costly than if it had been done simultaneously with the mine development, but always behind the needs. Faulty living, social, recreational, and civic conditions are changed, one by one, as the operating heads have the time to devise correct methods.

The feeling of the miner has not changed, however, for in the short time spent in a place he has not seen enough of the corrections to be convinced that the company really does desire to make conditions good and to improve his lot. A miner seldom witnesses the entire development of a camp. As a rule, he works a few years here and a few years there. He hears disagreeable things and often goes to a camp with a prejudice against it, and he is the type with whom the company has to deal.

The last stage of development comes with old age, the deposit worked out, the camp moribund and the community likewise. Even here some development may be going on, and the satisfaction of the men during this period is dependent upon the conditions that have existed in the previous stages.

It might be entirely possible to make classification of mining communities based upon the relation between the progress of the development of the mine and the start and progress of the community development, and thereby measure the comparatively harmonious condition of the community and its relative freedom from social dissatisfaction and labor disturbances. There are cases when a mine comes into a community already organized, or when a new company buys a mine already developed.

It must be remembered when a mining company is sinking shafts, driving drives, etc., that it is building a plant for the production of ore, that it is continually building that plant, and that parts of its plant are continually becoming obsolete and useless. Therefore, in any way to compare factory industrial relationship activities with those of a mine, it is necessary to study the betterment activities taking place while the factory is being built and terminating when the factory building is completed. The welfare activities taking place during factory construction are usually nil.

NEED FOR INDUSTRIAL RELATIONS MANAGER

By virtue of the fact that mining operations are necessarily retarded in starting industrial relationship activities because of the different fundamental factor under which a mining organization is operating, it is necessary to make far greater speed to catch up with the procession. While undue haste means mistakes, it is impossible to get any great speed of development when the industrial relationship problems are studied solely by the operator, who must give his major time and thought to production problems. Hence no industry needs a man whose sole duty it is to study and supervise industrial relationship problems more than does the mining industry. It is backward to start, and even with the best of conditions it is hard to catch up.

Good physical conditions within a plant are probably the most fundamental factors in sound industrial relationships, and here a mine has inherent difficulties. Safety, sanitation, and lighting can be designed in a factory but a mine is built as it goes along, and to make a place safe it is necessary to work men in an unsafe place. Sanitation and lighting of underground workings have obstacles that can be readily understood and appreciated.

When one realizes that the temperature underground increases one degree for every fifty-three feet, and that practically all mines are operating below the ground water level, the discomforts due to heat and water are considerable and inherent in the industry. This added to the fact that oxidation of sulphide ore produces a good deal of heat, often enough to cause spontaneous combustion, makes the problem of ventilation, cooling, and fire protection of vital importance in maintaining good physical conditions. Also, it is impossible to create the better conditions until the poor conditions are encountered which makes it necessary to endure the heat and water until the necessary equipment can be provided and installed.

In the mining industry men are scattered through miles of workings doing their work in small groups, and they are under the eye of the boss but a small part of the time. They are therefore far more on their own responsibility than in a factory where a whole floor or room may be under the eye of a foreman. The 1919 type of foreman, who is a teacher and leader rather than a driver, has less opportunity in a mine to supervise continuously and correct work as a teacher should.

The roving nature of the population of a mining camp often means the continual changing of schools for the children of the miners, each change being accompanied by a loss of time and of school standing. This results in the average age of students being higher in mining camps, and before sufficient education has been acquired, many are at legal age where school attendance can not be forced. This condition makes necessary strong inducements on the parts of the school, and special educational facilities to get the older boys and girls to remain with their school work.

The ordinary typography of a mining camp adds greatly to the housing difficulties. Often, playground space is not available, athletics is something to be read about on the sporting page, and the mountainous rocky hillsides offer few opportunities for the development of home gardens.

PENSIONS AND PROFIT SHARING

While it is appreciated by the mining industry as well as other industries that a man who has given the best part of his life to an industry is entitled to some consideration in his old age, pension plans are frequently remote from the thoughts of the mine management. This is because a mine has a life, that life being shorter and seldom longer than the usual twenty or twenty-five years of service that places this social obligation upon the industry. When the ore is gone, the money ceases to come in and unless very large funds are set aside to be used for

pension payments after the mine is through, it is impossible to fulfill the obligation.

Profit and loss comes very much nearer being a mathematical problem in ordinary industry than in mining. Mining has natural risks that are large. The plant may be equipped, and then produce nothing. The inherent risks in mining are solely risks of capital, and this naturally requires larger profits from the mine that does make good to pay losses of those that do not. If mining could be assured of only eight or even ten per cent, profit on the investment from the mines that become profitable, capital would never risk its money in the development of new mines. Mining profits should go to capital that takes the risk, and this makes the question of profit-sharing in the mining industry one presenting many difficulties. Sometimes it is possible to show profits which are the product of increased effort on the part of the worker, and it is believed that such profits should be shared with the employees. This plan is being worked out in many mines today, but it is entirely separate from the larger question of profit sharing.

In spite of its inherent difficulties in the solution of industrial relationship problems, mining is in no way backward. Practically every device known to produce better feeling and equitable treatment is in use in the mines of the West. These often cost many times the sum necessary to install them into factories. Some operators show practically all methods used within the same operation. These statements apply largely to the profitable and successful operators and it does not require a very clear vision to see why smaller operators with mines in the development stage are slow in pushing personal relations work; they do not know whether their work terminates tomorrow, next week, or next year. Mining operators are thoroughly alive to the problems and their necessity for solution, and are operating strictly on a square-deal policy. The realization of the difficulty of the problems has made the study more acute but has not diminished the speed.

CHAIRMAN TILLSON: We certainly appreciate Mr. Gidley's presentation of not only his own subject, but the allied paper of Mr. Willis on a kindred subject. In opening the discussion of that paper, I made one note which I would call to the attention of those present if you wish to consider it. In the attempt to correlate some of Mr. Willis' suggestions with those of Mr. Gidley, it will be noted that Mr. Willis indicates that the attraction of women into mining camps and the performance of some industrial functions there which will hold them is highly desirable which brings up the inducement of various factories employing women to take part in the mining life.

DISCUSSION

PROF. R. M. RAYMOND (Columbia University, New York City): I wish Mr. Gidley would give some account of the good work being done by the Copper Queen, and an example of the training being given by that institution and some other good kindred institutions.

MR. GIDLEY: In answer to that question, I am very glad to state that for the last year the Phelps-Dodge Corporation has conducted a vocational school at Bisbee. This school is absolutely free to all employees and is very highly patronized. They are taught there practical methods of mining. Papers by the various department heads, all the mine foremen, many of the shift bosses, are prepared and presented to this school and are discussed. The papers, of all the various operations in the mine, are written by the different department heads for the benefit of this school.

One boss may write a paper on drifting; another on one method of stoping; one may take top slicing, and one may take the cut and fill method; one man, car setting, etc. These are all presented to this mining school and are studied by the pupils. The pupils are required to pass a certain examination, and after passing this examination, the company issues a certificate, which signifies their attendance at the school and enhances their chances for promotion.

They require an examination from this school now before a man can be eligible to advancement in the mining industry. This school has been carried on for one year, and is continually going on. Arrangements have been made to conduct this school throughout the year 1920. The school is open to everybody on the job, absolutely free.

MR. A. H. TRESTRAIL (Pickands, Mather & Co., Palatka, Mich.): There was something in the remarks that have been made about the miner being taught to recognize safe and modern methods and be subject to rules laid down by the organization. I would like to ask in reference to these rules laid down, whom do you term the organization?

MR. GIDLEY: When I speak of the organization, I mean the entire governing organization of the mine, and rules laid down by the organization, of course, must be respected if we are going to get anywhere.

In the management and training of men, we have a great many different kinds of men to deal with, but absolutely the greatest problem is dealing with the pessimist. I have an idea that perhaps you may have had some experience with that class of men. By the pessimist, I mean the fault-finder, the man who is looking on the dark side of everything; the man whom nothing suits; the man who is continually finding fault with his partner, and the man who thinks he has the worst boss on earth. As a rule, I believe that pessimism is absolutely the worst factor of human nature with which we have to deal.

There are several ways in which a man can be made to realize the importance of the rules of the organization. The attitude of the boss, right then and there, is the most important factor. Right there it shows whether the boss is an asset or a liability to his company. If the boss has the ability to use moral suasion, get right down on the level with his men, he is all right. He can't get up on a bench and look down; neither can he get down in the cellar and look up. He must get on a level with the man. It is strictly a man-to-man proposition. When the boss is willing and broad-minded enough to get right down on the level with his men and talk these things over and use moral suasion in convincing the man that these rules are for his personal benefit, his care and protection, he

will experience absolutely no difficulty in persuading the man to live up to his organization.

MR. TRESTRAIL: When I spoke of the organization that lays down these rules, I meant does the management do it, or do the employees have anything to say about the matter of forming the rules?

MR. GIDLEY: Every organization has different methods of framing their rules. I recently framed a bunch of rules for governing our steam-shovel operations. I believe I sent a copy of those rules to you, didn't I, Mr. Sullivan? I submitted those rules to the management for their approval. After they had received the approval of the management, I called a representative body of the workmen, one man for every sixty men employed, and we went over the rules thoroughly. I told the men I wanted their criticism. I told the men I wanted to find if there were any weak points or any rules they could not conscientiously obey. The matter was threshed out for the mutual benefit of all.

MINE RULES IN KENTUCKY

MR. J. W. REED (Consolidation Coal Co., Fairmont, Va.): In speaking of framing of rules, I think that the present system of mine rules as laid out in the State of Kentucky is about as good as any. In that state, the mine rules are gotten up by the company and they have to be gotten up with considerable care because after getting them up, they go to the Department of Mines, and the head of the Department of Mines goes over them and makes such alterations as are necessary to see that the rules do not conflict with the state laws and also sometimes takes them to the Attorney-General to see that they are of such a nature that they are capable of being applied as laws. After that is done, he approves the rules and by an act of the State Legislature of the State of Kentucky, his approval of those mine rules causes them to become laws and they are enforceable through court.

MR. GIDLEY: The only objectionable feature I see to that is that new conditions are continually demanding new rules. As we mine, take for the last few years, there have been many new methods introduced in the mines, and occasionally we find a problem in mining that requires absolutely new rules to govern, so our rules must be framed so they are subject to quick amendment.

Of course, it depends a great deal on whether or not your men at the head of the Bureau of Mines are qualified to pass on those rules. The large per cent of them are college graduates, you know. Many men who have had the technical education are not qualified to go into the detail end of the work until they have gotten down and obtained the practical experience.

MR. REED: I don't know whether you took the wrong impression of what I said or not, but I might have specified a little more clearly that those rules only apply to the company that they are got out for. They do not become state laws, but apply only to that company, and according to the desire of the chief inspector, those rules can be changed.

MR. TRESTRAIL: Providing these rules were violated, would the company be liable to prosecution by law?

MR. REED: The rules are made up for the safe operation of the mine and ordinarily do not cover things for which the company would be subject to prosecution, but rather, the rules for which the men have to have consideration in working in the mines in safe ways and by safe methods. Your state laws cover the rules for which the operator would be prosecuted if he did not live up to them.

CHAIRMAN TILLSON: Mr. Reed, what happens in the case of violation of these rules? What prosecution develops?

MR. REED: The man can be taken before a magistrate, or county court and prosecuted for misdemeanor and fined according to the county court's verdict. I can't say right now what the Kentucky law specifies, but I believe it is from \$10 to \$100 fine.

MR. J. O. DURKEE ("The Coal Industry," Pittsburgh): It appears to me that we are apparently crossing our wires in regard to the special teaching of men. Mr. Roberts, if I remember accurately, stated that a certain man in Montana, by having special men for the different vocations, had acquired great efficiency, not only in the matter of securing greater production, but with greater safety.

We are led to believe from the paper, quoting from it, that the day of the old miner is passing, who was driller, miner, and all the other accomplishments that go to make up a mine. That has been divested in a number of different men. Is it our impression, or are we led to believe, then, that the specializing of the different occupations of men, in a mine, is going to lessen the efficiency of men, or make them more dangerous, or what are we led to believe concerning that?

CHAIRMAN TILLSON: Mr. Durkee, I can give my impressions as I have read these papers in the past. It seems to me that Mr. Willis' intent was to indicate that the increased specialization of all of our industry left an aching void which most of us had not as yet filled, and due to that the standards of interest of our men in the industry had been lessened in the particular application of their minds to their jobs.

It seems as though it came down to a point where we realized that what was very largely required in this present-day unrest and inefficient production was the development of the interest of the workman in his workmanship. In days gone by, when the school of apprenticeship was in vogue, and a man actually had to pay in years of labor and his support for learning a trade, he was a skilled worker who had considerable pride in the work which he did and, therefore, performed it with ability, completeness, and at the same time with safety to himself, as far as means permitted.

SPECIALIZATION TENDS TO LESSEN INTEREST IN WORK

Now, by a tendency, with the specialization of certain fields, to limit the horizon of a man's viewpoint in regard to the work in which he is engaged, we have taken away his interest to a certain degree, by reason of

the fact that he becomes a machine-like automaton in his labors. The reason these two papers come before you now is due to the realization that the problem of mutual interest between the executive side of business and the more manual side of business had a correlation with the intense consideration of the subject of safety to the workmen, and to the public at large, because a man who is satisfied, contented, and really interested in his work and in what he is doing, will also be interested in the way in which he does his work, and will, furthermore, appreciate that the best way is the safest way. Therefore, the subjects are before you, with a desire for complete discussion, in the hope that those methods, which we can adopt toward developing all men in industry to take a broader interest and a more concentrated interest in their own industry, in their own work, will be brought forward.

The possibilities are great of any concern more openly indicating to its muckers or trammers the necessity for their making production on a proper basis, in order that they support allied departments, the coal breaker, or the concentrating mill, and ultimately the smelters and the consumers, who are so vitally dependent on his individual efforts that really a worker is performing a function toward the world at large in doing his mechanical share of labor.

As a homely illustration in the zinc industry, it seems to me that the very fact that things come so close to home to a man when he realizes that this shovelful of ore that he is placing in a car is needed in order that he ultimately may benefit by having a zinc sheet beneath his stove in his own home or his wife may have eyelets of zinc in her corsets would bring to him a realization that his productivity is necessary for the welfare of himself in many indirect ways, and his neighbors at large, and he will feel then that he is one unit in partnership with industry in according the good things which are enjoyed by himself and others.

I hope there will be discussion as to how we can best stimulate pride in workmanship in our workers, shift foremen and everybody else, giving them a breadth of horizon in which they feel their responsibility to the world at large.

MR. R. D. HALL ("Coal Age"): It appears to me very much as if we lay too much stress upon preparing mine foremen, shift bosses, etc., for their work, and too little on the varied forms of occupation in the mines of possibly a lower order, but in which a great deal of intelligence can be used. We lay too much emphasis on the bossing of the other fellow, and too little on the man being an efficient boss of his own work.

As I go around the mines, I have come to the conclusion that our miners today, while they are specialists, doing nothing else but a certain kind of labor, day after day, are doing it worse than ever they did it before. I have seen headings that were driven away back. I think, in about the year 1860 that were very much better than any I have seen today, and there is a general disposition today to slight work because there doesn't seem to be an intense interest in the way in which it is done and I really believe what we need is education, not applying directly

to the directing forces of the mine, but to apply to positions which we are likely to regard as inferior.

I don't think they are inferior, because they pay good wages, sometimes better than the foremen of the mine. We have gotten into the habit of thinking that it doesn't require much intelligence to dig coal, but that the man who is to show him and who is to watch him do the work should require all the intelligence. I think we have overlooked the fact that the men who perform the work are intelligent artisans. We don't have schools for motormen, miners, drivers; we don't have schools for dumpers, and we don't have schools for mining except for some man who wants to better his position.

I think if we would get the idea that the man who performs his duties around the mine is a man really worth while, no matter whether he is dumping rock, loading coal, or whether he is shooting it down, that it is something worth while that he should be taught to perform properly. I think we would find an entirely different aspect would be given to the work around the mine.

EMPLOYMENT OF WOMEN

As to women, I was very much interested to find that in Colorado in nearly every office there was one woman employed as a clerk. Strange to say, we have gotten around to using nothing but male help in mines for clerical work. Stenographers are almost unknown in these little mine offices. In the larger offices, they appear in larger numbers, but in the small local offices, it is very rarely that you see any women. I think it would be better if there were. I think the order and general appearances of the offices would be improved. It is very disgusting to go around to the average mine office and see how dirty they are and how dirty the men go about. Of course, they have some very dirty work. Many of them have to go out and crawl over the cars. We know that, but they seem to delight in having that mine office as gloomy and dirty and unattractive as it can possibly be.

In Colorado they hadn't given the matter much attention, but they had managed to get a few woman workers around the mine office. Of course, in Pennsylvania it is customary to have a lot of women around the mines. That could only be done in places where there is an idea that mine work will be permanent. There are many other industries that could be introduced in a mine region in which women are employed, the making of overalls, etc. I don't see, however, how isolated camps, which only have a limited time to operate, could do that. I think our camps are altogether too mannish. There are too many single men and too little settling down to the business of life, and it would be very much better for our whole mining life and organization if we could change that condition.

CHAIRMAN TILSON: The final paper on this session's program is on "Labor Turnover and Its Relation to Mine Accidents," by Mr. E. E. Bach. Mr. Bach is now Director of the Americanization Bureau, State of Pennsylvania, Philadelphia. I expected Mr. Bach here. Since he is not here, I will read the paper.

LABOR TURNOVER AND ITS RELATION TO MINE ACCIDENTS

E. E. BACH, DIRECTOR, AMERICANIZATION BUREAU, STATE OF PENNSYLVANIA,
FINANCE BUILDING, PHILADELPHIA, PA.

This is a subject of great importance to the mining industry and one worthy of most careful consideration, and deserving of a most exhaustive investigation. To arrive at any reliable conclusion in this matter, it is necessary that every step in the process of reasoning should be fortified by ample records obtained first hand from reliable sources in the mining industry. I know no industry which has less reliable records than this one in which we are so greatly interested. I know that the United States Bureau of Mines has been trying for many years, to standardize mine accident records. It has sent to the various collieries, printed forms upon which have been itemized the specific accidents which are most commonly used in the compilation of records. Immediately following a National Safety Congress, new records are begun and are religiously kept for a short time and then the ardor languishes and the records die. The purpose of hav-

ALL MINING COMPANIES SHOULD USE SAME ACCIDENT FORMS

ing all mining companies use the same accident forms is very commendable for the reason that comparisons can then be made between companies with some degree of intelligence. I personally know that these forms have been compiled after a most careful examination of the best accident records available and can be had without cost to any company. Although they have been distributed for a number of years, I will venture the assertion that there are not one dozen mining companies in the whole United States which are using this form from the Bureau of Mines. As long as such conditions prevail, there can be no reliable mining statistics; there can be no basis of comparison as between companies, and there can be no concerted effort toward the elimination of even a common accident.

Since the compensation laws of Pennsylvania have become effective, there have been some few earmarks of reliability as to the various accident records in industry. Yet, those of you who have to do with the accident records of a mining company, where competition between various sections has been keen and where bonuses have been given for reduction in number of mine accidents, know how easy it is to camouflage records.

You are aware that the labor turnover side of the proposition is replete with "voluminous fund of information and available records along these lines." It would seem to me that a large industry, ranking as does mining in this great country of ours, should take some steps toward compiling adequate records along all practicable lines. I am quite sure that from the purely selfish side of hard dollar economy, such a course would be highly justifiable.

By labor turnover is meant the employment of too many poor men

to get a standard organization. There was a time in the history of mining when the employment of a great number of men seemed to have no meaning whatever. New men appeared at the pit very morning for a job and were hired. Others who had worked in the pit appeared with the same mathematical regularity at the pay window for their money because they were going to leave their job. No one seemed to think there was anything in this process which might be translated into dollars and cents upon the debit side of the ledger.

Since the advent of the efficiency engineer, there has been created in all the large industries, what is known as the employment department. Its purpose is the selection and the keeping of the right man in the right place. No more "square pegs in round holes." No more bright boys entering a "blind alley" occupation. It is a proven fact that ninety-seven out of every hundred boys stick to the trade or occupation which they elect at the onset and in the final analysis it is discovered that this is the trade which they are best fitted to follow. There is no better field for an ambitious boy than mining, because it contains thirty-five trades and occupations. One of the most effective methods for reducing the labor turnover in any industry is to give vocational training, through the public schools, to the boys in mining towns. Industry might well invest a few thousand dollars in necessary equipment and place it in charge of the schools.

THE PROBLEM OF STABILIZING LABOR IN INDUSTRY

It is a commonly accepted fact that every time one man replaces another, it is at a cost of real dollars and cents to any company, no matter how seemingly menial the job. Personnel, welfare, industrial relationship, and all other departments in industry, under whatever name, which have to do with the human factor in industry, have for their objective the reduction of labor turnover. The greatest problem which confronts industry today is that of the reduction of labor turnover or the stabilizing of labor in industry.

This is especially applicable to the mining industry because of the great percentage of foreign-born miners. Where no effort is made to give them an intelligent understanding and a working conception of their job, a decent place in which to live, adequate recreation for themselves and children, places to worship God in the manner which they choose, facilities for self improvement and for the education of their children, you will find that the labor turnover is enormous and a most costly proposition. Immigration has practically ceased, and the mining industry now faces the problem of holding the men which it has and having those men so efficiently trained and so well contented that the depletion in the number of men employed must not effect the volume in production.

The process for the accomplishment of this seemingly impossible task will very much resemble the process of "making two blades of grass grow where formerly but one blade grew." It will require a most stringent conservation of the health and strength of the workman, accentuated by the improvement of his working, living, and social conditions. He must as-

same, in return for this consideration, a loyal and interested attitude toward his work which will guarantee to his employer a staple and regular production at a reasonable cost.

Industrial unrest, whether it be due to anarchistic doctrine, Bolshevik propaganda, bombastic utterances by organizers of labor, unreasonable attitude of the captains of industry, uncertainty of governmental policies, undue influence of other countries, or any one of a thousand or more other reasons, must be allayed or this seething, boiling caldron will overflow and will submerge all reason, in which case it might invite the calling forth of those brute forces which hark back to the time when battle grounds were staged for the survival of the fittest.

A satisfactory reduction of labor turnover will be accomplished when a more general practice is made of the teaching of the lowly Nazarene, as comprehended in the Golden Rule.

An accident is something which should not happen. A successful investigation of an accident proves an individual a liar who says that it should happen. We are coming to have a different conception of the meaning of an accident in industry. It is no longer possible to write after the name of a killed workman the common sentence of death, namely, "Killed as a result of his own carelessness." Accidents are no longer considered "Acts of God." Safety men who have made a careful study of all accidents have come to the conclusion that 75 per cent of all accidents are preventable. Seventy-five thousand (75,000) men are annually killed in the United States through accident. Thirty-five thousand (35,000) of these deaths are charged to industry. In round numbers, there are annually two million (2,000,000) non-fatal accidents in the United States. There are one hundred sixty thousand (160,000) accidents to the eye annually. Of one hundred thousand (100,000) persons that are blind in this country, ten thousand (10,000) have lost their sight as a result of accidents in industry. Loss of time due to accidents represents four million, eight hundred thousand (4,800,000) hours per annum. Aside from the loss to industry from accidents, there is a loss of \$2.00 per day through illness and \$1.00 per day from medical attention in the United States to thirty million (30,000,000) workers. Of the fourteen million (14,000,000) deaths in the United States due to disease and accidents, it is estimated that three hundred fifty thousand (350,000) could be prevented.

ACCIDENTS DUE TO INABILITY TO READ AND UNDERSTAND ENGLISH

To be specific as to one of the real causes of accident, I desire to state that there are three million (3,000,000) workmen in industry in the United States who are unable to speak or understand English. There are in Pennsylvania, alone, five hundred thousand (500,000) who cannot speak English. The mining industry of Pennsylvania contained in 1916, three hundred twenty-eight thousand, five hundred and five (328,505) coal miners comprising thirty-five nationalities. Of the total number of one hundred eighty-four thousand, eight hundred forty-four (184,844) accidents reported in the State of Pennsylvania, the mining industry is

credited with fifty-one thousand, eight hundred eighty-three (51,883). Of the total number of sixty-nine thousand, nine hundred twenty (69,920) compensation accidents in Pennsylvania, the mining industry is credited with twenty-three thousand, one hundred sixty-one (23,161). Of the \$11,639,915 compensation paid in Pennsylvania to all industries, the mining industry received \$5,125,749. Incidentally the wages lost to the miners because of accidents amounted to \$3,040,304. This is out of proportion to all other industries and there seems to be but one explanation that the predominating number of foreign-born workman is responsible for this undue number of accidents. The most illuminating information to carry out this statement is the following recently authorized by Director Van. H. Manning, of the United States Bureau of Mines:

"That the inability to read and understand English places the foreign-born in danger of his life, is the striking fact brought out in his last monthly statement of mine fatalities by Van. H. Manning, Director of the United States Bureau of Mines.

"The rate of accidents among the non-English speaking miners is not only greater in all the great mining districts of the country, but the increased ratio is uniform in all districts. This demonstrates clearly that the inability to read warning signs, to comprehend fully the company's instructions, and to understand their foremen, places an unnecessary hazard upon the foreign-born.

"The figures show the difference in the rate of serious accidents in the mines among the English speaking and those from the countries of continental Europe, almost entirely non-English speaking.

FIGURES FOR PENNSYLVANIA

"In the Pennsylvania anthracite mines, 43 per cent of the employees are English speaking and this number is charged with only 28.8 per cent of the fatalities, whereas the other 56 per cent sustained 71 per cent of the fatalities. This is a comparative ratio of 699 to 1,268 against the non-English speaking.

"In the Pennsylvania bituminous mines the ratio is 771 to 1,123 and in the West Virginia district, 790 to 1,424.

"Mr. Manning concludes his report with this striking statement: 'Had the fatality and injury rate for the English-speaking American been maintained throughout the three groups, there would have been a saving of 716 fatalities and 900 very serious injuries, a strong argument for Americanization and education of the miner.'"

From the personal investigations that I had the privilege of making covering a period of seven years, I feel perfectly justified in stating without fear of successful contradiction that the accidents in the mining industry are in direct ratio to the labor turnover; reduce the labor turnover and you lessen the number of accidents.

DISCUSSION

Mr. C. W. GOODALE (Anaconda Copper Mining Co., Butte): Mr. Chairman, with the help of Mr. Boardman, we started to prepare some curves

showing the relation of accidents in the Anaconda Mine in Butte, and we didn't find quite what we expected.

We have among the men employed in Butte, 53 per cent from non-English speaking countries. That doesn't imply that 53 per cent of the men cannot speak English at all, but they are from non-English speaking countries, and I think a very interesting line of thought has been suggested by Mr. Fay's paper, as to the number of accidents occurring among the men who could not speak English, but the Operating Department is always making an excuse or explanation of high accident rate as our safety measures are not bringing about results. Their assertion is that it is due to the great labor turnover.

STANDARDIZATION OF ACCIDENT RECORDS

MR. GIDLEY: The standardization of accident records depends a great deal upon the care exercised by each individual company in making those records. For instance, some companies are very careful in going into every detail regarding all accidents. Some companies require an accident report completely filled out for some very slight scratch, while other companies give an accident of that character absolutely no consideration. Until such time as those things can be gone into and properly adjusted so that all accidents will receive the same consideration from all employers, why it seems to me it is beyond the range of all possibility to get anywhere in standardizing accident statistics.

You take a man who occupies a position like Mr. Fay, for instance. Those things would have a tendency to benefit a person in his position wonderfully. If the very character of the accident could be gone into thoroughly, requiring a report, so that every operating company would have a standard to go by, then the records gotten out by Mr. Fay would be of material benefit to the entire mining industry throughout the country.

I have endeavored on several occasions to compare mine accidents of various operating companies with the Phelps-Dodge Corporation, but due to the fact that accidents which require a report from some companies are paid absolutely no attention by other operating companies, renders it impossible to get anywhere near a comparative statement.

CHAIRMAN TILLSON: I can't second too strongly these comments regarding the comparative value of accident statistics, as I have long felt that if you are going to spend money in doing what you should do, you had better get busy and make your records so that you can compare with every other line, so you can see whether you are getting anywhere or not. You had better change your methods and do things right. It seems to me it is like a man attempting to run a business without taking an inventory. If he has a big fund of wealth, he may think he is making money, though he may be losing, and not know it. If you don't get busy, those of you who are not keeping your accident statistics in refined form so that you won't have to worry in future years, you are wasting that much money. It is not business to keep your accident records in any other than a refined form.

Mr. Fay, from my conversations with him, would desire a greater refinement than he is able to get. He has felt that there is so much difficulty in getting a true report on a general basis that it was foolhardy to ask for anything further, and it is quite a derogatory thing that we have accredited to ourselves that we are in this condition. We have had an Accident Statistics Committee of the Mining Section for the five years since it has been in operation, but there hasn't been the support of industries in taking the trouble to get the information and get it to the Accident Statistics Committee, and Mr. Fay gets them anyway in his official capacity. He has been the Chairman all along. He is the best posted of any man in the country on mining accidents, and he finds it difficult with all the official Federal backing he has.

I think we have a function to perform as disciples so that people get information, so that we can realize whether it would profit us to get systems that are good when we compare the relative value of life and property with the accidents of some plants.

DIFFICULTIES IN STANDARDIZING

MR. FAY: May I interject a word on standardization? I have worked on this proposition for the past six or seven years until I am both bald and gray. There are forty-eight states in the Union and those that have metal mining have metal-mining laws, and those that have coal mining have coal-mining laws and each state tries to lay out what shall be reported, what companies shall report, and what not.

There are some five thousand coal-mining companies in the United States, and each wants to be a law unto himself and use his own judgment. There are three thousand metal-mining companies, and it is just about the same with them. There are five thousand quarries, operators, etc., and each acts according to his own mind. When it comes to standardizing, it is rather visionary. It is almost an impossibility and I feel a little discouraged myself. I have worked hard at it. I suppose some good work can be done. I have distributed some of those tabulation sheets, and I can vouch for about one hundred metal-mining companies who are using them.

CHAIRMAN TILSON: How many coal-mining companies?

MR. FAY: About ten or fifteen. The metal mines, however, keep writing in asking us to send twenty-five, thirty, or forty sheets at a time, and those companies are sending in the reports. All of the larger companies are sending in A-1 records and I feel that for the larger companies, we are getting representative figures, even in the metal-mining industry. We have no data on the coal mining. We attempted the work on coal-mine accidents and we have worked out fairly well on the reporting fatalities.

I am contemplating to stick to the monthly statement for coal-mining industries. I hope we can get a clerk to work in the different states and dig out of the state records something which they already have, and which are complete records in the state, but until I can do that, I can't see much hope of real standardization.

CHAIRMAN TILLSON: I don't know but what it would be in order for this body to show its liveness by the formulation and passing of a resolution urging the value of sufficient funds being expended to give the mining industry records which the states themselves have not been able to compile. If this meets the approval of the body, let's do it.

MR. FAY: If I can get \$75,000 for the accident work at Washington, that would help.

MR. JOHN L. BOARDMAN (Anaconda Copper Mining Co., Butte): I think Mr. Fay or the Federal Government wouldn't have much difficulty in getting standardization of accident reports if they didn't have such a complicated notion of what an accident really is. They want us to report a number of accidents for the number of men employed. We might have two thousand men employed. I think it is the province of the Federal Government to standardize this thing, but I think it ought to be reported on the basis of actual risk run, which means so many accidents per so many shifts run, and not men employed, and I think if it were worked on a basis of that kind, everybody would be willing to report on that basis.

CHAIRMAN TILLSON: I think Mr. Fay's intention is to get it that way if he can.

MR. FAY: In the coal-mining industry, it is difficult to get the hours of labor, or the days, or shifts, because so much of the work is done by contract by ton, yard, foot, fathom, etc. To get the actual hours performed in the coal mine is almost impossible. In some phases of metal mining, it is equally as bad, especially on contract work. If it is possible for us to get the actual number of days' labor, it can then be worked out on any other unit having the eight-hour shift previously. That is the basis on which they ought all to be reported to get comparative figures. That takes in the actual time supposed to be put in on the industry. If we can get on that basis, we can get better results.

MR. W. D. SCHOFIELD (Safety Engineer, Inspiration Consolidated Copper Co., Miami Ariz.): Wouldn't it be as well to put it on a basis of per thousand tons mined? If you put it on the per thousand tons mined basis, wouldn't that get away from the amount of time your men are underground. Wouldn't it standardize it?

MR. FAY: Not necessarily. I am handling it both ways.

MR. SCHOFIELD: So are we.

CHAIRMAN TILLSON: Of course, the viewpoint is very common that the hazard is dependent chiefly upon the length of time the man spends under unsafe conditions. He might be standing still, but he would be under that hazard for that length of time.

RESOLUTION FOR APPROPRIATION OF FUNDS FOR DETAILED MINE ACCIDENT
STATISTICS

MR. R. H. SEIP (New Jersey Zinc Co., Franklin, N. J.): I will make that motion as you stated it, or as you suggested: That the Mining Section of the National Safety Council recommend to the director of the Bureau of Mines that sufficient money be appropriated to provide means

for securing from all the states more detailed mine-accident statistics, for the benefit of the mining profession and industry.

MR. FAY: May I add to that, utilization of standardization?

(The motion was seconded by Mr. Gidley and unanimously carried, and Mr. Shearman, the Secretary, was instructed to see that a notification of the above motion be sent to Mr. Manning, Director of the Bureau of Mines.)

Adjournment.

FRIDAY MORNING SESSION

THE meeting was called to order at 9:30 A. M., Mr. B. F. Tillson presiding.

CHAIRMAN TILLSON: Mr. M. W. Price is on the program for the first paper. He is not present, so I thought it might be wise for us to ask Dr. Knoefel, who is to present Mr. D. J. Parker's paper, to present that first, although in some ways it is unwise to vary from the program. I haven't had any word as to whether or not Mr. Price is coming.

DR. AUGUST F. KNOEFEL (U. S. Bureau of Mines, Terre Haute, Ind.): Mr. Parker asked me to present his regrets at his inability to be here. As you all know, there has this week been held a dedication of the Bureau of Mines, and as there are some two hundred Mine Bureau men in the field, situated throughout the country, these various men, mining engineers, car foremen, etc., have been called in for the dedication, and now that they are in, they are holding their annual conference. It was impossible for Mr. Parker to get away, as he is the mining engineer at the head of safety. He asked me to represent the U. S. Bureau of Mines and present this paper.

THE DESIRABILITY FOR STANDARDIZING MINE RESCUE TRAINING AND PLAN FOR STANDARDIZATION

D. J. PARKER, MINE SAFETY ENGINEER, U. S. BUREAU OF MINES EXPERIMENT STATION, PITTSBURGH, PA.

The modern mine rescue breathing apparatus is a self-contained device, the function of which is to permit the wearer to penetrate irrespirable gases formed by mine fires or mine explosions.

There are several types of breathing apparatus, one of which depends on liquid air for the breathing supply, a second depends upon the generation of oxygen from a chemical compound, a third depends upon normal air under pressure, and a fourth, which is most widely known in America, depends upon pure oxygen under high pressure for its air supply.

The history of breathing apparatus dates from the year 1868, when a device was used similar to the submarine diver's helmet. Practically all succeeding forms were built along similar lines until 1896, when the present portable self-contained type was devised and used abroad. The first self-contained apparatus to be used in the United States were four

sets imported in 1907 by the Anaconda Copper Mining Company of Butte, Montana. In September, 1908, breathing apparatus was purchased by the Technologic Branch of the United States Geological Survey, for use in mine rescue and recovery work, which at that time was in charge of that branch.

Today the Bureau of Mines has ten rescue cars, five rescue trucks, and eight safety stations distributed throughout the mining regions of the United States, equipped with some 300 complete sets of such apparatus, while several thousand sets are owned by State mining departments and mining companies having rescue crews trained in their use.

Breathing apparatus may be divided into two types as regards the length of time the apparatus will furnish pure air on one charging; these are the half-hour type, principally used on vessels or where men are only exposed to dangerous atmospheres for short periods of time, and the two-hour type which is the kind used in mines. In mine rescue and recovery work the apparatus wearer may have to travel considerable distances from his base and two hours has been adopted as the maximum period of service compatible with lightness and convenience of portability. Only the two-hour type is considered in this paper.

In the United States there has been a steady growth in the use of breathing apparatus by the mining industry. As with many other new devices when they first appear mine operators and owners were at first decidedly skeptical as to the merits of the apparatus. However, owing to the progressive spirit of numerous operators, both coal and metal, the ingenuity of apparatus manufacturers, and persistent effort of the Bureau of Mines, a more intelligent understanding of the use and limitations of the apparatus has been attained.

As a result of the combined efforts of those appreciating the necessity for such a device for safely penetrating noxious atmospheres, a tremendous impetus has been given to its use in the mining industry, especially within the last three or four years.

I believe that all of you will agree that the apparatus occupies an essential and permanent position in the mining industry, so it does not seem necessary at this time to point out instances where lives have been saved directly by the use of the apparatus, or to give even approximately the figures showing the value of the vast amount of property saved to the nation annually.

Today there is not a mining district in the United States that cannot on short notice in time of disaster obtain the services of trained men equipped with apparatus either from State or privately owned rescue stations or from the Bureau of Mines. Most of the larger companies also have rescue equipment and organized safety crews.

STANDARDIZATION OF TRAINING METHODS

On account of the constantly increasing demand for apparatus training, the Bureau of Mines has for some time appreciated the necessity for a standardized course of such training.

Thorough and systematic training are essential to insure the safe

and economic use of the apparatus. Such training can best be insured through standardization of training methods. As a result of a standardized course, it is believed that more attention will be paid to the selection of the proper type of men for rescue crews, efficiency will be increased, and higher appreciation of the value of the apparatus will result.

The reasons for standardization are, in fact, so obvious that it hardly seems necessary to dwell further on this phase of the subject. It might be mentioned, however, that there are two essential reasons, in addition to those already mentioned, for such standardization.

(1) It is the policy of the Bureau of Mines, upon request, to give a thorough examination to men trained either at privately or State-owned rescue stations, with a view of qualifying them for mine rescue certificates issued by the Federal Government. A standard course of training would most assuredly be tremendously advantageous to both the examiner and the examined.

(2) Trained men going from one mine to another mine would be decidedly at a disadvantage when called upon to wear apparatus, assuming that the men at each mine had received a different course of instruction. This would hold true even though their training had been with the same type of apparatus. As an illustration, it has been known to occur that where one instructor would require the evacuation of the apparatus of all normal air, another would require the inflation of the breathing bag with exhaled air, while another would permit the wearer to don the same type of apparatus containing normal air. Such diversity of instruction may result in serious difficulty for the wearer.

THE PLAN

It is believed that a course similar to that pursued by the Bureau of Mines in the standardization of first-aid instruction should be followed in this case, i. e., by the wide dissemination of a publication on the subject.

I will now attempt, without going into details, to give a few of the fundamental principles that might form a basis for such a publication.

On account of the extremely hazardous work of wearing rescue apparatus in deadly atmospheres, too much attention cannot be given to the selection of an apparatus and the training of the wearer.

Many of us are inclined to think of a course in apparatus training as so many hours under oxygen in an irrespirable atmosphere. In reality, this phase of the course, though essential, is second in importance to a thorough and scientific knowledge of the use and the mechanical and physiological limitations of the apparatus.

No one should be accepted for training without first receiving a thorough physical examination by a competent physician or surgeon.

The length of the course should not be less than five periods of four hours each. At least eight hours should be spent under oxygen and in an irrespirable atmosphere. Wherever possible the apparatus work should be given underground. The course should include standard lectures on each of the several types of apparatus now in use in this country. Such

lectures should dwell at length on the various tests of the apparatus, in order that the wearer may know to a certainty that his apparatus is functioning properly before entering a zone of poisonous gases. A person to be skilled in the use of apparatus should not only have a thorough knowledge of the use and care of the apparatus and oxygen pump, but he must also have a working knowledge of mine gases, that is, he should be familiar with their methods of occurrence, physical properties, effects on man, and methods of testing for their presence, particularly those gases encountered after mine fires and explosions. Knowledge of at least two types of flame safety lamps is desirable on the part of the apparatus man trained for work in coal mines. This is not so essential in the training of metal miners. The standardized course should specify the purity and method of manufacture of oxygen to be used in the apparatus. Oxygen manufactured by the electrolytic process may contain a certain percentage of hydrogen. The Bureau of Mines has, therefore, tentatively specified to manufacturers who supply oxygen for use in mine rescue apparatus, that the oxygen shall not contain more than 2.5 per cent nitrogen nor more than 0.2 per cent hydrogen. Also the purity of the regenerating material should be specified.

In addition, the course should deal at some length with the method of procedure following mine fires and explosions, including the duties of the captain of the rescue squad.

Publication regarding such course of standardization is now contemplated by the Bureau of Mines.

The necessity for such standardization is now, I believe, universally recognized among the manufacturers and users of breathing apparatus: by the whole-hearted cooperation of apparatus manufacturers, safety engineers, and the mining public such standardized training will be established and oxygen-breathing apparatus made a safer and more efficient agent for the help of mine owner and miner in times of trouble and disaster.

CHAIRMAN TILLSON: Gentlemen, we are indebted to Dr. Knoefel for presenting this paper, and we shall be pleased to have active discussion of the points raised in it, or any other points which come to your mind in regard to the method of rescue contest which you saw take place at Pittsburgh, which probably would bring to mind any features which it might be advisable to try to improve upon, if such were possible.

DISCUSSION

PROF. R. M. RAYMOND (Columbia University, New York City): I would like to know if any here have used or heard of some one who has made use of the Gibbs apparatus. This has been found very valuable by the Bureau of Mines.

(Some one suggested that John L. Boardman, of Butte, was familiar with all the different kinds of apparatus. Mr. Boardman was not present at this time, but was sent for.)

MR. G. B. SOUTHWARD (West Virginia Coke & Coal Co., Elkins, W. Va.): While we are waiting for Mr. Boardman, there is just one point that Mr.

Parker's paper did not bring out. It seems to me that it is very important in mine-rescue training to have a recurrence of training possibly every six months. I took the training two years ago, and haven't had on a helmet since. If I had to use one today, I wouldn't know how. I think it is a very important point to be considered.

CHAIRMAN TILLSON: I think your point is very well taken, Mr. Southward. I have heard it expressed before.

MR. OSCAR A. DINGMAN (East Butte Copper Mining Co., Butte, Mont.): I might say, before Mr. Boardman gets here, that he is in charge of the party and he does most of the mine-rescue work and first-aid work in Butte. It is handled through the A. C. M., and all of the other companies follow what the A. C. M. does. This paper given here has been carried out practically to the letter.

(Mr. Boardman entered the room.)

CHAIRMAN TILLSON: Mr. Boardman, I don't know whether you have had a chance to read Mr. Parker's paper or not, but it seems as if everybody wants to hear from you in regard to Gibbs vs. Draeger apparatus.

MR. N. D. HUBBELL (W. J. Rainey, Uniontown, Pa.): We started out with the Fleuss, not the Draeger apparatus. We first picked the Fleuss as superior to the Draeger. Now we have taken the Gibbs on account of the fact that the oxygen supply is automatic. In the second place, all the apparatus is on the man's back, and in crawling over a fall of slate, getting through a comparatively small opening, it is desirable that the man have nothing on his chest that could in any way compress or shut off his breathing. You take a soft breathing bag on his chest and it is quite likely to become compressed so he is not getting a proper supply through it. The Gibbs has everything on the back and for that reason we chose the Gibbs. It is true that the Fleuss and the Draeger have a continuous flow of oxygen that has to be adjusted by the wearer. We figured that the wearer had enough on his mind without worrying about whether his oxygen supply was used up or not.

TYPES OF MINE RESCUE APPARATUS

MR. JOHN L. BOARDMAN (Anaconda Copper Mining Company, Butte): Unfortunately, I did not hear the paper, but Mr. Dingman informed me of some of the points in the paper.

In regard to the question just brought up with reference to the Gibbs as against the Draeger, I think that there is no comparison at all between the new type Gibbs and Paul and the Draeger machines, all the points being in favor of the Gibbs and Paul types for the reason that such types of machines as Draeger, Fleuss, Westphalia, and the so-called constant-feed machines are now rapidly becoming obsolete. The reason for that is that this type of apparatus gives a constant feed of from two to three or four liters of oxygen per minute. We have records of cases where a man might use as high as six liters of oxygen under certain circumstances.

The machines are now provided with a by-pass, but the by-pass always makes it necessary for the man to manipulate the machine in addition

to the work he is doing. As opposed to that machine, we have the Gibbs and Paul types, which feed the oxygen only as the man requires it. These machines have a reducing valve which reduces the oxygen pressure so that it can be easily handled by means of an admission valve.

This admission valve is controlled by the volume of oxygen in the breathing bag, so that when the breathing bag becomes partially empty, the valve admits more oxygen into the bag. This type of machine will undoubtedly take the place of all constant-feed machines within the next few months, depending, of course, upon the desire of different companies to change over from one type to another.

We have found in Butte that it is absolutely necessary that a man should take a physician's examination before he is even admitted to take mine-rescue training. Following this line of procedure, we have done more actual work with breathing apparatus in Butte in the last three years than has been done in all the rest of the United States put together, and we have lost but one man wearing breathing apparatus. We have saved quite a number of lives by taking men out of places imprisoned by gas.

In the case of the one man that was lost, since he is not here to tell us what happened, we don't know exactly, but here is what I suspect: The man was wearing a half-hour Draeger machine. He had been trained to wear both the half-hour and the two-hour Draeger types. In the two-hour Draeger type, our men are taught to inflate the breathing bag before they enter the gas. That, of course, is to give them a residual air which permits them to go immediately to work. This man knew better than to inflate the bag of the half-hour machine, but it is just presumed that he mechanically inflated the bag of the half-hour as he would the two-hour machine, and the result was that his bag was full of oxygen. He had been taught not to open the oxygen valve until the bag became flat.

You understand, in the half-hour machine, the valve must be manipulated by hand. It appears, from investigation of the accident, that this man went in alone, contrary to the orders of the boss, and walked perfectly straight for about 200 feet into the drift. He did about five minutes' work and he had used about five minutes of oxygen out of his cylinder.

He evidently then got weak or nervous and started to retrace his steps. He walked perfectly straight until he got within twenty feet of the fresh air and then fell and died. We found the man lying face down with nose clip in place, the oxygen feed turned off and no gas of any kind in the breathing bag. Death was due to lack of oxygen.

The theory that bears this supposition out is that a man inhaling and exhaling his own breath through a regenerating can, as a caustic soda can, has no desire to breathe. Respiration is caused by the irritation of carbon dioxide on the nervous system of the lungs, the respiratory nerves, and the air that this man was breathing was going in and out of the bag through the regenerator and there was no carbon dioxide, no irritation on the lung nerves. The man had no indication of distress at all. He felt

perfectly normal until the oxygen became so low that he simply collapsed, and then didn't even have strength enough to take off the nose clip. Had this man done a similar amount of work without an oxygen apparatus he never would have become unconscious.

We are making that statement from analysis of gas later which was not very strong, non-poisonous, and had enough oxygen to keep him alive for considerable longer time than he was in there.

STANDARDIZING TRAINING OF THE MEN

In regard to standardizing training, I mentioned the doctor's examination. That is the most necessary thing in beginning to train a man in mine-rescue work. We find in giving mine-rescue training that it is necessary to train about three hundred men to get from sixty to eighty good mine rescuers. The mine-rescue man has to have a mixture of several very good qualifications.

First, he must not be too large. He shouldn't weigh over 180 pounds, although there are some heavy men who are good men. He shouldn't weigh less than 130. He should be given at least a six-day course in the use and care of the machine, as a preliminary course only, and, if possible, three days of these six should be spent in actual mine-rescue work with a trained crew. We find that we get better results by giving a man three days' training in fresh air or in a smoke room and then sending him down with the regular crew to do regular mine work. We have a larger percentage of our men turn out to be good rescue men than by giving the six-day course of training without actual work, and then letting them go for a while.

The mine-rescue man has to have considerable nerve at times, although he will acquire this quality if he has a good crew with him. By all means a mine-rescue man should be almost absolutely unexcitable, under any circumstances, because there are exciting circumstances which will come up from time to time and if he is of excitable nature, he is likely to cause the crew some difficulty.

Unless a mine-rescue man, after he has received the six-day training, is put in service, he should be given one-half day or two full hours at least in the smoke room and two hours' instruction at least every three months. I should say that the longer period of inactivity would not do.

If I understand the paper correctly, the intent is to standardize mine-rescue training throughout the United States. I think that is a remarkably good idea. At the time of our North Butte fire, I presume we had twenty-five or thirty men apply at the gate for service as helmet men who had Bureau of Mines certificates. To my personal knowledge, in the early days of the Bureau of Mines, men have received certificates with one day's training, others with two days' and so on up to six. This is not a criticism on the Bureau of Mines, but more or less criticism on the impossibility of doing the work properly at that time. These men had the same certificates as men trained later by the bureau who had the full six-day course, and we had no way of telling how fit the man was.

The result was that we hired a number of men who worked two or three hours and backed out.

Personally, I believe it would be a good idea to train every man in the United States who takes up this work with exactly the same hours of training and make this ample, so that when the man leaves one camp and goes to another, this certificate would mean that that man could be relied on as a good mine-rescue man. Otherwise, we are going to have a good deal of trouble.

If a man comes out and applies for mine-rescue work in a time of disaster, it is necessary that we hire him. If he is not what his certificate represents him to be, there is a chance that he will be killed, or cause the death of some one else by being inefficient. In Butte, we are willing to cooperate with the Bureau of Mines in giving any standard course of training that they may prescribe, reserving, of course, the right to add other training to fit the man for our own peculiar needs.

I think that is about all the discussion I can give on the paper, since I haven't read it. If there are any questions about what we are doing in Butte, I should be glad to answer them.

CHAIRMAN TILLSON: We appreciate your discussion and interest, and later in the session this morning you may have a chance to glance through that paper and any further comments that come up may be brought up later.

MINE-RESCUE BONUSES

MR. N. D. HUBBELL (W. J. Rainey, Uniontown, Pa.): There is one question I would like to ask Mr. Boardman. We are rather new in mine-rescue work. We are using it for coal mines and the question has come up as to whether or not we will pay our men a set bonus or a percentage bonus of their wages, just on account of the fact that they are qualified mine-rescue men. Our men are doing other work all the time. Some are minor officials. The question comes up whether we shall pay them extra for doing their regular work merely because they are qualified as mine-rescue men, the idea being, of course, that if they did not report for mine-rescue drill once in three months or once a month on first aid, they would likely not be fit.

MR. BOARDMAN: All I can do is to tell you what we do in Butte. During the war we had twenty-eight operating mines and some of the foremen were very lax in their interest in mine-rescue work, so I asked the general superintendent to attempt to systematize the work, and we got it done in this way: All mines employing 100 men or less are required to keep a trained crew of five men working in that mine. They may work at anything that the mine affords for them to do. Mines employing over 100 men maintain a crew of ten men or more. Some of them have as high as sixty, but ten are required. These men are paid their regular wages for the time occupied in taking mine-rescue training. They are not supposed to be paid for taking first-aid training.

As soon as a man completes his training, he is given an additional duty which we call a "fire bug." He might be a repair man in the mine or work at any regular work. The other men might go to work at 8 in the

morning while he goes to work at 9. Then he acts as "fire bug" from 4 to 5. He goes through the mine on regular beats and looks for fire. He works eight hours, coming in an hour later and going home an hour later, but he is paid 50 cents extra. That has been recently raised to 75 cents. We recognize our helmet men in that way, by giving them an eight-hour shift with 75 cents extra pay, and the station men are to report a man to the regular timekeeper when he shows up for regular mine-rescue training.

We have about three hundred men drawing such mine-rescue bonuses and we have an additional three hundred, approximately, waiting for positions on the fire-bug crew. You see it will operate in this way: A man desiring that extra money will ask the foreman if he can take mine-rescue training, so he can fill in.

CHAIRMAN TILLSON: Mr. Boardman, there is one question that came to my mind and that is as to what number of rescue apparatus in your experience you consider the minimum which should be on hand for use, the number of outfits?

MINIMUM NUMBER OF SETS OF RESCUE APPARATUS

MR. BOARDMAN: I shouldn't have any equipment with less than four sets, and that is a very small number. The reason for that is that in any mine-rescue crew, working in a tunnel or mine filled with smoke or gas, a man is likely to stub his toe and fall down a hole, or a rock may fall on him and temporarily put him out of commission. That leaves only three to get him out to fresh air and if any of you men have had any experience in taking a man out of a mine, you will agree that three is about the minimum that can be used, especially if the man is delirious.

MR. SEIP: I think, Mr. Boardman, what Mr. Tillson means is where you don't have any other equipment available at short notice. I know that is the way we are situated and we would have to depend entirely, probably the first day, on our own equipment, and therefore I believe it is desirable to have enough for two crews of a minimum of four men, and preferably five.

MR. ORR WOODBURN (Globe-Miami District, Globe, Ariz.): It is rather terrifying to have to wait for one crew to go in and wait for possibly two hours, even though you have a crew waiting at the fresh-air base. We have taken care of it by pooling our equipment. The various companies of the district had twenty sets of equipment, so we have now pooled our interests on mine rescue and first aid, thereby giving each company three times the equipment available. Where there are several companies near each other, I think arrangements should be made to pool their equipment.

MR. BOARDMAN: In reply to the first question, I stated that four machines would be the absolute minimum in any installation. I agree with you if you are going to put any equipment in a remote place (and by all means get a power-driven pump, don't depend on the hand pump) you should have more equipment.

In regard to Mr. Woodburn's statement, I think he has touched upon a

very vital point. Recently, I was called upon to leave Butte and take some mine-rescue men with me and put out a fire in another mine in Idaho, a distance of about 200 or 300 miles from Butte. When we got over there we found them with nine sets of apparatus. Two of these were purchased in 1916 and had never been taken out of the packing cases. Their experience was something like this:

They put seven sets of machines on seven men, of course, and asked these men to go 1,200 feet through the gas in a drift to play a hose on a fire at the bottom of a raise. These men got in varying distances of 100 feet to 400 feet from the fire and were overcome. Other men rushed in and helped them out, put them to bed and took the apparatus, re-tested and recharged it—or thought they did—and sent in five other men.

Three of these five succeeded in getting the hose to the fire, but the others dropped along the way. They didn't get the nozzle of the hose pointed right, and two more became unconscious. The man remaining conscious dragged them 1,000 feet before he fell. Fortunately, they got them all out.

When we got down there, we found by using the bags we took from Butte, and tearing down all their apparatus, we were able to get two good machines out of their nine. Taking the three we brought from Butte with us, we had five good machines. I am only telling you this as an illustration of what might happen if you put in four sets instead of twenty, or don't keep in good condition the apparatus installed.

Up in Butte, we have 65 machines in condition to operate at all times. We have a total of about 70 machines, or 72, I think. Of course, we are figuring on 5 or 6 of these being in the shop. That gives us a constant equipment of about 65 machines. That is just the one company. The Butte Superior Black Rock mine has 12; East Butte has 6; North Butte has 8. You see we have over 100 machines in Butte.

In Butte the A. C. M. has two rescue stations and we have a man at each of the stations on each of the eight-hour shifts who does nothing else but repair machines and give them out and take them in when being used. It is criminal to put in mine-rescue equipment without making it the duty of some one to keep it in shape.

The machines should be inspected and reported on every week. Each machine we have goes on this report once a week.

CHAIRMAN TILLSON: Mr. Boardman, may I ask whether a copy of such a report can be included in the minutes? I think it would be of value as a matter of public interest. [See page 864.]

MR. WOODBURN: Mr. Boardman says to make it somebody's duty to inspect the apparatus. I happen to be one of those men whose duty it was to inspect apparatus. Of course, I had other duties and most of my time was being spent on these other duties. It is very easy to neglect this inspection. You may go in and look over the equipment, but unless you get out the things and wrestle with them and wear them, you won't be able to discover the trouble that may develop. I have had machines that would hold up fine on the weekly test, and the first time we would go out, something would go wrong.

respect to the condition of apparatus as sent out by the manufacturer. The development of mine-rescue work in the United States, as you all know, has been a development first of importation up until the war broke out, and practically all of the apparatus that was used in the United States prior to the war was made either in England or in Germany. The manufacturers, or rather the distributor, in those days had to depend very largely upon the exigencies of transportation from foreign countries to obtain rubber parts and they were, therefore, not able to know how long such equipment had been in stock prior to shipment. There were times, possibly, when parts that were distributed by the particular company with which I was affiliated at that time were in stock six months. I doubt if there were any of the parts that remained in stock longer than that in our own warerooms, but that does not say how long they might have remained in stock before they were shipped to us.

In the early days of manufacture in the United States, it was largely a matter of necessity, due to the conditions brought about by the war (at least so far as that company in which I am interested is concerned) to depend upon other companies to manufacture some of the parts and to have them assembled in our own plant. During those days it was almost impossible quickly to equip a manufacturing company for a work so entirely new in the United States, because it was a new industry and no one in the United States knew a great deal about the manufacturing of such apparatus.

The time has now come, however, when the manufacturers—I think it can safely be said—are getting their organizations more perfected; they are making the parts themselves—at least our company is. We manufacture practically all of the parts, buy the raw rubber in sheets, make the breathing bags and such other material needed in the construction of the apparatus, the same being true of many metal parts. Gauges and castings are purchased, and small stocks of parts are kept to meet the immediate requirements of the users of the apparatus.

I believe that within a very short time the condition that Mr. Reed has mentioned will largely be overcome. I think the suggestion he has made in regard to the dating of the parts when manufactured is an excellent one and I want to say that I will put that into effect within a very short time, practically immediately. I think the idea is an excellent one and I am thoroughly in accord with it.

CENTRAL RESCUE STATIONS

I would like to make a comment on a subject that was brought up a few minutes ago by Mr. Woodburn. I think it is one worthy of consideration. As distributors of apparatus, our company has at times run across the situation that small coal companies or mining companies of any kind find the investment in a rescue station a somewhat large one for the one company and occasionally a pooling of the interests of several companies in a certain district has resulted in a central rescue station. There are, I think, possibly a half dozen, so far as my knowledge carries me, that have been entirely successful in installing central rescue stations,

stations is one that has been put up by a few small independent operators who have pooled their interests and although we haven't any definite agreement so far as pooling goes, still there is the ordinary courtesy, and if anybody is in trouble, we all turn out with all of our apparatus. Three of the companies are equipped with Gibbs and we would have a fairly uniform set of apparatus if each station were to turn out the full set of ten apparatuses, and there would be at least twenty-five trained men, the idea being that you could get your own team in and have a crew of five on the outside until more arrive. We are going along that line, keeping one man on the outside with a helmet on for every man who is inside.

DATE OF MANUFACTURE

J. W. REED (Consolidated Coal Company, Fairmont, W. Va.): In regard to repairs of rubber portions, I think we overlook one point. We are all considering proper care of the apparatus after we receive it, and I think there is a very big point to be made in the care of the apparatus on the part of the company from whom you purchase it. I feel that they also should use the same precautions to see that the rubber portions that are furnished to the various companies on their orders are in good condition and comparatively new. Along that line I feel that it is going to be necessary at some time to require of manufacturers of breathing apparatus that the same shall be stamped and marked with the date of manufacture. Then when you purchase a thing you will have some idea of the age of it when you get it. In other words, if you purchase a breathing bag and expect to get twelve months' service out of it, and it has been in stock six months, you are purchasing defective material.

The system that we are working out is not to purchase in large quantities, but to arrange a schedule whereby all the apparatus we have on hand will have the rubber portions renewed on a certain schedule which will be approximately the same length as the life of the rubber portions and to stretch that out over the number of sets of apparatus. In other words, where there are a half dozen sets of apparatus in a small station, the rubber portions would be ordered every six months or every two months, so that in a year's time we would have new rubber portions for each of those sets of apparatus, and the other rubber parts would be thrown out after the length of service which we consider would be safe for a breathing bag.

We haven't as yet arrived at exact figures on that, but we feel from ordinary experience around laboratories, etc., on rubber, that it never has a life of over two years. Safe life on that will probably not be over a maximum of fifteen months, but I feel that we should know something about the material when we purchase it, and I would like the opinion of some of the others as to whether they should be required to date the rubber parts on manufacture. I believe that the companies perhaps would install a system of that kind if it was suggested by most of the users of the apparatus or practically demanded by them.

Mr. F. F. MORRIS (American Atmos Corporation, Pittsburgh): I assume that it might be apropos for me to add a word to Mr. Reed's comment in

MR. F. F. MORRIS (American Atmos Corporation, Pittsburgh): I assume that it might be apropos for me to add a word to Mr. Reed's comment in

MR. JOSEPH E. WATSON (Timber Butte Milling Company, Butte): Speaking of standardizing methods for the training of mine-rescue men, why not get down to some standard method for the care of apparatus? I know of one case where two sets of Draeger apparatus hung in a mine office over two years without being taken off the nail. One of those two sets of apparatus happened to be included in the nine that Mr. Boardman mentioned in the Idaho fire. If you are going to standardize the training of men for the preservation of their lives and the preservation of property, I believe really we should make some efforts to standardize the care of machines and see that the machines on hand are properly cared for.

MR. GEORGE W. RIGGS (Mine Safety Appliance Co., Pittsburgh, Pa.): It was my duty in the State of Nevada as safety engineer during the six months that I was there to take care of 64 sets of breathing apparatus. We had three kinds, Draeger, Westphalia, and Fleuss. It is a high, dry climate. When I went out there we had to buy considerable repairs. We made a dugout, where we had twenty-four sets. We kept rubber beltings, spare rubber parts for breathing apparatus, etc., in this underground dugout and also gave them a bath in lukewarm water about once a week. In that way we kept the rubber parts up in better shape than before.

MR. HUBBELL: Our idea may not be worth very much—we can't tell how it has worked out, but this is a tentative scheme as to how we are going to handle that particular problem. The room, of course, will have to be kept at living heat and we were afraid that steam heating was going to force some of the humidity out of the air. We have arranged for a metal locker which is air-tight, and we are going to do a little experimental work with some of the rubber parts to arrive at a definite humidity point and keep the locker at that point. I don't know what that will be. We haven't completed our work on it, but are working on it now. That includes just the rubber parts of the apparatus. The other will be stored.

MR. H. G. DAVIS (D. L. & W. Coal Co., Wilkes-Barre, Pa.): The railroad company coal department at their mines in Wyoming Valley in the early part of 1910, if I remember, equipped all their mines with four sets of Draeger apparatus, and also equipped a car called the rescue car with eight more sets, and I found in my experience that the rubber goods on those machines deteriorated very quickly, particularly where steam heat was used for keeping the rescue rooms and other rooms in good condition. We did away with steam heat and equipped the rescue car and stations with stoves, with the result that the rubber goods lasted much longer.

I agree with these gentlemen that four sets of apparatus is not sufficient for any place where there are not four more available. We started out with thirty-two sets. All the parties had four sets each and were within a short distance of each other. The rescue car could be brought into any of the mines in about an hour. I think it is important to have a sufficient number of sets, at least eight; more if possible.

MR. HUBBELL: Along that point, we have ten, but there are four other rescue stations within a radius of twelve or fifteen miles. One of those

All the parties had four sets each and were within a short distance of each other. The rescue car could be brought into any of the mines in about an hour. I think it is important to have a sufficient number of sets, at least eight; more if possible.

MR. HUBBELL: Along that point, we have ten, but there are four other rescue stations within a radius of twelve or fifteen miles. One of those

MR. JOSEPH E. WATSON (Timber Butte Milling Company, Butte): Speaking of standardizing methods for the training of mine-rescue men, why not get down to some standard method for the care of apparatus? I know of one case where two sets of Draeger apparatus hung in a mine office over two years without being taken off the nail. One of those two sets of apparatus happened to be included in the nine that Mr. Boardman mentioned in the Idaho fire. If you are going to standardize the training of men for the preservation of their lives and the preservation of property, I believe really we should make some efforts to standardize the care of machines and see that the machines on hand are properly cared for.

MR. GEORGE W. RIGGS (Mine Safety Appliance Co., Pittsburgh, Pa.): It was my duty in the State of Nevada as safety engineer during the six months that I was there to take care of 64 sets of breathing apparatus. We had three kinds, Draeger, Westphalia, and Fleuss. It is a high, dry climate. When I went out there we had to buy considerable repairs. We made a dugout, where we had twenty-four sets. We kept rubber beltings, spare rubber parts for breathing apparatus, etc., in this underground dugout and also gave them a bath in lukewarm water about once a week. In that way we kept the rubber parts up in better shape than before.

MR. HUBBELL: Our idea may not be worth very much—we can't tell how it has worked out, but this is a tentative scheme as to how we are going to handle that particular problem. The room, of course, will have to be kept at living heat and we were afraid that steam heating was going to force some of the humidity out of the air. We have arranged for a metal locker which is air-tight, and we are going to do a little experimental work with some of the rubber parts to arrive at a definite humidity point and keep the locker at that point. I don't know what that will be. We haven't completed our work on it, but are working on it now. That includes just the rubber parts of the apparatus. The other will be stored.

MR. H. G. DAVIS (D. L. & W. Coal Co., Wilkes-Barre, Pa.): The railroad company coal department at their mines in Wyoming Valley in the early part of 1910, if I remember, equipped all their mines with four sets of Draeger apparatus, and also equipped a car called the rescue car with eight more sets, and I found in my experience that the rubber goods on those machines deteriorated very quickly, particularly where steam heat was used for keeping the rescue rooms and other rooms in good condition. We did away with steam heat and equipped the rescue car and stations with stoves, with the result that the rubber goods lasted much longer.

I agree with these gentlemen that four sets of apparatus is not sufficient for any place where there are not four more available. We started out with thirty-two sets. All the parties had four sets each and were within a short distance of each other. The rescue car could be brought into any of the mines in about an hour. I think it is important to have a sufficient number of sets, at least eight; more if possible.

MR. HUBBELL: Along that point, we have ten, but there are four other rescue stations within a radius of twelve or fifteen miles. One of those

Rigid and constant inspection and frequent use is the thing to keep your equipment in shape. To set a definite time for inspection is difficult. The equipment may fail only once, and that once may be any time.

MR. BOARDMAN: In reply to Mr. Woodburn, I would say that the minimum period I would let the machine go would be one week. In our country we have a very low humidity and rubber goods are hard to keep. We overcome that in a measure by scalding rubber parts. Whenever the machine becomes rigid from not being used, we simply throw all the rubber parts in a hot bath once a week and that keeps them in good shape. They are also kept in lockers.

[illegible]

MR. BOARDMAN: We had one case 130.

MR. MORRIS: I would like to emphasize the point I made at first in regard to the contributing conditions that exist in the use of rescue apparatus as limiting the distance that a man may go or a group of men may go and the importance of taking those conditions into consideration, that I believe it is an unfortunate thing to attempt to make any estimate of distances that a man may go into fire areas with rescue apparatus on. Those conditions vary so widely, in respect to the conditions of the entries, the temperature and the humidity, and the progress of the work, that it must be left entirely to the judgment—and it must be good judgment—of the man in charge of the crew.

VICE-CHAIRMAN DAVIS: I wish to state that, having had charge of this rescue work, I arbitrarily fixed the distances that those men should travel, knowing the ground over which they did travel. I would say, "Now, you go to such and such a place. We will give you so much time and if you are not back by that time, there will be a crew looking for you."

I think that can be done if you know the ground. Of course, it cannot be done in a strange country. In a country with which I am familiar, I would fix the crew's distances, and, of course, keep moving your base forward as much as possible at all times.

MR. WOODBURN: My question as to whether or not it is advisable to carry the stretcher at all times has not been answered.

MR. RIGGS: There is a stretcher on the market now, the Wind-flex, that weighs three and a half pounds. You fold it up until it is three feet in length and from the experience I have had, I would not go in without some stretcher, or an improvised stretcher, whether that be a piece of pipe that we can thread together and put a canvas over, or something else. Mr. Boardman has a very good rescue stretcher.

MR. WOODBURN: It wasn't so much the kind of stretcher that I am interested in, but the question as to whether we shall carry one. I have always instructed my men to pick up empty cars, and desert those as soon as others are found. They can always put anything heavy on this car, pushing it ahead, and then, anyway, a car is better than a stretcher. It is much easier to transport a man that is down on a car than on a stretcher.

SHOULD A STRETCHER BE CARRIED?

MR. RIGGS: From my experience, I would take a stretcher.

MR. BOARDMAN: We expect to train our crews so they can take care of themselves. When we send a crew into the mine we have no reason to expect that anything is going to happen. It sometimes happens, it is true, but our men are instructed to watch their crew sufficiently to be able to get a man out to fresh air before he is unable to walk. Of course, it might happen that the man might not be able to walk. I wouldn't send a stretcher with a crew unless it is definitely known that you are going after men.

MR. WOODBURN: Men sometimes go down when they are working in a

hazardous place, where they are liable to injury, outside of the use of their equipment. I was wondering whether or not it would be advisable to carry the stretcher.

MR. BOARDMAN: I don't think it is necessary for the rescue crew to take a stretcher when going on ordinary work.

MR. WOODBURN: Do you think it advisable to carry an extra piece of equipment (a half-hour machine) for the protection of your crew?

MR. BOARDMAN: We usually carry an extra two-hour machine and hang it up near where the work is going on.

MR. WOODBURN: I take exception to carrying equipment any great distance. Just three weeks ago tonight, we had a fire and I helped carry in extra equipment. We had plenty of helmets. We were simply carrying in the machines. I carried two, and, of course, it was an emergency and we went at practically a dog-trot, but you dog-trot half a mile with 86 pounds and the next morning you will know that you've been somewhere.

MR. WATSON: I might say for the benefit of the members present that Mr. Boardman's statements are accurate. He is fighting fires day in and day out. In the coal-mining districts you have a fire every few years, but Mr. Boardman's crews are fighting fires day in and day out.

CHAIRMAN TILLSON: Gentlemen, we have one more fire to fight this morning, and we are getting along well, too. I mean we are having lots of good discussion, and I want to compliment you. Somebody said that the Mining Section was the liveliest bunch in the whole convention.

There is one other thing on the program. We had hoped to tackle it this morning. That is a Safe Practices pamphlet which has been prepared and was retained from distribution awaiting discussion by this Section. This pamphlet is in regard to Mine Car Haulage and there are copies here for distribution. I am open to the opinion of those of us assembled as to when we want to tackle this, whether you want to postpone your lunch to a later hour, or whether you would really like to hold a later session and come back after lunch.

We have one more paper on the program, "Fire Prevention in Anthracite Coal Mines and Necessary Equipment for Fighting Mine Fires," Mr. M. W. Price.

(Mr. Price was absent, so Mr. Tillson read his paper.)

FIRE PREVENTION IN ANTHRACITE COAL MINES AND NECESSARY EQUIPMENT FOR FIGHTING MINE FIRES

M. W. PRICE, EFFICIENCY ENGINEER, G. B. MARKLE COMPANY, JEDDO, PA.

The prevention of fires, the necessary fighting equipment, and the best ways of extinguishing mine fires, on account of the various conditions under which they occur and the hazardous work connected with them, together with the loss of life and destruction to property, furnish a topic for discussion among mining men, which, it seems to me, is not surpassed by any other subject in mining.

The prevention of mine fires necessitates a careful and constant examination of some sections in the Anthracite mines due to physical condi-

tions over which no control can be had. The elimination of wooden structures in the mines has been the means of preventing numerous fires, and permits more time and thought to be spent in trying to prevent fires in heavily timbered sections and in sections where the "robbing of pillars" is being done. Workmen engaged in timbering should not be permitted to use the common oil lamp on account of sparks and the careless manner in which old wick (cotton) is thrown around when it becomes necessary to put a new wick (cotton) in lamp. The careless manner of handling oil which is used in lamps quite often causes timber to become saturated and is the means of causing disastrous fires. Again, I have seen night patrolmen using the common oil lamp while making their examinations. This seems to me, a grave mistake. They should be furnished with an improved electric lamp and also have a safety lamp of the modern type; thus equipped, they will be prepared to perform their duties in a proper manner.

The "robbing of pillars," especially in the Mammoth Vein, on account of its great thickness and by its continuous crushing, generates a heat which causes everything to become so dry that a very disastrous fire will develop in a short time. Added to this risk is the possibility of encountering methane (marsh gas) while driving up chutes in the pillars. In sections like this, where the fire risk is so great, I have seen careless workmen engaged in timbering add to this risk by permitting a trolley wire to touch the timber instead of having the wire hangers properly support the wire. In sections of this nature a water line on the gangway with branch connections arranged about 200 feet apart with a 50-foot section of fire hose placed at each branch, will enable a person discovering a fire to apply water on it in a very short time. This method of "fire lines," as it is called, will be of vital importance to the patrolman by night who, upon his examinations, discovers a fire and is forced by lack of system to travel a considerable distance for equipment and help.

ORGANIZE MEN FOR FIGHTING FIRE

Various methods have been advanced for extinguishing a mine fire, setting forth good results obtained such as flooding and smothering sections affected, depending upon conditions; and while numerous discussions have taken place describing in detail the methods used at various fires, and carefully noting the results, there seems to be very little said about having men properly organized for this particular kind of work. The results of poor organizations have been demonstrated where the work at small mine fires, improperly directed in the beginning, has been the cause of large disastrous fires. The importance of the mine foreman in some instances is not properly realized or appreciated. His thorough knowledge of the mine, for instance, the circulation of air currents and the quickest way and place in which they can be changed to bring about results, together with the exact conditions of each working place—whether or not it happens to be a place which is giving off gas or a place with a dangerous roof—makes him the most valuable man available. The delay which will be caused by an accident happening to the foreman under such

circumstances does not seem to be realized, since, invariably, he is the one man who can always be found in the most dangerous place. Then again, it is no uncommon sight to see the Superintendent right in the most dangerous place. I fully realize the anxiety which is caused by a mine fire, but nevertheless I maintain that the proper place for the directing heads is a safe distance back from the scene of the fire, where they can think and properly direct the work, for there is nothing which spells disaster at such times like losing the directing heads.

The extinguishing of a mine fire today in the older mines of the Anthracite region requires keen thought and especially prompt action. The virgin mining being finished, the reclaim or "pillar robbing" being done very rapidly, makes it difficult for even the most efficient mining men to control the air currents. Air being a predominating factor in performing work at a mine fire, it can, therefore, be readily understood that the conditions of a mine govern the method which can best be used.

I have had the opportunity to assist in the work of extinguishing quite a number of mine fires, some of which were of an exceptionally serious nature, and have seen various methods used with very good results. Owing to "pillar robbing," causing in some places the strata to be crushed and broken, it becomes a very difficult proposition to flood or smother a fire in some sections without seriously affecting several sections, which is quite different from what it was in former years, in the Anthracite region. In seams where the coal is of a soft and shelly nature and fire occurs, which causes caves to develop, thus preventing direct work, good results have been obtained by taking a piece of 2-inch or 2½-inch wrought iron pipe and closing the one end in the form of a pick point after which the pipe is drilled with ⅜-inch holes in a spiral manner the entire length of the pipe. This drilling is continued until the entire pipe is reasonably filled with holes. The pipe is then forced through the caved or loose ground after which a hose is attached to the open end of the pipe. In this manner water can be forced onto the fire thereby extinguishing it and cooling the material so that it can be loaded into cars. This spray method can also be used in and around burning timber to very good advantage.

Bore holes are sometimes drilled for the purpose of running water down on to fires, and while this will be the means of extinguishing some fire, still it does not accomplish very great results due to the fact that the water takes a natural course and by not being able to increase the original supply through the hole the results are not what is expected. Good results were obtained at a large fire, which had burned up into a caved section where "pillar robbing" had been done by placing on the surface a large tank which had a capacity of about 60,000 gallons. Two large mine pumps discharged their water into the tank and the gate was opened by a mine locomotive pulling on a tackle which had been properly arranged. This large quantity of water was run into the caves and on account of the measures being all broken permitted the water to pass down over the fire. In this manner considerable fire was extinguished which, on account of caved conditions, would have been very difficult to reach from the inside.

VALUE OF MINE RESCUE APPARATUS

Mine rescue apparatus that is available today permits men to penetrate fire zones and lay water lines from which hose can be used, to apply fire extinguishers directly on the fire, and to build air brattices for the establishment of necessary ventilation, and to do various other underground work. Thus we are able to perform what might be termed direct fire fighting which seems to be the right procedure, in that you are in a position to note the progress and changes which are constantly taking place at a mine fire.

This brings out the importance of a mine rescue equipment and the vital necessity for the proper training of men to use it, since the work performed by a well-trained corps of men in the use of the apparatus at the beginning of a fire will prevent both the possible loss of life and the great destruction of property.

The establishing of a fire equipment to consist of fittings, pipe, hose, nails, brattice cloth, boards, tools, telephone, and a fire pump, which should be kept intact at all times, is a valuable asset to all mining properties; and again quite often steam and air lines, coming from the surface into the mines, can be converted into water lines in a very short time. By taking advantage of such conditions and thus securing a supply of water quickly has been the prevention of what might have been very disastrous fires. Available lines of this description are sometimes overlooked due to the excitement caused by a fire and the lack of a proper organization.

In conclusion, I would say that the organization should be such that when a mine fire does occur, each man will fully understand his duties thereby preventing dangerous delays in making up an organization at the beginning of a fire.

DISCUSSION

VICE-CHAIRMAN DAVIS: I want to take exception to some of the things Mr. Price has said. He refers to putting out a fire by the use of a tank and flushing from that tank, filling the tank full of 60,000 gallons and letting that go down the mines.

In 1910, I had an experience of that kind in Wyoming Valley, and I found the plan adopted had carried the fire down 1500 feet, and before we got down to the point where it had been carried by these floods, it had extended about 900 feet. You can't fight a fire down here in Cleveland. You have got to be on the ground. Maybe that worked when Mr. Price used it, but in the particular case to which I referred, it was a failure.

I think Mr. Price touched upon some very good points in connection with fighting mine fires. In the anthracite coal regions we get one fire in six months, perhaps, but I want to tell you that fires in the Wyoming Valley are of almost daily occurrence, particularly where coal is being blasted by black powder. Since the companies have used permissible powder, the fires have been less frequent.

I notice that Mr. Price didn't touch on the effect and use of chemical

extinguishers. The D. L. & W. has an additional chemical engine. This is on a truck. It has two tanks of about 80 gallons capacity each. Attached, there are three lengths of hose, 50 feet long. This engine has been used in putting out fires in their incipiency.

We can't say that that apparatus is the proper thing for fighting mine fires, but when your fire lines are back, we are positive that there are fire lines on all the gangways. We have a fire car which contains pipe, hose, canvas, and every conceivable thing that you would need to fight a mine fire. This is brought to the mine just as soon as the fire is first announced.

(Mr. Tillson resumed the Chair.)

MR. ROBERTS: I want to take exception to what was said a while ago in regard to having no fires in coal mines. I want to state that in the northern fields of coal, I will venture to say that there isn't a single place where there isn't a fire existing continuously.

USE OF PORTABLE FANS IN FIGHTING FIRE

MR. WOODBURN: There is one point in that paper that I was watching for that was not mentioned—the use of portable fans in connection with fighting fires. I should like to have the experiences of some of you men in regard to the matter. We are purchasing a portable disk fan to be connected to the electric wiring in the mine, where we want to use it, where the wire is already strung.

MR. DAVIS: I want to say I have used electric fans in connection with mine fires, but I wouldn't want to recommend them.

MR. WOODBURN: I mean temporarily.

MR. DAVIS: I was very much surprised at one place, to see a foreman connect a fan where the discharge end was only a six-inch pipe. I found that it gave a splendid current of air and helped us materially.

Have any of you gentlemen ever used inert gases in putting out fires? I saw an article in the "Coal Industry"—the September number—on that written by Mine Inspector Joseph J. Walsh of Wilkes-Barre.

PROFESSOR F. W. SPERR (Michigan College of Mines, Houghton, Mich.): I think the Calumet and Hecla Company used carbon dioxide quite extensively in attempting to put out a fire about twenty-five or thirty years ago, before I went up there, and part of the apparatus was still there on the shaft a short time ago when I happened to pass there. I have no doubt that their experience has been published, but I can't recall now what the results were.

MR. ROBERTS: I have known of a number of people who have tried carbon dioxide or sulphur dioxide, but I never knew of a case where fire was put out with it. If you could keep it tight, so that the carbon dioxide would get into contact with the fire, it would do it, but there are always leakages, and it is impossible to hold the gases in contact with the fire long enough to put it out.

MR. WOODBURN: Isn't that what we are trying to do with our sealings?

I had occasion at a recent mine fire to get to a raise that was off of a sub-level and it was on fire. We couldn't remain there long, and it was

connected up with the sub-level below. That was where we believed the main part of the fire to be, so just for good measure, we did take down five gallons of Pyrene (carbon tetra chloride). We dumped it in the top of this raise and three weeks after, we were able to get to the top of that raise and the timbers had just burned about half way through. Why it went out, I can't see any reason except the Pyrene. That was just an experiment.

MR. BOARDMAN: The title of the paper seems to be "Prevention of Fires" but I see the author digresses to organization and training for fires. A little over-zealousness on the part of a foreman of ours, one time nearly caused trouble. We had a fire in the West Calusa Mine. (I don't want the impression to get out that Butte is such a fire-trap. We have had two or three fires there that were started by leasers and a few from the Heinze quarrel that has been more or less continued for a number of years. Our new fires are very scarce.)

We had twelve fires in 1918 and eight were new fires and seven of these were caused by poor electric installations. In 1919 we have had only five new fires and they were all extinguished within the first few minutes after they were discovered, some by the use of breathing apparatus, and some without. The time to fight a fire is within the first three minutes after the fire starts and if you can get there, of course, you have done well.

In this instance, two young mining engineers went into a part of a mine which they believed to be free from gas. The foreman discovered that part of the mine was not free from gas, and told them that they should lay off and not go in. However, they went in, contrary to instructions. They went on the ten-hundred level, where they felt the effects of gas. One of them, the boss of the crew, crawled through to the ninth, and the others started back. This man who got through to the ninth, was just able to crawl up the shaft and there gave the alarm before he became completely unconscious.

The mine foreman made the mistake of rushing in to do this work. He summoned six men, I believe, and with waste over their noses, they rushed over the ninth level and attempted to climb where the man went back. They got down two floors when the man ahead became unconscious. The next two men succeeded in placing a chain about his chest and tying the chain to the rope in the timber slide, and then they came back to the ninth level again, and were so nearly overcome that they all had to navigate on their hands and knees. A hurry call was sent to the rescue station for some apparatus.

The foreman had gathered up four shift bosses and a couple of other men and had rushed in to try to get this man out before he died, leaving everybody outside without any supervision. They succeeded in getting the man out, also the rest of the crew. The foreman should never take his organization and rush in to do a thing with his own hands that he has equipment for doing otherwise.

USES OF CHEMICAL EXTINGUISHERS

In regard to the use of chemical extinguishers: We had a fire in Fleming, Kansas. The fire was in the face of the drift, and the fan was deliv-

ering 8,000 feet of air through the drift, twenty feet back from the face of the drift.

The over-lying strata there is of such a nature that steam or high humidity will cause it to slack, a sort of fire-clay. Where fires of this kind have been fought with water, this sloughing of the roof has caused trouble. Realizing this, we used Pyrene. The thing was very hot; in fact, about ten feet of that entry was incandescent, and so hot that one of the men had blisters all over his face when he got out.

We used ten gallons of Pyrene at intervals of five minutes. We succeeded in charring the face of this burning coal to such an extent that when we got the fire out the roof did not slack enough to cave. We had only a small fall. It did not hurt any one. The Pyrene gas filled the mine so full that it very nearly killed a mule that they kept to use in hauling in water. They just barely got him out in time.

In using a chemical extinguisher, care must be taken, if there is improper ventilation, that the fumes do not overcome the crew.

Mr. WOODBURN: About your smoking underground, the Miami Mine prohibits smoking underground. In the Old Dominion Mine, they permit smoking underground. It is my opinion that it is safe to smoke where you use open lights. The Miami has had several fires that have started presumably from smoking on the sly, and giving a flip to the cigarette or match when they saw somebody coming.

I would say that the chemical extinguisher is the most valuable thing we have in our metal mines, and I would like to see one in everybody's reach. If you can get action on your fire immediately, you can put it out. There is no deterioration and if you should want to dismantle your mine, you have something to sell. We have had a great deal of success with it.

In one of our mines we were a little slow in providing these extinguishers. Finally, we had nineteen put in. That was done on Thursday and on Sunday, we put out what might have been a very terrible fire.

There is another thing that I would urge particularly in the metal mines, and that is, that you get an inspection after every shift comes off. We had an eight-day fire in our district due to lack of proper inspection following the men's coming out. The fire was not discovered until nine o'clock at night. At 11 much harm had been done, at 12, the men threw up their hands. It was 1:30 before we were called, and had men on the ground, and it was morning before we had the fire under control.

The Miami Mine is very careful to work three shifts so that you always have a shift relieving another shift. I don't believe it is too strong to recommend that that be done as it is the best investment you can make.

Mr. SEIR: I would like to ask Mr. McLeod about their sprinkler system.

Mr. ANGUS McLEOD (Butte & Superior Mining Co., Butte): The shafts are both equipped with rings of pipe about every two or three hundred feet—the metal open-head sprinkler. The control valve is on the surface. Every four hundred feet going through the shaft—eight, twelve, and sixteen hundred. There is a shut-off valve for the purpose of being used in case of fires. You can go to twelve and shut off the valve and you get the

force of your water to the twelfth, and the water going on down the shaft would keep the rest of the shaft in shape.

DEAD ENDS FOR PROTECTION OF MEN

There is another thing that I haven't heard much about here. In the metal mines, whenever we have a fire, it seems that a bunch of men are lost before we can get down to the first level. The gas spreads so quickly that no matter what the opportunity is to get out, they don't seem to get away. We have established a rule to put in dead ends on every side and level.

These dead ends are 250 feet. There is a cement door 10x10 by 30 inches thick. Then there is a metal lathing over that and that makes a solid steel door. It can be chinked in a minute's time through that bulkhead above. There is a water barrel and in case of a fire, your men can flock in to those dead ends.

There have been fires in which from three to one hundred twenty-one men have been lost, when if there had been dead ends to get into, the majority would have been saved. We have provided these dead ends and have used the flash system for flashing danger signals. We have signs posted, stating that so many flashes, following the flash of a level, indicates a fire in a certain place, telling the men just where the fire is, whether they will have to hurry to get to the dead ends.

We also have inter-communicating telephone systems so that you can throw a switch and communicate to different parts of the mine. There are so many places in a metal mine that you want to send warnings to where the signals don't extend to your workings.

We have another signal, although we have never had occasion to use it. We took a common oil cup, going into the air line. We took valeric acid and put it in the oil cup and in forty seconds after we turned it in they have had the smell of the acid, very noticeable, on the eighteen hundred level. Inside of two minutes after the acid has been turned loose in the air receiver, it penetrates every corner of the mine. That is printed on the signs to make everybody in the mine acquainted with the warning.

Several fires have been caused by fires going down the shaft. We have made iron casings, used a little sheet iron, something medium heavy, and we have the wires go down through this sheet iron because it burns out there and does not come into contact with the timber.

Those are some of the things that we are working on. None of them are completed, but we know they are going to be successful. The value of having these dead ends is very great. It is in the first few hours of a fire that we lose our men.

MR. GEORGE SWAN (Davis Daly Copper Mining Co., Butte): Have you had any actual fire experience since you have put in these dead ends?

MR. McLEOD: No, we haven't had any actual experience. We have experimented by going in and pulling the doors shut. We have fans installed on trucks either as blowers or suction—it can be used either way—and we have pulled those up and blown gases in, and not a thing ever went through.

PROFESSOR SPERR: The difficulty they have had in the mines in some of

our districts, is that where they have put in the same kind of bulk heads, when they got a fire, the smoke went around through the rock.

MR. McLEOD: We have never had that experience. We haven't had a door yet, up to the time I left, through which the gas penetrated, and we had tested seventeen. One was tested six months after installation. We turned the fan on and the men inside couldn't notice a thing. These doors close as solid as this wall.

CHAIRMAN TILLSON: If there is no more discussion on this paper, Major Arthur S. Dwight, who is attending the Mining Section meeting as the direct representative of the American Institute of Mining and Metallurgical Engineers, has a discussion of the proposed Safe Practices pamphlet on "Underground Mine Cars, and Haulage."

(Major Dwight read the comments of Mr. Hugh Archbald, of Scranton, Pa., on the proposed pamphlet, and these were referred to the Safe Practices Committee for consideration.)

CHAIRMAN TILLSON: While listening to Major Dwight, the thought struck me that if you are agreeable, it might be wise if you would all take the time between now and tomorrow morning to go over this paper and jot down your comments opposite each paragraph, sign your name to it, and if we get crowded tomorrow morning, you will be prepared to leave your copy of the paper with the signed comments for the use of the National Safety Council. In making your revisions, I trust you will take notice of the attached papers, which are the criticisms and suggestions of some of those to whom the pamphlet was sent before this meeting. At least, indicate whether you agree or not with their comments.

If you can cite some illustration or say you can furnish some illustration that would indicate a better practice or design of equipment, why note that, and then reply to the request for that information when it comes from headquarters.

I don't think I am asking too much of you. I think that this will possibly be one of the first pamphlets as a direct technical function, and I trust it will be something that we will be able to hold as a standard.

You will find attached, at my request, a Safe Practices pamphlet, which was issued by the National Safety Council, covering the subject of manila and wire rope. I asked that this be done. If any of you whose interests are so vitally correlated with the use of rope find something in this Safe Practices pamphlet with which you differ, now is a good time for us to get your views, either orally or written, so that whenever this pamphlet is to be revised, it may be revised with those views under consideration.

Adjournment.

SATURDAY MORNING SESSION

THE meeting convened at 9:45 A. M., Mr. B. F. Tillson, Chairman, presiding.

CHAIRMAN TILLSON: Gentlemen, even though we are not all assembled, I think we had better start in with our program, as we will have plenty to do. Mr. Mitke not being present, I will read his paper at this time.

A COMPILATION OF CHUTE TYPES FOR LOADING ORE INTO TRAM CARS IN METAL MINES

CHARLES A. MITKE, MINING ENGINEER, PHELPS-DODGE CORPORATION,
BISBEE, ARIZ.

CHUTES

Chutes are used principally for passing ore and waste to different levels in a mine. They are also used for storage, and frequently, when not necessary for ore or waste, are kept open entirely for ventilation.

In general, chutes are 100 feet high (the usual distance between levels). Some exceptional chutes are much longer, while others are shorter than this figure. When a raise is driven, it is customarily divided into two compartments, one for the manway and timber-way, and the other (the chute) for the passage of ore or waste.

The various types of raises which are commonly used are as follows:

TWO-COMPARTMENT RAISES (one for chute and the other for men and timber).

6-post, square set raise, generally used in square set stopes in medium ground.

4-post, square set raise, occasionally used in caving methods. This raise is similar to the 6-post raise, with the exception that the compartments are much smaller.

Crib raise, used in square set, top-slice, cut and fill, and shrinkage stopes in heavy or broken ground.

Raw chute, usually oblong in shape, about 4 feet x 7 feet, with no timber except a partition between the chute and manway. Used only in hard ground mined by cut and fill, shrinkage, and to some extent by caving methods.

ONE-COMPARTMENT RAISES (Chute only)

4-post, raise, used in caving methods in medium ground.

Crib raise, used in heavy ground mined by caving methods. In rare cases angle iron is used in its construction to prevent excessive wear.

Raw chute, or "finger raise," circular, about 3 feet in diameter, no timber employed in its construction. Used only in medium or fairly hard ground.

Rock built chute. Constructed in the shape of a well, generally about 6 feet in diameter. This class of chute is built in loose ground.

Concrete chute. For heavy ground. Usually circular. Used where there is a great deal of wear in a chute.

REQUISITES FOR A STANDARD CHUTE

The requisites for a standard chute are:

Safety in location and operation.

Efficiency in handling ore and waste.

Economical construction and upkeep.

SAFETY

Formerly, chutes were located in the center of drifts, so as to facilitate the dumping arrangements and permit the use of end-dump cars. While this was a great convenience from the haulage point of view, it carried with it the constant danger of men falling into the chute. Boards were to be laid over these openings and to be removed when cars were dumped. Frequently, however, miners would forget to replace them when the cars were empty and many a man has lost his life by falling into an opening of this character. In some states this practice is now prohibited, the law stipulating that the chute shall come up at the side instead of in the center of the drift.

The manway, adjacent to a chute, should be located far enough from the haulage track so that the men climbing up and down the ladderway will not step directly in front of a moving train.

One of the principal things to be avoided is the "hanging up" of a chute. It is usually a dangerous procedure for a runner to bring down a chute which has been choked or "hung up." Should this occur some distance up, for instance 80 to 100 feet, it may cause an air blast, which would break the chute and injure the trammer.

Clearance for cars. The chute mouth should be high enough so that a man will not have his fingers caught between chute and car. This is very difficult at present as there are mines where five different kinds and sizes of cars are used, all being loaded from the same chute. Such a diversity in sizes of cars naturally results in insufficient clearance for the larger ones and too great a clearance for the small cars. This latter condition, in itself, creates a danger, as, when small cars are used, the ore, dropping from a distance at high speed may injure the runner, especially when the car is about full and it is necessary for him to close the chute gate immediately.

Trolley wire. In all average drifts having electric haulage, the trolley wire is immediately above the mouth of the chute. The larger drifts have the advantage of an extra set above the trolley wire, upon which the chute runner works, there being a flooring between him and the wire, thus preventing his coming in contact with the electric current.

Some provision must always be made in the smaller drifts to protect the runner from the trolley wire. In some instances, the live wire is insulated and carried along the opposite side of the drift, the overhead wire being dead for a distance of about ten feet and acting merely as a guide for the trolley wheel. In other cases, the overhead live wire is boxed in with boards on the sides and has a hinged door beneath, which can be pulled up and hooked, in this way completely isolating the trolley wire. Another practice is to have a switch near the chute so that the current in this section of the wire can be turned off and on at will. In exceptional cases the trolley wire is cut about five feet on each side of the chute mouth, and may be detached and moved away bodily. This, however, involves considerable trouble.

Clearance for chute runner. A by-pass is frequently made by taking out a half set of ground immediately opposite the chute and a bench is

provided upon which the runner stands. This should be high enough to enable him to reach across and tap the chute and also to use a picky-poke to advantage in loosening the large boulders which frequently clog up the mouth. The by-pass is a great safety provision in that it gives the operator an opportunity to step out of the way in case there is an unexpected rush of ore out of the chute. In caving methods, where there are lines of chutes on both sides of the drift, a by-pass is impossible and the runner must load his cars by standing at the side of the particular chute which he is drawing.

EFFICIENCY

It is important that all chutes be properly located with respect to the levels above and beneath the stope through which they pass. Upon the location of the chute depends the convenience of the stoping arrangement as well as the tramping distance.

A chute should be adapted to the particular needs of the ore body in question. In certain classes of ore large chutes are necessary, while in others smaller ones may be used to advantage. In some cases a great many thousand tons of ore must pass through before the chute is finally abandoned, and the tonnage grades down from this to but a few tons in other cases, consequently, the construction of the chute in the first instance must be stronger, more lasting, and naturally more expensive than the type of chute which would do in the second place.

The construction of a chute should also be such that the ore will flow readily into the cars. One of the difficulties with chutes that has not yet been overcome is the fact that all ore has a tendency to "hang up," or stick in the chute. A suggestion which has been made and tried out is to have a breaker staggered on each set right down the chute. The ore, on being dumped into the chute on the level above, strikes the first breaker and is thrown across onto the breaker on the other side, and from there zig-zags down the entire length without stopping until it gets near the chute mouth. These breakers impede the progress of the ore and prevent it from packing solid in the bottom of the chute. Naturally, the chute is less liable to "hang up." Very good results were obtained from a trial of this chute, the only objection being the extra cost of construction in placing the breakers on the sides.

The inclination of the chute mouth has a great deal to do with its efficient operation, as certain classes of ore run much more readily than others. The character of the ore, therefore, must be taken into account before adopting a standard chute and mouth.

ECONOMY

The cost of constructing chutes should be kept at a minimum. It would be a waste of money to have a chute constructed to last far longer than the life of the stope. While, on the other hand, it would also be poor economy to have a chute so lightly constructed that it will need constant repairs long before that section of the stope has been abandoned.

Formerly, chutes were made having a wooden bottom and the ore taken

out immediately beneath the chute mouth. As a consequence, the ore dropping down the chute soon wore out the bottom and then filled in the sides of the drift. As a matter of fact, this is still practiced in a number of districts, even though it involves an unnecessary expense to the company for upkeep and repairs. This practice is obsolete in the most up-to-date mines.

Wherever possible, the bottom of the chute should be in the solid ore or rock, so as to decrease the cost of upkeep, as ore striking on a wooden bottom would soon cut through.

When the size and character of the chute, with due reference to the class of ore, has been worked out and decided upon, it is then economical to have the timbers selected and cut to measure on surface, so that the total number of pieces necessary for its construction can be sent down at any time and the chute mouth installed without any additional cutting underground.

VARIOUS KINDS OF CHUTES, DOORS, ETC., IN USE AT PRESENT

(With a critical discussion of each type)

HAND TRAMMING DRIFTS

Figures 1 and 1a represent a chute mouth used for loading small cars from stopes containing high grade ore which are operated by the square set method, or in stopes mined by caving methods where frequent blasting is done.

The chute mouth is made of 3-inch boards, having the proper inclina-

FIG. 1. FRONT VIEW OF CHUTE MOUTH AND LOCATION OF CAR

FIG. 1a. SIDE VIEW Post cut away to show loading platform

tion and a clearance of approximately 4 inches should be allowed between the chute mouth and car. The door which controls the flow, consists of three boards, operating in slots which are parallel to each other. The mouth of the chute is about $4\frac{1}{2}$ feet long and the ore dropping down the raise strikes on the hard rock which has been left there for the purpose, and then runs toward the car as the chute is drawn off.

Figure 1 shows the front view of the chute mouth, location of car, etc., while Fig. 1a gives the side view of chute and end view of car.

This type of chute mouth is generally used in small drifts ranging from 3 feet x 6 feet up to 5 feet x 7 feet in the clear.

In drifts, where ore is drawn from square set stopes, the chute runner usually loads his car by standing on a bench opposite the chute mouth. Sufficient ground behind him has been taken out beyond the regular drift set so as to allow a certain amount of room for him to step aside in case of an unexpected run of ore from the chute.

In caving methods, however, he loads his car by standing at the side of the chute instead of in front as, owing to the chutes being so numerous, they are generally placed opposite each other and there is no room for a bench.

In loading, he uses a 5-foot iron bar to pry up the three boards and allow the ore to run into the cars. In case a boulder should get fast in the chute and hold up the ore, he uses his bar to dislodge it. Should he be unsuccessful, he must then get powder, tie it to the end of a stick and put it near the boulder. After the shot is fired, the boulder is usually broken and the ore continues to run down the chute. When the car is full he uses the bar to strike each board in succession and cause them to drop, thus cutting off the flowing ore. In the event of one of the boards sticking fast and refusing to drop, enough of the chute mouth will be covered by the other two to stop the ore from running.

Another type of door is that shown in Fig. 2, which has an iron gate bolted to the sides of the chute. This iron gate operates similarly to the boards, with the exception that it has a handle so that it may be raised

FIG. 2

FIG. 3.

by the man getting up on the car and taking hold of the handle, or by standing on the track and using the bar to pry it up. This gate has a bolt on each end and operates on hinges, as shown in the drawing.

MULE, ELECTRIC, AND AIR HAULAGE

In drifts of this character larger cars are used, the area of the drifts are larger than those of hand tramming, and the chutes are either operated from the drift or from the extra pony set above the drift. The chute

and chute mouth shown in Fig. 1 are frequently used in drifts of this character, being, of course, built in proportion to the size of the drift.

Fig. 3 is the same kind of a chute and chute mouth as those shown in the preceding illustrations, but has a different type of door. This door is built in the form of a sector, made of iron, and has a handle. A piece of iron pipe may be used on the handle in order to give the operator greater power. Built to a smaller scale, this chute mouth and gate is occasionally used in hand tramping drifts in square set stopes, but more frequently in the larger drifts with, of course, proportionately greater dimensions. This door may be operated either from the level, in a hand tramping drift, or from the floor above in a motor haulage drift. In the latter case, the chute door is, of course, high enough so that the operator can open it by standing in the pony set and also punch the chute from that floor. This class of door is in common use on main haulage drifts where block caving is the mining method employed. However, the chutes leading directly on to the main haulage level are usually located in ground that is not very heavy and will therefore not be subject to change.

FIG. 4.

FIG. 5.

Fig. 4 represents an iron door which is operated with a slide and small gear wheels on the ends with a larger wheel to give the operator more power. By turning the larger wheel the small gears run up a geared track and raise the iron slide. When operating this wheel the operator stands to one side of the chute.

Fig. 5. The construction of this door is similar to that shown in Fig. 4 with the difference that it is operated by a compressed air cylinder. The operator merely turns a compressed air lever, which raises the slide and allows the ore to run. When the car is full and he desires to close the chute, he turns off the compressed air by reversing this lever, and turns on a second (lever) which forces air into the rear end of the cylinder and closes the door. If a boulder should get caught it may then be necessary for him to open and close this door several times in order to dislodge it.

COMMENTS

The principle in the construction and operation of both the chutes shown in Figs. 1 and 2, for use in hand-tramping drifts, is practically the same.

Both have rock bottoms and the raises (which include chute and manway) are not immediately over the drift, but off at the side. Sufficient ground has been taken out under the manway compartment so that the ladderway will be far enough from the drift to prevent a man from stepping out in front of a car. The door in one chute is of boards, while the other is of iron. Fig. 1 illustrates the chute and door in use at most of the mines where block caving methods are used, while Fig. 2 is used principally in top-slice stopes and not so frequently in other caving methods, the reason being that the drifts in which Fig. 1 is used become very heavy, the chutes soon go out of shape and require a change made in the size of the door, which can easily be done by cutting the wooden gates to suit the changes caused by crushing, whereas an iron door could not be so readily adapted.

These represent two of the best types of chute mouths and gates for use in hand tramming drifts. They are economical, durable, and, if the bar is employed and the men use care, they are comparatively safe.

It is often found advisable to use the wooden door, shown in Fig. 1, in large chutes on mule, electric, or air haulage drifts, where the ground is heavy and the chutes are apt to lose their shape, because as mentioned previously, the boards can be cut down to meet the circumstances, whereas the iron doors are not so adaptable.

Of the three iron doors shown in Figs. 3, 4, and 5, the last is far superior to the other two and can be used in every instance where these other doors are used. It is absolutely safe in operation and requires very little repairing. The amount of compressed air used is also small. Its cost, as compared to the other doors, is, of course, somewhat higher, but is justified in places where a large amount of ore must be handled.

The matter of clearance for safety depends entirely on the type and height of car. As stated before, in one of the most up-to-date mines five different types and heights of cars are used, all loading from the same chute. In this instance it would be very difficult to specify what amount of clearance between the chute and the car should be adopted as standard. Therefore, before a standard clearance can be decided upon, first of all it is necessary to decide upon the standard size and height of car which is to be used on that particular level.

The clearance between cars should be sufficient to permit of a man's passing between them.

The discussion of a standard car raises at once the question of a standard gauge. The 18-inch to 22-inch is still the practice and a standard gauge of about 20 inches should be maintained in practically all metal mines. In deciding on a standard gauge, the main point to be borne in mind is that it must be suitable for the size of drift or tunnel which has been found to be the most practicable and economical for prospect work. The larger gauge of 24 inches to 30 inches is of course used on main haulage drifts, where the ore has already been proved up and the expense of driving the large tunnel for the haulage train is absolutely justified. It would, however, be entirely out of the question to ask operators to drive large tunnels of this character for prospect work merely to standardize on the gauge.

In general, a large number of companies use two gauges, the 20-inch for all prospect and ordinary working drifts, and a larger gauge, about 30-inch, for the main extraction tunnels only. At the present time there are mines in the Southwest which have already standardized on the gauge and type of car. In one particular mine, the 18-inch gauge is used throughout the entire mine, with only two types of cars, both being the same height, which simplifies the matter of chutes and chute doors, the chute mouth shown in Fig. 1 being used throughout. It might well be said that this company has standardized on gauge, cars, chute, chute door, and clearance.

Standardization of methods of haulage is therefore a very important consideration in metal mining, where the prime requisites are safe and efficient operation coupled with economical construction and maintenance.

CHAIRMAN TILLSON: Discussion on the paper is now open, I would call your attention to illustrated dump covering door and also to a system

FIG. 6. SCHEME FOR OPENING DOOR COVERING DUMP IN CENTER OF TRAVELING WAY

of timbering to keep travel of man away from electric haulage. (Figs. 6 and 7.)

DISCUSSION

MR. A. H. TRESTRAIL (Pickands Mather, Palatka, Mich.): In the paper the statement was made that state laws required the opening to raises to be put on the side of the drift or sub-level, and it says that previously the opening was made in the center of the drift, in order to allow the use of end dump cars. In our property we place our raises at the side of drifts, and we use the end dump car. Simply have the car run right into the little cut-out, and we are able to dump right down the chute.

It is pretty hard underground to have all the room you want, especially if the ground is of a nature that breaks readily, but I think one way that that will help, is instead of having the ladder come down directly on track, have it placed sideways, then in order to get on the track a man

be almost by deliberately pushing his bar in between this small opening.

CHAIRMAN TILLSON: In answering Mr. Boardman about the relative size of the chunks of ore to the size of chute, I may say in the ore with which I am familiar in New Jersey, the grizzlies have an opening of twelve by fifteen inches. Our experience in the past has been there is a strong tendency to use for chutes, raises that are too small for the purpose, and we drive the small raises first and strip them up to larger size and save a whole lot of money in the course of a few years.

MR. R. D. HALL ("Coal Age," New York City): Would you please give the size of those raises?

CHAIRMAN TILLSON: Eight by eight feet.

PROF. F. W. SPERR (Michigan College of Mines, Houghton, Mich.): That would have to be worked out for each separate ore—the relative sizes as between the pieces and the chute.

CHAIRMAN TILLSON: Well, I don't know that you need any refinement. I believe if you had an eight by eight chute in most ores, that you'd have comparatively little trouble unless you have an ore with distinctly cementing qualities or mixed with clay and had lain there for about six months.

PROF. SPERR: Are you considering inclined or vertical?

CHAIRMAN TILLSON: Ours are all inclined. The flattest which we deem it advisable to operate is 50 degrees, and we believe that somewhere about 50 degrees works out the best. In other words, the flatter you can run your raise, the less trouble you will have of blocking. The steeper it is, you get the jamming and arching effect in your raises.

MR. A. H. TRESTRAIL (Pickands Mather, Palatka, Mich.): I want to ask Professor Sperr in regard to breakers in the raise. How are they put in?

PROF. SPERR: Make offsets.

MR. BOARDMAN: In regard to inclined raises, don't you think in properties where the ore has a tendency to cleave and slip off, you have to have the offsets more prominent?

(The Chairman and Mr. Boardman at the blackboard.)

CHAIRMAN TILLSON: You probably see Mr. Boardman's sketch of the common way on the left, and the way he suggested on the right.

MR. BOARDMAN: This (indicating common way, Fig. 8a) is the ordinary trolley boxing in which the wire is straight up between the boards. On this side we have the right angle trolley boxing (Fig. 8b). This is what we sometimes call the back or timber across here. Now, the trolley pole is simply swung in there, and the wheel put in contact with the trolley wire.

In case this is on the side of the drift opposite the chute, the man has his back against this board here. For instance, if I were loading a chute here, the chute would be on this side, and this board would be at my back, so it would be impossible to push a bar in there. On the other hand, should the trolley wire be on the same side as the chute, or under or above the chute, which is very uncommon, you might possibly get the

chute bar in that slot but it is almost a deliberate act if you do so.

MR. A. H. TRESTRAIL (Pickands Mather, Palatka, Mich.): In regard to this right angle arrangement, is not the trolley wheel and the arm on the swivel, so you could have one chute on one side and another on the other in many levels?

MR. BOARDMAN: The swivel is here in connection with the pole. That is right at the head.

MR. TRESTRAIL: Do your miners wear heavy rubber boots?

MR. BOARDMAN: Some of them do, but not very many.

MR. J. W. REED (Consolidated Coal Co., Fairmont, W. Va.): Would that

FIG 5c. SUPPORT OF TROLLEY WIRE UNDER A CHUTE AS USED BY N. J. ZINC CO.

type of pole give any trouble in keeping the trolley wheel on the wire when you are going over a trolley frog?

MR. BOARDMAN: Doesn't give any trouble at all.

MR. REED: It looks to me like it would have a tendency to pull the wheel back.

CHAIRMAN TILLSON: You have a swivel up here on the goose-neck, haven't you, Mr. Boardman? I imagine there is a swivel here as well as here.

MR. BOARDMAN: Yes, you are right; the sketch isn't very plain there. I just got the information from Mr. Concannon here that the kind of joints used on the trolley wheels are the ball joints—a small ball joint on a pin under the wheel, and then the swivel on the pole.

CHAIRMAN TILLSON: I want to call your attention to a plan for the chute mouth. I think all of you have seen the plan in Mr. Mitke's paper. He mentioned different types of chutes in which there were boards fitted

in slots between the two chute sides, and which required to be barred up. It seems to me that that type of chute is very awkward, inefficient, and a very dangerous type of chute to use. If you have a chute mouth with cleats and a board fitting between you can readily see that in barring that up you would have one side tending to jam. You are in continual difficulty with that type of door.

Your next step is to make the corners of those boards slightly rounded in order to try and avoid that, but still you have the tendency for jamming, for a man with his bar doesn't always get in the dead center, or the friction of a shunk against it will hold it back at one point and the other side is free, and there is always considerable difficulty in shutting off the flow of ore when you want to, and there is also the tendency for the ore to flow over and drop on somebody's foot.

Now, the other type of chute which Mr. Mitke mentioned; namely, an arc gate swinging down this way from below, has some difficulties too, because if there is a big chunk of ore and a small chunk of ore, when that gate comes down on the big chunk it is blocked and the rest of the material runs out on your car and overflows on the track.

For that reason I want to call your attention to a type of chute gate which we not only know is practically correct, but it seems

FIG. 9. CHUTE GATES USED BY N. J. ZINC CO. WITH ELECTRIC HAULAGE

to be theoretically correct. That is an arc gate which is underslung, it being supported from some point above or at the side of the chute. (Fig. 9.) Now, the effect of that gate is, in opening the gate it swings down and lets the ore gradually flow over the top of the gate. In other words, the ore in the chute has come up to its angle of repose, in which the fraction upon it does not permit it to flow any longer. The moment you drop that gate, you come below that angle, and it starts to run out slowly.

When you are raising that mass of ore up to its angle of repose there is nothing in the world that can block the delivery and control at the chute's mouth. So far as the control of the chute gate is concerned, it

seems both practically and theoretically correct, and I would highly commend it to your attention for any installations which would be in service long enough to warrant the installation of metal chutes. We have found that it is possible to so proportion the weight of those parts that as you operate you raise the center of gravity and then upon releasing it you get very prompt and immediate action. It swings down to position possibly two-thirds closed and requires then a few turns to bring it up to the closed position. So you get very prompt effect in controlling the delivery of your ore.

MR. W. D. SCHOFIELD (Inspiration Consolidated Copper Co., Inspiration, Ariz.): What is to prevent your stuff from bouncing over?

CHAIRMAN TILLSON: Actually the top comes in here a little further. From that point out here is flatter than the angle of repose, and it won't flow over.

MR. SCHOFIELD: It doesn't now, but if your chute is empty you have a tendency of bouncing over.

CHAIRMAN TILLSON: You should never empty your chute. Any empty chute will cause you trouble.

PROF. SPERR: The trouble with this chute here is that you are using it the wrong way. Now, Mr. William Kelly described that chute and its use in the report of the Lake Superior Mining Institute about twenty-five years ago.

(The chairman rearranged the sketch.)

FIG. 10

FIG. 11

PROF. SPERR: Now you've got it. By closing the door down, as in Fig. 11, a lump of ore is liable to catch under the door and prevent it from closing the chute entirely. In Fig. 10 the door closes upward so no lump of ore can prevent its closing. We use that type of chute, and when the handles go down it comes up just as he illustrates it there.

CHAIRMAN TILLSON: That is the very common way of using it, but I maintain that is the wrong way.

PROF. SPERR: Well, the reason we do that is because we want everything above the car and nothing below, so the car goes under the lip. In order to get it above we sacrifice the ease with which you work the chute.

MR. W. W. GIDLEY (Phelps Dodge Corporation, Bisbee, Ariz.): I think we have all entirely the wrong idea of Mr. Mitke's illustration here. This illustration is taken from the standard door that is used now by the Phelps Dodge people. It is taken right from the mines in Bisbee, and is the type of chute door adopted as a standard. It works very successfully.

In regard to what the Chairman said a few moments ago, it doesn't project down below the chute lip at all.

In addition to the door there is also a little board that is commonly known as the tail board, used in case of a run of ore, and in studying out the different types of doors in order to arrive at a standard, many different designs were tried and considerable time devoted to it. The result was that this iron door was adopted as a standard, and is now being used in every chute in the Phelps Dodge works in Bisbee. We found it to be the most practical chute door in use.

Another feature about the door, as you will notice, is the handles on the side, which practically compels the man to stand at one side of his car in order to work the lever. In case he is required to use the tail board, he uses it with his right hand. All of us who are interested in safety know that our most frequent accidents occur from loading. Men get their hands bruised or fingers smashed, especially those who haven't had a great deal of experience in loading. You may have all the side boards or protection you wish, but it is almost impossible to get the ordinary loader to use them. So by having this door with a handle on the side, it practically compels the loader to stand at one side of the car.

We had a very serious accident in Bisbee caused by a boulder striking a man, and we are working on an arrangement to have a baffle down in front of the chute made of steel, so that the loader will be compelled to stand behind it. It is an experiment, and we haven't thoroughly tried it out yet, but I am convinced from the experience I have had that that is a very practical kind of chute door.

Another word in regard to the trolley wire. All of our trolley wires on main haulage chutes are by-passed. We have no overhead trolley, no live wire at all over the chute when the loader is loading. We have a block signal system established in the main haulage drifts. All our ore on the Phelps Dodge properties in Bisbee is hoisted through one shaft over conveyor belts automatically, and when the motor leaves this particular shaft on the main line back through the main drift, it automatically turns on the red light.

There is a red light at every junction of all the lateral drifts throughout the line, and as soon as they see this red light they know that the motor on the main line is approaching. It works very satisfactorily.

CHAIRMAN TILLSON: Do you consider that first type of trolley guarding unsafe? How is a man going to get his bar against it?

MR. GIDLEY: We use that a great deal. We have many very heavy drifts, and drifts that require a great deal of timber, and which are constantly settling. We use those guards wherever our trolley wires are at all low. But I do believe it is much safer and more practical to have the trolley wires by-passed.

PROF. SPERR: (Michigan College of Mines, Houghton, Mich.): Let us again refer to the method of stopping the flow of ore from chutes. It is a common practice in many mines to use boards which fit in slots in the chute.

In regard to this method of stopping the chute boards, I wonder whether the people who use it never thought of cutting off their chute right there (illustrating by sketch), and dropping the boards in here, and letting them stick through.

CHAIRMAN TILLSON: I was going to draw a sketch of that. (Figs. 12a,

FIG. 12a. DETAILS OF STOPE SETS

12b, and 12c.) That hasn't any of the objections I mentioned for the other chute door.

PROF. SPERR: And you can either have one hook here or a succession of hooks for each board to hold the boards one on top of the other.

CHAIRMAN TILLSON: They may be hooked separately on the side, or placed one on top of the other. That brings up the other question that is mentioned in the paper, where in certain instances the chutes are fixed so that men will load from the side—from the end of the car or side of the chute—and the question I want to ask Mr. Gidley, who is acquainted with that practice, is why that isn't required in all instances. Isn't that the safest way to load a car—from the side of the chute or end of the car?

MR. GIDLEY: I don't quite understand your question. You mean that a loader should always stand at the end of the car?

CHAIRMAN TILLSON: Whenever the chute loads from the side of the car.

MR. GIDLEY: It is almost impossible for a loader to do that if he is loading out of an ordinary wooden door. He practically has to stand in front of a chute, particularly if he has ore that is inclined to be sticky.

FIG. 12b. TYPES OF CHUTE HOOKS

CHAIRMAN TILLSON: In order to raise these boards?

MR. GIDLEY: No, in order to take his bar and have free access of the

FIG. 12c. PLATING AND BRATTICING CHUTE

chute. He practically has to stand right in front of the door in order to load with the old type of wooden doors.

CHAIRMAN TILLSON: If you made the wooden doors of that type with

planks sticking out of the side of the chute and cut your planks down a little at each end so he couldn't pinch his fingers; one plank rests on another one beneath it. The side of the chute comes down to here, and the loader stands on the side and can handle those planks without prying up his boards. The men can stand at the end of the car here, and reach over the end or around back here and bar up the planks, and if anything happens, if the bar sticks, leave it there; and all they have to do is to step back out of the way of the flow of ore, and there is no difficulty in handling the material or barring the chute.

I speak by virtue of the fact that we have operated entirely that way for a great many years. And I have noticed in the past there have been many illustrations. I have seen some western mining practice, in which they have made all sorts of arrangements permitting the man to stand in front of his chute and bar it out, and the only condition in which we have to practice standing in front of a chute is where it happens to be a dead-end drift due to the slope of the ore. The chute comes in the end of the drift and has to be loaded from the end of the car. Then if that is cramped too much, he may have to be in front.

MR. GIDLEY: Wherever a main haulage chute is built in the Phelps Dodge properties our safety rules compel them to have six feet in front of every chute. In the past we have had serious, and in fact, fatal accidents, from men being buried by chutes running away, and if there is not sufficient room behind a car, why, it is more or less difficult for him to make his escape should the chute start suddenly to run, but if he has plenty of room it is almost certain he will get out of the way.

Of course, in loading a car in the end of a drift conditions very often demand that chutes be built that way. In the end of the drift perhaps they may be following a string of ore or something that wouldn't justify a great deal of expense in building the regular type of chute, and in that case some small chute, commonly termed a "joke chute" is erected in the end of the drift, and loading is done in the end of the car.

But there is one thing Mr. Mitke speaks of—that is when the chute hangs up the loader would have to take powder and blast it out. I want to say that he would practice that about once in a mine of mine. The thing of allowing the loader or any green man to handle powder to blast the chute is absolutely out of the question in these days of safety. If it is necessary to blast a chute, why, we have rules governing that. The loader notifies the nearest miner, who comes, and if necessary does the blasting—but not the loader. It would never do to have a loader blast a chute.

MR. BOARDMAN: One thing in regard to loading the chute I'd like to bring out here. Up in our mines we have a number of accidents caused by men loading from the opposite side of the car. They lean over the car in this manner, and the car catches them right where it shouldn't. In leaning over the car they sometimes forget to put their board in between their body and the car, and of course the fleshy part of the thighs and some other things get across the top of the car, and the ore spills down and catches them. We have had some very serious accidents in that manner, and I think in that case it is necessary to load from the side of

the car, but there should be very stringent rules requiring men to place boards between them and the car.

MR. A. H. TRESTRAIL (Pickands Mather, Palatka, Mich): We have both those installations Professor Sperr spoke about, where you have a bar on the outside of each chute and boarding across, and we also have the arrangement where the man stands in front and blocks the chute from the front. If you have chunks, then I think it is pretty nearly impossible to work a chute without having a man in front with a bar, or at least on one side of the front to pry down the dirt, and keep it running.

I think the paper spoke about the building of a platform on the side of a car so the men could get up and have plenty of room, and a chance to jump to one side in case of a run of ore.

Sometimes in our dirt there will be fine stuff and rocks mixed, and it is necessary if it starts to run to bring that board down pretty fast. So the fellows used to grasp the board on the top and get their fingers caught. So we tried to experiment by putting the handles on the outside of the chute board, and then he wouldn't have to put his fingers over the top. First we put them this way, and that didn't give them any leverage, so we turned it around so he could grasp it at a side angle and save his fingers.

CHAIRMAN TILSON: Couldn't they stop the flow of the ore with boards on chute-hooks in the front?

MR. TRESTRAIL: We have that installation, but I stopped at that particular property just before I came down here, and watched them load several cars, and they still had to get around in front with their pryrs and loosen it up. They used bars, standing back to one side, to pry it up. If it doesn't run, they have to get powder. And in regard to a loader blasting a chute, I agree with Mr. Gidley that that is out of the question. They have an experienced man to look after that part of the work.

PROF. SPERR: With that type of a chute board, when you have to bar your chute you will always have at least one board over the top where you are barring, and if a rush starts you drop it quickly and there is absolutely no danger, even if standing in front of the chute.

MR. TRESTRAIL: As a rule they generally leave the cross bar on top.

PROF. SPERR: Yes, one board, and another is up at the top to stop it. Then instead of having one hook for all the chutes, I have seen a succession of hooks used. The first hook, you see, stops the rush, and then there will be hooks inside that you can drop boards into lightly.

MR. TRESTRAIL: Instead of the boards we use the cleat.

PROF. SPERR: But, first of all, will be a hook.

MR. TRESTRAIL: Yes.

MR. W. W. GIDLEY: During the Spanish-American War, in 1898, I was employed in Butte, and in speaking of the hanging of chutes, there was a method in vogue there at that time—it wasn't used at all of the chutes, but it was in occasional use in various places—where we used to have a chain strung through the chute from the collar top of the chute to the door. The ore, while often it was wet, was not sticky, but the hanging of the chute was usually caused by the arching of boulders. If you'd take hold of that chain at the bottom and give it a little shake, invariably it

would start the chute to running. It worked very successfully. I don't know whether they are still using it in Butte or not.

MR. J. C. CONCANNON (Anaconda Copper Mining Co., Butte, Mont.): I think the talks we have heard this morning are something very enlightening. Now, I have been a loader for the A. C. M. Company for quite a while, and this is my idea of a perfect chute—where I think I would get the greatest returns without going into great risks to the men. This is how I would do it: A chute of a hundred feet should have three setoffs, but not too wide for the chute to hang up on.

This chute should have an angle of 45 degrees. Now, when it comes to the loading, what I would advocate is this: Have a controlling door for each of those three offsets. This controlling door is about half an inch thick and covers the entire breadth of the chute. That is worked by a lever from the man who stands on the platform at the side of the chute.

I would also say that a man should never stand in front of a car, or sit down on it and put his legs across the car, because he is liable to be hit below the belt if he ever did that.

MR. R. D. HALL ("Coal Age," New York City): As a coal miner, I hesitate to get into the discussion at all, but it seems to me when we come to talk about wires, it might be a good suggestion to leave them out altogether. It seems pretty hard to induce anything in the way of a storage battery locomotive, but it does seem to me that will be the ultimate result, and of course it might be a combination of both trolley and storage battery; the storage batteries being used where there are chutes, and the trolley being used where there are no chutes.

It seems to me that matter ought to be looked into because it offers a great possibility of getting rid of the wires. I also think that hardly any matter would be more prolific of good than a bulletin issued by the National Safety Council on chute doors. It seems to me when you have solved that matter of mining cars as best you can, with the present state of knowledge, then you might take up the matter of chute doors to great advantage. Being used in the anthracite region, it really is a matter which interests the coal-mine man just as it does the metal-mine man. However, the former has the advantage of knowing just about what he is after, and making his installations without any question about the probability of their being used to a large or small extent.

MR. R. H. GUERRANT (National Safety Council, Chicago): In regard to chutes becoming blocked, I picked up an idea from the Oliver Iron Mining Company. They provide a room at the side of each chute for barring down the ore if it gets blocked over the chute entrance. I will make a sketch of the arrangement. (Fig. 13.)

In their main haulage ways they have some trouble in loosening the ore, so their general manager conceived this idea: At the bottom of the chute they have dug out a room ten feet long. A man can climb up into this room and loosen the ore with a bar, and he is not in danger of being crushed. Where they recently loosened it through the chute, they experienced much trouble. They claim this is an ideal way of loosening

ore. The floor of the room is on a level with the bottom of the chute.

MR. A. H. TRESTRAIL: If the man can get in there to work there must be an opening.

MR. GUERRANT: He goes up at the ladder at the far end of the room.

CHAIRMAN TILLSON: We could spend the whole day on chutes, but I will ask for the paper on "The Importance of Safety Measures to the Miner," which is to be presented by Major Arthur S. Dwight, who comes to us, we are very much pleased to say, as a representative of the American Institute of Mining and Metallurgical Engineers. This is the first

Courtesy, Oliver Iron Mining Company

FIG. 13. A SAFE ARRANGEMENT TO PERMIT DISLODGING WEDGED ORE IN CHUTES

time the Board of Directors of the American Institute of Mining and Metallurgical Engineers has officially sent a delegate to address the Mining Section of the National Safety Council. We hope it is an omen of the closer cooperation to take place between those two famous bodies. Major Dwight.

THE IMPORTANCE OF SAFETY MEASURES TO THE MINER

MAJOR ARTHUR S. DWIGHT

CHAIRMAN, INDUSTRIAL ORGANIZATION COMMITTEE,
AMERICAN INSTITUTE OF MINING ENGINEERS, NEW YORK CITY.

There is no calling that is more vitally interested in safety measures than that of the miner. He faces continually the perils of falling rock,

caving ground, high explosives, poisoned air, gas explosions, fire, flood, high tension electrical currents, besides all the ordinary dangers of machinery made doubly perilous by the darkness and the discomfort in which he often works. The calling has always been a perilous one and necessarily, in order to exist at all, the miner had a safety code, the proper understanding of which was a very important part of the skilled miner's equipment. In the old world, mining was from ancient times an hereditary occupation which developed its own traditional methods and rules to suit the special conditions found in the several mining districts, and these rules were handed down from father to son.

As the New World began to open up its mineral treasures, skilled miners from these old mining communities of Europe were attracted, and brought with them their old country methods, and their unwritten rules of safety underground which had been developed in the centuries of experience in the mines of Cornwall, Devon, Saxony, and Bohemia. These ancient unwritten rules are still the basis of underground practice today, though obscured somewhat by the multitude of "don'ts" that have come in as modern engineering has replaced the simpler implements of the ancient miner with power drills, high explosives and powerful hoisting, pumping, ventilating and transportation machinery. Moreover, the old breed of miner has mostly disappeared, and the unwritten laws of safety underground have been largely forgotten, because unwritten. With us, the miner is seldom born to the business; he has to be shown.

It is my purpose to discuss here only metal mining. The coal miner was early confronted by certain hazardous conditions peculiarly his own, explosive gas and fire danger, and was long ago forced to adopt safety measures on a large scale, and not only to codify his safety rules, but to establish a system of rigid inspection to enforce them. The metal miner is perhaps the one that now most needs enlightenment and cooperation. It is necessary that the unwritten law of safety underground be written, and incidentally written in all languages under the sun to reach our present complex mining population, and then backed up by a good Anglo-Saxon punch.

COMMITTEE APPOINTED TO DRAFT SAFETY CODE FOR METAL MINERS

The need for a safety code for metal miners to meet this situation of increased occupational complexities with diminished skill in the miner, came to a head at the 1906 meeting of the American Mining Congress, at Denver, Colorado, and a committee of five eminent mining engineers was appointed to study the situation and draft "a modern law governing quarrying and metalliferous mining," which could be recommended to the several states for adoption, in the hope that the passage of a uniform law by the mining states would tend to lower the number of fatal and serious accidents. The engineers composing the committee were Walter R. Ingalls (chairman), the late James Douglas, James R. Finlay, J. Parke Channing, and John Hays Hammond. Much valuable preliminary work was done and discussion in the technical press awakened, and in 1909, the American Institute of Mining Engineers, and the Mining and Metallurgical Society of America became interested, and asked to participate in

but they are certainly on the right track, and Mr. Fay's statistics will doubtless show steady improvement year by year.

The next thing is to reach the proprietors of the small mines, and induce them to adopt safe methods. The work of the big companies will in time have its effect on the smaller operators, but other steps should be taken. The most effective, of course, is the adoption of well-drawn state laws, adequately backed up by generous appropriations for adequate inspection of the workings, and prosecution of those who violate the law. That may come in time, but meantime it is believed that the principles of safety should be inculcated not only from the top down, but from the bottom up; in other words, some form of educational campaign might be started that would appeal in the first place to the small mine proprietor who employs only a handful of miners, and in the second place to the itinerant miners who largely make up this class of employees. I shall not attempt to suggest the means of doing this, realizing that the experience already gained by the National Safety Council along this line is worth more than any ideas of mine. The records of the U. S. Bureau of Mines would doubtless furnish a valuable mailing list for reaching these small operators.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS

The American Institute of Mining and Metallurgical Engineers is glad to cooperate with the National Safety Council in promoting safety methods in the mining industry. Perhaps we have been slow in giving official recognition to the movement. Except for the work of the Committee on Mining Safety Law, already mentioned, which began in 1906, and was formally endorsed by the Institute in 1909, practically nothing was done in the way of safety activities until 1914, when the Museum of Safety was officially recognized by the appointment of a Consultation Committee. In 1918, a Committee on Industrial Organization was appointed with nine sub-committees, one being the sub-committee on safety, for cooperation with the National Safety Council, and it is to be hoped that this community of interest may result in lasting good to the mining industry.

The American Institute held a meeting in Chicago last week. There was an attendance of 700 at the Banquet, and it is significant of the present trend of thought in the profession, that every one of the speakers that evening, each in his own way, led up to the one all-absorbing topic which Mr. Charles M. Schwab, one of the speakers, aptly referred to as "Human Engineering." The subject is presented to us now as never before, and the conservation of human life is the first element in that plan. That is the noble purpose for which you are striving, and you may be assured of the sympathy and cooperation of the mining profession.

CHAIRMAN TILLSON: We are greatly indebted to Major Dwight for his paper, and discussion on the subject is now very welcome.

DISCUSSION

MR. A. H. TRESTRAIL (Picands Mather, Palatka, Mich.): In regard to the statement about the itinerant miners of small mining companies not

using safety standards, does not that seem to indicate that the itinerant miner is a dangerous man, and from the fact that he works, as a rule, for these small companies, why, the small mines would have a larger disability or fatality rate on account of the kind of help that naturally goes there for employment? The company that employs the safety standards as a rule has a steadier force of men, because men knowing the dangers of the occupation prefer to work in a mine where things are well regulated.

COMPARISON OF EUROPEAN FATALITIES WITH THIS COUNTRY

In regard to the comparison of European fatalities with this country, is it not a fact that in this country the stress has been laid upon the number of tons per man, and I believe in one of our previous conventions it was shown the production in this country was very much greater per man than in the European countries. In Duluth that point was brought out by a practical man from Europe who stated the production in this country per man was greater than in Europe.

COMPARISON OF LARGER WITH SMALLER COMPANIES

MR. M. J. FLYZIK (State Safety Board, Olympia, Wash.): Our experience in Washington has been somewhat different relating to the small companies. The Medical Department of the Industrial Commission has tabulated the last five years' contribution to their Department, and we find that the larger companies in the state are contributing more to the Medical Department, as a result of a greater percentage of accidents, than the smaller companies. For instance, there is a mine employing about seven hundred men. They have injured for the year 1916, 33 per cent of their total force. Another and smaller mine employing but one-half the number of men only injured about 26 per cent of their total daily force. What is true of the coal mines, I am informed is also true of the shingle mills of that state. Our experience shows that the smaller plants, operating with smaller numbers of men, are far ahead of the larger employers, so far as the Medical Department is concerned.

Now, in that state the workmen contribute one-half, and the employer one-half of the actual day's work for medical treatment. We only have a seven-day waiting period, which perhaps knocks off about 10 to 12 per cent of our trivial accidents. But we get our figures very accurately from injuries that go over this seven-day duration. I am only speaking from our experience in the state of Washington.

CHAIRMAN TILLSON: Mr. Flyzik, do both the large and small plants have the same number of working days in each year?

MR. FLYZIK: Practically so. In fact, we find that the smaller plants operate more days than the larger ones, due to the fact that the railroads purchase their coal.

MR. TRESTRAIL: I know it is a fact if you take the small property for or six years?

MR. FLYZIK: I am speaking for that one year, but at the end of December, 1919, we expect to have complete data for the five years.

MR. A. H. TRESTRAIL: How long a period was that comparison—five

one year it may run along with a very nice percentage for that one year, but in the next year if they have one accident of maybe fifty to a hundred days' disability, that property's record is ruined for the year. The small accidents in a big property mean a very trivial thing, whereas in small properties as affecting their percentage, why, it runs up. For instance, in one case a small property had a percentage of .2 of a day in every hundred days' work, and a large property had a percentage of .4 in every hundred days' work. But in the succeeding year the small property, through one accident that was calculated a thirty-day disability period based on a hundred days, why, its percentage ran away up.

MR. FLYZIK: If you take your figures on a percentage basis, based on the number of men employed and the actual days worked each year, that shouldn't vary with a thousand or a hundred men—as long as you have based your statistics on that principle.

MR. TRESTRAIL: The only variance would be in which mine operated the more safely. The statement has been made in this paper that the small mine was the more dangerous mine to work in, and the only difference in the figures would be as to which mine had the safest schedule of figures. That is the proper way, according to my notion, to figure it out. If the small mine is more unsafe to work in than a large one, the small one is going to have the larger percentage of disability. That is what I was getting at.

MR. J. W. REED (Consolidated Coal Co., Fairmont, W. Va.): I believe the gentlemen are all right, but I think the figures, if compounded on a few small mines, will be very misleading. It is about the same proposition I am up against in working out individual records for single mines as compared with the total records for our company as a whole.

Now, as regards the small mines and the large mines, I am in a position to say something, having been a state mining inspector for some time and having had about a hundred and some mines under my inspection at one time. I find that the small mine and the small organization is in some instances a great deal safer from the fact that perhaps the president of the company or the owners are directly in touch with the interior of the mine and get in there. Then if there is something that comes up which must have attention, why, the man who owns the pocketbook and has charge of the purse strings is able to open it up and go ahead and do it or not do it; while in your larger organization you continually get further and further away from the man who holds the purse strings, and improvements have to go through a number of different channels to reach him, and you have a longer length of time elapsing.

But when your large organization becomes interested in safety, and makes it its business to go down through the mines and improve the conditions, I believe it is a hard thing for the small mine to equal the conditions for safety that the larger organization can produce. That in general, was my experience in Kentucky. We had a number of small mines under small ownership, and I don't think I ever in my life saw mines which were kept in better shape and were safer than those small operations. We also had larger companies, and their mines were in equally good condition, but we had in-between companies where the conditions

would vary from good to bad. So that when you come to a final summing up of the thing, I believe that your small intermediate organization will be equally as good, depending on the man in actual charge of the work. There isn't any line which can be drawn to say the small man works under dangerous conditions, and I don't think you can say that the larger operator always has good conditions. He may want to have them, but perhaps the man he puts in charge of the mine is not getting the service he thinks he is.

EDUCATION OF THE MEN AND THEIR FACULTIES OF IMAGINATION

MR. J. E. WATSON (Timber Milling Co., Butte, Mont.): A great many of the companies throughout the country today are publishing and editing papers that are distributed among men on safety work, and safety measures are being put into use at the different mines. We have a paper out in Butte, that got to almost all the employees a short time back, in which was an article that dealt with imagination and its bearing upon safety work.

If you have a man, no matter how many safeguards you throw around him, or no matter how many installations you may make to take care of his health and welfare, if he doesn't have his imagination educated so he can see what might happen to him if he does a certain thing, your safeguards are not going to work out very well. If you have a man with a vivid imagination, who knows he is doing something that may result in a broken arm if he continues that thing, he will try to take care of himself, and you will have a great deal less danger from him than from the one with little imagination as to his welfare but with numbers of safeguards about him.

I think the education in safety of the men working in the plant is one of the important issues—not only the installation of safety devices, but education of the men and their faculties of imagination.

MR. A. H. TRESTRAIL: Along the line of education of the men, a great many of the mining companies have found it a reasonable thing to go even a little farther and try to educate that man's family. That is, they realize the mental condition of the working man is largely affected by the home conditions, such as the kind of food he eats, the sanitary condition of his home—and as a result of that they have a visiting nurse who calls regularly at those homes, which they find is an important part of their safety work. As a consequence, they endeavor to make that part of his life brighter because if it is so he is a much more efficient man when on the job.

THE GIVING OF PRIZES

MR. C. W. GOODALE (Anacóna Copper Mining Co., Butte, Mont.): Several years ago the company put up a considerable bonus for the foremen who went through the year with the least number of accidents. One thousand dollars was given by the company—\$750 to the foreman showing the best record, and \$250 to the foreman showing the next best. Now, the mines on our properties vary considerably. Some of them are large, with

perhaps 20,000 shifts in a month, and others are small with not over five thousand shifts in a month.

We soon found that the larger mines, regarding each man as a risk, were not drawing any of the prizes at all. In one certain case one of the larger crew drew a second prize, but in no case did one of the larger draw a first prize. That led to some dissatisfaction, and the foremen of the larger mines said, "What's the use? We've got 20,000 risks against 5,000." So the company gave up that plan of offering the foremen a bonus or reward for a good accident record.

But some little evil crept in. For instance, the accident rate was based upon the State Compensation Law, which allowed fourteen days. If a man was injured, perhaps seriously, we found in some instances where the foreman had practically chased him out of the hospital in order to get him back within the fourteen days, which was rather a serious objection to it. Sometimes they were unfit to go to work after the fourteen-day period, and then should they go on the job they would be liable to another accident or to infection.

PLAN OF MERITS GIVEN TO FOREMEN

I don't know whether any of the members of the Mining Section have given attention to the paper written by Mr. Evanson of the U. S. Coal and Coke Company of West Virginia, but he had a very thorough paper about five years ago in the transaction of the American Institute of Mining, outlining a plan of merits given to foremen with good records. It was based on the system that if a foreman got through a month without an accident he was awarded \$5.00 added to his pay for that month. After he had gone six months without an accident he got \$10.00 a month in addition to the \$5.00 as long as he kept that record up. In one case I saw a record of a foreman who had gone thirty months without a serious accident under his supervision. In that case for twenty-four months he had been drawing \$15.00 a month in addition to his regular pay. In that case it was perhaps somewhat easy because the number of his men was not less than twenty nor more than twenty-five. However, this was true of the other foremen competing with him at that time.

In the case of our Butte mines in many instances one shift boss can look after fifty or sixty men at a time, so we found it rather difficult to apply that system of awards or merits or additional compensation. Mr. Evanson had a record there before he started this system of 100,000 tons of coal mined per fatal accident. In the course of five years that had increased to 500,000 tons per fatal accident, and he attributed it largely to the system he had inaugurated.

Any one can see that the effect of that would be this: If a foreman sees something that is not quite safe, instead of merely standing there and telling the man to do thus and so, he will stay there until it is done that way. He knows his pay is going to be increased if he gets through the month without accident. But when you do have an accident, it is sometimes very difficult to run down the responsibility, and in the case of the U. S. Coal and Coke Company there were many accidents where the foreman simply had to say, "Well, that's my bad luck."

I'd like to inquire if that system has ever been applied, or is now used in any other coal or metal mines.

MR. N. D. HUBBELL (W. J. Rainey, Uniontown, Pa.): I might give you a few facts. I am sorry I haven't the figures here. Such things as that I usually carry around in a bag instead of my head. For the past three and a half years, almost four years, there has been considerable interest on the part of our company in safety work and reducing accidents.

We have nine mines operating. Four of them are comparatively large bituminous coal mines, and the other five are comparatively small. The situation is a little bit different from the small mine as we speak of it out West. As a matter of fact, they were large mines in the beginning, but we mined out on the retreating system, and along toward the end of the mine it begins to get in nearer the pit mouth, and as a general rule you have a class of employees in the small mines who are the old timers, who have been there for some time. Now, these miners know the work, and have had, some of them, twenty-five and thirty years' of experience in this same mine. So there is an element entering into the safety factor there that would be a little different.

We started out with a first, second, and third prize for lowest compensation liability, and we ran into all sorts of trouble, as you would readily realize. That was based on the compensation liability for a six-month period. The second period it was based on a small factor of the number of weeks' liability incurred, but we divided it into two classes. We gave first and second prizes for rectangular or larger plants, and a first and second prize for the beehive.

Now, the most interesting thing in connection with the effect on accidents was this: We had five curves along for the same period; one representing the fatal accidents, one representing non-fatal accidents, another representing compensatable accidents, that is, accidents in which the lost time was more than fourteen days called for by the Pennsylvania State Law, and one for time lost but not compensatable, lost time, but less than fourteen days, and still another representing no lost time.

The two curves that worried us most—the fatal accidents, and the compensatable accidents—showed a slight decrease in 1917 compared with the 1916 figures. Nineteen eighteen showed a slight decrease compared with the 1917 figures, and 1919 so far seems to be running neck and neck with 1918.

On the other hand, the two curves—lost time, but non-compensatable, and no lost time accidents—showed a decided decrease. I dare say our figures for 1919 will be less than 20 per cent of the 1916 accidents in those two classes.

Just what we are going to base the prizes on next year I don't know. We are going to change the basis, and try to involve new factors: One, the number of days lost on account of accidents in proportion to the total number of days' work; and the other, the number of days lost on account of accidents in proportion to the total number of tons of coal mined. I am trying to work out a scheme that will work in these two, to give us some kind of an average representing the two factors we are most interested in.

MR. A. H. FAY (Bureau of Mines, Washington, D. C.): The small mines Mr. Goodale referred to I don't think are a good comparison to the small mines to which Major Dwight referred in his paper, for the former have all the advantages of modern equipment and engineering experience and hospitals and doctors that are available for his largest mine. These small mines to which Major Dwight refers are those small gold mines, lead, tungsten, etc., in the far West, fifty miles from a hospital; some of them have no mine doctor, and their equipment is not what Mr. Goodale referred to in case of his small mines. Mr. Goodale represents twenty-five or thirty mines in the Butte district, but in my tabulation it is called one—the Anaconda Copper Mining Company. I have kept all records from what you might call the standpoint of management instead of mines. So when Major Dwight referred to some two hundred mines, employing some eighty or ninety men in each, it is very different from the small mine in the Western states employing ten or fifteen men, which is about the average for the majority of the gold mines. Some of them are simply prospects out in the hills with half a dozen men, and every one of those men handle the powder. They all do the blacksmithing work. Every one is an all-around man, and there is no specialist there on the job. The hoisting equipment is sometimes of the very poorest. Sometimes there are no cages, and perhaps no guides on the cages, if they do have any.

This is shown very plainly in the Joplin district. There are very few cages in the Joplin district, and not only few cages but few guides to take care of the buckets going down a two-hundred-fifty-foot shaft.

SAFETY IN THE SMALL MINE

In 1911 I picked out those companies on our tabulations employing ten men or less. I counted up the fatalities on that group as compared with the ones employing more than ten men. I found in that bunch of the small mines, twenty-five fatalities, which represented a fatality rate of almost 8 per cent of the men employed, as compared with about 4 per cent for the other group. The fatality rate for the United States that year was 4.41 per cent of the men employed. I am inclined to think that the small mine, as a rule, is more dangerous than the larger mine, but there are conditions in the small mine which may be considered safer than in the larger operations. For instance, take a small gold mine with a vein two, three, or four feet thick—there is not as much chance of danger for a body of ore to come down as there is in some of these Michigan iron mines and large copper mines in the West, where they are fifty or a hundred feet wide, and give room for a large fall or a roof cave-in of the entire mine.

Another condition which also tends toward safety in the small mine, is that if the superintendent has any scruples at all he is there on the job, and he can look after it and follow up. But from my experience around the mines, they have not done this as well as they do in the larger properties.

In my work, for the last four years, I have been able to pick out com-

panies and tabulate their accidents by mining methods, and in each of my reports for the last four years there are details given of the caving method, overhand stoping, room and pillar, and door mining, and if any one is interested in those, they need only to send for a copy of the reports. I can't keep all those figures in my head, but I do remember in those companies I have tabulated (about 250 or 75 each year) in the four methods of mining operations there were about 330 non-fatals per year: while the records for those small mines to which Mr. Dwight referred show about 150, or approximately half.

I have a reason for believing that the accident rate as tabulated under the mining methods group is about complete, because these companies are rendering complete reports, and I applied that to the official returns I got from the state of California, and I find that the returns of these returns of the larger companies as compared with the actual returns from the state of California check up about even. I found when the figures of California did come in they checked to within 13 out of 6,000 accidents. So that we can feel pretty safe that 330 is not far wrong on non-fatal injuries of duration of one day or more.

MAJOR A. S. DWIGHT (American Institute of Mining and Metallurgical Engineers, New York City): It is very gratifying that Mr. Fay did not entirely repudiate the conclusions which I drew from his figures in his annual report, which were made up entirely on my own interpretation of his figures, and which were not intended to show that the small mine per se was more dangerous than the large one, because the reverse is true, generally on account of conditions prevailing, and the ability of the proprietor himself to give personal attention to the safety of his mine. But my purpose was to call attention to the fact that in spite of that advantage which the small mine has, the statistics show it is more dangerous to work in the small than the large mine, and thereby to express the hope that the National Safety Council in its efforts to carry on a campaign of education would give attention to these small mines which are not directly reached as are the large mines.

Now, most of the representatives in the Mining Section in this room are representatives of those large mines that have had the broad vision and have seen the business necessity for taking extraordinary measures to study and devise plans for considering the life of their operators. But the small mines in out-of-the-way places are up to the present time almost forgotten. They will be reached in course of time by the state laws, which perhaps will be gradually improved and brought to bear more and more from time to time to control the operations in those cases, but at present they are almost out of reach of the campaign of education which has done so much to improve the conditions for safety in the large mines, where the dangers are really greater than in the small mines.

CHAIRMAN TILLSON: Major Dwight has fittingly led up to a subject mentioned in the paper which is to follow and which has been delayed on the program, so if it meets with your approval the Chair will rule that we proceed with our program and consider the subject, "The Need for a Definite Technical Service in the Mining Section of the National Safety

Council." Major Dwight's comments referred to the need of development of interest of the small mines in safety work.

This subject now in hand, I may say for the benefit of some of the mining members, is rather close to the hearts of some of the other sections, and to the Executive Committee of the National Safety Council. The consideration of this in the various activities of the National Safety Council as it applies to these other sections is a problem which is now calling for some attention.

NEED FOR A DEFINITE TECHNICAL SERVICE IN THE MINING SECTION OF THE NATIONAL SAFETY COUNCIL

BENJAMIN F. TILLSON, CHAIRMAN MINING SECTION, NATIONAL SAFETY COUNCIL; ASSISTANT SUPERINTENDENT, NEW JERSEY ZINC COMPANY, FRANKLIN, NEW JERSEY.

To attain real efficiency in safety work we must *keep our men interested*, and this requires persistent work and ingenuity in sustaining their support and enthusiasm. No one safety engineer can think of enough "stunts" to last 365 days in the year and the realization of this has drawn us together from many different industries to one central coöperative organization—the National Safety Council. We whose interests lie within the field of one of the most important industrial groups of this country—Mining—were desirous of concentrating our attention upon our specific problems at the same time we profited by the broadening influence of the experience of the other industries and we therefore formed the Mining Section as a part of the National Safety Council.

What has it profited us? What are our future needs, and how may they best be met?

A resumé of the service rendered by the National Safety Council at large and the Mining Section in particular in the past should indicate the lines along which an analysis of our own advance in safety work would show a profit from this association.

BULLETINS

The National Safety Council as a whole has provided a weekly service of bulletins of which about 840 have been on general topics of safety, welfare, and health and suitable for our plant bulletin boards; in addition there have been about 160 Mining Bulletins dealing with both coal and metal practices. Even the largest of us would not have felt we could devote the time, money, and attention to have produced this bulletin service for direct appeal to our workmen. Only one other section, the Electric Railway, can compare in specific sectional bulletin service. It has issued about 20 more bulletins, but the rest of the sections have only from 15 per cent to 75 per cent of the number which has been received by members of the Mining Section. However, if our interests are so ramified as to make the activities of other particular

sections of service we have at our disposal some 700 additional bulletins issued by nine other sections.

WEEKLY LETTERS AND EXECUTIVES' BULLETINS

We, as executives and safety engineers, have further profited by having our attention called each week to the experiences and successes of others in Safety Work; and this stimulation to our interest and enthusiasm is vital but incalculable. This has been accomplished by some 300 "weekly letters" and 150 Executive Series Bulletins which have come to us without the asking or any effort on our part. These have also kept us in touch with the times in regard to labor relations, employment problems, and welfare work. How else could we have obtained this service?

SAFE PRACTICES PAMPHLETS

Some 27 different pamphlets have already been printed to give us the authoritative information we needed in regard to the safe construction and operation of different elements common to most of our plants, such as ladders, stairs, boiler rooms, cranes, belts, shafting, engine guarding, oiling devices, knots and slings, floors, scaffolds, grinding wheels, goggles, etc.; and two pamphlets produced have been very pertinent to mining, namely—Ropes, and Mine Car Haulage. Only one other section has had a safe practices pamphlet prepared for it. In these pamphlets we have the collaboration of some of the best engineers of the country who have thought along Safety lines, and nowhere else is similar information available.

ANNUAL CONGRESS AND ITS PROCEEDINGS

Finally, we had the privilege of associating with each other at the Annual Congress, and we have thus rubbed shoulders, compared notes, and argued our mutual problems in Safety, Health, and Welfare with men in whose veins flows the virile blood of the day—men whose duties have brought them in contact with problems similar to ours and whose viewpoints vary from that of the workman to that of the foreman, safety engineer, executive, insurance agent, doctor, teacher, lawyer, or other professional man. Not only have we been able to concentrate our discussions upon our peculiar problems by reason of our grouping together as the Mining Section but our programs have also been arranged so that we might join in more general discussions with representatives of other industries and furthermore could attend the sessions of other sections (such as the Health Section) whose interests would supplement our own.

He who has never attended one of these Congresses may wrongly think of it in terms of the occasional engineering or business convention where there is but little tendency for the attendants to speak freely and fully of their experiences, where formal, innocuous, boring papers are written in so historical a manner as to produce no discussion, and where questions from the floor elicit no satisfactory replies. If such an impression exists it may readily be refuted to the satisfac-

tion of even a stranger to the meetings of the Mining Section, for the extensive printed transactions record that *over one third* of the information presented during the last three congresses was developed in the discussions.

Perhaps the *Round Table* is a new idea to some of us. If so, it must be experienced to be appreciated—unless we think in terms of the exciting conferences we have held with our confreres at which we have participated in informal discussions of ways and means for accomplishing some object of mutual interest and have defended our views and "hobbies." A Round Table Session is like that, "only more so", for the Chairman with watch in hand is forced to limit an individual's remarks to three minutes in order to give an equal opportunity to all, and his gavel may fall in the midst of our "one last thought". Such a session is provocative of clear, concise thinking and produces that nervous tension so necessary to stimulate the enthusiasm which makes us tenacious of our ideal plans and smoothes the rough drudgery necessary for their consummation. These Round Table Sessions are held not only as a part of the Mining Section meetings but also in the general meetings of the National Safety Council, and we all enjoy the privilege of profiting by the experiences of others and gratifying our own modesty by proclaiming our successes or seeking the solutions for our unsolved problems.

However, if business or other conditions prevent our attendance at the Annual Congress we still may profit by its Proceedings. Nowhere else is there so encyclopedic a source of authoritative information in regard to the problems of Safety, Health, and Welfare as is presented in the published proceedings of the National Safety Council since its inception in 1912. They comprise over 5800 pages, 6x9 inches in size, of which about 680 pages are devoted particularly to the mining industry. Perhaps the summation of the last three year's proceedings is more indicative of the amount of information now annually being made available for reference. The total for these years was about 4200 pages of which 550 pages were the proceedings of the Mining Section. It should furthermore be born in mind that this literature is the coöperative effort of individuals, representatives of both large and small industrial organizations, Federal and State agencies, and engineering and other societies.

Perhaps it has not been amiss to enumerate thus the activities of the National Safety Council and its Mining Section; for its benefits are dispensed so continuously that we may have come to receive them thoughtlessly and so have lost the perspective which is given us when we ponder upon the subject as a whole; and we should not fail to add as a benefit the opportunity which exists any day for us to present our special problem to the competent engineering and executive staff of safety specialists at National Safety Council headquarters, who have at their convenience an exhaustive library and file of information and who stand ready to share it with us. So much for what we have or should have received if we had sought it.

WHAT ARE OUR FUTURE NEEDS?

Our work and our life is yearly becoming more technical and general information must be supplemented with specific knowledge in order that it may be practically applied. We are living in an era when specialists are a necessity and we all require the services of a Mining Safety Engineer if we intend to make any considerable progress in the reduction of accidents. Compensation laws, insurance ratings, and general safety propaganda have made it plain to us that *safety pays*, both for employer and employee, but both are prone to forgetfulness in the matter and require continual reminders.

EDUCATIONAL SERVICE

With some concerns the size of their operations makes an extensive safety organization feasible, and they may therefore feel that they can "go it alone" as they would have more to give to such an organization as the National Safety Council than they would receive in return. It would be wise for them, however, to consider several things. Are not their safety engineers so tied down to plant details that they find it difficult to get away and have the entree to other plants for observation of the problems and solutions of others; and would not many of these other plants be so remote that they could not spare sufficient time or money to visit them? Does not the continual educational campaign which it is necessary to have for the workmen, whether by bulletins, lectures, courses of study, or moving pictures, require resources outside of those available in the operations of any one company, in order that the reiteration of advised safe practices may be made attractive by their novelty of presentation? Does not the giving out of information devoid of trade secrets pay, both by reason of our own analysis and more thorough understanding of that which we desire to make clear to others, and also because our generosity begets a similar attitude in others and we receive much value from the coöperative effort produced? If so, no company is too large to receive adequate benefit from their coöperative support of a skilled technical man who could put at their disposal, in proper shape for them to use, the information, bulletins, etc., which he had gleaned from others, and who also would make it possible for them to reciprocate with the least effort. Let the doubting Thomas try but one experiment, namely to plan a program for 100 meetings of his safety committees which will so hold the interest of his men as to induce them to attend without pay and which will also show value in accident reduction. It will destroy any feeling of self-sufficiency and indicate that his safety engineer who may be responsible for many more of such meetings deserves all of the outside aid that he can obtain and that the efficiency of his plants is well worthy of such help. Remember, we are considering *Definite Technical Services*—for general information might here be an entirely different story.

On the other hand there are thousands of small plants who can not see where their operations could stand the expense of a man devoting

all his time to safety work. With some the Safety Spirit may be present and with others lacking. The former may not require the general information but they both will need specific help, not only in regard to the proper practices in design and operation to overcome their hazards, but also with respect to prepared educational matter for inaugurating and maintaining a safety campaign.

Even more for these small companies than the larger and wealthier ones is it imperative for them to receive the intensive technical service which will show immediate marked results in accident reduction and correspondingly lower costs in production and insurance ratings, for they cannot afford to make a "long swing" investment in Safety with faith in the ultimate profit, as their resources might be dissipated before the time for reaping the profits.

REPORTORIAL SERVICE

Most of us desire to respond generously to appeals from others as to how they can better conserve human life and endeavor, but the urgency of our duties and pleasures mightily interferes with our preparation of complete and technical descriptions and illustrations of the methods we have used and the results we have produced. No, it is not because of a lack of willingness that we have not helped each other more in the safety movement; it is because of the lack of a suitable agency. Writing or dictation is laborious because it requires the logical correlation of our ideas with much data which is not carried in our memories, and because it is performed in an office or home environment where we cannot reap the benefit of contact with physical conditions in stimulating our memories by the association of ideas. If a trained safety engineer should visit us, look around the plant, and consult our records and drawings, he would acquire a vastly greater fund of information from our casual and disconnected conversation as elicited by his inquiries, or our observations if we should happen personally to show him about, than we should probably ever attempt to write down even though we did take time from our other activities with the intent of presenting the subject in the form of a letter or address. Why? Because he would make it his business to do this one thing and it alone, while we could not avoid the distractions of other duties. Also, we should have become so familiar with many of our old practices that we should not appreciate the novelty and interest they might have for others and so we should neglect to mention them unless they were called to our attention by a stranger.

Is it not clear that if no other purpose were accomplished than to send a capable man around to various mining properties, to dig out information for them and for others as to what they are doing that would increase safety, it would warrant a considerable expenditure by each of us?

PUBLICITY AND MEMBERSHIP SOLICITATION

When can we expect the greatest potential returns from our member-

ship in the Mining Section? Is it not when we have every mine in the country an ardent supporter? Then let us increase the value of membership through the service we render to such a degree that no company will fail to realize that they can't afford to neglect the opportunity for joining our ranks. Will not the travelling of a keen and technical executive secretary on his visits to various mining camps and his personal contact with representatives of various mining companies give us greater and more valuable publicity than could be obtained in any other way? Should not his conversation and presence be more effective than any solicitation by correspondence? If so, the benefits accruing from increased and more representative membership would warrant our making an additional investment for such a worthy object.

FORMULATION OF STANDARDS

We are in an era of diverse and profuse legislation—so much so that it seems as though almost every one else knew more about how we should conduct our affairs than we do, and desired to make us follow their beliefs or fancies. Foolish as this may sound, it seems to be a reality; and if by chance we do not know how to conduct our business with greatest economy in material and human factors, we should make haste in learning if we hope to survive industrially; while if we do know, we should so formulate our practices as plainly to demonstrate that fact, or else we may suffer from ignorant or mischievous legislation. The principal ingredient for a cure of either alternative is a complete code of safety standards in respect to mining. The apparent object of most of the mine laws and regulations upon the statute books of various states is the protection of the lives and unimpaired health of the workmen and the public at large. The Mining Section has the same objects in view—but what are we accomplishing in that direction? True, we are originating and assembling much valuable information and recommendations, but are we doing it in a systematic, painstaking, and final manner—let us be honest and properly say *technical* manner? No, not as we should. Then what is wrong? It seems astonishing for a chairman of a section so to flaunt his incompetency, if he is truly responsible for this state of affairs. Generously grant that the chairman and his executive associates have not failed in the duties which could be expected of them, and consider the organization as a whole in order to see whether anything else might be responsible for this deficiency. You find a section more highly organized than any other of the National Safety Council, with its officers and committeemen well representing the different phases of the mining industry both geographically and industrially. You note an extensive organization of committees—Executive, Membership, and Publicity, Standardization, Accident Statistics, Ropes and Safety Devices in Hoisting and Haulage, Mine Hygiene and Sanitation, Mine Fire Prevention and Fighting, Mine Rescue and First Aid Contests, Program and Publication. You also find that their functions and activities have been thoroughly outlined and correlated. Then what

is lacking? Naturally and properly the members of these committees are widely separated geographically and are men of affairs with absorbing business interests. If their time was not of considerable value to their industries their opinions would not be worth so much to the Mining Section or to you as a participating member. Such time as they can devote to the interests of the Mining Section should be utilized with the greatest economy and this would be accomplished by removing from them all routine labor. This is no more than your company's practice towards its own executives. Would you not feel more tempted to serve on these committees if you knew that your knowledge and ability would be drawn upon in an advisory capacity without your being expected to steal extra time for petty details and drudgery? That situation can be met only by the employment of an Executive Secretary for the Mining Section, who will make it his business to reduce the amount of correspondence between officers and committeemen and prepare inquiries in such form as to permit their knowledge and experience to be available with the least expenditure of time and effort on their part. He would outline the general features of Safe Practices pamphlets, which would ultimately become a code of Standards, and would utilize these committees in an advisory capacity to fill in the essential details which could be obtained in no other way than from the store of such varied experience; and the seal of approval of such advisory committeemen would be a respected guarantee of the recommendations made. That is why we have not achieved more in these essentials—because we had no funds to pay for such Technical Executive Secretary.

Other expenses also will naturally be involved in the production of such Safe Practices pamphlets or standards. From time to time the settlement of a question will involve research work, and while this probably could be "farmed out" to some industry whose interests would parallel ours, yet we should be in a position to assume any contingent expenses or in some cases all of the expenses. A technical man as secretary would also be required in the follow-up of such work.

COÖPERATION WITH ENGINEERING SOCIETIES

The profession of mining is an extremely broad one as it requires knowledge not only in the specific field of mining engineering but also in other engineering fields, such as, mechanical, electrical, civil, and sanitary engineering. The problems of safety, health, and welfare in mining require coördination with the activities in these other branches of engineering. In the national engineering societies representing all of these branches considerable attention is naturally devoted to the same or kindred subjects which are before us in the mining section of the National Safety Council, and standards committees in these other societies will also consider standards to meet the needs we will strive to meet. It is therefore highly important that there should be close coöperation between all of these agencies; and to be efficient, this service should be performed by one who is devoting all his time to the

activities of the Mining Section. Again we find need for a Technical Executive Secretary.

COURSES OF INSTRUCTION

Our present foreman and miners, as well as the present and coming generation of mining engineers, need definite and concrete courses of instruction in the "hows" and "whys" of safe mining practices. But how are they going to get this information? There are no schools and colleges prepared to teach it, nor books from which they can find a thorough or able presentation of this information. Must they all learn in the rough and expensive school of experience, or shall we aid them by preparing such courses of instruction which may be used in the schools and by classes at our plants? If we do we are engaging in a task which we could never hope to complete properly through the sole agency of volunteered services. We must be prepared to pay for the outlining, editing, writing, and publication of such a work and wait and wait for our returns at a later date from its sale and use. Again we find a need for definite paid technical service.

To the writer the reasons for this need seem legion. If the few he has presented do not demonstrate the fact incontrovertibly, it would be useless for him to attempt further to demonstrate a theory which seems to him axiomatic, and he will rest his case with the observation that no engineering society of prominence, including the National Safety Council, attempts to operate without a paid, technical, executive secretary. When we consider that the wealth involved in the mining industry exceeds \$5,000,000,000 and the labor involved exceeds 2,000,000 persons, it appears that the Mining Section of the National Safety Council has been given responsibilities in assuming a prominent position in the promotion of safety, health, and welfare measures in the conduct of this industry. Are we going to meet our obligations? If so we must render more and more service and to be true service it must be technical.

FINANCIAL RESOURCES

How can we finance the demands made by a more technical service? The answer is extremely simple—by increasing the dues of mining members, and we might well call the increase a surtax if that term had not achieved unpopularity from its association with our income taxes.

For the conservative growth represented by the engagement of an experienced mining and safety engineer as our technical and executive secretary in the Mining Section, for his travelling expenses, and for other expenses contingent to his work and that of the volunteering officers and committeemen we should have an additional yearly income of about \$10,000. The necessary office and clerical assistance might properly be expected from the National Safety Council Headquarters, with the same bulletin, printing, and other service which we have been receiving, in return for the regular dues which we are now paying.

Although the Mining Section and the Metals Section stand on a par as the two largest sections of the National Safety Council yet the membership and dues for each amount to only 7 or 8 per cent of the whole Council. Our membership on August 1, 1919 was 253, of which 165 were coal mining and 88 metal mining companies, and paying in dues respectively \$6,532.50 and \$3,877.50, or a total of \$10,410. The largest amount paid by any company is \$157.50 per year and the average is \$41. Of course more than half of the membership pays less than this average.

In view of the fact that the maximum amount involved for any one company seems to me slight compared with the benefits which should accrue, and the average amount involved for each company is so small, I strongly urge the members of the Mining Section to increase their dues to double those they are now paying to the National Council, with the understanding that the excess above their present dues be devoted to the specific activities of the Mining Section.

I trust that there will be a free expression of opinion as to the need and advisability of this step, and an authoritative communication from the various individuals and companies who are members, as to whether they would approve and support such action.

Gentlemen, this paper was sent out at a late date, owing to the fact that it took time to get it printed. Up to date there have been a few replies which arrived at my office before I had to come to this conference. All of those replies—some of them coming from coal-mining companies ranging from West Virginia to Pennsylvania, and some from metal-mining companies—were strong endorsements of this policy. The members stated their complete willingness to pay double their dues for such definite service, providing that was the desire of the other members of the Mining Section. Some comments were made in these letters. One, from one of the large companies, paying dues nearly the maximum limit paid by any member of the Mining Section, was to the effect, in short, "Pay enough to make it worth while or don't pay anything."

Another large coal-mining company in the anthracite district stated they considered it of vital importance that a practical mining man should visit the various plants; and a metal-mining company stated they highly approved of the plan, and that committees in that section should be advisory, that the plan of safety pamphlets would require a man, and furthermore, they strongly endorsed that policy. One of the bituminous coal companies in the Pittsburgh district stated this feature was much needed.

I may further say that before leaving Pittsburgh I had discussion with Mr. George S. Rice, the Chief Engineer of the Bureau of Mines, in regard to his opinion in this matter, and asked his presence at this meeting in order that we should have his advice and coöperation of the United States Bureau of Mines in any steps which might be decided upon. Before leaving, Mr. Rice gave me a letter which I will read to you, and I might state I had the opportunity of presenting this letter to Mr. Manning, the Director of the United States Bureau of Mines, who, upon reading it, said he most heartily endorsed the views as expressed therein. So that this letter means the opinion of our federal agency along mining lines.

DEPARTMENT OF THE INTERIOR
BUREAU OF MINES
EXPERIMENT STATION, PITTSBURGH, PA.

October 1, 1919.

"Mr. B. F. Tillson,
"New Jersey Zinc Company,
"National Safety Council,
"Cleveland, Ohio.

"Dear Mr. Tillson:

"I much regret my inability to attend the National Safety Council meeting at Cleveland. As I mentioned to you the Bureau has assembled all of its mining engineers from various parts of the country in Pittsburgh for the First-aid and Rescue Competition, also to attend a business conference regarding plans for the present fiscal year. As the head of the Mining Division, I cannot therefore be absent from the Bureau conference.

"As concerns the proposition that you expected particularly to discuss—To increase the usefulness of the mining section of the Safety Council—I feel very sympathetic toward anything that can be done in that matter. It is evident that a great field of usefulness can be accomplished by concentrating the attention on the specific needs of the mines and the safety problems connected therewith and the standardization of safe practices. While the work is parallel to part of the work of the Bureau of Mines, the National Safety Council is not limited in its recommendations of specific things in the way that the Bureau is often limited; that is the Bureau of Mines says what should not be done but it is not always able to say what is the best thing to do where there are a number of ways which might be held to be permissible.

"I heartily hope you will meet with success in your endeavors to increase the usefulness of the Mining Section.

"Yours very truly,
"(Signed) Geo. S. Rice,
"Chief Mining Engineer."

CHAIRMAN TILLSON: Gentlemen, this paper is open for discussion. I trust you will all give your viewpoints very freely and openly.

DISCUSSION

MR. S. J. WILLIAMS (Secretary and Chief Engineer, National Safety Council, Chicago): May I ask as a matter of information how many replies you succeeded in getting to your inquiry? I know how difficult it is to get replies from that sort of thing.

CHAIRMAN TILLSON: I have had eleven replies so far.

MR. WILLIAMS: Have you anything on which to base an opinion as to the sentiment of the remaining hundred and fifty?

CHAIRMAN TILLSON: I hope we shall have that from the representatives here at this meeting.

MR. JOHN BOARDMAN (Anaconda Copper Mining Co., Butte, Mont.): I

of the National Safety Council and affiliate if possible this First-aid Society, already in existence, with it. Now, if the Mining Section of the National Safety Council would consent to become a governing head for such a Society, and the co-operation of the Bureau of Mines could be secured, I think by combining all of these organizations under the head of the Mining Section of the National Safety Council we could make considerable progress, and the value received from that would be to get the miners themselves interested in safety work.

Safety engineers, of course, are necessary, and most of them are very efficient, but an investigation of conditions prevailing will show you that most safety devices and most safety ideas—that is, most of the safety ideas that result in good, originated with the miner himself. The reason for that is that although the safety engineer might be efficient and intelligent, and his ideas are usually good, they are looked upon with more or less skepticism by the operating heads. They think he is a sort of dreamer, while, on the other hand, the practical miner will develop an idea and put it into practice before he says anything to anybody about it, and the operating official then comes along, sees this thing, and says, "That's a fine thing. Just look what I did!"

In that way, by getting these miners to belong to the Mining Section of the National Safety Council as individual members, through the locals of course, we will get them to present their ideas to the Mining Section of the National Safety Council, and we will be able to do a great deal of good in having those ideas adopted and keeping the interest of the miners.

DISCUSSION OF PERMANENT SECRETARY FOR MINING SECTION

MR. VAN SCHAAK: Mr. Chairman, without attempting to suggest the course which this meeting should follow, I would like to say if the Mining Section decides upon employing a permanent secretary, or sectional engineer, or whatever he may be called, the Aetna Life Insurance Company will do its full share of financial support.

MR. J. W. REED (Consolidated Coal Co., Fairmont, W. Va.): I feel that specialized service for the Mining Section is necessary. In fact, we have to have it if we are going to get anywhere with it. However, I feel the means adopted to finance and get the specialized service are something which require very careful consideration as to the future effect upon the growth of the Mining Section. If we double the dues in the Mining Section, and then establish mining locals in the various communities, which are to be supported—if they are supported in the same way as the Pittsburgh local chapter is at the present time—by the payment of dues equivalent to your original dues; that will mean the members of the Mining Section will be paying three times the dues of the ordinary member.

Now, as far as any present member of the Mining Section is concerned, I don't believe it will make the least difference to him if he pays the present dues or two or three times the present dues, but I do feel it may make a considerable difference in getting in new members, especially the

smaller man who was mentioned earlier in the day as being a very important portion of our membership we should go after.

I feel a great deal of good can be done in mining communities by local councils in their neighborhood, and I am going to assist as far as I am able towards organizing some locals of that sort in the region where our mines operate. At the present time we intend to affiliate with the Pittsburgh Chapter, which will take care of about twenty of our mines in Pennsylvania. In fact, we have already had a little experience in connection with the secretary of the Pittsburgh Chapter, who has assisted us in some very live safety work in one of our mining camps, and while the mining members may think that a safety rally around a mining camp must be limited to the number of men around that camp, I will say that in a certain part of Pennsylvania where there are no railroads or trolley cars, we held a rally at a mine which employs about two hundred men, which is rather centralized in a mining group within ten or twenty miles of other mines surrounding it, and from fifteen hundred to two thousand men attended. So it shows that regardless of there being but a small number of men at the mine, you can get other men to come, and all you have to do is interest the people by letting them know you have something there that will be interesting and of benefit to them, and the coal miner of today is fortunate in that he has his own means of transportation, or his neighbor has, and he will get there some way, even if he has to walk.

So I think a great deal of good can be done by the section of a local chapter; a great deal more than we anticipate, because you will not have to limit the service to the community but will be able to figure on men from a circle of perhaps twenty or thirty miles coming to take part in such an affair.

I am especially interested in the increased technical service, and I hope that some means will be worked out whereby we can get it. I don't feel—I am not speaking only from the opinion of my own company, but I mean from the Mining Section as a whole—I don't feel that the increased dues will cover the thing. I believe that such technical service should not only be in the section, but should be extended to all sections of the National Safety Council wherever it can be, and that body should give as much service as possible, and if it is simply a matter of dollars and cents I believe the body as a whole will see its way clear to divide with the bunch to produce the technical service in all branches. In other words, I would approve a raise of dues from the entire association until adequate service along all lines can be given to all sections, but if we can't get that, why, I guess we'll have to take what we can get.

We will have to take the lead in this movement, even though it is going to make membership a little harder, and should increase our own membership dues until we can take care of the work as we think it should be done, and perhaps by that time we can convince the rest of the sections we are on the right track and they will fall in line and bring the dues of the entire body up to a sufficient amount to give everybody adequate safety service.

MR. BOARDMAN: I am afraid we have digressed from the subject under

discussion. But I think the easiest way in which the Mining Section could give this technical service, and the way in which it could do the most good, would be the organization of locals of mining sections, requiring each of those locals to pay at least as much dues as the individual corporation pays. I believe should an organization of this kind be formed in Butte, that we could pay a hundred dollars a year dues to this section, and if you had, say, two or three of those locals over the mining country, your financial support would be there. I know we have no difficulty whatever in getting \$3,000 a year to spend on the miners' picnic, and the First-aid Society has no trouble in getting \$200 or \$300 for a dance whenever it wants it. I feel that the mining communities throughout the country are able to pay the amount which would be required for those things.

CHAIRMAN TILLSON: Mr. Boardman, I feel that that is a coming thing, and will come one of these days. The object is to sell the idea from the executives down to the miners in the various sections of our country in order to have the material with which to build up those locals.

MR. BOARDMAN: The experience of the First-aid Society has been this: We had no finances to start with, either, but we have initiated a large number of members who are continually writing back to get copies of rules and by-laws to organize similar societies in other mining camps, and I think all we have to do is to start.

MR. R. D. HALL ("Coal Age," New York City): Mr. Boardman's suggestion is an extremely unjust one. Mr. Boardman's company is very willing, possibly, to accept that injustice as against a company, but because they have a local section they are going to contribute to the Mining Section of the National Safety Council in support of its work. If they didn't have a local they would escape entirely that obligation. Now, it seems to me there are lots of us not going to have the benefit of that local and we are going to escape paying anything to the Mining Section of the National Safety Council beyond our regular dues.

It seems to me it should go all over the country. If a man belongs to a local, he shouldn't have to pay additional to the Mining Section just simply because he is in the local. Of course it wouldn't come in direct, but through the local. It would seem highly unjust that they should pay such a contribution. It seems to me we should pay it as members of the whole Mining Section of the National Safety Council. It is unjust for those in the locals to pay for the dues of those who do not have local councils. They are doing more for the safety movement than anybody else, and it seems to me they shouldn't be called upon to pay for the deficiency of the other people.

MR. BOARDMAN: The reason we want local sections is because we want our men to be tied to some national body; keeping them interested in their work, and the purpose in paying these dues is to pay for a technical secretary. It would be up to the locals to use up the time of that technical secretary, and we'd certainly see that we used up our share of his time.

MR. C. W. GOODALE (Anaconda Copper Mining Co., Butte, Mont.): It

occurs to me that for the first year the local section would get some support from the National Council fund, and that we might attempt to organize a local that would include not only the mining people, but public utilities and other concerns that are really interested in the matter, and at least we can try it out for one year and see how it works.

For the first year we might undertake to have our expenses nominal and try to get enough enthusiasm to start it up and then let the secretary try to finance it in some other way. As I understand it, 20 per cent of the first year's dues go to the local section.

CHAIRMAN TILLSON: What would be your official vote in regard to the Anaconda Company's paying double dues for the proposition?

MR. GOODALE: I am quite sure they will be willing to pay it.

MR. R. D. HALL ("Coal Age," New York City): I think Mr. Goodale has made it even plainer that there is an injustice, because the public service corporations would be paying additional dues to the Mining Section, and they would feel that their money was given to some specific object and the Mining Section would be getting more out of it than they themselves.

MR. O. A. DINGMAN (East Butte Copper Co., Butte, Mont.): Why, I think, if I understand correctly, that the Mining Section sees the need of a technical secretary in order to stimulate membership and to give better service to the association. Now, the plan is offered that in order to pay this man and pay his expenses they double the dues, and that is a means toward that end. If they want to go ahead and form these local sections to create local interest, that will offer a place for this secretary to go and begin his work. It seems to me that what they want in this paper is the secretary, and if we want to go ahead and form these local societies, well and good, but what the Section wants to know is whether or not we want the secretary. Isn't that it?

CHAIRMAN TILLSON: That is the question.

MR. DINGMAN: So it seems to me we ought to decide whether or not we want the secretary. If we do want him, have that increase in dues as a means to pay him, and the locals then can form as they see fit.

MR. C. H. WILSON (Utah Copper Co., Garfield, Utah): Do I understand we have sent communications out to all of the members of the Mining Section—that is, the companies themselves?

CHAIRMAN TILLSON: Yes.

MR. WILSON: Soliciting their support in the appointment of a secretary?

CHAIRMAN TILLSON: That is right, Mr. Wilson.

MR. WILSON: The point I want to make is this: Probably there are very few of us here that can pledge the companies we represent as to how far they will go. Now, the company I represent pays perhaps one of the maximum amounts in the National Safety Council, and no doubt the management will be influenced or governed by the recommendations of their representatives who have come to this meeting, and I think we could well have some time set for making a report to the Mining Section as to what the attitude of the companies would be.

Personally, I would have to go back and make a report on the recommendations that have been brought up here, and make a further recommendation as to whether or not we should be in favor of that. As for myself, I assure you I will do everything possible to get our company to go as far as any one will, and up to this time we have never had any difficulty in getting appropriations for any of this work. I feel satisfied that the Utah Copper Company will go the limit, but perhaps that is what we are all up against, more or less. There are very few of us here who can pledge our company and say that we will do so-and-so without having the approval of the management. I couldn't do that, although I feel positive there will be no difficulty in getting that appropriation. The company appreciates the service we are getting, and the increased benefits we will get surely will be worth the increased amount of dues.

MR. J. O. DURKEE ("The Coal Industry," Pittsburgh): In case a mining section is established with the dues increased it may be possible in some of our locals for members still to retain their membership in the Mining Section and still not support this technical service. I don't say that it will be done, but it may be done where members belong to the National Council without reference to whether they have paid for a secretary, and they also get service from this paid secretary without supporting him if that could be the case.

Will it be the definite plan of the National Safety Council to have all members come in on the same rate? If they do, then some persons will be receiving this technical service without paying the pro rata share.

CHAIRMAN TILLSON:—I don't see how any scheme could be satisfactory which did not require all to come in on the same basis. There could be no discrimination. It would require a corps of clerks to decide whether they received any more service than another man. It would have to be a sound basis of everybody in this section joining in the support of it.

MR. VAN SCHAAK:—Might I make a suggestion to the meeting, that probably a great many men here can state now whether they are in favor of this idea of a technical executive secretary. Now, would it be possible for the Chair to receive assurances from them that they would go back and do their best to get the companies to agree to this, and then either the Chairman or some committee communicate with the men who actively represent the members of this section, who could go to the executive officers and see what their attitude was? It seems to me that would facilitate matters.

I take it that from the failure of but three or four of us to express our views it is because they are not in a position to make any pledge, while if this meeting knew that the men here were in favor of it themselves, and would go back with the assurance in getting their executive officers actually to say they would agree to it, we could then get the final pledge by correspondence with the representatives. I think we could get a general expression of opinion as to their support or non-support at this time.

MR. ORR WOODBURN (Globe-Miami District, First Aid Association, Globe, Ariz.): Just to bring this thing to some head, I would like to make a motion that we go on record—those of us present—as being heartily in

favor of your plan as outlined, Mr. Chairman, and would be willing to give it our backing when we return to our respective companies.

(The motion was duly seconded.)

MR. F. P. SINN (New Jersey Zinc Co., New York City): Just before a vote is taken, I want to say that work which a local does is the work of stimulating personal interest and getting the different men in the community to go to work on the safety problem. It doesn't seem to me it will be economical in the long run for any local to give technical service—real technical service—which is to be for the benefit for all members interested, which in this particular case would be all members of the Mining Section. In voting on this question it seems to me it is a question of giving all the mining members technical service, and Mr. Goodale made a very strong point, I think, and that is when you form a local it is much better to form a local of the whole National Safety Council to cover all of the National Safety Council's interests in that community.

MR. H. G. DAVIS (D. L. & W. Coal Co., Wilkesbarre, Pa.): While this association is essentially an employers' organization, yet I have been a member of it for several years, and I would gladly vote today my personal vote for the employment of a technical secretary, but the company I represent here today has only been a member of the Council for the past three months or so. I can't pledge their support and vote for the matter. For that reason I think it would be advisable from my viewpoint to lay this matter on the table until our next meeting, and that everybody in the meantime use their influence to bring about this increase in dues.

As I said before, I am willing to pay double the amount I am now paying, which would be \$15.00 instead of \$7.50, as far as I personally am concerned.

MR. WOODBURN: My idea in putting this motion was that we don't have the power to pledge our companies, and the only thing we can do is to offer our influence and to go on record as being heartily in favor of the plan, and then it remains to be seen whether or not our companies will sanction it. If they do not sanction it then the thing falls through and it will have to lay for another vote but let us go on record as being heartily in favor of endorsing the plan.

MR. C. H. WILSON (Lead Company's Representative): It seems to me it would be a mistake to lay this on the table. I am heartily in favor of the paid secretary. I think we have some good reasons for it. There are so many that there shouldn't be any question about it. I would like to see some date set, if possible, that we could make it a point to get our report in to the Mining Section as to the attitude of our companies. Personally, I can't help but feel that every company should be very much in favor of it.

MR. VAN SCHLAACK: It seems to me the motion made by the gentleman does not propose laying this on the table at all, but it simply suggests one means of finding out whether it is going to become an active thing or not at the earliest possible moment, and having found that out, a meeting can be called to approve or disapprove such plans as may be made for carrying out the proposition in regard to this technical secretary. It

seems to me that will facilitate matters, rather than laying it on the table.

DR. A. F. KNOEFEL (U. S. Bureau of Mines, Terre Haute, Ind.): This matter may be settled by January 1, giving them two months and a half.

CHAIRMAN TILLSON: Dr. Knoefel, don't you think anybody can make up his mind before two and a half months?

DR. KNOEFEL: I was trying to bring a happy medium between Lehigh and Utah. (Laughter).

CHAIRMAN TILLSON: Here is an extract of the letter sent out to all of the companies:

"On the mornings of October 2, 3, and 4, the Mining Section of the National Safety Council will hold its meetings, as a part of the Annual Congress of its parent body, in the Hotel Statler, Cleveland, Ohio, and it is hoped that your company will have a representative present to participate in the varied discussions pertinent to mining practices, and qualified to advise in regard to the attitude of your company when the subject, 'The need for a Definite Technical Service in the Mining Section of the National Safety Council,' is presented on the morning of Saturday, October 4. You of course realize the desirability of a presentation of the replies to this canvass at that time."

Another paragraph of that letter states:

"Where there is insufficient time for the transmission of word by mail, a telegraphic response would be greatly appreciated."

The replies were requested to be in prior to September 24, but unfortunately there have been only eleven that have reached my office. I was supposed to have received a telegram from my office giving the synopsis of a number of replies received and votes "Yes" and "No," but I fear that the telegraphic service or Hotel Statler service, which I would be quite willing to suspect of inefficiency, has made that telegram entirely lacking at this time.

This letter was sent out on September 19.

MR. VAN SCHAAK: To whom was the letter addressed in the various companies?

CHAIRMAN TILLSON: The opening paragraph is this:

"It is to be hoped that this communication will be brought to the attention of the safety engineer for his comments and recommendations, and that as a result the managing executive will take definite action and will advise the writer at the earliest date practicable, and at the latest, prior to September 24, of the decision reached, together with any approved suggestions or recommendations."

MR. VAN SCHAAK: If the executives haven't brought it to the attention of their safety men, let's get the safety men to bring it to the attention of their executives.

CHAIRMAN TILLSON: That was my idea—if we didn't get it one way we'd get it the other.

Is there any further discussion on the motion? If not, will those in favor of the motion signify by saying "Aye"?

(The motion was unanimously carried.)

CHAIRMAN TILLSON: Is there any choice in the time at which we should expect the letter ballot to be returnable for definite action by the Executive Committee of the National Safety Council?

MR. C. H. WILSON (Utah Copper Co., Bingham, Utah): Say the fifteenth of November—surely that would give everybody plenty of time. I make a motion that we set the date for having the replies in as November 15.

CHAIRMAN TILLSON: I think it might be wise to include something about definite action being taken as a result of the proportion of replies for or against the proposition.

MR. WILSON: I will include that the majority of the members you have heard from at that time will be the governing factor.

MR. R. D. HALL: ("Coal Age," New York City): That might better be in the form of a ballot than anything else. Why not send them a ballot?

CHAIRMAN TILLSON: Would you care to amend that by having another copy of this paper sent with that ballot, as a reminder?

MR. WOODBURN: It is my opinion that we are doing a lot of worrying about this. I don't think any of the companies are going to block this thing. If it requires double the fee, I feel sure there isn't a company in our district but what would be glad to make that contribution. I think we are worrying about something that is unnecessary.

MR. REED: There isn't any doubt as to what the Consolidated Coal Company will do. As I stated before, I don't think any company will refuse to come across. They will all pay. I think the only place there is any question at all is to what effect the increase will have on future members. And if the present members will get out and explain to the other fellow and bring him in, we won't have any trouble there, but if we get a little careless about telling our neighbors what the benefits to be derived are, your secretary will probably have a little bit of trouble in increased dues. That is the reason I am not so much in favor of it. I would sooner see that extra amount of money come by getting five times the present membership, and then saying to the National, "Now that we have gotten all of these new members, won't you kindly pay our secretary?"

MR. WILLIAMS: Every new member that comes in gets back more than half of his membership dues just in stationery, stamps, etc., let alone anything else, and there is not much surplus left.

MR. REED: Well, I made a suggestion that if your dues are not sufficient, put them up.

MR. WILLIAMS: You have outlined the very course I think will have to come. This section will set the pace and then other sections will unquestionably see the advantages and take it up.

MR. WOODBURN: This isn't going to interfere with future membership. If we are going to provide a definite, positive and first class service, it is going to tend to bring in the members. Our service now is more or less questionable, so if we provide the best service, it certainly will bring in new members.

DR. A. F. KNOEFEL (U. S. Bureau of Mines, Terre Haute, Ind.): Some of you may know, or if you don't know you ought to, that there has been a bolsheviki movement to revive the American Mine Safety Association (and I am not guilty, or I wouldn't have mentioned it) and the reason given is lack of service. Now, if these men—bolshevists—want service, why, they will expect to pay for it, because I have an indistinct memory that this American Mine Safety service could have been very much improved upon.

CHAIRMAN TILLSON: May I not ask if you weren't the past president of the American Mine Safety Association?

DR. KNOEFEL: I was. (Laughter).

MR. H. G. DAVIS (D. L. & W. Coal Co., Wilkesbarre, Pa.): Mr. Chairman, I am sorry it is getting so late. This subject ought to have been taken up and discussed before. As a rule, the bolshevists and the likes of them are generally kept out of such movements, but in this particular case they seem to be highly honored. I am the only one here who was present at their meeting, and I think it was an outrage.

CHAIRMAN TILLSON: We have a motion before the house, and if there is no further discussion I will ask the question. The motion was that a ballot vote be taken, sending a copy of this present paper to all of the members again, and making our decision on the majority vote at that time as to the increase of the dues. What is your pleasure in regard to the motion?

(The motion was unanimously carried.)

The election of officers is next. I will ask Mr. Hall, the chairman of the Nominating Committee, to kindly report the suggestions that they have to make in regard to officers of your section for the coming year. In doing so, I will call your attention to the fact that nominations from the floor will be equally well received. The Nominating Committee's function is merely to see that somebody is nominated.

REPORT OF NOMINATING COMMITTEE

MR. R. D. HALL ("Coal Age," New York City): The nominations have been somewhat equally balanced. While the suggestion for chairman is a metal-mining man, the first vice-chairman is a coal-mining man, the second vice-chairman is a coal-mining man, and the third vice-chairman is a metal-mining man. So I think it has been pretty well divided.

Your Nominating Committee respectfully submits the following for the officers of the Mining Section of the National Safety Council for the ensuing year: For Chairman, B. F. Tillson, Franklin, N. J.; first Vice-chairman, H. G. Davis, Wilkesbarre, Pa.; A. F. Knoefel, Terre Haute, Ind., second Vice-chairman; C. A. Mitke, Bisbee, Ariz., third Vice-chairman; and W. H. Shearman, New York City, Secretary.

CHAIRMAN TILLSON: Gentlemen, This is a situation which makes it incumbent on your Chairman to express his great appreciation of the honor which your Nominating Committee has done him in suggesting that his tenure of office should not be ended, and in view of the fact I consider it an honor because of the unsatisfactory nature that the service of the Mining Section has been to all of us. It is only natural that the

present Chairman who has served several years should appreciate being relieved of the responsibilities of further service. It is furthermore only natural that he should also take considerable interest in seeing the Section progress along these advocated lines of technical service which has been his hobby, and which he has felt it necessary to have discussed during the past three years.

He would much rather some one else would take up the reins of government and instill new blood and life into the organization, so as to dispose of any criticism to the effect it was a life job for one man. I would therefore strongly urge upon you to nominate some one else for that position. Of course, if no other names are offered, why, your present Chairman has the interests of the mining safety movement sufficiently at heart not only to appreciate the honor, but to see that the void is filled.

I now request further nominations from the floor in addition to the slate as suggested by your Nominating Committee.

MR. A. H. FAY (Bureau of Mines, Washington, D. C.): Mr. Chairman, I think our present Chairman is making a mistake when he says the Section has not progressed. I think the Section has progressed, and wonderfully! I therefore move that the recommendation of the Nominating Committee be adopted.

(Prof. Sperr seconded the motion.)

(Vice-Chairman Davis took the chair.)

VICE-CHAIRMAN DAVIS: Gentlemen, you have heard the motion that the report be adopted. What is your pleasure?

(The motion was unanimously carried.)

VICE-CHAIRMAN DAVIS: I want to say I appreciate the honor of being recommended for the Vice-chairmanship, but I would prefer to see some other younger fellow in that position. I am getting old now, and I'd like to see some one else nominated to fill that place.

MR. VAN SCHAAK: I move the nominations for first Vice-chairman be closed, and the Secretary cast a unanimous ballot for Mr. Davis.

(Mr. Wilson seconded the motion, and it was unanimously carried.)

MR. WOODBURN: Just to prevent any further speaking in apologetic tones on the part of any of the recommended officers, and in appreciation of their efforts of those who have served us so well, I would suggest that our Nominating Committee has used very good judgment, and I would like to make a motion that we accept their nominations, and they stand closed as they are.

(Mr. Reed seconded the motion and it was unanimously carried.)

CHAIRMAN TILLSON: Gentlemen, there is little I can say, except that this is your Section. It doesn't belong to your Chairman or any of its Executive Committee. They are merely your servants, and this Section is not what they make it, but what you make it—and "Inasmuch as ye give, so shall ye also receive." If you will take that to your hearts and remember it three hundred and sixty-five days in the year, and give and do nothing but give, your Executive Committee will do its best to correlate your giving so that it will be of greatest value not only to you but to the others in your profession. In such a manner may we hope to grow

into the true importance which the mining industry is properly deserving of.

In that respect, I would call your attention to the fact that the income tax returns for the year 1917 showed that the mining industry was responsible, next to the railroad industry, for paying the largest income returns to the government. And the only reason that the railroad industry partly surpassed the mining industry was that the mining industry shipped four million tons of its product daily over the railroads, and that amount was twice the total amount of freight from every other industry. So you see you have a responsibility on your hands, although the group is small, in pushing it on to a successful conclusion.

"UNDERGROUND MINE CARS AND HAULAGE"

MR. GOODALE: In regard to your suggestion about the discussion on this paper or pamphlet on "Underground Mine Cars and Haulage," I think that all of us perhaps are a little tired or don't care to attend an afternoon session, so I would suggest that this having now been submitted, it be requested that the comments be put in writing and sent in to the Secretary.

CHAIRMAN TILLSON: There is one other thing we should think of at this time. A former member of the Executive Committee of the Mining Section, and Chairman of the Program and Publications Committee has passed into the new world of greater joy. I refer to Mr. John P. Reese, of the Superior Coal Company, Gillespie, Illinois. I think it would be highly fitting for this body here assembled to send a properly written tribute to Mr. Reese's family, expressing the sorrow which we all feel at losing so strong and ardent a supporter of not only the Mining Section but of the Safety Movement in general as it applied to mining.

MR. H. G. DAVIS: I move you that the Secretary send to the bereaved family of Mr. Reese an appropriate expression of sympathy.

(The motion was duly seconded and unanimously carried.)

CHAIRMAN TILLSON: Is there any new business?

DR. A. F. KNOEFEL (U. S. Bureau of Mines, Terre Haute, Ind.): I don't know whether any of you gentlemen have attended any of the other sections, but this morning I cavorted over to the Health Section, and was rather discouraged. I heard two excellent papers, but on the first paper there was one discussion, and on the second there were two discussions, and I want to express my gratitude to the Mining Section for the excellent discussion that prevails at your meetings.

MR. DAVIS: I want to say that the papers read here on the first day have not as yet been discussed. We could discuss these questions for another week.

CHAIRMAN TILLSON: In that respect, I may say there has been considerable expression of opinion in that the men from the mining districts come a long distance to attend these sections, and that is the reason why we are small in number, and although we have representatives here from Montana, Washington, Utah, Nevada, and over to the Eastern shores of our country, New Jersey, but the desire is very strong that we spend more time than we have for discussion. We should like to devote three long

half days to our discussions, and if that can be arranged in the future Congresses, I think it will have a strong appeal to and have the support of the companies that are paying considerable, to send delegates to get down into the really practical subjects which we need.

PROGRAM FOR NINTH ANNUAL CONGRESS

PRESIDENT RICHARDS: Well, I'd like to say, if I may have the privilege, that it seems to me that before the program for the Ninth Annual Congress has been prepared there ought to be a meeting of the chairmen of the various sections for the express purpose of outlining a program and finding out how much time each section wants. Then when we find out how much time each section wants, to arrange to give them that time regardless of other meetings, because really we come here as mining men, or steel men, or railroad men, and what we want to hear more than anything else is something about our own industry that is going to help us in carrying on our work.

I think there ought to be time given for that purpose regardless of whether or not it may interfere with a general session. That, it seems to me, is a question that can be well decided by the chairmen of the various sections when they get together for that purpose.

(The motion was unanimously carried.)

If I may be allowed to make the suggestion, if such a meeting as that is not decided upon favorably by the Executive Committee, as I am only one of that Committee, it seems to me that here is one thing we ought to impress upon everybody, and that is there ought to be a limit to the time any man should have to read a paper. I think of what Mr. Brown said last night, that "No souls are saved after twenty minutes," and that is very apropos. While most of us exceeded twenty minutes last night, it seems to me any paper that takes more than twenty minutes is taking too much time of the section in which it is read, and that the real thing we get at these meetings is not what may be said in the paper, but the discussion that the paper brings out. So we ought to have more time for discussion and less time for papers.

If all the chairmen of the various sections feel that way about it perhaps we can arrange some standard plan by which the chairman will be excused from feeling he is being put in a difficult position by saying merely that it is the general rule.

MR. WILLIAMS: Mr. Chairman, in sending out the invitations this year we specified definitely that every speaker was to be limited to twenty minutes, with the exception of one or two cases in the general sections. My only excuse for getting up now is that I don't get to meet in this section very often, and I want to say that you'd be absolutely in line with the policy of the headquarters office if you strictly cut the people off after twenty minutes. We have been told in some cases that men could not say what they wanted to in that time. Of course they could have more space in the proceedings, but when it came to reading the paper, they were simply to leave out some of the details and limit the actual presentation to twenty minutes. We tried to do it this year, Mr. Richards, and

with your help and the help of the chairmen of the sections, we will do it a little better next year.

CHAIRMAN TILLSON: For the information of those present, I may say that your Chairman has kept time on every paper presented during this section's sessions this year, and there was only one paper that exceeded twenty minutes in its presentation. The discussions have been long, but the Chairman has permitted the discussions to run over a long period of time because he felt that that is what we have come here for, and that it was only by free discussion and an interchanging of ideas and suggestions that we develop.

SUBJECTS FOR DISCUSSION

Now, it would be in accordance with our action last year to make suggestions as to what subjects are of most vital interest for consideration in the preparation for safe practices pamphlets during this coming year. Your Chairman calls your attention to the fact that this year we had with us in our second meeting probably one of the most representative groups of experienced mining men who have dealt with the problem of mine fires and their prevention and recovery. I would therefore suggest that that topic might well be covered in the safe practices pamphlet. Another subject has been suggested, I think at this meeting, in regard to the arrangement and loading of ore into cars from chutes.

MR. GOODALE: It would seem to me as a matter of logical sequence that that perhaps would be a very natural topic to take up the next time. We would have the transportation of mine car haulage in this pamphlet, and it looks to me as if the matter of chutes would come next. Another topic is that of mine signals underground. That is a very important matter.

MR. FAY: In the coal mines about 45 to 48 per cent of the fatalities are due to falls of roof; in the metal mines, about 35 per cent. I think there is a chance to reduce accidents, by attacking the largest item in the whole series of causes. That might be well to lay on the slate for consideration. Possibly somebody might be able to prepare a good paper on that particular thing.

MR. WOODBURN: The falls of roots are undoubtedly constituting the greater number of our accidents, but at the same time of great importance is the prevention of fire and such disaster, and the recovery of the wounded, burned, etc. Personally, I would say there are several of us here who make a specialty of mine rescue and recovery, and while we are interested in all of the other phases, we'd like especially to pick up all the data we can along those lines. I have talked with several members about the feasibility of providing a little more time; either that, or say we had a special session for this, and those who are interested in it could attend in an afternoon period when there was something of a general session that we didn't care so much about. I would like very much to see papers brought out on that line because it concerns everybody to more or less degree, and many of us especially.

CHAIRMAN TILLSON: I think the questionnaire sent out on mine fires

will receive a very cordial support from those who are present at this meeting.

MR. REED: In regard to subjects, I would like to remind the members at the present time that the subject of explosives, their handling and transportation and uses, is rather vividly before the mining industry, especially in the Eastern portion of the United States, and it is a subject upon which there is a great deal of argument as to what are safe practices and what are permissible in the way of handling explosives. I think that subject might profitably be given some consideration by this body.

SECRETARY SHEARMAN: I would like to suggest that the men here send in any suggestions for our next annual meeting as soon as possible so we can line up some papers, and also with the suggestion of a subject, also suggest the name of the person you think best qualified to present the paper.

CHAIRMAN TILLSON: Before closing the meeting, I want to request that Major Dwight do what he can—which I know he will be glad to do—to bring some definite results in seeing that the size of these meetings will be increased considerably by the attendance of many other engineers of the American Institute of Mining and Metallurgical Engineers.

MAJOR DWIGHT: I can assure the Chairman I will consider myself as an enthusiastic convert to the new principles and will do all I can to spread the doctrine throughout the Institute.

MR. GOODALE: We haven't come to any decision in regard to this paper on "Underground Mine Cars and Haulage."

CHAIRMAN TILLSON: Does any one wish to remain for an afternoon session?

A motion was made, seconded and carried to adjourn, it being decided that those to whom a copy of the proposed pamphlet was given should review it and send it in to the National Safety Council headquarters with any comments.

Adjournment.

Meat Packers' Section

October 2 and 3, 1919

A. B. DRUMMOND, Chairman

Wilson and Company, Union Stock Yards, Chicago

G. L. MALLERY, Secretary

Swift and Company, Chicago

MINUTES

THURSDAY MORNING SESSION

THE permanent organization of the Meat Packer's Section was completed at the National Safety Congress at Cleveland, October 1 to 4, 1919, and if the interest shown by the several delegates present indicates the manner in which the idea is being absorbed, surely this organization will be a power for good, and reflect much credit upon itself, its individual members, the firms they represent, and the National Safety Council.

The meeting was called to order at 9:30 A. M. Thursday, October 2, by the temporary Chairman A. B. Drummond of Wilson & Co., Chicago, with Mr. G. L. Mallery, Swift & Co., Chicago, acting as temporary Secretary. The Chairman opened the meeting with a very brief resumé of the organization meeting which was held in Chicago in July of 1919. As the need of a section of this kind was thoroughly understood by the delegates no time was lost in explaining the purposes of the organization.

The Chairman appointed Mr. T. K. Lowry of Armour Mechanical Co., Chicago, Mr. Schuler, Swift & Co., of East St. Louis, and Mr. Faulkner of Morris & Co., Chicago, to act as the Nominating Committee. The meeting then swung into a round-table discussion of the many accident problems peculiar to the Packing Industry.

ROUND-TABLE DISCUSSION

KNIFE CUTS AND THEIR PREVENTION

The first subject for discussion was Knife Cuts and their Prevention. Many interesting and ingenious means of overcoming this most common

accident cost were brought out. Mr. W. F. McClellan of Armour & Company, Chicago, exhibited a number of knives, showing the guards which they had installed as a result of their experience. Mr. Mallery of Swift and Company spoke on the knife question. The discussion brought out that about 30 per cent of the accidents occurring in the packing industry were knife cuts, and that about every sixth knife cut resulted in a permanent injury. Mr. Mallery stated that they have been very successful in getting the men in their plants to use the type of guards exhibited by Mr. McClellan. He also spoke of a method of guarding the handle of sharpening steels by means of a leather disc slipped over the handle, and stated that they were using this guard on most of the cutting floors throughout the plant.

BURNS AND SCALDS

Burns and scalds was the next subject for discussion. The experiences of different firms were related. It was agreed that the injuries for the most part, were caused by repair jobs and emergency work, as the plant is usually well protected. The development of an automatic ice puller by Morris and Company, was reported to have eliminated the hazards of burns and scalds in thawing ice cans. Mr. Schuler reported that at the East St. Louis Plant, Swift and Company, they have developed an automatic door-closing device which eliminates any possible danger of the operator falling into the thaw box. It was agreed that the hazard of scalds and burns was that which is usual to other industries and could be overcome by closer supervision and mechanical changes.

FREIGHT ELEVATOR HAZARDS

Mr. Faulkner, Morris & Co., Chicago, gave a talk on freight elevator hazards which was very interesting. The doors and vestibules of the St. Paul Plant of Armour and Company came in for quite a bit of praise. Swift and Company said that they test their elevators by cutting the ropes, allowing the elevator to drop about eight inches. Morris and Company are using an elevator inspection form which is filled out weekly by the elevator operator and an inspector from the mechanical department. They also stated that they have a triple inspection of cables. Swift and Company claim they have eliminated the wood-guide strip and substituted a steel type of guide rail.

The following recommendations were referred to the Standardization Committee: That all wire cable ends be shackled and babbitted and that all counter balance weights be equipped with a double eye bolt draw bar. That steps should be taken to discontinue the practice of giving elevator operator jobs to old and crippled employees, as a recognition of long and loyal service, and make the elevator man's job one requiring young men of an intelligent and efficient class, having the job graded on a higher wage basis than the ordinary laborer's job. That elevator gates be automatic in closing.

A representative of the Government Bureau of Standardization gave

an interesting discussion on the value of inter-locks. He quoted some statistics showing the value of those already installed.

At 12:30 P. M. the meeting adjourned until 9:30 A. M. Friday.

FRIDAY MORNING SESSION

THE meeting called to order by Chairman Drummond who asked for the report of the Nominating Committee. Mr. Faulkner reported as follows:

REPORT OF NOMINATING COMMITTEE

For Chairman, 1919-1920, A. B. Drummond, Wilson and Company; Vice-chairman, W. W. Pierce, Morris and Company; Secretary, G. L. Mallery, Swift and Company.

No other nominations were made and upon motion duly made and seconded it was carried, that the officers selected by the Nominating Committee, were elected unanimously.

The Chair appointed Mr. G. L. Raymer of Cudahy Company, Chicago, Chairman of the Membership Committee; Mr. A. D. Russell, Cudahy Company, Kansas City, Chairman of the Bulletin Committee; Mr. H. G. Ellerd, Armour and Company, Chicago, Chairman of the Standardization Committee; Mr. J. M. Eaton, Libby, McNeill and Libby, Chicago, Chairman of the Educational and Publicity Committee; and Mr. F. L. Faulkner, Morris and Company, Chicago, Chairman of the Program Committee

SAFE-GUARDING PACKING HOUSE MACHINERY

The round-table begun at the first session was resumed. The first subject considered was The Hazards of the Machinery Peculiar to the Packing Industry. After much discussion, it was agreed that most of the hazards of this class of machinery were common to machinery in general, but the subject was so big that no definite action could be taken at this meeting and that a special Standardized Committee be appointed to prepare a Safe Practices pamphlet, that should be distributed to all members of the Section covering the mechanical safe guarding and the elimination of unsafe operations.

LOADING AND TRUCKING HAZARDS

The Hazards in connection with Loading and Trucking. While much interesting data was given as to past experiences, it was decided that much better progress could be made by turning the subject over to the Standardization Committee for full supervision.

SLIPPING AND TRIPPING HAZARDS

The Unusual Number and Results of the Accidents due to Slipping and Tripping on Floors and Stairways of Packing Houses were discussed, but nothing of much value was brought out. The consensus of opinion

seemed to be that a cement or concrete floor with a roughened surface would show better results in point of service and efficiency than the brick or wooden floors commonly used. A great deal of discussion took place regarding foremen who were lax in allowing the men to do work in their own way, without seeing that all possible safe guards had been placed around the operation. Chairman Drummond stated that any discipline would have to come from the top, and that Superintendents and General Superintendents must be behind the safety men at all times when questions of safety arise. He also suggested that perhaps a system of charging the cost of medical care and the cost of compensation directly to the department, would probably make the foreman take more notice of safety matters. He quoted the results of the "No Accident Week" in the Wilson and Company plants, showing that eight plants came through the "No Accident Week" without a single lost-time accident.

Safety Committee plans were discussed freely and all present agreed that a Plant Safety Committee to consist of the Superintendent, Master Mechanic, Fire Marshal, and other men of authority, should act as a Clearing House for the consideration of all matters affecting safety conditions.

The meeting adjourned at 12:30 P. M.

The delegation left feeling amply rewarded for their trip on account of the great educational advantages accruing to those present at the meeting, and with a determination to do everything in their power to impress the Safety thought upon the minds of those responsible for the operation of their several plants, and to interest those not yet affiliated with the National Safety Council with a view to a larger representation at the next Packers' Sectional Meeting.

Paper and Pulp Section

October 2 and 3, 1919

A. P. COSTIGANE, Chairman

Ontario Pulp and Paper Makers' Safety Association, Toronto, Canada

C. E. JACKSON, Vice Chairman

Consolidated Water Power and Paper Company, Grand Rapids, Wis.

C. B. MILNER, Secretary

Hammermill Paper Company, Erie, Pa.

THURSDAY MORNING SESSION

THE meeting was called to order at 9:30 A. M. by the Chairman, Mr. A. P. Costigane, Ontario Pulp and Paper Makers' Safety Association, Toronto, Canada.

DELEGATES ATTENDING SESSION

N. S. Stone, Wausau Sulphate Fibre Co., Mosinee, Wis.

Thos. Frost, Eastman Kodak Co., Rochester, N. Y.

G. E. Morgan, Employers' Mutual Insurance Co., of New York, Buffalo, N. Y.

H. H. Matthieson, Crown Willamette Paper Co., Portland, Ore.

E. C. Gildenzopf, York Haven Paper Co., York Haven, Pa.

David Miller, York Haven Paper Co., York Haven, Pa.

H. J. Myers, York Haven Paper Co., York Haven, Pa.

C. B. Milner, Hammermill Paper Co., Erie, Pa.

H. St. J. Jarvis, Don Valley Paper Co., Toronto, Ont.

C. Nelson Gain, Don Valley Paper Co., Toronto, Ont.

A. P. Costigane, Ontario Pulp & Paper Makers' Safety Association, Toronto, Ont.

Erling Riis, Wausau Sulphate Fibre Co., Mosinee, Wis.

John F. McElgin, Carthage Sulphite Pulp & Paper Co., Carthage, N. Y.

Ira Wyman, Strathmore Paper Co., Mittineague, Mass.

Clarence E. Jackson, Consolidated Water Power and Paper Co., Grand Rapids, Wis.
 F. P. Young, Interlake Pulp & Paper Co., Appleton, Wis.
 M. J. Foster, Consolidated Water Power & Paper Co., Stevens Point, Wis.
 F. H. Eberhardt, Consolidated Water Power and Paper Co., Grand Rapids, Wis.

 A. T. Buckhout, American Writing Paper Co., Holyoke, Mass.
 Al. Kroes, Employers' Mutual Liability Ins. Co., Wausau, Wis.
 Nesta C. Edwards, Consultant Industrial Service Work, Chicago, Ill.
 R. B. Woolson, General Casualty & Surety Co., Detroit, Mich.
 Fred A. Feller, Employers' Mutual Liability Ins. Co., Milwaukee, Wis.
 W. S. Brown, General Casualty & Surety Co., Detroit, Mich.
 G. R. Huggins, Finch Pruyn Co., Inc., Glens Falls, N. Y.
 A. G. Richardson, Laurentide Co., Ltd., Grand Mere, Quebec.
 I. L. Lockney, Chief Safety Engineer, State Safety Board, Olympia, Wash.
 G. W. Dickson, Riordan Pulp & Paper Co., Hawkesbury, Ont.
 Robert M. Altman, Marathon Paper Mills Co., Wausau, Wis.
 S. F. Shattuck, Kimberly-Clark Co., Neenah, Wis.
 James L. Kerr, E. I. du Pont de Nemours & Co., Wilmington, Del.
 Wm. Powell, International Harvester Co., Chicago, Ill.
 Carl E. Gebhardt, Champion Coated Paper Co., Hamilton, Ont.
 M. G. Hoyman, Kimberly-Clark Co., Neenah, Wis.
 Virginia H. Evans, Kimberly-Clark Co., Neenah, Wis.
 Paul M. Bowen, Standard Accident Ins. Co., Detroit, Mich.
 O. F. Behm, Standard Accident Ins. Co., Detroit, Mich.
 E. S. Willis, Safety First Supply Co., Pittsburgh, Pa.

REPORT OF CHAIRMAN

CHAIRMAN COSTIGANE: In opening the sessions of the Paper and Pulp Section, it gives me great pleasure to extend to you all on behalf of the National Safety Council, a warm and sincere welcome. To those of you who have attended these conventions during the last two or three years I need say nothing of the benefits to be derived—the fact that you have come back is proof of a consciousness on your part that such conventions are of great value. To those of you who are here for the first time we hope that all you see and hear and all that you learn will so enthrall you that you will return home with such a glowing report that the companies you represent will realize they cannot afford to allow any future convention to pass without having a representative present. On behalf of the National Safety Council, it is my privilege to convey to you all a very hearty greeting.

Your Chairman during the last twelve months has kept in as close touch as possible with the activities of the section by attending whenever possible meetings of the Executive Committee of the Council. As soon as possible after the Congress last year at St. Louis, the chairmen of the

various committees were appointed and the detail work of the Section was entered upon with enthusiasm. The chairmen and members of the committees I desire to thank sincerely for their support and advice and also for the earnest way they have carried on the committee work. The reports of these committees will be submitted to the meeting later and you will have an opportunity of judging of the extent and excellence of the work done.

The Paper and Pulp industry of the United States and Canada is one of the largest, wealthiest, and most influential industries of the countries mentioned, and the Paper and Pulp Section of the National Safety Council should, therefore, take a correspondingly important place in the Council. Unfortunately this is not the case. What is the cause of this condition of affairs? Does the fault lie with us? We are all disciples in this humanitarian movement. Are we individually doing all we can to carry the gospel far afield? We all know of some one in the industry who has not come into the fold. Do we tackle such people in a determined but friendly way, and do not rest content until we have made a convert? Numerous letters have been sent out by the Council in connection with membership drives, with a certain amount of success, but far greater results can be obtained by interested members pointing out to friends who have not yet become members, the benefits, not only moral, but financial, to be derived therefrom.

If every one of us present today makes a resolution to secure at least one new member during the year, enthusiasm will develop which will soon place the Paper and Pulp Section in the position of importance in the Council which it should occupy.

I am sure the Executive Officers of the Section will have the coöperation and support of every member in bringing to a successful issue our program for increased membership.

We will now have the report of the Secretary. Mr. Milner.

REPORT OF THE SECRETARY

During the past year the membership of this section has been increased to one hundred eighty four. However, our membership has not increased to the extent it should have this year for this section has a very extensive field to work representing large and progressive industries.

I have been informed by the National Safety Council that they have appointed two assistant Field Secretaries, who will divide the territory, probably East of the Mississippi River, between them, and both of these men will be actually in the field all the time.

I would like to suggest that a mid-year meeting be held in some central location so as to enable the Chairman, Secretary and the Chairman of the various committees to get together to discuss various plans for their work. I am sure in this way we would be able to outline some very valuable ideas which would materially assist this section.

Respectfully submitted,

C. B. Milner, Secretary.

(On motion the report was adopted.)

CHAIRMAN COSTIGANE:—We should like to have the report of the Chairman of the Program Committee, Mr. Jackson.

REPORT OF PROGRAM COMMITTEE

MR. C. E. JACKSON: I have no written report. I do have, however, some voluminous correspondence in my files that will perhaps serve as a permanent monument to my efforts during the past year. My heart goes out in sympathy to the former chairmen of the various Program Committees that have acted in years gone by and I can more than appreciate the trials and tribulations under which they worked.

I am gratified, however, to say that the men that I have succeeded in placing upon this program are not only widely known but have the confidence of every member of this Section. I wrote about thirty letters, asking men if they could appear on the program. I extended no definite invitation, but I merely wanted to take an inventory of the situation. I received fourteen replies out of which there were four or five that were favorable and the men whom I did acquire are the ones I really wanted in the first place.

That brings to mind, three years ago I was invited to read a paper at a Congress, which was held at the Statler Hotel in Detroit. Being three years younger at that time and at my first meeting I felt a distinct honor had been given me. I feel now, however, that I was the last resort and the feeling I had for myself has diminished.

We should have at least seventy-five men in this room. Perhaps the reason we haven't seventy-five is that there isn't room, but next year we should, by all means, at least double our membership.

The absent ones don't realize that the ideas exchanged are valuable not only to themselves in their work, but valuable to the men whose work they are directing, and to those whose welfare and safety they have at heart. It has been shown by statistics that between 75 and 85 per cent of all accidents are due to personal carelessness of the workmen, so the Safety Engineer has rested on his oars somewhat and he has passed the buck to the workmen. In a discussion this morning at the "Round-Table" Session, it was contended that 75 to 85 per cent of all accidents are not due to the personal carelessness of the workmen, but are due primarily to the management.

If an accident is due to carelessness on the part of the workman, we might very legitimately ask ourselves, "Why is that workman careless? Isn't it because he was made careless by his own negligence?" So, I think any Safety Engineer or any person whose function it is in any industry to look after the lives of the workmen are neglecting their duty by not attending the Safety Congress if they can possibly come.

You know if you give me a dollar, you don't have the dollar any more, but if you give me an idea, you still have it. We can give things without losing them and we can take things without taking them away from anybody else. So, we may come to this meeting where there are sixty men present with one idea each, and go away sixty times as well educated in safety as we were when we came here.

This safety business is not a spasmodic proposition. It is continuous or there wouldn't be any results at all. This session is merely a breathing spell, an exchange of ideas so that we can go back to our work with renewed vigor and enthusiasm. I wish to urge the members here to follow out the Section's suggestions and not forget next year's Congress, and make an extreme effort to get others interested and get new members for the Council, because we must make a better showing than we have in the past.

(The report was accepted.)

CHAIRMAN COSTIGANE: In the absence of Mr. Phillips, Chairman of the Bulletin Committee, we will ask Mr. Altman, Chairman of the Safe Practices Committee, for the report of his committee:

REPORT OF SAFE PRACTICES COMMITTEE

R. M. ALTMAN: Immediately upon my appointment as Chairman of the Safe Practices Committee, I set about the task of selecting a working committee, and due to good fortune rather than good judgment on my part, I met with success. The members of the 1919 committee were workers and it is their energy, desire for coöperation, and willingness to work that has helped make my association with them this past year most pleasant and interesting.

The committee as originally chosen consisted of C. E. Jackson, Consolidated Water Power and Paper Company, of Grand Rapids, Wis., F. H. Rosebush, Nekoosa-Edwards Paper Company, of Port Edwards, Wis., Erling Riis, Wausau Sulphate Fibre Company, Wausau, Wis., Mr. Wood Champion Fibre Company, Canton, N. C., and your chairman. Due to the inability of Mr. Wood to attend meetings or to give us any other help, Mr. Eberhardt, of Grand Rapids, Wis., was selected to take his place.

The first meeting of this committee was held at the office of the Marathon Paper Mills Co. at Rothschild, Wis., March 24, 1919. Three weeks earlier I mailed to each, copies of outlines of the work to be covered so that when the committee met each member had an inkling of what was required. The outline was thoroughly discussed, and the various subjects to be covered were selected and assigned to members. The meeting was held in connection with the Wisconsin River Valley Readjustment Convention which was in session at Wausau. Since the subjects discussed at this convention were readjustment subjects most interesting to the safety worker, the committee members were well repaid for their time and trouble in coming to Wausau.

On April 4, lists of mills members of the National Safety Council, were furnished the committee and numerous letters were written requesting material for the proposed pamphlet, but with one or two exceptions these letters were not even answered.

On April 28, the Second Annual Industrial Conference was held at Milwaukee under the auspices of the Industrial Commission of Wisconsin, and your committee took this opportunity of meeting with the State's deputies, and safety engineers and thoroughly discussing safety problems in paper mills that had come to the notice of the deputies. The dis-

cated by a green cross. There are certain restrictions as to the use of the red cross, so it is well to be familiar with them before adopting this sign. Ordinary signs or notices giving such information as "Office," "Stores," "Exit," etc., may be carried out in white letters on a blue ground. These suggestions will serve to illustrate the basis on which a system of signs may be built up, and may be amplified to suit the conditions.

By adopting some such standards as these we are but carrying out the same idea as is used in advertising. Many a successful business is built up about a striking design or slogan. It is identified with the product and advertised in every magazine that you pick up. It makes no conscious effect on us when we see it, so we think, but when we need a certain article the advertisement of a certain brand immediately presents itself to our minds. Whatever be the psychology of this, let us apply it to our danger signs. Every day we may pass a red sign lettered in white. "Fire Hose" or "Hydrant." Now if our danger sign system is correct, the first thing you will do when you hear the fire alarm will be to "beat it" for that sign. The color or design of that sign was impressing itself on your sub-conscious mind every time you walked past it. So, I would say keep to standards, have a design or a color or both to express one idea.

SIGNS FOR PROTECTION OF EMPLOYER

There is another class of sign to be considered—the ones placed for the employer's protection. Take two examples, a railroad right-of-way is generally protected at crossings by a "No Trespassing" sign. Or again, there is a sign mounted on a certain machine "It is forbidden to oil this machine or to throw belts on or off while it is in motion." Now there always will be a certain group of venturesome citizens, and they are usually of an energetic disposition, who conclude that these signs are out of date and the methods recommended are too slow. They are willing to take a chance, generally realizing that they are taking the full responsibility on their own shoulders. Unless we are prepared to carry out the above signs to the letter, that is, fine or imprison trespassers on the railroad track, and discharge the man who oils his machine while it is running, might we not better put these signs in more truthful form? We might say "All persons walking on the railroad property do so entirely at their own risk." And the same thing might be addressed to the machine operator—he is doing it entirely at his own risk. He probably knows this when he sees the sign forbidding him oiling the machine while it is running. The question is: which sign will affect him most directly, to be forbidden to do a thing, or permitted to do it at his own peril. It is to be hoped that the discussion will bring out some opinions on this point.

SPECIAL "DANGER" SIGNS

Another group of danger signs are only displayed at certain times. When a man goes into a boiler for repairs he hangs a "Danger, Man in

Boiler" sign on the steam- and blow-off-valves. A lineman goes to work on a circuit protecting himself with a "Danger, Working on Line" sign hung on the open switch. This should be warning enough to fellow-employees of ordinary intelligence, but the protection may be made complete by locking the valve or switch with a padlock and chain.

A handy method of keeping such danger signs ready for immediate use is to have a pocket holding the sign set up at the point in question. When required, the sign is taken from the pocket and hung with a wire loop or hook on the valve wheel or switch handle. This is shown by accompanying slides.

When the hazard is great, and absolute security is demanded, as, for example, when men are charging acid towers, it is well, in addition to the danger sign, for the man in charge to lock the switch of the gas fan, and carry the key until the towers are again closed. A home-made lock is shown as applied to a Gen. Elec. K-20 switch.

As to the materials used for danger signs—it seldom pays to paint a few words on a piece of tin or on a board. Permanent signs, enamelled on steel plate, are a good investment. They can always be cleaned to look like new, and are more likely to attract attention than a faded, poorly lettered, home-made sign. Makers now carry signs in stock with almost any wording and in almost any language, so that it is seldom necessary to go to the expense of having special signs made up. For electrical work the fiber sign is preferable to the enamelled steel sign, as it is not liable to form a short if inadvertently placed across switch terminals.

Slide 1 shows an ordinary starting panel for a mill motor with a danger sign in bracket for use of men who may open switches.

(Showing Slide 2) That is the second position. The switch is open and the "Danger" sign is hung on the switch handle.

(Showing Slide 3) The K-20 type of switch in addition to which we put a small attachment or trigger that slides in behind the handle so that when the switch is open, the handle of the switch cannot be thrown in. The trigger is held in position by a padlock which locks the switch open when the men are charging the acid towers. This switch operates the gas fans. The motor is shut down and the switch is locked open in that position. The men who are charging the acid towers bring the key back with them and unlock the switch.

(Showing Slide 4) This shows our method of locking the blow-off valves on digester when men are working in the blow-pits. When the men go to work in the blow-pit they lock the blow-off valve, take the key into the blow-pit with them and it remains locked until they come out of the blow-pit again.

(Showing Slide 5) There is another application of the danger sign. The men were changing a cable on the elevator, the "Danger" was hung on the elevator gate.

CHAIRMAN COSTIGANE: We have all listened with great pleasure to Mr. Dickson's paper and as it is a subject that lends itself to a good discussion, you will now be given the opportunity.

I am sure some one present must have had experience in danger signs. Tells us of your experiences.

DISCUSSION

MR. JACKSON: We heard yesterday about industrial autocracy and we can perhaps apply that to safety work particularly in the matter of putting up signs. I agree that one outstanding fact is this: There are always a certain number of employees who either carelessly or maliciously disregard safety signs and it seems necessary for the company to make threats perhaps of a mild nature, or perhaps make a ruling that if certain regulations are disregarded employees will be discharged. I think, however, in putting up signs, instead of making them threatening, it would be better if we would substitute something like this: "If such and such a thing is done, you are not only endangering your life but lives of other members." I think that appeals to men more than that they will be discharged. It may also take away the desire of the young employees to see if they can do things perhaps of a malicious nature and get away with them. The sign will be a constant incentive to them to do the right thing, if we put it up to their own honor.

MR. A. KROES (Employers' Mutual Liability Insurance Company): A good point brought out here this morning in the nature of signs, is the steel enameled surface of the sign.

In my trips to mills I see signs of all descriptions, some even made of cardboard. These get dirty very easily, and torn down, so that steel enameled signs are more preferable.

They always look neat. Sometimes, of course, they get grimy and dirty and what Mr. Dickson said about cleaning them is very important. If the sign is neglected, you, as safety engineers, are also neglecting your work in the workman's estimation. So, to keep a sign clean is about the same thing as putting up a new sign.

CHAIRMAN COSTIGANE: I would like to take up one point that Mr. Jackson has already touched upon, the point of giving men the option of doing things at their own risk. As far as we in Ontario are concerned, that is not a solution of the problem because under the "Workman's Compensation Act" it is specifically stated that no matter when, where, or how a man is injured in the discharge of his duty, he is entitled to compensation.

If there is no further discussion, we will now take up the paper on "Sulphate and Sulphite Hazards" by Mr. Erling Riis.

MR. E. RIIS: I have been fortunate enough to be on Mr. Altman's Safe Practices Committee. Mr. Altman as a good leader assigned special duties to the different men on this Committee. I am a sulphate man, and he delegated to me to prepare the sulphate part of the pamphlet.

SULPHATE AND SULPHITE HAZARDS

ERLING RIIS, WAUSAU SULPHATE FIBRE COMPANY, MOSINEE, WIS.

The hazards in the sulphate and sulphite pulp mill are very similar although the principles on which the chemical process is based are exactly the reverse. We will therefore treat them together up to the point where

there really is a marked difference where the sulphate and sulphite hazards will be treated separately.

The logical way to treat the subject would be to follow the manufacturing process from the time the logs enter into your pulp yards until the pulp is delivered as a finished product.

THE PULPWOOD YARD

The place in the pulp mill that has the most accidents is the yard. This has its reason in the following two factors: First, there is a greater labor turnover in the yard than in the interior plant, consequently you are always employing men with less experience than you do in the rest of the mill; second, even in the best organized pulpwood yard there are certain hazards which it is practically impossible to overcome.

Pulpwood is unloaded from the cars either by cranes or by hand. The pulpwood which comes to the mill loaded on flat cars or gondolas is always held in place by means of car stakes which are wired together. Before the cars can be unloaded these wires have to be cut which always is more or less of a dangerous operation. Of course, patent car stakes have been introduced and are used to a great extent within the mill yards but very seldom used by the railroads. This has its reason not only in the fact that the safety movement has not boosted them sufficiently but also in the fact that the railroads claim they have a tendency to come loose and therefore are very dangerous on long traffic. The cutting of the ordinary stake and the clipping of the wire must therefore be mentioned as a great hazard.

We will not dwell on this subject here as it will be fully covered in the safe practices pamphlet which Mr. Altman will deliver in a few minutes.

If the wood is unloaded by hand it is generally because it has been shipped in box cars where cranes cannot be used. A runway must then be staged from the car to the pile. Men carry the logs and bolts and of course there is danger of stumbling when climbing the piles. In picking up the logs or bolts it is necessary to use hooks. As the work is very monotonous the attention of the workmen is quite frequently divided between their work and conversation. This leads to the two most common

TWO COMMON CAUSES OF ACCIDENTS

causes of accidents in unloading wood in this manner; where the hook, not being securely fastened into the log, slips out; or where the workman while jabbing the hook in the log hooks in a different direction and misses his log, the hook flies by it and generally hits him in the left knee or thigh or hits his fellow workman.

Many things have been done and many others suggested to minimize the accidents from these causes but the only suggestion that really has proved of great value is education. Education by direct contact with the men, by publication, by lectures, and last but not least by bulletin boards. The heavier logs, when being unloaded by hand, must be handled by two men, the lighter logs by one man; but whether the log is being carried by one or two men the carriers are always exposed to the danger of stumbling

while walking on the log piles. It is general practice to form terraces from the car to the piles most remote from the track so that the piles take the appearance of a stairway from the car and back. The safe practice, of course, is to lay the logs perpendicular to the tracks and if 4- or 8-foot lengths are used, there will be vertical air spaces every 4 or 8 feet from the first tier and back. If the men are very careful about piling the logs neatly there will be no danger of a man getting his foot down in these spaces but if the greatest care is not taken, here is a very common cause for a broken leg, or a sprained ankle.

Regardless of how strongly you impress upon the man who delivers your pulpwood that you will not accept 4- and 8-foot lengths in the same car, he is apt to ship you wood mixed in this way. As two 4-foot tiers will take up more space than can be covered by the length of one 8-foot log when the wood is mixed in this manner, it is plainly to be seen that here is another great danger for a man to get his foot caught.

If the wood comes in gondolas or on flat cars, it is generally unloaded by a crane. Presupposing that skillful men handle the crane, that the cables are always being watched, brake bands kept in good condition, buckets inspected for cracks, etc., the handling of cranes is always a dangerous operation and here as well as with unloading by hand the danger is multiplied when logs of various lengths come in the same car, because a longer log sticking out farther is apt to slip out of the bucket without being noticed by the man on the pile. Many an accident has been caused in this manner.

These same hazards which we have in unloading the wood, we also have in reloading it on cars from the yard. But in the pulpwood yard the car with the safety stake should be used exclusively not only because it is safe but because of the great financial saving affected in unloading the car at the sawmill platform.

SLASHER MILL

In the sawmill or slashing mill of a sulphate or sulphite factory the hazards were numerous but it is very interesting to see how in later years they have decreased, merely due to the fact that unguarded saws, carriages without railings, etc., are hardly ever to be found any more.

The wood rooms are of the most varied construction. The object of a wood room is always the same, i. e., to remove the bark from the wood and chip the wood into chips of the desired size. The chips are now screened, the screenings rechipped or conveyed to the boiler room for fuel.

There are three types of barkers: The knife barker which is operated either by hand or machinery, the periodic barking drum, and the continuous barking drum.

The knife barker operated by hand has led to many accidents although they are generally minor accidents such as the cutting off of the tips of fingers. The knife barker has been equipped with an attachment to revolve the logs while the bark is being removed which has minimized this danger and on some barkers in fact entirely removed it.

The continuous barking drum is operated in such a manner that the bolts come into one end of the revolving drum and out of the other. Some bolts, however, will not be completely barked and have to be returned by a special conveyor and re-fed in the drum. The danger of accidents is very small and the accidents generally result in a slight squeeze or bruise. If, however, a man should fall into the barking drum death is almost certain.

The periodic barker requires a hopper above the barking drum of a construction similar to a chip bin over a digester. This hopper is filled by means of a conveyor. The hazards here are smaller than with either of the other two methods of barking and as the barking drum stands still at the time it is being filled and the continuous barker is always rather small, seldom more than 8 ft. by 8 ft., the danger if a man should fall into the drum is not very great and the probabilities of falling in the drum are also very small.

The hazards on the chipper are mainly the jumping back of the bolts from the chipper spout. The operator should therefore have an opportunity to stand somewhat on the side of the spout while feeding the chipper. A shield of steel or 2-inch plank hung in front of the chipper in such a manner that it acts as baffle plate for these articles will fully protect the crew in the wood room. Most chippers are belt driven and have tight and loose pulleys or they are belted direct from an individual motor. However, in some mills we find them belted from the main drive shaft of the wood room without tight and loose pulleys so that when knives have to be changed in the chipper the whole wood room has to be shut down. When the disk has to be turned in order to change knives, the fly wheel of the steam engine driving the wood room must be turned in similar manner. This is a dangerous practice as there is always a danger of misunderstanding the signals and this has been the cause for many a lost finger or hand. Whichever arrangement a wood room has, there are always a good many conveyors and there have been numerous accidents due to men being caught in conveyors or being hit by bolts falling from the conveyors. These things should always be investigated. The switches, if the conveyors are motor driven, should be easily accessible so that any conveyor can be shut down on a moment's notice.

Where pulp is being made from slabs, it is customary to make the chips by means of a hog. The chute leading from the conveyor into this hog will always have a tendency to clog up. Great care should be taken that the men are instructed never to descend into the chute to unplug this while the hog is in motion. One very great hazard wherever a hog is being used is the danger of the disk exploding, especially where this is made of cast iron without wrought iron bands surrounding it.

THE CHIP BIN

From the wood room the chips are carried by means of conveyors to the chip bin from which they are put into the digesters. A properly constructed chip bin is not a dangerous place for a man to work. How-

ever, the majority of chip bins throughout the country are constructed in such a manner that a man has to go up into the chip bin in order to pick the chips loose to make them slide down into the digesters. There has been a case of a man losing his hold, going with the chips into the digester and being smothered to death. When chip bins are so constructed, steam pipes or compressed air pipes should lead into the chip bin to break down the arches of chips which form while filling the digester. This minimizes the danger to the man.

DIGESTING

The cooking process is somewhat different in the sulphate and sulphite digester and will therefore be handled separately.

1. *Sulphate Cooking:*

The sulphate digester is generally a small digester yielding from two to three tons of pulp. It may be a tumbling digester or stationary. It should always be welded seamless and not be riveted as no riveted digester will stand up under the strains of expansion and compression without commencing to leak and as the cooking pressure in the sulphate process generally is very high, 100 to 175 pounds, the liquor will invariably squirt out through the leaks and if anybody is hit by the liquor he will be severely burned. If the leak is very small a fine spray will come from a digester as a fog that can hardly be detected but the fine particles of liquor and steam will be flying around in the air and these particles are very injurious to the eyes.

As the liquor used in a sulphate process does not attack iron to any great extent, the digesters need no lining and do not offer much chance for explosion. Where tumbling digesters are used, the steam line enters the digester through the trunnions. There is then always a danger of this steam line breaking which is one of the greatest hazards in the digester room of a sulphate mill. The operating floor of the digester room should therefore have plenty of exits. If the boiler pressure is higher than the pressure allowed on the digester, a steam reducing valve should be placed on the high pressure steam line where this enters the digester room. There should also be all iron check valves on each branch of the steam line of the digesters and on the main line right behind the steam reducing valve preventing black liquor from backing out of the digester into the steam line and back to the boiler room.

Samples of the pulp have to be taken out of the digesters while this is under full pressure and in most mills this is done in a very primitive manner by blowing the pulp into a barrel or a box with some sacks or old paper mill felt wrapped around it. This seems to be traditional and few mills have been willing to install a cabinet with baffle plates, etc., into which their samples could be blown overcoming the danger of splashing liquor on the operator and wasting it on the floor. As this substance is very slippery there is always a danger of slipping on a concrete floor full of liquor and if a man falls in it he might be severely burned.

When a sulphate digester is to be blown into a diffuser, a system of signals is generally used between the digester man and the diffuser man so that the latter is aware of the fact that blowing is about to take place and he can take the necessary precautions. The digester man, however, should never blow until he has received the return signal to go ahead. Even with this precaution there is danger that the blow pipe is connected up to a wrong diffuser and the pulp is being blown into the diffuser which is in the process of being emptied with the result that the man on the bottom floor is badly burned.

2. Sulphite Cooking:

In the sulphite process the digesters are generally larger than in a sulphate mill, in fact five to ten times as large. The liquor used in this process releases the gases of sulphur dioxide which are very offensive and choking. The liquor should therefore not be filled into a sulphite digester from the top in the same manner as is used in the case of a sulphate mill but should, after the chips are in the digester, be pumped in from the bottom. Also here samples are taken as in the sulphate digester but with this difference that if the liquor splashes on a man's hand or clothing, it does not affect him. What does affect him however is the strong gas. The greatest danger in the digester room of a sulphite mill is the blowing of a digester. The valve might burst and the man operating the valve will be scalded. Remote control of the digester valve is recommended and where it is absolutely impossible to install this, a strong partition between the valve and the hand wheel of the valve should be installed. This danger is generally recognized by all sulphite men as the greatest danger in the sulphite mill and should be given due consideration by everybody in authority to improve this condition.

WET MACHINES, ETC.

After the stock has been washed in the blow pits or the diffusers it is handled in the same manner in both the sulphite and sulphate mills either over deckers, wet machines, or dry pulp machines. Pulp from the wet machines or dry pulp machines has to be trucked and as simple as this operation seems to be it is peculiar to note how many accidents occur during trucking. This, however, does not seem to result from any other cause than the fact that truckers very often are young men who have just commenced to work and still like to play and ride the trucks or they overload the trucks so badly that the loads tip over on them. The handling of wet machines must be considered as a rather safe operation while the dry pulp machines offer a few more dangers more similar to those on a slow running paper machine.

We have now covered the manufacture of the pulp throughout, starting with the logs, and will next turn our attention to the manufacture of cooking liquor.

LIQUOR MAKING

1. Sulphate:

The cooking liquor in the sulphate mill is a mixture of sodium hydroxide, sodium carbonate, and sodium sulphide. The liquor is originally

made in the causticizer room where the solution of sodium carbonate is causticized by means of quick lime. In putting the lime in the causticizer there is always danger of splashing and as the liquor besides being highly caustic also is extremely hot, these burns are very disagreeable. A bottle of acid acetic should always be kept on hand for immediate application which minimizes the danger.

The handling of lime is an exceptionally disagreeable job especially in hot weather and the lime bin should be well ventilated and the dust sucked right out. Even at that the lime dust in itself will always attack a man's skin. The men should therefore be instructed to have their jackets buttoned tightly around their waists, a muffler around their neck, and wear muzzles.

After the lime sludge has settled to the bottom of the causticizer, the clear liquor is drawn off by means of a siphon pipe and used directly in the digester.

The sulphate mills always recover their liquor. The process which takes place in the recovery is primarily a process of evaporation, secondarily purification and in the third place dissolving.

The first step of evaporation is with a vacuum evaporator such as the Swenson, Scott, or Webre evaporators with multiple effects. These evaporators have been known to explode and burn the operators severely. This is, however, something which happens very rarely. The main danger in the evaporator room of a sulphate mill is from the escaping gasses which have a tendency to injure the eyes. The sulphate men have never succeeded entirely in overcoming this danger but have in later years reduced it to a minimum by piping all condensed water into enclosed sewers outdoors. From vacuum evaporators the liquor passes to the disc evaporator which is nothing but a big pan in which are revolving large steel disc plates. The whole thing is entirely enclosed and really offers no danger to anybody.

From the disc evaporator the liquor runs into the rotary furnace. The dangers in the rotary furnace are the forming of rings of black ash within the rotary stopping the liquor from getting towards the front end while the heat from the smelting furnaces will have a tendency to ignite and melt the black ash which is in this end. When ultimately a ring breaks and the liquor runs into the molten soda ash in the rotary explosions are very apt to happen. When the liquor has passed through the rotary furnace it falls out on the floor in a dry state as black ash and the process of evaporation is completed. This black ash contains the sodium salts from the cooking liquor with the lignin from the wood. This is with salt cake shoveled into the smelting surface where, upon being ignited the lignin will burn and smelt the sodium salts which purified will drop into molten form as so-called melt down into the dissolving tanks, where it is dissolved and pumped into the causticizer room.

There are certain trade hazards connected with a smelting furnace. These are blast furnaces and the blast pipes have water cooled nozzles. At times these nozzles burn out and the water will run into the melt

and cause terrific explosions. Furthermore, these smelting furnaces at times have a tendency to clog up at the bottom so that all the melt which is being made in the furnace does not run out but accumulates. If the operator does not detect this immediately a good deal of melt will have a chance to accumulate before he gets a chance to run a steel rod in through the opening and unplug same. When he does this the melt will rush out with terrific force and in striking the solution of liquor in the dissolving tank, there will be minor explosions with sparks flying in all directions. It is then up to the man to be on the lookout so that he can get out of the way before the melt has had time to reach the tank. It appears plainly that the main thing is to have well-trained and experienced men to do this work. It is also recommended that in each soda recovery there should only be one man designated to handle the water valves for the blow nozzles so that these never run dry and give chances for explosions.

2. Sulphite:

In the sulphite mills the cooking liquor is very seldom totally recovered but new liquor is always being made. Cooking liquor is here calcium bisulphite. Some mills use pyrites but the most commonly used is sulphur. This is burned in sulphur ovens either stationary or rotary to sulphur dioxide gas. With the drafts properly manipulated there is very little chance of any gas here escaping so the dangers are very small indeed. This gas passes through a cooling plant. During the operation of this cooling plant there is very little danger of accidents happening to the men due to the nature of the process. When the plant is shut down, however, and the cooling system has to be cleaned the gasses really are very strong and men have been known to be overcome. These gasses pass through high towers filled with limestone meeting a stream of water or weak acid which absorb the gasses making the acid. The sulphite mill operated by the tower system must have at least two towers, a weak and a strong liquor tower. The strong liquor tower must be tightly sealed at the top while the weak liquor tower may be left open at the top as long as there is a steam jet to take care of the SO_2 and CO_2 gasses, this tower being filled with limestone. The greatest danger here is that in unsealing a tower for filling it with limestone, a man might make a mistake of unsealing the strong liquor tower which will expose him to the danger of being overcome by gas. As these towers are very high and limestone has to be carried to the top, they are always equipped with an elevator. These should always be furnished with a locking device so that nobody can lower the elevator while the operator is on top.

When the acid has been made in the towers it is generally weak, a test of approximately 3 to 3½ per cent. It is, however, before being used in the digesters, strengthened in a series of tanks by means of the gas-off coming from the digesters. Here as through the rest of the acid plant there is really only one danger and that is the escaping of gas.

CHAIRMAN COSTIGANE: Are there any questions any one would like to put to Mr. Riis on this interesting subject?

MR. ALTMAN: If there are no questions, I would like to ask the members out of curiosity, how many representatives we have here of the sulphate process besides the Mosinee people?

CHAIRMAN COSTIGANE: I see no hand. I guess that answers your question.

It occurs to me that in the sulphite process there is considerable danger at the top of the tower by men being overcome by acid fumes; I would like very much for any one present to give us their experience, and tell how the danger is overcome. I am sure some one has had such experience.

DISCUSSION

MR. DICKSON: Mr. Chairman, we have had some experience along that line in the top of the tower in the acid process. When the gas fans are in operation and the gas is circulated through the towers, if the top of the tower is unsealed and more limestone is put in there certainly is a very great chance for an accident. In fact, we have had our lesson.

One scheme is to have an emergency switch extended to the top of the tower so that you can throw off the gas fan from that point. That can be done by having an additional switch with a long distance control, either with light chains attached to it, or light wire cables, or it can be done by running a loop from the low voltage release of the controller so that when you open the switch at the top of the tower, it shuts down the tower by throwing the low voltage release.

GAS MASKS

CHAIRMAN COSTIGANE: There is a point that occurs to me, regarding which Mr. Riis might give us a little more information. He mentioned incidentally gas masks. Will you tell us, Mr. Riis, what type of gas masks you found most efficient?

MR. RIIS: I think Mr. Altman knows more about that than I do. He has some new masks at the Marathon Paper Mills.

MR. ALTMAN: We have the regular army gas masks, secured from the Ordnance Department. The chemists in the mill have been able to fill the canisters to offset either the sulphurous gas or the chlorine. In other words, we have three or four canisters for each gas mask, so that whenever a millwright goes either in the digester or in cleaning up the storage acid gas tanks, he has a proper mask to use.

MR. RIIS: Are those masks with or without mouth pieces?

MR. ALTMAN: They are the regular army gas masks, with mouth-piece.

CHAIRMAN COSTIGANE: I will now ask Mr. Altman for particulars on the Safe Practices pamphlet with a view to opening a discussion on this topic.

"Safe Practices" is interesting and vital to every one of us connected with this industry and I am sure that there should be a great number of good suggestions come from this meeting today. These suggestions I am asking for with a very conscious idea of the work that has been put through by the Safe Practices Committee because I sat on the same Committee the year previous and it is no light job. I am sure the Safe

Practices Committee will welcome any suggestions that can be included in the pamphlet.

SAFE PRACTICES PAMPHLET

MR. ALTMAN: [After reading the prepared copy of the pamphlet which will be issued as the second in the series of Safe Practices pamphlets for the Paper and Pulp Section] While I don't pretend to answer all questions, I hope with the help of the men who helped me get this up, we will be able to answer most questions. I have a number of photographs here on display for any one wishing to see them.

MR. JACKSON: Has anybody here had experience in connection with reversing of the reels when the machines run more than say 475 or 500 feet per minute, and what difficulties were encountered in introducing the system? Can you reverse the direction of the reel on a fast speed and get the same results?

MR. ALTMAN: We haven't done it on our machines though it is one of the Industrial Commission's orders. Some of us in Wisconsin find that it is impracticable to comply with two or three of these orders.

MR. JACKSON: It is easy enough to change the mechanism but it is a question of how to handle the paper after you have the machine changed over—to feed the paper on the reel.

MR. ALTMAN: There are a number of things that machine hands will complain of at the time, but later on they are perfectly willing to try out. You haven't had a chance to try it yet. You haven't changed those drives.

MR. KROES: In Paragraph 1, you speak of annealing chains. Have you any method to suggest in which way to anneal them?

You remember in former years there was quite a discussion of how to anneal chains. Wouldn't it be well to add suggestions on this?

MR. ALTMAN: We want to put in additions and if any criticisms are necessary we are perfectly willing to make them. It is for that purpose that we put this upon the program.

MR. KROES: I would think that only additions are needed—like annealing of chains. Mr. Lockney is here. Maybe he can give us some information.

MR. I. L. LOCKNEY (Chief Safety Engineer, State Safety Board, Olympia, Wash.): I would suggest that if you want to insert anything in the copy at all, you say that if any one wishes to get information regarding the correct methods, or most improved methods of annealing chains to consult the National Safety Council because they have a lot of information regarding that for the purpose of distribution.

MR. S. F. SHATTUCK (Kimberly-Clark Company): Paragraph 9, relating to unloading lime. I just got the information the other day through Miss Edwards that one mill in the East, in unloading lime, had a barrel of vaseline handy and the men were encouraged to smear themselves with vaseline and that offered an absolute protection against the injurious effect.

Page 5, Paragraph 11 on the stacking of pulp: I imagine most mills have had accidents from this cause. We have signs printed to hang on the

face of a pile of pulp. It gives instructions on how the stack is taken down, so when a man goes there he has his instructions and because these instructions are there they can't help but be seen; we have also a warning sign that we make a reduction of 15 per cent in compensation if those instructions are not followed.

CHAIRMAN COSTIGANE: Do you have power to do that?

MR. SHATTUCK: We have investigated that and find we are within the state law. That is perfectly true in Wisconsin, the Commission will reduce the compensation 15 per cent.

CHAIRMAN COSTIGANE: I understand that does apply to the compensation law in some of the states, but it does not apply to the compensation law in Canada. There can be no reduction in compensation there.

MR. ALTMAN: The sign simply giving instructions on taking the pile down should be valuable, although it may not be absolutely fool-proof. It would give the workmen a warning of the danger in unloading, even if you do not add the reduction in compensation. However, the reduction would be a very good thing to add where allowed.

CHAIRMAN COSTIGANE: Do you have these signs in English, or do you use other languages also?

MR. SHATTUCK: We have always used only one language, English.

CHAIRMAN COSTIGANE: The whole idea of submitting this pamphlet to the meeting is with a view of having a keen discussion and to get ideas which may be better than those in the pamphlet before having the pamphlet printed.

We want to guard against the possibility of suggesting to mills methods which may already have been put out of date by some better methods. We want to know the best methods being used in the talks so that they can be embodied in this pamphlet.

MR. KROES: What do you do about the old wire laying around the place? This forms tripping hazards.

MR. ALTMAN: As far as we are concerned, we have a man with a team going around and picking up the old wire and selling it. I think it sells for about the cost of gathering.

MR. KROES: In addition to your splendid paper, could something be said about elevators?

MR. ALTMAN: That is just the point, we don't want to digress into various subjects such as elevators and annealing, because we have a pamphlet already issued by the National Safety Council on "Elevators." When anything is to be said in regard to elevators we can refer to this pamphlet.

CHAIRMAN COSTIGANE: Instead of repeating what is already in print it is intended to refer to existing publications covering that subject.

MR. E. C. GILDENZOFF (York Haven Paper Company): Page 9, regarding Chip Bins: Our sulphite digester room and blow-pit room is all one room which isn't the case in the more modern mills. We had two men up in the chip rooms and the men blowing off the digesters neglected to close the manhole door and also to close the doors of the wet room.

Of course, when the blow-off lines were used the gases got all through the digester room and up into the chip room.

The two men working there were shifting chips from one bin to another. A warning was given them by means of a bell that we have installed. When that bell was rung they knew what it was of course, but they thought there was no danger from gas up there. One got out all right but the other was overcome with gas, because there was no way of getting down out of the chip bin except down the stairway through the digester room. We have since made an exit, on each end of the monitor on top of the digester room and have placed a platform from the end of the monitor out to the digester room with a safety ladder attachment.

We have built a platform from the end of each monitor. In our case, a wood room is on one end and an acid room on the other, so one doesn't have to go down through the digester room to get out. In more modern mills, in case a blow-pit is left open it would make no difference because they have several blow-pit rooms. But in our case suppose a gas valve or gas pipe should burst while men are up there, the same condition arises; they now have no trouble in getting out.

CHAIRMAN COSTIGANE: Have you a platform at the point from which the ladder starts so that a man who is overcome by the gas can rest in the open air?

MR. GILDENZOPF: Yes.

MR. G. A. UMBERHAM (Northern Paper Mills): On account of a recent accident at our mill, when a helper was caught between a bottom felt and a crush roll the Safety Committee attempted to overcome the crush roll. I was wondering if any one had any suggestions on this point. There doesn't seem to be any way to do without this crush roll.

MR. ALTMAN: Is it a frequent practice to get underneath to scrape the roll?

MR. UMBERHAM: Some would say, "Shut the machinery down." But generally we do not shut a machine down so the fellow crawls under and scrapes off the roll.

MR. RIIS: When the pulp or paper stock slips off a felt like that, it is generally due to the felt not containing the right amount of moisture. Some mills have tried to overcome it by a hot-air blast on to the felt. Probably some one else can give additional information as to what experience they have had with paper sticking on the felt, and what results they get from the hot-air blast.

MR. UMBERHAM: Bear in mind that this was a new felt, just put on.

MR. RIIS: Well, then wash your felts better.

MR. KROES: On Page 7, the Slasher Mill: In the sentence, "If the walk is inclined, the flooring should have cleats to prevent slipping." Nothing is said here about the railing or toe-board.

MR. ALTMAN: It is well known that any of these walks should have toe-boards and railings, but cleats may not have been considered. Reference to toe-boards and railings will be made in the pamphlet.

MR. ALTMAN: In connection with the dryers and the danger of burns, I remember when burns used to be a very frequent occurrence and I have

been wondering if any one here is using the Sheahan rope carrier over the dryer.

MR. F. J. Mc ELGIN (Carthage Sulphite Pulp and Paper Company, Carthage, N. Y.): I have seen several used.

MR. ALTMAN: I think it is one of the best devices we have. It not only eliminates danger so far as burns are concerned but it is a sure carrier.

MR. A. G. RICHARDSON (Laurentide Company, Limited): We have six of these in operation, and have found them very satisfactory.

MR. GILDENZOFF: Will they work on heavy paper as well?

MR. ALTMAN: I recommended that to the Cornell Wood-Board. They are manufacturing a board like beaver board. I haven't heard whether they have installed one or not. I have asked them to install one for trial and if it worked to let me know, so I could give this information to any one who has a board machine.

We have a cylinder machine, also, used as a board machine. The material on our Fourdrinier is sometimes sixty-five and seventy pound stock and it carries that satisfactorily.

MR. GILDENZOFF: I understand it saves the paper from following the dryers around. How does it work in the case that the paper breaks?

MR. ALTMAN: It depends where it breaks. If it started on the first dryer, it would continue right along like a new sheet should.

MR. Mc ELGIN: Will there be a hazard in spearing it off the dryers?

MR. ALTMAN: I have never seen that occur. The arrangements of the ropes would make that impossible.

MR. Mc ELGIN: I have seen it carried all the way up to the dryers in the hanging paper. If it breaks before it gets on the dryers, it drops there.

MR. RUS: There is nothing that will stop the paper from winding around the dryer at times and I thought you meant, Mr. Gildenzoff, would the rope be in the way of getting it out. I can tell you it is not. It is right behind the frame and does not interfere with that part of it.

MR. JACKSON: Isn't your machine at the Mosinee carrying a device to take the paper through the calender?

MR. RUS: Not through the calender.

MR. LOCKNEY: There is one point not well taken. You advise painting obstructions white so that people will not run into them. It is a good thing to make black stripes around them. A white background can't be seen. If you have black stripes, they bring it out stronger.

MR. KROES: If you mention gas masks, wouldn't it be well to mention the kind you use?

MR. ALTMAN: We once used a Burrel, and it isn't as satisfactory as the regular army gas mask. A list was sent in by the Ordnance Department and a gas mask was selected.

SECRETARY JACKSON: The Mine Safety Appliance Company are making a mask similar to the army gas mask without the mouthpiece and they furnish canisters for different gases and different acids.

MR. ALTMAN: I don't think too much good can be said about these army masks, especially for cleaning acid storage tanks.

MR. GILDENZOFF: We have a mask on the order of a diving helmet but

I can't remember where we got it. A hose connected to a blower is attached. You can't give a man too much air. After a certain determined pressure is reached, a valve opens and permits the excess air to escape. We have had very good success with it.

The other day our acid pump went wrong. This pump is located in a very close place, little if any air gets to it. A man wearing the mask repaired the pump and was not troubled with the sulphurous gas surrounding him. This gas, as you know, quickly burns the eyes.

MR. ALTMAN: Your hose has to be long enough to serve every purpose. That is the reason your canister mask is the better, because the man carried the entire equipment with him all the time.

Adjournment.

FRIDAY MORNING SESSION

CHAIRMAN COSTIGANE: The Chairman of the Bulletin Committee, Mr. Phillips, is not able to be present and I have just received a letter from him this morning enclosing his report. I will ask the Secretary to read this report.

REPORT OF BULLETIN COMMITTEE

Your committee, composed of Mr. G. W. Dickson, Rlordon Pulp and Paper Company, Hawkesbury, Canada, Mr. Harry Ballou, Manasha Paper Company, Ladysmith, Wis., Mr. A. G. Richardson, Laurentide Paper Company, Grand Mere, Quebec, and myself being so widely separated geographically, were unable to get together in conference.

Since the meeting of the Section one year ago, however, bulletins have been issued regularly by the National Safety Council, every two weeks and distributed to the members of the Paper and Pulp Section. These bulletins covered the various hazards of the Paper and Pulp Industry, and the most of them were illustrated by photographs and cartoons.

We have, however, found it no easy task to procure suitable material, that is ideas for good live safety pictures illustrating the hazards peculiar to the Paper and Pulp industry.

Your Committee feels very grateful to Mr. Fullum of the International Paper Company for the excellent cartoons which he sent us.

As some of you know, especially those who have served on the Bulletin Committee what a problem it is to get up bulletin material, bearing specifically on hazards existing in the Paper and Pulp industry, I suggest for the benefit of the Committee which shall be appointed at this conference for the ensuing year, that every member of the Paper and Pulp Section be requested by the Bulletin Committee of the National Safety Council, to submit a list of danger points and bulletin subjects, covering the important and hazardous operations peculiar to the Paper and Pulp Industry, and a list of these suggestions to be sent to the Chairman of the Bulletin Committee of this section.

Respectfully submitted,

G. W. PHILLIPS, Chairman.

(On motion the report was accepted.)

REPORT OF NOMINATING COMMITTEE

CHAIRMAN COSTIGANE: I will now ask Mr. Riis, Chairman of the Nominating Committee, to make their report.

MR. RIIS: The Nominating Committee has met and decided on the following gentlemen to fill the positions of Chairman, Vice-Chairman, and Secretary:

Chairman, R. M. Altman, Marathon Paper Mills.

Vice-Chairman, G. W. Dickson, Riordan Pulp & Paper Company.

Secretary, N. S. Stone, Wausau Sulphate Fibre Company.

(These men were elected.)

CHAIRMAN COSTIGANE: I have pleasure indeed in vacating the chair in favor of Mr. Altman. I have known Mr. Altman for some time and I know the affairs of this Section will be in first class hands. He will not suffer under the same drawback as I did, having been so far away. I think that one of the points made by Mr. Riis is very good that the nucleus of the organization should be fairly close together, so that the officers can meet together from time to time, have a heart to heart talk, make suggestions and proposals, meet with other people and get all the information possible to make the meeting of this Section of the National Safety Council as interesting and effective as possible.

MR. ALTMAN: I want to thank you gentlemen for the honor that has been bestowed upon me. I don't feel that I should thank the Nominating Committee. (Laughter.) I know exactly what the proposition is but I will say this, seeing that I am to take the part, I will do the best I can and trust that every one present here today will cooperate with me in making the meeting next year as successful, if not more successful than it has been in the past.

There is just one point that I wish all you members would bear in mind before you leave today, that is to work for a larger representation next year. Let's see if we can't have one of the big sectional meetings here, instead of a meeting of thirty, forty or fifty members. I heard yesterday the Paper and Pulp Section has about 184 members and that our efforts should be to increase the membership. I think the better policy, is to see that all the 184 members send representatives to the next congress.

CHAIRMAN COSTIGANE: We will now ask Mr. H. H. Matthieson to give us his paper.

SOME UNSAFE PRACTICES IN PAPER MILLS—THEIR COST IN MONEY AND MEN

H. H. MATTHIESON, SAFETY DIRECTOR, CROWN WILLAMETTE PAPER COMPANY,
PORTLAND, ORE.

Unsafe practices or, if you please, "sins" against safety and common sense, are quite as prevalent in Pulp and Paper Mills as in any other branch of industry and, perhaps due to the varied and peculiar conditions

under which these operations are carried on, certain of these practices are even more prevalent in our Industry than in any other. In considering this subject, one's mind at once begins to enumerate a list of forbidden unsafe practices, with which we are all quite familiar and against which we are all continually combatting. Such unsafe practices, for the most part, produce 80 per cent of the accidents with which the Industry is charged.

In passing, however, permit me to mention a few common, every-day, unsafe practices which are continually coming to our attention, and more particularly prevalent in the Paper Industry, such, for example, as the wearing of loose, ragged clothing while working around machinery; not using safeguards or leaving them out of place; poor housekeeping; horse-play and scuffling; throwing pulp balls; burrowing "tunnels" in wood piles; not wearing goggles while doing work which is dangerous to the eyes; dropping wood and other materials on the hands or feet. In studying these several unsafe practices, let us re-classify them, listing them, if you please, under some physical or mental condition of the individual himself,—such as "Thoughtlessness," "Inattention," "Indifference," "Ignorance," and "Chance-taking,"—and to ascertain, if possible, what may be done through safety training or other means, really to reach the individual workman and, by neutralizing or eradicating these causes, get at the root of our accidents and thus eliminate them. These "sins" against safety and common-sense are the underlying elements of all unsafe practices, and unsafe practices are the primary cause of accidents.

You will note, in passing, that in the various causes listed above, I have omitted the term "Carelessness." This was intentional. I do not like the word "Carelessness" as so often applied to the causes of accidents because of its misuse. It so easily covers such a wide field that we are all apt to use it inadvertently, and the mere statement that "Carelessness" is the cause of a certain accident covers the whole field, leaving no further investigation or inquiry necessary. The mere fact that a man is "Careless" closes the chapter. Carelessness is merely an excuse, or rather a very handy way of shifting responsibility. I fear that this word is too freely used and that, were it not so commonly used, and a little more effort and thought put toward carefully investigating the real causes of accidents, we might discover more ways and means of avoiding many of the accidents which we now have. A thorough investigation will often reveal some other cause than "Carelessness" and often one which will suggest a remedy. The word "Carelessness" should be used with greater caution and reserve than is commonly done.

With your kind permission, let us now endeavor to develop this subject in a broader and more comprehensive sense,—to cover, in a more general way, some of the unsafe practices occurring in industry as a whole,—and discover, if possible, some efficient, effective, and practical methods of dealing with these unsafe practices and causes of accidents, with a view to making them so unpopular as to reduce their frequency and thus reduce our accidents to a minimum. We will thus divert our attention somewhat and study this subject of unsafe practices from the angle of complete elimination thereof through safety training.

Let us first assume, therefore, an ideal condition in our plants all over the country; that is, a complete practical safeguarding of all dangerous parts and machinery. In fact, safety work, in so far as safeguards are concerned, because of the passage of the various state laws, because of regulations laid down by insurance companies, and because of public sentiment, the safeguarding of dangerous parts has been so featured that now the unguarded plant is becoming the exception rather than the rule, and everybody, everywhere, is demanding safe working places and safe working conditions. The problem, then, of really getting results in accident-prevention work, has shifted from the safeguarding problem to that problem sometimes called "Human Engineering," which tends to enlist the interest, help, and coöperation of the individual workman, his family, and the whole community by instilling into their lives and make-up what is known as the "Safety Spirit."

DEVELOP PUBLIC SAFETY SPIRIT

The Spirit of Safety must become popularized and be made a public proposition. The Safety Spirit should be so propagated that the Public as a whole, will know it, believe in it, and consider it in the same way and the same class as they consider the Red Cross, Pure Milk, Public Health, or any other necessary proposition. Safety must be made a part of the public make-up and so thoroughly known and believed in as to be a part of every man's, woman's, and child's inner life. This, to my mind, is the Safety Man's mission; it is his opportunity; it is 80 per cent of the battle of really getting results and eliminating accidents.

The question then arises: how to develop this Safety Spirit and how actually to sell it to the workmen and the people at large.

Much has been written and much study given to the subject of how to sell safety to the management, to the superintendent, and to the foreman,—but, how about the workman? He, too, has an individuality and must be sold, too, for he, after all, is the man we really have to reach.

Do not misunderstand me—that I am under-estimating the necessity of selling safety to the "big boss"; such is not the case, but I often feel that many of us think, when this is done, the whole problem is solved. Gaining the backing and coöperation of the higher-ups is only the first important stepping stone. There is an old saying "You can lead a horse to water but you cannot make him drink unless he wants to" and it sometimes appears that we are trying to make the workman "take" this safety propaganda whether he wants to or not. He has an individuality: he must be "sold" Safety, just the same as any one else.

The Safety Committee is recognized by all, as the very best means of enlivening this interest in the workman. It is a well-known fact in the political world that in order to get one's interest in a political proposition: you must give him something to do; therefore the practical politician arranges to enlist the services of as many voters as possible by placing them on committees and giving them a part to perform. The workmen likewise should be given something to do in the safety world. He does not want this Safety Spirit forced upon him from "above." He wants

to be a part of it; he wants to help prevent accidents in his plant and community; he wants to consider it his business, too.

Do not try to sell safety to your man as a charity or a welfare proposition, nor to make it appear wholly for his individual benefit. Aside from the humanitarian standpoint there is also a commercial and patriotic standpoint to Safety. He is aware of this fact just as well as you are, so do not try to deceive him; be frank and truthful with him. He appreciates frankness and only in this way can you gain his confidence and get his loyal support.

We must extend this work even beyond the Safety Committees and endeavor, through personal contact and personal interest, through the foreman, through the plant publications, through safety motion pictures, through bulletins, through daily messages on a conspicuous blackboard, and through the schools, the churches, the newspapers and local ordinances, to get this man, his wife, and his children, to consider the safety idea as an integral part of their lives and to consider it as such, rather than a mere necessity or philosophy which is forced upon him by the foreman or by the Company for which he is working.

I sometimes think that we have been trying to bombard the workman's position with reference to safety for so long a time, along the same lines and methods, that a change of attack and new ideas and new methods are necessary now to make greater progress. More attention must be given to developing safety as a community proposition as outlined above and in the endeavor to interest the individual citizen, his children, his wife, and his whole family in habits of safe practices. Safety is everybody's problem; it is everybody's business.

COST OF ACCIDENTS--IN MEN

Aside from considering the humanitarian side of accident prevention work, that is, the pain, suffering, and misery caused thereby, accidents are an economic and commercial loss, not alone to the individual and to industry, but also, to the nation. The great war has taught us that the man power of a nation is without doubt, the greatest asset it has, and anything which tends to deplete or undermine a nation's man power is striking at the very heart of that Nation. Unsafe practices and their resulting accidents are annually injuring, maiming, and killing thousands of our people. Accident prevention activities then, become a patriotic proposition which can best be demonstrated by the following statistics:

During the great war just closed, the United States' fatality loss in France amounted to 56,227 men killed. During these same nineteen months, while we were engaged in war, back here at home, many miles away from the bloody conflict, something over 126,000 men, women, and children met violent deaths in the United States because of accidents; that is on an average, 220 accidental deaths every day for the nineteen months we were in the war, nearly two and a half times as many people killed by accidents as by war.

During these same nineteen months, over 200,000 of our soldiers were

injured or wounded in battle. At the same time at home over 2,000,000 of our people were injured by accidents (though not fatally) but so badly injured that they were disabled for four weeks or longer; ten times as many injured at home by accident as were disabled by war. This, Gentlemen, is the cost of unsafe practices and their resultant accidents in man-power of this country of ours. This is a loss which I am positive that systematic, thorough safety work can reduce many fold, in fact, some of the most optimistic of us believe it can be reduced thereby, over 75 per cent as approximately this proportion of our accidents are directly traceable to unsafe practices and acts in our every-day life.

An accident should be considered as a terrible calamity, and we should learn to look at unsafe practices and their resultant accidents as one of the Nation's great curses, and to endeavor to imprint in our minds and on the minds of the people of this Nation, the awfulness of the crime of "Carelessness."

THE COST OF ACCIDENTS—IN MONEY

In addition to the great cost of accidents in man-power, accidents also cost money. This is the commercial side of safety. I once had occasion, in a plant where I was employed, to ascertain the average cost of each time-lost accident occurring in that plant. From the records we ascertained the number of accidents occurring over a certain period of time, comprising all classes of accidents, including fatalities; we first compiled the compensation payments, funeral expenses, and other expenses connected with these accidents (not including the medical cost nor the loss of wages). We allowed an estimated cost of \$30.00 per man for replacing the injured men with new men, which, by the way, is a very conservative estimate; compiling these figures, we found that 292 accidents covering this period, cost our industry \$46,758.35, or an average of \$160.14 for each and every lost-time accident occurring during that period. This was the average cost per lost-time accident to the industry only; in addition to this, we estimated a total loss of \$22,708.00 in wages lost, because of these 292 accidents, over and above what the compensation of that State allowed for such injuries, and a like amount for the medical care of these 292 injured men. Taking the sum total of all these items into consideration, the cost of these 292 accidents amounted to \$92,174.35 or an average total cost of each accident, amounting to \$315.66. This sum, Gentlemen, was the average total cost of each lost-time accident to that particular industry and the community at large. These figures may perhaps vary somewhat for the various industries, the various state laws, and the particular experience of each individual industry, but when the cost of your accidents is calculated on this basis, the figures will astound you.

Taking, for example, the above average cost as the cost of each disabling accident, to Society and to Industry, and considering the millions of accidents which occur in the United States every year, the greater majority of which might be eliminated by proper safety training; the wastage, the total cost and the loss occasioned thereby, if saved, would retire our National debt in a comparatively short time.

I may have wandered somewhat from my original subject, but when we stop to consider that the unsafe practices enumerated above are in a measure, the cause of 80 per cent of this outlay of human life and enormous cost in men and in money, we realize perhaps more than ever before, the great opportunity which is afforded us in endeavoring to spread the Safety Spirit to all, thus not only performing a humanitarian duty but a patriotic and an economic one as well. Safety should be handled just as we handle the production end of industry,—as a good sound business proposition. It should be given a dignified place as an indispensable part of an efficient organization. Do this and we will succeed; go at it half-heartedly and we will fail.

As a result of these efforts,—namely, to make Safety a by-word of every man, woman, and child in the Nation, permit me to paint before you, a picture in words, showing the contrast between the old conditions of a few years ago, the "Plant of Yesterday," and the new ideals of the future, the "Plant of Tomorrow":

In the Plant of Yesterday, there was little or no thought given to accident prevention work; safety ideas were ridiculed and considered lightly, as a joke, or passed by with scorn. Unsafe practices and chance-taking were prevalent and quite permissible,—passed by with a shrug of the shoulders—and accidents were considered a necessity to industry and to production. Men were killed, maimed, and injured, for lack of proper safeguards and proper safety training. We seemed to be in the business of producing widows, orphans, cripples, and suffering. The ambulance was a frequent visitor at the front gate to haul away the poor unfortunates whose broken bodies in many cases were cast out on the scrap heap of humanity as a by-product of industry.

But a new era has dawned on the horizon; some one had a vision that accidents were unnecessary to production, that they were a humanitarian and an economic waste, and that they could be entirely eliminated by proper safeguards and safety training,—a vision which was put into practical effect; thus, the Plant of Yesterday fades into the Plant of Tomorrow:

In the Plant of Tomorrow we shall know nothing of industrial accidents, for every plant will be completely and practically safeguarded; unsafe practices, chance-taking, and carelessness become so unpopular as to be looked upon with scorn by all and be considered as criminal acts; every person in industry, from the President to the humblest employee, will be imbued with the Safety Spirit, and safe practices, safe thoughts, and safe acts will have become a habit with all, and all will have come to believe that the safety way of performing work is the best way. In this plant, through frequent Safety Committee meetings, the employer and the employee will "get together" and become acquainted with each other and find that each is human, that each is "his brother's keeper," and that each is not such a bad fellow after all, and, all working together, hand in hand, will ultimately win the battle for Industrial Democracy.

That, Gentlemen, is our opportunity; that, is the ultimate goal of Safety.

CHAIRMAN COSTIGANE: Would any one present like to ask Mr. Matthieson any questions on his paper? His paper covers a very broad subject and should lend itself to an animated discussion.

DISCUSSION

MR. DICKSON: I would like to ask Mr. Matthieson in referring to the safe practices as more of the spirit and education, if it has been his experience, or if it is possible to commence that safety education in the homes or in the schools, and if he is able to give us any information about that?

MR. MATTHIESON: I might answer that question from a personal experience I had in my safety work in various localities. We have been trying to bombard the man for so long and from different angles, I believe that the new way is through the home. I am using moving pictures, sending circular letters to the homes so that the home folks will be brought to the realization that safety is their business.

I well remember an experience I recently had. We got certain safety films from the National Safety Council. I got in touch with the School Board and told them what I proposed to do; they called the Superintendent and told him to close the schools and send all the children to the free moving picture show. We had 2,000 little folks from all grades to the high school. We showed them safety pictures and talked to them on safety.

I told the boys and girls we were trying to make the mill safe and have no accidents, but that my job was too big and asked if they all wanted to be Safety Scouts and help me. They all held up their hands.

Next day a man came to me in the mill and said, "What was this stuff you told the children yesterday in the moving picture show?" Well, I didn't know what was coming. But this man said, "Well, my boy told me last night, and the little fellow crawled up in my lap, and he said, 'There's a Safety-first man down there at the show this afternoon and I want you to go tonight and see the pictures. He told me about the mill. It is quite dangerous and men get hurt quite often and, Daddy, I got to thinkin' what would happen to me and sister and mother if something happened to you. And, Daddy, I want you to be careful for my sake.'"

Then this man said to me, "Matthieson, that little boy's talk did me more good than all the preaching in a year."

MR. RUS: You mention that tunnels were being made in piles and pulp balls were thrown, etc. Do you mean that there is more horse-playing and more unsafe practices going on in the pulp and paper industry than in any other industry?

MR. MATTHIESON: I might answer that, by yes and no. Yes, because in the paper and pulp industry there are so many various lines of work carried on. We start right out in the woods in the logging operation; we have railroading; we have the sawing operations; we have transportation and we then have the various operations in the manufacture of paper.

Around the paper mill proper, as you know, a great many operators have a lot of time on their hands and they seem to have to do something

with their reserve energy. That is what brings up the horse-play, throwing pulp balls, etc., but take the industry as a whole, I think we can safely say there is a greater variety of sins against safety committed in that industry than in any other.

MR. I. WYMAN (Strathmore Paper Company): Mr. Matthieson brought up the question of old clothing and also falling objects. What has been done in the past to remedy that question? Ninety per cent of our accidents last year were caused by falling objects and by falls.

MR. MATTHIESON: The first question about ragged clothing. We made it so unpopular to work around the machine with ragged clothing that the men will not permit one of the fellows to wear ragged clothes.

Falling objects—that is a personal question. The only thing you can get, in my opinion, to counteract this influence, is through very intensive safety training. You can't safeguard a man's toes very well, to resist a block of wood, or his fingers against knocks, but if you will analyze those accidents there is a personal influence we must get at and try to make the safety idea so prevalent in the plant that men talk about it among themselves.

Last night I was taking a car ride out on the East side to visit some friends, and our car collided with a Ford. It broke up the street-car pretty badly but didn't hurt the Ford. I went out to size up the situation and found no one was hurt, so I started to go back to the car and it was so congested at the door of the car I couldn't get in. A fellow on the car said, "Don't you know this is Safety week? What are you trying to do, allowing the people to get on that way?"

If you could get every man in the mill to exhibit the spirit of the man on the car, you are going to get at and stop the men throwing things on hands and feet.

CHAIRMAN COSTIGANE: This is an interesting topic, gentlemen, I am sure there are some other questions you would like to put.

I would like to ask Mr. Matthieson if he has dealt with the term "carelessness" as far as accidents are concerned. I think the trend of his remarks is to show that the word "carelessness" should not be used. It might not be entirely eliminated but the use of the word might be largely decreased.

I have quite a lot of statistics to make up in connection with the paper and pulp mills of Ontario. I would like to ask Mr. Matthieson as to what term in making up those statistics I may use in exchange for the word "carelessness."

MR. MATTHIESON: I don't want you to think I mean entirely to eliminate the use of the word for I used it in my paper but I do think we use it far too freely.

I once made inspections for an insurance company and would go to a plant and have a talk with the superintendent or manager and almost invariably he would say something like this, "We don't have many accidents here. They are all caused by carelessness."

I would say to him, "What do you mean by carelessness?"

He would start to tell me how a man was injured in a certain way. I would say, "That man wasn't careless. You're at fault."

"No, he was just careless."

I would say, "You never did anything to train him, or to change the conditions."

You see that man said the word "carelessness," closed the deal, relieved himself of all blame and put the full burden on the injured man.

I have made statistics. The very first thing I did was to sit down and take all the accidents and study them carefully. I resolved that I would use the word "carelessness" just as carefully as I could and I studied every one of them over and I want to tell you it took a lot of investigation to get around that resolution. I was forced to charge five or six to carelessness.

I sometimes found on the face of the report "Carelessness" written very boldly, but if I took plenty of time to study out each one of those accidents, I found some other very good cause for the accident.

I find that if an accident is caused by chance taking, there's our chance for educational work. If it is caused by indifference, there's a chance for educational work, but if it is caused by carelessness, there is no chance to do anything.

CHAIRMAN COSTIGANE: I thank you. I'm convinced that we shall still have use for the word, not in a loose way, but a little more specifically and possibly with a little more information behind it.

We will now close the discussion on this paper and pass to the paper by Mr. S. F. Shattuck of the Kimberly-Clark Company, Neenah, Wisconsin, on "How to Make Safety Meetings Interesting."

MR. SHATTUCK: I am expecting some back-fire on this because we, not knowing we were exceptional at all, have made at least a temporary change in our safety policy which for the time being eliminates the usual type of Safety Committee. This was done since I promised to give this paper back in early July.

HOW TO MAKE SAFETY MEETINGS INTERESTING

S. F. SHATTUCK, KIMBERLY-CLARK COMPANY, NEENAH, WIS.

This subject, regardless of the form of safety organization employed, is vital to an enthusiastic and successful safety program. A dead or uninteresting safety meeting sends a thinking man back to his work with a case of brain fog and such a mental attitude tends to anything but safety.

At the present time, in our organization, we are varying our safety program by the abandonment of the usual type of safety committee and centering all responsibility on the foreman of each shift or department. This plan contemplates periodic meetings of foremen instead of the former elected or appointed safety committee. It was at a meeting of foremen that this plan was suggested and evolved. The sentiment was strongly voiced that the safety of a department is "up to" the foreman, and our

comparative results since July 15, when this new order of things went into effect, have abundantly justified the change.

FOREMEN ASSUMED RESPONSIBILITY

This incident and its results point the way to the secret of interest in safety or safety meetings. Our foremen have taken the initiative, have assumed a responsibility, and are now proving up by lowering a previous record. Pride in, and record of achievement are vital factors in maintaining interest in safety meetings or any safety program.

Along with this must go a system for providing each foreman with his record of achievement in comparison with other foremen. We have hit upon the simple psychology of giving each foreman each week a record of man days elapsed since the last accident within his jurisdiction. In addition, this record goes onto the desk of every officer of the company and proper publicity is given to this fact. The reaction on both sides is wholesome and the effect upon the safety record has been the constant widening of clean spots.

The sporting element is also a valuable factor if properly utilized. We have pulled off almost every conceivable form of safety contest between our several mills and departments and the relative standings are, of course, features of the safety meetings.

To bring before a safety meeting all possible new safety ideas in tangible form helps to fix interest. For instance, when one of our mechanics developed a foot brake for two-wheeled trucks, we had this device demonstrated, prior to adoption, before several of our safety committees. For years, in paper and pulp mills, men have stumbled over the handles of four-wheel trucks. Recently, one of our men invented a handle that, as soon as it touches the floor, will spring back to an upright position. This idea was demonstrated before the plant safety committee and is now under observation.

A campaign for clean toilets, elimination of horse play, and new schemes for advertising the safety program have their logical inception and periodic boosts in meetings of safety committees.

INVITE INJURED MEN TO MEET WITH PLANT SAFETY COMMITTEE

We have tried the idea of inviting injured men to meet with a plant safety committee. If these men are treated with just the right tact and consideration, this practice is good and lends a genuine interest to the meeting. Much depends upon the attitude and personality of the chairmen. If the injured man can be placed at his ease and robbed of the embarrassment which may well attend an invitation, which amounts to a summons, to appear before the committee, much good may result through getting the first-hand views of the injured man, and causing him to feel that his misfortune is being used to a constructive end. But if such meetings are conducted along inquisitorial lines, the sooner this feature is dropped the better for the good of all concerned.

For some years we have had, as the executive center of our safety pro-

gram, a monthly or quarterly meeting of department heads—men whose chief concern is production. The source of sustained interest in such a group, granting that all are well sold on the safety proposition, is definite responsibility. Recommendations of the Safety Director are here brought up for approval or disapproval. If approved, responsibility for execution is placed and an accounting is subsequently called for. Interest with men of this type is the kind of interest that obtains in the carrying forward of any necessary or important phase of manufacture. Furthermore, the steady backing of such a group may be counted upon provided the Safety Director conducts his program in a sane, cooperative spirit.

SAFETY MASS MEETING

In our Company, we hold annually a Safety Mass Meeting to which wives and sweethearts are welcome, and nothing is left undone to make them "regular" events. Advance advertising, free transportation, admission by ticket, and plenty of delegated responsibility are the advance agents of an interesting meeting. Such meetings, staged on right lines, may do much to develop a family feeling through an organization and it is this feeling that industry is so sadly in need of these days.

For the "family reunion" of our Fox River Valley mills this year, we secured the new chapel of Lawrence College, seating approximately 1,800 people. This auditorium contains a magnificent pipe organ and we engaged the services of the best organist in the state for an organ recital to precede our regular program. Then followed a community sing, which was a joy forever. The volume and quality of the singing was the surprise of the meeting. Most folks like to sing when they are not embarrassed by the sound of their own voice and few influences weld a large body of people into oneness of feeling like song, properly conducted and heartily entered into.

A simple and impressive feature of our program was an idea, presumably borrowed, as are most of our good ideas, from some good friend in the safety game, namely, "A Procession of the Blind Man and His Friends." A blind man is led onto the stage by a little child; behind him follow at intervals a dozen varieties of cripples. When all have reached the far end of the stage, they turn their backs to the audience and upon the back of each cripple is a placard, "I was careless"—"I didn't think"—"I forgot"—"I didn't know it was loaded", etc. Any safety committee can readily find willing "victims" for such a stunt and a point of contact with an industrial audience is instantly established. We have always tried on these occasions to have one or more addresses by men capable of getting home with their messages. The homlier the message and the more simple the mode of address, the better.

Thus far, the movie has closed every program, and even though everybody is now well "fed up" on movies, a good safety film never fails to hold its own. At such mass meetings, any new phase of the safety program or anything akin to it may be touched upon with good grace. For instance, when dentistry was about to be instituted in our mills, we took occasion to give one of our company dentists a place on the program and

there is little question that the smoothness and enthusiasm with which this service moved off had its roots in the favorable impression given at the safety meeting.

Our mass meetings are invariably held on a Sunday afternoon, a proper time for such a gathering. It has also seemed to us appropriate to invite a local pastor or priest to open the session with prayer.

To summarize, I would say that our experience has made clear seven factors making for sustained interest in safety meetings:

FACTORS MAKING FOR SUSTAINED INTEREST IN SAFETY MEETINGS

1. Develop a personal and group pride and initiative.
2. Provide foremen and groups with comparative records of accomplishment.
3. Utilize the sporting element.
4. Bring into the meeting as much tangible illustrative material as possible.
5. Make the committees development centers for new ideas.
6. Conduct meetings in a business-like manner and localize responsibility.
7. Occasionally inject the inspirational element to maintain the tone of the organization.

DISCUSSION

CHAIRMAN COSTIGANE: Are there any questions?

MR. JAMES L. KERR (E. I. du Pont de Nemours & Company): I want to know if I understood you correctly. Have your safety committees been abandoned?

MR. SHATTUCK: Yes, temporarily. We will go back to the other, but we wanted to get a change of atmosphere, a change of outlook and wanted to make the foremen feel the responsibility more.

MR. KERR: We have also come to the conclusion that a safety committee does not get to the right point in safety work. Our foremen are the men we wanted to get at and make them responsible for their own department. By putting the work in the safety committee's hands, we took away from the foremen part of that responsibility.

In another plant, we utilized a safety committee in this way. We had a foremen's committee and a safety committee go around and make their inspection. The superintendent utilized the recommendations of the safety committee to impress on the foremen that they should have found those hazards themselves. In this way we have to get the foremen to watch out for safety in their own department.

MR. SHATTUCK: That method of procedure contemplates a Foremen's Club of the Safety Committee.

CHAIRMAN COSTIGANE: Are there any further questions?

MR. SHATTUCK: Mr. Hoyman, our new Safety Director, is here and has brought a chart that we have placed near the time clocks.

MR. M. G. HOYMAN (Kimberly-Clark Company): The chart is placed on a solid background and we move those flags every day. In some places

we use the name of the foreman or the name of the room. We try to place the chart where all men have to pass it and they watch it closely. The way to find out is to slip a red flag when there was no accident. Not only the foremen watch but the men are very anxious to see that no red flag is posted against their department.

We also get out a weekly bulletin and post it on the bulletin boards. We attach a great deal of importance to the bulletin boards and have them placed in each department. Our weekly accident record gives not only the name of the department, but the name of the foreman and shows how many men there are under them, how many accidents occurred during the week, the percentage, and how each accident occurred. I go around, talk to the foreman when an accident occurs, get the foreman's explanation of how it happened as well as the man's and see if he cannot suggest some way to eliminate a like happening in the future. I find the foremen are much interested.

The foremen are keen men and so far this plan has proven very successful because accidents have been decreased about 65 per cent in the last three months. The large drop may be due partly to luck but I have given the foremen the credit. I credit them with good records and don't dwell too much on the bad ones. I find the foreman is like any other man, he likes a pat on the back and it is working out fine.

MR. DICKSON: One more word about the foremen's meeting. The foremen as a rule are pretty hard men to get hold of. The foremen were here before the safety engineers and I think have a certain sense of resentment, feeling that the safety men are to a certain extent undermining their authority. Some foremen are a little suspicious that perhaps they are getting knocked, but if you can get them to understand what you are striving for, you will get good support and you will get their confidence.

MR. MATTHIESON: How to make safety committees interesting? I think that is a question each one of you here, perhaps every safety man in the land, works overtime on—to find out ways and means to make safety meetings interesting.

I know you will agree with me that the safety committee meeting is the most important, and vital organization we have in safety and the thing we have to get at is not to make safety the safety man's business, and the superintendent's business, but everybody's business. In order to do that you have to give everybody something to do, advertising it that everybody in that plant is on a safety committee.

I have stopped asking for suggestions in safety committee meetings. You will waste too much time telling about the way a nail is put in the top of the sulphite department. Though it may sound a little bit radical, I think it is better not to waste a lot of time in committee meetings on minor suggestions but get right down to studying ways and means of preventing accidents and the suggestions will take care of themselves.

I once heard of a young pastor talking to one of his parishioners. He had just come out of college and he said, "It's easy to get up and preach. I just get up there and open my mouth and talk." The old man said, "Well, your sermons sound like it."

Too often we go into a safety committee meeting and the safety man is

trying to do it all. I tell the fellow the reason I am fat is because I let the other fellow do the work. When you get somebody else to do something for Safety, you are accomplishing something. I know the minute when I get a man to do something for Safety, I've got him. If I can get a man to turn down a nail without being told to do it, he is on my side of the fence. That is what your safety meetings are for. You can't do it by preaching. You can't do it by asking for a few suggestions. You want to get right down to brass tacks and study ways and means for preventing accidents.

I have found in foremen's meetings, it is better for me to sit in the background. I let the foremen do the work and let the fellows handle their own safety committee meetings and let them think they are doing it all. At our Workmen's Committee, I generally preside at the first two or three meetings. Our meetings run for three months. I pick out one man among them to preside. You want to get a man who can talk. I have seen some men who can talk in a group but put him up in a meeting and he can't, but get a man who can preside at a workman's meeting and you will have the best safety committee meeting you ever had. Give the men something to do. Appoint a sub-committee in that meeting to inspect the plant and bring back a report. Get the fellows to do something.

I might mention a little incident. We appointed a new committee the first of the year in one of our mills. I prevailed upon the Superintendent to start the thing off. We appointed an old man to preside. Everybody liked the old gentleman and he was just the ideal man to preside. He liked to do it so well, he kept on coming to preside. He liked the job. He called the roll one night and he said, "Mr. Secretary, how many men are supposed to be in this meeting?" I said, "Thirty." We counted and found there were thirty-three.

We asked one fellow why he was there and he said, "I am on the night shift and just thought I would come over an hour earlier this afternoon."

We asked another fellow why he was there and he said, "I am on the midnight shift—the grave-yard shift—but I liked that committee so well that I just came in here."

Another said, "I'm not on duty now but I felt I was still on the Safety Committee."

I think those meetings were interesting or those three men wouldn't have come on their own time without being invited.

MR. ALTMAN: There is one more little point that I think is worth while mentioning in the foremen and safety committee meetings. How to get into the Safety game the foreman who thinks he knows it all and is not pliable enough to take interest in a new game like Safety.

I have one man in mind we have in our mill, who has been in the business for twenty-four years—finishing foreman. We couldn't go out and tell him anything in regard to certain safety essentials that were necessary because he had been in the business for twenty-four years and he knew how to run the safety room. It is the usual thing in paper mills especially, when a man in charge of one department not to really get in touch with other foremen of other departments and see what is being done. They are in their own department the entire day and when they

get through they are ready to go home and not think of the matters in their department until the next morning.

I had the opportunity of getting this man in the safety meeting and he saw from the various talks of the other foremen that they were interested in the safety work. It was wonderful to have seen the change in the four or five meetings he attended until now I find that he is dreading an accident in his department, for the reason that he doesn't want his department to stand out as the department that has many accidents. He did have them but he doesn't have many now because he is looking after his department more carefully.

This is a matter that doesn't apply so much to those mills where the safety work has been going on for some time, but more especially to those starting out on it.

MR. RUS: This is a very important thing and I have been waiting for somebody to touch upon the subject of how many should constitute a workman's committee. Mr. Matthieson mentioned thirty.

I would like to have that point brought out a little clearer. How many ought there to be on a safety committee? How many departments are represented when you have thirty representatives, and how many have others found as a good number for a safety committee? The number constituting a safety committee is a very important factor and I would like to have some more light on it.

MR. MATTHIESON: I may differ from some of you on my opinion of a safety committee. I believe a safety committee is a safety school and if I can get a bunch of men, one from each department, perhaps two from the large departments, to meet, I will have thirty men and at the end of the year I will have four times thirty who will be on the job for Safety to eliminate accidents.

In order to do that you have to get every man of every nationality in your plant fully conversant with the safety proposition. You can't reach a man very well if you have four or five men on a committee. Give me a man from every department. When I mentioned the number of thirty in that particular mill, we had two men out of a saw-mill of about 1,000 employees, one from every shift of the pulp mill and went right through the plant taking one man from each department. We had eight machines in that mill and a man from each machine. We had a representative from the office, a representative from the hotel. Every department in that mill was represented in the safety committee.

We have a safety school also. We are studying how to eliminate accidents. I am not the teacher, those men are the teachers. I tell them when they graduate from the safety school, every one is a safety instructor.

CHAIRMAN COSTIGANE: We have consumed the time for discussion of this paper and will now pass on to a paper entitled, "Poster Talk" by Al Kroes, Employers' Mutual Liability Insurance Company, Wausau, Wisconsin.

POSTER TALK ON SAFETY

AL KROES, SAFETY ENGINEER, EMPLOYERS' MUTUAL LIABILITY INSURANCE COMPANY, OF WAUSAU, WIS.

I am exceedingly glad of this opportunity to discuss with you the important subject of safety. Of course, the very best I can do in the time allotted, is to handle this on the skip-stop plan. Indeed I can only present to you in part the method used by our company to get close to the men, and I may say at the outset that I never lacked an audience or never failed to get the strictest attention. And while these words are not directed to you, it is still possible to pick up a seed here and there which I hope you may take home with you and plant in some fertile corner of your mill.

Gatherings of this kind are and always have been the national stepping stones on the stream of safety and the National Safety Council deserves great praise for their policy of engineering these better every year. What can do more for all-around efficiency than for a number of paper-mill superintendents of different states, to come together in brotherly fashion and exchange ideas on their chosen profession? The younger men are rubbing elbows with the veterans, gaining valuable knowledge, and the older fellow gets some up-to-the-minute stuff from the newly appointed, and from that crucible the real facts come to all of you.

I am intensely interested in this work of reducing the horrible toll of accidents everywhere throughout our beloved country. For some years back I have come to the conclusion, that after all is said and done, the most important cog in the whole safety movement is "to get close to the men." Now these six words and what they imply seem simple enough, but mind you, they constitute "some job," big enough and worthy enough for the best man in your midst.

Speaking to men of qualified leadership, men of authority, I came here to tell you, that to get close to the men is distinctly *your job*. Furthermore the responsibility of accidents in your mill is yours. Don't try to shift the burden, don't pass the buck. It's yours, and without your coöperation the safety movement becomes a dead issue.

Army officers are held to strict accountability for the safety of their men; a captain of a ship feels responsible for the comfort and lives entrusted to his care; a railroad engineer with keen eye is watching the signals by day or in the dead of night. He feels keenly that upon him depend the lives of his passengers and crew. Why then, my friends, should a superintendent neglect his men and their comfort, not to mention the resulting horror of a home destroyed.

That, my friends, is the heritage of being a leader of men; and this splendid Congress is to be congratulated, for including in their various discussions the great worth-while subject of safety in paper mills, in separate sessions.

Superintendents or safety engineers must be safety enthusiasts and I am sure they will be, if they tackle this safety movement from the right angle.

adding happiness to the home of your fellow workers. For every man with red blood and a normal heartbeat, will do the safe thing for home and mother and for the kiddies who are waiting by the gate to welcome Daddy, when the day's work is done.

And right there, my friends, you are reaping your reward. All of you curse the accident after it happens. I know that your heart is in the right place—like the engineer on the speeding train and the captain of the great ocean liner you will feel the great responsibility in caring for the men in your charge.

And in conclusion I will say that I am not blind to the shortcomings of these workmen—In the daily panorama of shop life the utter indifference to safety of most of them is amazing. But still, deep in men's hearts lies the desire to do right. To awaken that spirit and steer it in the channels of safety is your, almost sacred duty.

MR. E. S. WILLIS (Safety First Supply Company, Pittsburgh, Pennsylvania): After hearing Mr. Kroes' speech, I would like to ask that a rising vote of thanks be given Mr. Kroes.

MR. ALTMAN: We are very much indebted to Mr. Kroes today. I take great pleasure indeed in expressing to Mr. Kroes the appreciation of this meeting.

(A rising vote of thanks was given Mr. Kroes.)

CHAIRMAN COSTIGANE: The discussion is now open on Mr. Kroes' paper and I hope it will be as vigorous as his own presentation of the subject.

DISCUSSION

MR. JACKSON: I would like to ask Mr. Kroes just what has been his experience in presenting illustrations. We discussed that last year and there was quite a difference of opinion. Some thought that the gruesome illustrations had a better effect on the average workman.

GRUESOME BULLETINS

MR. KROES: That is another part of my work, to make bulletins, and we have made a lot of them of various kinds. Some real scarecrows in the line of blood-poisoning but in some plants the managers don't want them up. That is a personal feeling. Some don't like to have them on the bulletin boards.

I am a sort of a detective. I like to ask the men what they think. One fellow said, "That's a mighty good thing. These guys don't know enough to go to the first aid. They ought to be tied to a chair and made look at them for two hours."

Another fellow said, "They're all right but we don't want them up there too long."

A very gruesome picture of a blood-poisoned hand or any other part of the body is repulsive but if you can't bring it home to the fellow in any other way, let him walk past that for a while.

I think the opinion of most of the men I have talk to was that they would just as soon have them there. Most of the managers, if they don't have any personal feeling in the matter, don't care.

I had one man say, "My men will look at that stuff, and the first thing you know they will have it."

So, I think it is a matter of education, but I don't like too many of the terrible ones myself. Does that answer the question?

MR. JACKSON: By individual detective work you might find in the shop, from the men themselves an idea of what they like or don't like.

I remember the National Safety Council had a bulletin not long ago, showing an arm, something like the one you showed us, but it was a horrible picture. I think that particular one was not well executed. It looked like the arm was afire. That was really a horrible thing. While I have got all respect for the National Safety Council, still if they make posters too terrible I think they are taboo.

MR. RYAN: I would like to ask what you think about certain of the Council's bulletins that I have torn up immediately. One that I thought would antagonize more than it would do any good, was the bulletin of Mars standing behind capital and Labor and Capital says, "Good morning, sir, I thought you wore a club," and Labor says, "Good morning, sir, I thought you wore a silk hat."

In my mind, such things would tend to create discontent and antagonize, consequently we did not put up those bulletins and there have been others which have come from the Department of Labor which we did not put up. I would like to hear what the rest of the men think about these bulletins. If they think they are worth having or not.

MR. JACKSON: I will confess that I use about one-third of the bulletins that I receive. It might be because these bulletins are not all of them applicable to our particular industry, it might be because I think some are not very well gotten up. I think you have to study the character of your men. Certain industries have a certain type of men and the bulletins might not do good but do harm.

We receive bulletins from the National Safety Council, and we have received bulletins from the government, Department of Labor, for the last eight months periodically but I haven't used one of them, and the reason has been it seemed that those bulletins appealed to a class of men who perhaps are more ignorant than the ordinary. They seemed to appeal to his sense of loyalty and assume that he wasn't loyal, and while it might be true that they would appeal to other classes of men, I didn't use them at all. You have to study the help you have in the shop and make it apply if you can.

MR. WILLIS: Are there any of the men here who give their safety committees, or the men in the plant, a chance to pass on these bulletins as to which ones should go up?

CHAIRMAN COSTIGANE: Speaking for the mills in Ontario, I don't think there are any such privileges extended to the men, though it may be through the safety committees. The usual practice there is for the bulletins to be handed to the safety committee, discussed and the best ones put on the bulletin board. I don't know if that is the general practice or not.

MR. KROES: This is not the bulletin party but so long as we are speaking on bulletins, I want to say too many of them hang around in the

office. I am not saying this as especially complimentary to Mr. Shattuck, but in an organization like theirs or in any other well-organized mill I know of, those things do not happen. The bulletins get to the right place, to the safety engineer, or the man in the office who opens the mail distributes them where they belong.

In so many mills, it is left to the judgment of the office mail opener. If they don't look good to him—zing! Into the waste-basket they go! There is a point that should be eliminated. Call the office mail opener's attention to the fact that they are valuable.

The safety committee is not always the committee that might have the balance of judging power, but I believe if you get to the safety engineer, or the safety man and let him judge, he will find the right place.

CHAIRMAN COSTIGANE: In using a general term for the safety committees, I have in mind the plan we have adopted in Ontario. The safety committee is divided into departmental committees, and each department is responsible for its accidents. The chairmen of each of these departmental committees are members automatically of a central committee which represents the whole of that plant. On that central committee there are also representatives appointed by the management so that such a committee is perfectly able to judge as to the nature of the bulletins and which are the proper bulletins to distribute through the factory, because of the viewpoints given from both the management and the direct representation of the employees.

Are there any other questions, gentlemen?

MR. KROES: Just one more minute because I am going to that Bulletin Luncheon. I have a bulletin here that I would like to have your opinion on. Some years ago in the Judge magazine I saw a little picture of a man kicking himself. I read the picture and being somewhat of a cartoonist, I drew it on a piece of cardboard and had a cut made and used it on a bulletin (showing the bulletin). We had some vigorous kicks from a fellow and he tore the bulletins up in disgust. He said we proposed to make his bulletin board a comic supplement and that we needn't send any more. I want to have your opinion on that as to whether a bulletin of that kind is offensive. I would trust your judgment more than I would this fellow's.

Here is another one of a different nature. I thought after that something must happen to balance this up. (Shows bulletin.)

The oil-can with the oil dripping down, and the safety man. (Reading from the bulletin.) "Two of a kind. The shop oiler keeping the machinery in fighting trim. When he stops oiling, the equipment goes to pieces and production stops. The safety man supplies the oil for the safety movement. When he stops oiling, accidents will occur and you may be the goat. Stand by these men. They are mighty factors in your shop. When both do their duty everything will go smoothly. You are interested in that kind of oil. It is far better than having an oil well with some fancy name."

I did that to counteract the "kick" from the "self-kicker". I just wanted to know if that fellow was warranted in writing such a letter. One fellow said, "That's the stuff. I wish I had a model of it." And others

say, "That's all right." This is just an incident. I really wanted to get your opinion.

If any of you gentlemen want some of those bulletins we would be pleased to send them to you, whether you belong to the company or not.

MR. ALTMAN: I know the time Mr. Kroes came out to our mill, we had a noon talk. When the time approached for one o'clock, our General Manager happened to be in at the meeting and he sent word not to have the whistle blown until Mr. Kroes was through talking.

MR. RUS: There is one thing I think we all here ought to do before we part and that is to thank Mr. Jackson for the program he was able to get up. Mr. Altman yesterday, Mr. Kroes today, Mr. Shattuck, Mr. Matthieson, and others have proven that a better program could not have been gotten up and I think we all ought to offer Mr. Jackson our hearty thanks.

MR. JACKSON: I would like to add another vote of thanks and recognition to Mr. Costigane. I think that I can infer from the correspondence I have had from him that he has had his mind on this Section for the entire past year and his efforts have been sincere and have been productive of results. I move that we extend to Mr. Costigane a vote of appreciation for his work.

MR. KROES: I want to amend that motion by a standing vote of thanks to Mr. Costigane.

(A rising vote of thanks was given Mr. Costigane.)

CHAIRMAN COSTIGANE: I appreciate, very much indeed, the kindly feelings you have expressed in that motion. I may say that the work of this Section has not been a task, not by any means. It has been a pleasure. It has taken a little time. Perhaps I have not been able to devote as much time to it as I should have done to make it even more efficient than what it has been during the last twelve months, and I am sure with the change of officers, the executive officers being closer together, there will be even greater interest in our convention next year. I am looking forward to a bumper gathering at our next Congress.

I hope that every gentleman here today will make it a point to come back next year. By so doing, your motion of thanks will take practical form that will appeal very strongly to me. Thank you very much for this expression of appreciation.

We have completed our program and if there is nothing else, a motion for adjournment is in order.

Adjournment.

Public Safety Section

October 3 and 4, 1919

C. M. TALBERT, Chairman

Director, Department of Streets and Sewers, St. Louis, Mo.

J. H. HARVEY, Vice-Chairman

The Bracken Company, Kansas City, Mo.

DR. WILLIAM BURGESS, Secretary

—Chicago

FRIDAY MORNING SESSION

THE election of officers for the ensuing year was the first order of business, and the following officers were elected:

Chairman, C. M. Talbert, Director, Department of Streets and Sewers, St. Louis, Mo.—reëlected.

Vice-Chairman, J. H. Harvey, The Bracken Company, Kansas City, Mo.—reëlected.

Secretary, Carl L. Smith.

CHAIRMAN TALBERT: In the absence of Dr. Wm. Burgess, our Secretary, I will ask Dr. C. B. Scott to read the Secretary's report.

SECRETARY'S REPORT

The following brief paper is offered as observations which the office of secretary seemed to suggest.

The value of the safety movement in industrial service can hardly be over-estimated. But thus far the problem of public safety remains untouched except for two or three notable examples and experiments.

If life is of more value than material resources the fact that more than 50,000 deaths occur annually in the United States from accidental causes is one of the most appalling of the records of government mortality statistics.

And yet that the recklessness and irresponsible carelessness and in-

difference which result in such loss is amenable to education and regulation has been established.

Remarkable gains were shown in the Safety Week conducted by the National Safety Council at Rochester in 1917 and at St. Louis last year.

I was for 4½ years executive secretary of the Public Safety Commission of Chicago. In one year we showed a reduction of 464 coroner's cases of death by accident. We had four definite departments of service.

(1) *A Complaint Department* which served as a clearing house for reports of dangerous conditions, such as speeding, lawless driving, broken tracks and sidewalks, street obstructions, unprotected cellarways and coal holes, defective crossings, broken signs, gates, doorways, stairways, streets or slippery hazards of any kind, unguarded street repairs, inefficient or careless elevator service, overcrowding exits or other provision in public buildings. Thousands of such complaints came to us.

(2) *An Investigation Department* for inquiry into dangerous points and conditions of street and railway crossings, public buildings, factories, bathing places, school zones, etc.

(3) *Educational Department*. This work was carried on by campaigns in schools, clubs and churches, and by printed bulletins, danger signs, slogans, etc.

(4) *Legislation and Law Enforcement*; cooperating for legal enactments and with all departments of civic authority—of police, fire, health.

The financial support must come from a public educated to feel responsibility for its own interests. In Chicago a county appropriation was made annually for three years in support of its work. But this appropriation in course of time involved certain elements of patronage.

In Chicago there is a body of good men now planning an organization to be supported by public subscription and which will, I think, embrace the lines of service suggested here.

CHAIRMAN TALBERT: I will now ask Mr. Frederick S. Crum, Chairman of the Statistical Committee, to submit his report. Following is the report:

REPORT OF THE STATISTICAL COMMITTEE

The first task in connection with the attempt of the National Safety Council to have ultimately a nation-wide uniform reporting of public accidents is to prepare the blanks to be used as a first record of each public accident. The second task is to prepare a booklet of instructions, definitions, and uniform provisions to be followed in answering the questions contained in the report blank. The third task is to code and tabulate all of these original accident reports, at some central point. The fourth task is to classify and tabulate the accidents and injuries.

The sub-committee has first of all divided all public accidents into five groups as follows:

1. Accidents Peculiar to Public Highways
 - (a) those involving vehicles (except aircraft) and animals
 - (b) those not involving vehicles and animals
2. Water Transportation
3. Aircraft Accidents

4. Accidents Peculiar to Buildings and Other Structures (not home or industrial accidents)
5. General Accidents

A separate report blank is deemed advisable for each of these divisions. These report blanks will be filled out in every city where the statistics are to be kept, by whoever is designated to investigate and report on accidents. Presumably these reports or copies of same will be forwarded to the National Safety Council or other designated central authority or organization for coding and compilation purposes.

The following is a list of the questions and notations which have been prepared tentatively for use in Report Blank Number 1, Highway Vehicular Accidents:

REPORT BLANK FOR HIGHWAY VEHICULAR ACCIDENTS

A note to the following effect should be placed near the top of the blank:

"Write plainly in ink, as this is a permanent record."

Reference should be made to the manual of instructions and definitions. The following questions should be answered:

1. Kind of Accident
Be brief but follow instructions in booklet as to primary and secondary causes and types of vehicles involved.
 - (a) Type of Vehicle
 - (b) Kind of Accident
 - (c) Cause
 - Primary
 - Contributory
2. Time
Date, Day of Week, Hour of Day
3. Place of Accident
 - (a) State, County, municipality (village or city, taking 10,000 as minimum city population), open country.
 - (b) Did accident occur in public or private park, fair or exhibition grounds, cemetery, on bridge or viaduct, in tunnel, on factory premises, institutional premises, docks or piers, railroad premises, Government premises, or in congested business sections, non-congested business sections, congested residential sections, or non-congested residential or rural sections.
 - (c) Kind of pavement, whether concrete, brick, wood, stone, or other permanent pavement; or shell road, macadam, corduroy, dirt, sand or other temporary surface.
 - (d) Condition of road—snowy, slippery, muddy, very rough, rough, or smooth.
 - (e) Did accident occur at street crossing (rounding corner to right, rounding corner to left, or moving straight ahead) or in middle of block (on curve or straightaway).
 - (f) Did accident occur on side of highway or middle of highway.
 - (g) Was it within 300 feet of school building?
- (4) Speed of each vehicle involved in the accident.
- (5) Weather conditions—Clear, foggy, cloudy, rain, snow, not stated.

- (6) Give the name, sex, age, color, or race, nativity, and marital condition of the operator of each vehicle involved in the accident, whether injured or not. Was operator licensed or unlicensed.
- (7) State number of persons injured and the number of persons killed.
- (8) Estimate the property damage to vehicles involved in the accident. Estimate the damage to all other property. Note: If any one of the injured persons is apt to die before seven days elapse after the time of the accident, this report should be held up until the seven day period has elapsed; otherwise the report can be sent in immediately after the particulars are obtained.
- (9) For every person injured or killed, get the following information: Name, address, color, sex, age, marital condition, regular occupation or business, if any (use Industrial Occupational Code), was he or she operator, passenger or pedestrian. Could he speak English? Was he a naturalized citizen? Weight. Height. What physical disabilities did he have before the accident. Extent of injury (in accordance with Industrial Statistical Plan). Time laid up on account of injury. The number of dependents. Was competent first-aid promptly administered?
- (10) Names and addresses of witnesses.

Signed.....

Date of Report.....

Report blanks have not been prepared as yet for the other divisions of public accidents but the outline made use of for Highway Vehicular accidents will be closely followed for each of the others.

BOOKLET OF INSTRUCTIONS ON HOW TO REPORT PUBLIC ACCIDENTS

Every person who undertakes to investigate and fill out a report blank for any public accident should be equipped with a booklet of instructions. This booklet should go into detail respecting the classification of accidents. It should also outline in full the proper way to answer each question so that there can be no doubt as to any phase of the accident when it comes time for the accident to be properly coded. The committee has not as yet prepared the material for this booklet.

CODING OF ACCIDENTS

As report blanks are sent in from various parts of the country to some central organization, same will have to be properly coded. The committee has not as yet gone into the matter of coding but does not anticipate any serious difficulty in drawing up proper cards and series of codes that will adequately take care of all public accidents reported. The committee makes the suggestion that possibly some large insurance company would be willing to do this work for the National Safety Council at the start.

The final task of this sub-committee has to do with the ultimate tabulation of public accidents. The committee appreciates that there is practically no limit to the number of tables that can be prepared. A separate memorandum attached hereto outlines merely in a tentative manner the

substance-matter for the tables which will probably best serve the purposes of the National Safety Council.

Note: The sub-committee is at work on this last task and already has prepared a tentative or trial classification covering seventeen type-written pages. This is still too imperfect to submit at this time, but it will be improved at once by the sub-committee, multigraphed, and copies sent to several persons qualified by experience and special interest to give the sub-committee valuable advice and aid. When these criticisms and suggestions have been received the subcommittee will call a Round Table Conference of carefully selected advisors to meet in New York City, probably the latter part of November, for the purpose of perfecting the blank forms for original accident reports. The Conference will also carefully consider the probable primary classifications and more essential tabulations.

Immediately subsequent to this Conference these blank forms, some six or seven in number, will be multigraphed and sent to every member of the Public Safety Section of the National Safety Council. Our committee has had the invaluable assistance of Messrs. Ryder and Meltzer of the National Workmen's Compensation Service Bureau, of New York City.

We submit only a trial blank form for Highway accident reporting. Some six or seven other forms, corresponding to the main group classifications or divisions of public accidents, are being prepared. We do not anticipate any insuperable difficulties as the public and its representatives need just the data that we are seeking to secure. The need is visualized in the fact that about 45,000 fatal public accidents and about 5,000,000 non-fatal injuries by public accident are occurring annually in the United States.

CHAIRMAN TALBERT: I am going to ask Dr. E. George Payne of St. Louis if he will make a brief statement of the work done on safety education in the schools.

SAFETY EDUCATION IN THE SCHOOLS

DR. PAYNE: I think that we all recognize that the most fundamental element in the whole safety movement is education, and that the most fundamental and important part of the education is public school education. When we began to study accidents with reference to the schools, we found that there were only a limited number of situations in which accidents occur. The reasons for those accidents from the point of view of the educator are very clear. One is, that the child has not developed proper habits, and another is, that he hasn't the proper attitude, knowledge, or ideals about accidents, or about safety.

Now, what we have attempted to do is to go through the different grades and adapt the formation of these habits with reference to accident situations to the various grades, from the kindergarten throughout the school career of the child. Not only have we attempted to do that, but we have done it, knowing that accident instruction wouldn't get a "look in" if we added it as a special subject to the curriculum, because there are already about twenty subjects in the curriculum, and that is more than can be handled. At the same time, we discovered that it was

dren were more impressed with the pictures than anything else; and we did not have an accident to a child of school age during three months.

LIEUT. H. A. LEWIS (Portland, Ore.): We even go further than just showing the film. We take the children out on the street, and act the film first so that they know what causes the accident, to begin with. They see the film acted on the street, and just what leads up to the cause of the accident. In this way, the child will get experience. If you show him what roller skating in certain places, for instance, will do to him, you can teach him to avoid such places; but if you are going to leave it for him to get that experience, then it is no use, because the child might be killed by that time.

CHAIRMAN TALBERT: Mr. Barclay, Director of Education, Boy Scouts of America, New York City, is the first on the program, and I will now call on him.

L. W. BARCLAY: What I have to say now will deal more with the problems that are immediately facing our country in regard to Safety First and boys. Let me say in beginning, that it is a real pleasure to come out here as a representative of the Boy Scouts of America, as a fraternal delegate, to express in physical form our coöperation, our interest and our activity in education in a safety sense. In other words, that is what we are trying to do in this country as far as the Safety First movement is concerned. We are trying to develop a safety sense in the American people. As many of you know, the Scouts have done a great deal in that line, and we are doing a great deal more. I have with me manuscripts of two books which will be printed, one on Safety First for Scouts, and another on Firemanship. These books will be of great significance in the educational field.

WHAT BOY SCOUTS CAN DO FOR SAFETY

LORNE W. BARCLAY, DIRECTOR OF EDUCATION, BOY SCOUTS OF AMERICA,
NEW YORK CITY

The advantage of utilizing such an organization as the Boy Scouts of America, with its membership of half a million boys trained to personal efficiency and resourcefulness, in the furtherance of any movement, is apparent.

First aid, or knowledge of what to do *after* the accident occurs, has from the first been a requirement for the degrees of second and first class scout, and instruction in first aid has formed an important part of the training of each member of this great organization.

Perhaps we may seem to have stressed this "pound of cure" at the expense of the "ounce of prevention", inasmuch as specific instruction in safety first has not been made a matter of requirement; but as a matter of fact, scoutmasters, generally, have devoted much attention to safety instruction, impressing every lesson of chance opportunity, and identifying their troops actively with local campaigns in the interest of prevention, whether of disease, accident, or other destructive force.

SAFETY AN IMPORTANT PART OF SCOUT'S INSTRUCTION

Moreover, among the merit badge subjects open to scouts, safety first holds a conspicuous place, and scoutmasters are urging their troop members to qualify for this badge. National headquarters of the Boy Scouts of America is publishing a pamphlet for the aid of scouts who wish to qualify for this merit badge. The pamphlet has been prepared under the direction of Mr. Lew R. Palmer, Director of the Department of Safety and Personnel of the Equitable Life Assurance Society. A wealth of material was furnished by the National Safety Council and the National Board of Fire Underwriters, which, under the able editorship of Mr. L. R. Palmer, makes the monograph a most important addition to the literature of the Boy Scout movement. The issuing of the pamphlet in an edition running into the thousands will tend to focus the attention of the organization upon the importance of safety propaganda, and we may at this time expect a revival of safety instruction in boy scout troops as a logical reaction. *SCOUTING*, the official organ of the movement, will publish excerpts from the pamphlet and from other safety first literature, and will advocate an active campaign in safety instruction throughout the organization. To say that the National Safety Congress has the active coöperation of the Boy Scouts of America in the promotion of its program of prevention, is to state the case conservatively.

So much for our attitude on this most important subject. Now, as to the question, "What can scouts do for safety?"—the inquiry at once calls to mind such a multiplicity of instances of what scouts have done, that it becomes rather a question of selecting a few illustrations from the material available, as suggestive of the manifold ramifications of scout activity in the interest of accident prevention.

In an important city where the growth in population has exceeded the development of carrying facilities, at times of special congestion in the streets, as for example the fortnight preceding Christmas, it has been customary for scouts to assist the traffic police at the points of greatest congestion. Divisions of the troop, lining up on the four corners of a dangerous crossing, at the turn of the "Stop" signal by the traffic policemen quickly form a chain by clasping hands and throw this live line across the pavement thereby restraining the foot passengers until the turn of the "Go" signal releases the stream and transfers the line of scouts to a similar position of defense on the cross street. This maneuver is reinforced by the presence of other scouts carrying placards, "Keep to the Right" and "Help the Traffic Policeman—Wait for the 'Go' Signal."

TRAINING IN LEADERSHIP

The need for leadership in a fire crisis is met by training, of which the following illustration is typical: Fire drill is held at troop headquarters. This drill includes a study of all the fire prevention facilities of the environment, the location of fire escapes and the nearest fire alarm box, and the rehearsal of procedure under all the different conditions which might arise in case of fire. With this instruction as a guide, the

scout is sent back home to study all the conditions to be met in case of fire there and to work out, with the assistance of the other members of the family group, the fire drill under these conditions. This study of local conditions has even been extended to the study of the houses of the neighbors on either side, for in the case of fire (as in many another menace) responsibility extends beyond the individual home, and each is, in truth, his neighbor's keeper.

The point of emphasis in scout instruction is that, first of all, the proper authorities be notified. In the case of fire this means turning in the alarm. In the case of physical injury, notifying a physician or calling a hospital ambulance. In every case it means doing the thing which must be done pending the arrival of the expert. Scouts are trained to act promptly, efficiently, and intelligently in crises. "Safety" training means the use of the same powers and resources for prevention. It tends to increase the sense of individual responsibility.

I recall a case where many persons passing a building noted the odor of escaping gas, but it was a boy scout who stopped to investigate and discovered the janitor of the building unconscious from the fumes. To the scout, the odor was a challenge. It was his job to trace the result to its cause, and report.

To my mind, the chief contribution that scouting can make to the cause of safety first or any other movement, rests in this fact, namely, that scouts are trained to assume responsibility and to act.

In schools, safety patrols of scouts are organized to lead in fire drills or other emergency drills. Their precision and decisiveness impart promptitude and orderliness to other children and, in time of real danger, inspire courage.

The United States Bureau of Education has provided 20,000 copies of a fire prevention manual for the use of boy scouts.

STUDYING FIREMANSHIP

Just in passing, it may be well to call attention to the fact that firemanship is among the subjects which scouts can take up as a sort of elective course in scouting, thereby qualifying for merit badges in recognition of efficiency. Quoting from the Handbook for Boys:

"To obtain a merit badge for firemanship, a scout must:

- "1. Know how to turn in an alarm of fire.
- "2. Know how to enter burning buildings.
- "3. Know how to prevent panics and the spread of fire.
- "4. Understand the use of hose—unrolling, joining up, connecting to hydrant, use of nozzle, etc.
- "5. Understand the use of scapes, ladders, and chutes, and know the location of exits in buildings which he frequents.
- "6. Know how to improvise ropes and nets.
- "7. Explain what to do in case of panic, understand the fireman's lift and drag, and know how to work in fumes.
- "8. Understand how to use fire extinguishers; how to rescue animals;

how to save property; how to organize a bucket brigade; and how to aid the police in keeping back crowds."

The motto of the Boy Scouts of America is "Be Prepared." It is impossible to tell where or when a fire is going to start.

But if every boy of scout age were enrolled in the movement, fewer fires would get under headway, and life and property would be safer throughout the nation.

The practical application of the fire prevention instruction of the Boy Scouts has been productive of excellent results. Recently in Spokane, Washington, the members of the local council of the Boy Scouts were organized with the cooperation of Fire Chief A. L. Weeks, and the municipal authorities, into a brigade that covered the city in a thorough campaign of fire prevention.

The scouts were required to pass a written examination before they were enrolled as "firemen." They were questioned as to the proper way to send in an alarm, as to correcting the ordinary fire hazards of the home, and were generally quizzed along the lines of fire protection. Some of the answers received were amusing. One boy, for example, declared that gasoline was "dangruser than damanite." As he evidently meant dynamite and clearly realized the hazard of careless handling of gasoline, he was marked "correct" upon this question.

The boys who were appointed to constitute the fire prevention force, besides cleaning up rubbish, also distributed questionnaires throughout the city, together with a folder containing cautionary data. The questionnaires were printed upon cardboard, and householders were asked to hang them up as constant reminders of the danger of oil lamps and stoves, gas appliances, matches, oily rags, and the rest of the common hazards.

The cards were provided with a stub which was torn off by the scouts and returned as a report form. Altogether fourteen prizes and one hundred badges were distributed as rewards for the scouts who displayed the greatest interest and activity in the work.

HELPING IN EMERGENCIES

On another occasion boy scouts proved valuable aids as an auxiliary fire force in protecting a large city under unusual circumstances. This was at the time of the Cincinnati fire department strike. A great deal of trouble and confusion was caused during that period by the ringing of false alarms. The few volunteers who were manning the fire houses had all they could do to take care of actual blazes without having their energies dissipated by answering bogus calls, and it was realized that something must be done. The boy scouts thereupon stepped into the breach and stood guard over the alarm boxes until normal conditions were restored.

Incidentally, during this trouble the possibilities of carefulness as a fire preventive were shown in a striking manner. The word was sent broadcast urging every one in the city to exercise extraordinary precautions to prevent fires, as in the event of a large fire getting started a con-

flagration might ensue that would wipe out a portion of the city. The result of the appeal was remarkable. During the eight days of the strike Cincinnati's fire loss amounted to \$500, as against \$20,670 during the corresponding period of the previous year.

REQUIREMENTS FOR SAFETY FIRST BADGE

It is believed that a first class scout, expert in first aid as a requisite for this rank in scouting, and holding the merit badge in firemanship and safety first, will be recognized by a prospective employer as one trained for leadership in emergencies and therefore more valuable to the factory or shop.

Let us look for a moment at the requirements for the safety first merit badge. Quoting from the Boy Scouts' Handbook, page 61, we read:

"To obtain a merit badge for safety first, a scout must:

"1. State four or more dangerous conditions in the average home and indicate what steps should be taken to correct these conditions.

"2. Produce satisfactory evidence that he is personally responsible for the application of at least two constructive safety first principles in his own home.

"3. Name the most serious violation of public safety principles which has come under his observation and produce satisfactory evidence that he has done all within his power to correct the same.

"4. State in writing at least six of the most important regulations covering street safety to meet the conditions of the neighborhood in which he lives.

"5. State in writing at least six of the most important regulations covering street safety to meet the conditions of the school he last attended.

"6. Submit in writing an outline of his own plan for a school fire drill and explain the method of properly carrying it into effect.

"7. State in writing at least six violations of safety first principles which are responsible for accidents in connection with railroads.

"8. Stand a satisfactory examination showing a knowledge of the importance of the safety first movement and the most important principles it involves, and satisfactorily demonstrate his ability to assume leadership in case of a fire, panic, or other disaster."

To give an idea of the character of the instruction given in the pamphlet already referred to, which is just being issued by the national headquarters for the guidance of scouts qualifying for this merit badge, I quote the following passages:

"For the most part the scout is dealing with familiar subjects, in trying to win this merit badge. He starts right at home, for the first requirement is as follows:

"1. State four or more dangerous conditions in the average home and indicate what steps should be taken to correct these conditions.

"Your first move should be to make a list of your own of conditions in your home and in such other houses as you can learn about, that seem to you dangerous. Then bring your list back to this page without having

first gone any further in your reading, and check it back with the dangerous conditions named below as found in the average home. You may have some or all of these, or even others, on your list.

Dangerous Conditions in the Average Home

A		
Presence of flies		"Lost" pins and needles
Inadequate ventilation especially at night		Sharp knives and tools
Exposed garbage		Broken glassware
Exposed food		D
Rats and mice		Disposal of hot ashes
Presence of contagious disease		Christmas trees
B		Open fire places
Unprotected gas jets		Cooking in grease
Improper electric wiring		Boiling water
Use of kerosene and gasoline		Articles left on steps
Use of celluloid articles		Disposal of old rags and paper
Improperly constructed flues and chimneys		Refuse in dumbwaiter shaft
Improperly placed furnace		E
C		Lack of headroom in stairways
Use of matches		Gas leaks
Medicines and poisons		Back drafts in stoves and furnaces

"From this list, or your own, or both, select four or more conditions and indicate what steps should be taken to correct them. This implies some knowledge of safety first principles. For the most part, these principles are based on common sense, and if you will employ common sense in thinking how to correct the dangerous conditions that you select for your merit badge test, you will be on fairly safe ground. But you should make sure by proper inquiry of older persons, whether the steps that you would take would really correct the dangerous conditions that you intend to correct"

Look out for Dangers Like These

"You know that epidemics of typhoid fever, for example, can start from rotting garbage exposed in a public street, and that fine ashes blown about can ruin not only clothes but also eyesight, and can even carry with them disease germs. Whether or not there is any town regulation against exposed garbage or the carting of ashes in uncovered carts, if such things occur in your town, they are serious violations of public safety principles.

"The same thing is true of the omission of lights on vehicles at night: town rule or no town rule, a safety first principle is violated by such omission. Under other requirements, you will get acquainted with the traffic rules of your town and other street regulations. It is for you to decide whether the violation of one or another of these rules is a serious violation of public safety principles. For example, would you consider the omission of a red flag, or, at night, of a red light, on a load that

extends beyond the rear of the vehicle carrying it, a serious violation of a public safety principle? If so, why?

"Perhaps that last question will suggest how necessary it is for you to get all the fundamental facts that you can, and then carry your case to your parents or your scout-master, or a lawyer friend, or a physician, or a member of the town health board, or the police force, and obtain advice. But in the end you must use your own judgment based on all the information you can get."

We see from even so meagre a quotation from the safety first pamphlet that the presentation of the subject is essentially practical. It is hoped and believed that there will be at this time an awakening of the entire scout organization to the realization of the great service which can be rendered to communities and individuals by focusing attention upon safety first principles and instruction, and on behalf of the Boy Scouts of America I pledge that service.

(Mr. Arthur T. Morey, St. Louis, took the Chairman's place temporarily at this time.)

DISCUSSION

ACTING CHAIRMAN MOREY: I would like to ask Mr. Barclay if the National Safety Council was able to coöperate in getting out this new Safety First book for boys.

MR. BARCLAY: It was practically gotten out by the National Safety Council. The safety engineer of the Metropolitan Life Insurance Company really did most of the work on it.

HOMER J. HODSON (East St. Louis, Ill.): You all noticed in the first issue of the Congress News, the scheme which was promoted by the business men and the E. St. Louis Council of Boy Scouts, with reference to choosing the best scout out of three hundred who might deliver a lecture on scouting and safety. Gentlemen, I can think of nothing more inspiring than at next year's Congress to see every large city of any size, which has a Boy Scout Council, do the same thing. I have with me today Carl E. Wiemken, the Scout who will be used when we return to E. St. Louis for the purpose of lecturing before the Rotary Club, the Chamber of Commerce, and we have arranged through the Superintendent of Schools to have him deliver Friday afternoon lectures. I am going to ask Mr. Barclay what he thinks of the idea.

MR. BARCLAY: I think your plan would be a fine thing. A boy learns leadership by leading. He will learn Safety First by participating in Safety First activities. I can't think of anything that would be more inspiring than to bring 450 Boy Scouts from 450 different cities to this Congress and give them a Boy Scout session where they would all go back with the inspiration they would get from associating with men like you.

INSPECTOR E. H. MAY (Cleveland, Ohio): I don't know whether you would be interested in knowing what the Cleveland Police Department thinks of the Boy Scouts, but we have encouraged them on every possible occasion. We think, from a safety point of view, that it is the best thing

we can do. Not from the standpoint of safety from accidents so much as safety from crime.

ACTING CHAIRMAN MOREY: I want to introduce to you gentlemen, Mr. John R. Doan, the Boy Scout Executive of Cleveland.

MR. DOAN: The President of our university here is having us organize along that line to prevent the thing that brings about the spirit that is back of the thing we are trying to kill here today, and that is recklessness. That is what is the matter with America, we are utterly abandoning our attitude toward life. My object is not only to prevent crime and accidents, but to develop good citizenship by having the boys take part in proper activities. Seventy per cent of our boys in Cleveland are foreign born, and I believe that in their homes their parents' attitude is against the government. We have recently had here a great Bolshevik trial, and the reason for that was that the foreign element did not understand. They look upon the man with the uniform as the government, and as the big blue-coated enemy. If we can line up the boys to the understanding that they are working with the man in uniform as a friend and a citizen, when the boy goes back to that home and the door is shut, and they are back in the foreign land and atmosphere, the boy is in position to try to open the door and really do some good work in Americanization, as well as to teach them to be careful and to be alert.

ACTING CHAIRMAN MOREY: I wish now to introduce to you, Mr. Dana Webster, Safety Inspector, Aetna Life Insurance Company, Indianapolis, Ind., who will read a paper on "Elevator Hazards Affecting the General Public."

I want to say that the Aetna Life Insurance Company, which Mr. Webster represents, has certainly shown wonderful coöperation throughout this whole safety movement, and it is a pleasure to have with us one of their representatives. They have not only been big students of this problem, but have been very generous with their ideas. The elevator hazard in St. Louis is tremendous. Thirty-five deaths last year resulted from elevator accidents, and up until the first of September this year there were about twenty-two.

ELEVATOR HAZARDS AFFECTING THE GENERAL PUBLIC

DANA WEBSTER, SAFETY INSPECTOR, AETNA LIFE INSURANCE COMPANY,
INDIANAPOLIS, IND.

Before making any remarks on the safety of elevators, it might be interesting to cover briefly the gradual development in the manufacture of mechanical lifting devices.

MECHANICAL LIFTING DEVICES

Lifting devices were undoubtedly used by Julius Caesar, as far back as 256 B. C. as history mentions their lifting animals from the dens to the arena in the Coliseum of Rome. About the middle of the Nineteenth

Century, platforms or cable hoisted elevators were first installed in New York and Boston, but were not provided with any kind of safety devices, and strange to say you can find a few elevators without safety devices at the present time.

A few years later elevators were equipped with safety devices of such type that it was necessary for the hoist cable to break before the safety could actuate. There are a great many of this type of safety in use today, but with the introduction of high speed elevators, which were required to meet the demands of the public, quite naturally it necessitated a much better type of safety apparatus and a multiplicity of cables.

Accidents could and did occur from over-speeding elevators caused by disarrangement of controlling apparatus, and it became necessary to provide safety devices that would actuate should the elevator speed increase beyond a predetermined number of feet per minute.

The most essential elements of safety are the prevention of excessive speed from any cause, the over-running of the limits of travel at top and bottom, safe protection at the landing entrances to the elevator, and a regular examination of the cables and all parts of the elevator equipments.

CAR SAFETY DEVICE

The early type of the *safety device* was designed to stop the car instantaneously. This served the purpose satisfactorily for slow speed but was not adequate for the higher speed of 400 to 700 feet per minute. It, therefore, became necessary to provide a safety device that would stop the car with an easy and gradual stop. This is accomplished by the friction clamp safety which is actuated by a safety speed governor, usually set to trip at 40 per cent above regular speed. This governor will act should the hoist cable break, allowing the car to drop, or should the car over-speed from some defect in the machinery after the governor trips and the car has dropped far enough to take up the clearance of the safety jaws. The jaws are forced hard against the guide rail (like a vise), and the car will continue to slide until the friction is enough to stop the car entirely. The distance the car will slide after the safety takes hold, depends upon the load; but the farther the car slides the tighter the safety grips the rail. Usually a car will drop about six feet after the governor trips and clamps the governor cable.

OVER-RUNNING OF LIMIT STOP

The machine of all power-operated elevators should be equipped with automatic limit stops: that is, a device that will stop the elevator at the top and bottom limit of travel, regardless of the operator.

On *Drum* machines, the *Automatic Limit Stop* should be built with and made a part of the machine.

On *Hydraulic* elevators, the *Automatic Limit Stop* should consist of a *Cut Off Valve*, either in the to-and-from pipe, or in both the supply and discharge pipe.

On *Traction* type of elevators, the *Automatic Limit Stops* must be lo-

cated in the hoistway, and the power cut off by the travel of the car. As there is more or less slippage of the hoist cables on the drive sheave, a machine automatic would not be dependable. In addition to automatic limit stops on electric elevators, there are hoistway limit switches located so that should the car travel a certain distance by the automatic limit stop, the car would open a switch, thus cutting off the power and stopping the machine.

SAFE PROTECTION AT LANDINGS

The early types of passenger elevators—and in fact most elevators up to the present time,—are provided with landing doors equipped with a catch located on the inside so that the door can only be opened by the operator. The operator, however, in order to make speed,—and the public is partly to blame for this—starts the elevator before the door is closed, and quite often the door does not fully close and latch, thus providing a very dangerous condition. Many persons have opened the door when finding it ajar, and looking in the hoistway have either fallen or have been knocked down the hoistway by the car and severely injured or killed. I might say right here that statistics show that 85 to 90 per cent of all elevator accidents occur at the landing doors. Therefore, it has become necessary to provide the landing doors with a locking device that prevents the doors from being opened, unless the car is at the landing; also prevents the car from being removed away from the landing until the landing doors are closed. This is termed the *Interlocking Device*, or *Interlocks for Landing Doors*. While I believe all landing doors of passenger elevators and gates for freight elevators should be equipped with interlocks, I am sorry to say that at the present time only a small percentage of elevators are equipped with this device, although they are becoming more and more in general use.

CABLES

The *Cables* are the most essential parts of the elevator equipment, and their number and size should be equal to the load with a good factor of safety. The *sheave* should be of ample size and placed in alignment to prevent chaffing of the cables on the sides.

Great credit must be given to the manufacturers for the high state of perfection to which these devices have been brought. This fact must be admitted when considering the few accidents on elevators, compared to the large number of passengers carried. Statistics show that 10,000,000 passengers are carried in the Borough of Manhattan daily, and it is said that this number exceeds the number of passengers that ride on all the surface, elevated, and subway cars; in other words—more people ride vertically than horizontally.

A great many elevator accidents are not due to faulty design in construction, machinery, or safety device, but to the carelessness of the injured party. It, therefore, becomes necessary for the City or State to enact Ordinances and Laws regulating the construction of elevators, and enforcing their equipment with effective safety devices, in the interest of

accident prevention; that is to say—to prevent a person from being injured by his own carelessness, or by the carelessness of the operator.

ELEVATOR INSPECTION

ARE THE SAFETY DEVICES KEPT IN PROPER CONDITION? is one important question. The only way this can be accomplished is by having the elevator regularly inspected by a competent elevator inspector, who should inspect all the different safety devices, machinery, cables, etc., in fact, everything pertaining to the elevator. The landing doors should be tried to determine whether they can be opened from the outside. The car safety device should be tested to be sure that it would actuate and hold the car from falling, should the cable break. The automatic limit stops should be tested so as to be sure the car will not over-run and strike the overhead beams or bumpers. The slack cable device should be tested to be positive the power would be cut off, should the cables slacken. The brake should be examined to be sure there is no slippage. The cables should be examined very carefully for defects, as there is no part of an elevator that requires the exercise of more good judgment than the examination of the cables. It is just as essential that the safety devices, and all parts of the elevator, be kept in good working order, as it is that they should be installed in the first place. After an inspection has been made, the owner should proceed immediately to install safeguards and remedy any defects reported.

The elevator should be oiled and greased regularly by the engineer and looked over carefully for any defects at intervals between the visits of the official inspector. Oftentimes the engineer will discover some little defect which if fixed immediately may avoid a serious accident.

There is another feature that I wish to mention before closing; that is the elimination of mirrors, in fact all glass, from the passenger cars (except the electric light bulbs), not only because of the fact that they are liable to cause injury to passengers by getting broken, but also because of their attraction, which results in passengers failing to notify the operator promptly as to their destination. This necessitates a stop between floors, and a trip back to let them off. They also have a tendency to retard the loading and unloading of the cars.

DISCUSSION

ACTING CHAIRMAN MOREY: If an elevator began to fall, thirty or forty feet up, would the "safety" work?

MR. WEBSTER: That question has been discussed time and time again. No man can tell when a cable is safe or unsafe. One day you may see a cable with perhaps only one broken wire and the next day you will hear that the elevator has dropped. There are certain methods used whereby serious injury or possible fatalities are averted by the use of bumpers, when the car only falls 8 or 10 feet or even 30 feet. However, the safety, to work right, wants to have a distance to work in.

CHARLES ELLABES (Indianapolis, Ind.): I believe I can answer that question more fully. It can be proven by mathematical analysis that the

distance required even up to 800 feet per minute, for a safety to actuate is only about six inches. The velocity from rest to six inches will increase it.

One other point I would like to make in reference to Mr. Webster's paper, is the question of automatic stops. Automatic limit stops are most desirable but they are not always required. The architect of today is not inclined to give the elevator construction all the headway it should have at the top of the elevator. In other words, the head drums of the passenger elevator of today vary from three feet to six or seven feet. That amount of room is not enough in which to stop high speed elevators going 800 feet or more per minute, so the manufacturers have gone a step farther and provided slow-down switches at a certain distance below the top landing. They have put in a switch which will automatically decrease the speed of the car to a given amount. If necessary, they put in two of those so that at the approach of the landing the speed is decreased to about 100 or 250 feet per minute, so that if the car passes the last landing it will trip these automatic devices on the hoist limited switches and come to a full stop within the six feet which the architect has given us.

ELEVATOR SAFETY CODE

One other point, the Bureau of Weights and Standards has been coöperating with the American Society of Mechanical Engineers in the development of an elevator safety code which I believe is the very best which has been put out up to the present time. It is highly important that a code of this kind be formulated at once. We do not only want to see that the engineering principles in the thing are right, but we should see that the men administer the laws properly. We also want to see that the city officials get an idea of the engineering principles involved. We, at the Bureau of Standards, will be delighted to give any information we can on the subject.

MR. WEBSTER: Mr. Chairman, I wish you would call on Mr. Greenleaf, of the State Industrial Board of Indiana. I think he would have something to say along this line.

GEO. W. GREENLEAF (Indianapolis, Ind.): I don't know of any way to get at that proposition thoroughly unless it would be through a Federal law that would require a universal standard for elevators throughout the country. There is just one safeguard on which I think more stress should be laid and that is the question of a door on the passenger elevator car. On one of the hotel elevators this morning I stood with just about 4 inches clearance between my body and the floor projections of the elevator shaft. The slightest movement of someone back of me in the packed car would have thrown me over so that my chin would have caught on one of the floors, and part of me would have been up there now and the rest of me would be in the elevator pit. While I don't think it is necessary to close the car door on all occasions, I do think that when an elevator car is packed like that one was this morning and as they frequently are, that there should be doors on the cars, and those doors should be closed before the elevator is put into operation.

DAN L. ROYER (Ocean Accident & Guarantee Corp., N. Y.): Until you can get the public educated to the point where they are willing to slow down and admit of a perfectly guarded car, we are going to have the present situation. I am convinced that on passenger elevators we will have to come to the adoption of a perfectly guarded car with interlocking doors and inner-locking car gates, because as long as you have the human element to contend with in the operators, you will have exposures.

ELEVATORS SHOULD BE PROVIDED WITH SIDE AND TOP DOORS

MR. WEBSTER: There are other things of which I might have spoken in my paper. For instance all elevators should be provided with side and top doors. I know of a case where seven ladies were compelled to stay in an elevator car for nine hours because of the fact that no one there knew how to move the car, and there was no way for them to get out. If there had been a door either in the top or side they could have gotten them out that way.

Then also there is the question of toe guards which should be of metal instead of wood.

CHARLES ELLABES (Bureau of Standards, Indianapolis, Ind.): Mr. Greenleaf mentioned the question of a Federal law. I am connected with the Bureau of Standards. We have been working five hours on national electric safety codes, and we absolutely are opposed to a national law governing safety. That is a question of purely states' right, and the only way it is going to be worked out is by coöperation. The only way you will ever get it is by having your engineers, your public officials, your Federal officials and your insurance companies sit around a table like we did at Indianapolis at the National Society of Mechanical Engineers six different times for four days at a time, and iron the thing out.

MR. GREENLEAF: I cannot concede that I am entirely wrong in regard to the effect of a Federal law. This whole question of States' Rights has been thrashed out along a good many lines, and a good many things are being done through federal enactments which a few years ago were considered strictly a question of States' Right. For instance the child labor proposition was considered that way, but it has been taken up by the Federal Government. They didn't hit it right the first time and they tried again, and if they haven't it right this time they will probably try it again until they do get it right. I can see that probably it will not be possible for the federal government to enforce an elevator code throughout the United States, but they could proceed along the lines they have in other matters, and that is to provide that an elevator could not be shipped in inter-state transportation unless it was so and so. I think that would bring all the elevator manufacturers to the adoption of that code, because there are very few of them who confine their activities to any one state.

On the question of slowing down the speed of travel and that sort of thing, we have simply got to go back to the slogan of "Safety First". The elevator must be safe at any cost, and if it requires the installation of more elevators, then that is the solution.

LIEUT. H. A. LEWIS (Traffic Division, Portland, Ore.): As regards a Federal law, I don't think it is the intention to have the law enforced by the Government, but to have a foundation laid by the federal government for all state laws, not only in regard to elevator safe guards, but all safe guards. Unless we standardize all the way through, not only as regards elevator laws, but traffic and other laws as well, we are always going to have trouble.

(Mr. C. M. Talbert returned to the room and assumed the duties of Chairman.)

CHAIRMAN TALBERT: The next paper scheduled is one by Mr. J. M. Quigley, Chief of Police, Rochester, N. Y., on the "Proper Personnel of a Public Safety Committee." (Chief Quigley's paper was not read but was sent in for publication in the Proceedings.)

PROPER PERSONNEL OF A PUBLIC SAFETY COMMITTEE

JOSEPH M. QUIGLEY, CHIEF OF POLICE, ROCHESTER, N. Y.

When considering the matter of the forming of a committee which will assume the function of a study of accidents involving bodily injury or loss of life, we must first find out why we want to prevent such occurrences, and then select a personnel that will represent every phase of interest, particularly those most vital to the family, the community, and human economy.

The depth of the grief suffered by one's own kin when the life of a beloved father, mother, or child is snuffed out prematurely by accident cannot be measured by any human standard of value. Money cannot compensate a mother for the life of her dear child or the family for the loss of a devoted father or a loving mother. Yet there is something that will and does alleviate sorrow, and helps us to bear the burden of grief, namely, human sympathy, expressed in emotion and words and acts of kindness. The knowledge that our grief is shared by others seems to make us feel that our loss is not an individual deprivation only, but that it affects others as well, and to what extent depends upon the social relationship of the departed one.

Their taking away may be a community calamity too according to the extent one may have been interested in community activities or interests. Then again the sudden death of one skilled in mechanics and upon whom the direction of large numbers of co-workers has devolved, may and does cause an economic loss, at times so great as to be keenly felt by many who cannot afford to lose the time and consequent money loss occasioned by the stoppage for a temporary period of a great industry.

When death results from natural causes, there is always ample warning given of the approach of dissolution, and provision for any interruption of business can be anticipated, but not so in the case of accidental death, for seldom if ever do we learn of one so wise or prudent as to have prepared for the carrying on of his or her life's work in case of death by accident.

Every person is of value to the community in which they live, and their

death, if sudden, is a loss in proportion to the extent the community has leaned on the individual. And though the community as a whole will not in every case be conscious of the fact, yet the void has the effect to impair to a greater or lesser extent the equilibrium of the social and business affairs of the community. In large cities the taking away of an individual is not felt generally, and a human life as a consequence is not estimated at its true value.

I have thought that if an instrument could be constructed that would record publicly the loss of every life by accident as they occur and show in dollars and cents the actual loss to the community, we might arouse the people to a realization of the importance of accident prevention. How often do we hear it said by those who have been dependent on one who has met a sudden death, "I do not know what I am going to do. I must start all over again, for I left everything to him and never dreamed even that he would be taken away suddenly, and I have made no provision for such a contingency."

It is an awful affliction to have one on whom you depended almost wholly killed instantly, for in addition to the anguish suffered, there is always a financial loss, which may entail the deprivation of comforts that had been hoped for, if they had only been spared for the term of a natural life.

THE HUMANE EMPLOYER

The humane employer is solicitous for the safety and comfort of his employees, and will mourn with their associates when misfortune comes upon them in the form of an accident resulting in death or injury, because he looks upon them as members of his business family who share with him the vicissitudes and trials of commercial life, suffering or rejoicing as failure or success comes to him. And again he regrets because their removal permanently or temporarily means a financial loss to him according to the position they held in his business.

It is necessary, therefore, for him to protect his employees from accidents which may result in removing them from active participation in his enterprise, entailing a financial loss, as well as the inconvenience, delay, and often the suspension of work in other factories; on public works; and on farms, which may be dependent upon the production of the factory for material necessary in the manufacture of goods, the construction of buildings, or the cultivation of the soil.

I can recall instances when mercantile business was suspended, ships were unable to leave port, farmers were prevented from harvesting grains, and important public work delayed because of accident to employees; factories were hindered in the production of goods necessary for the merchant, the mariner, the farmer, and the builder to carry on trade, commerce, cultivation of the soil, and the construction of buildings.

In the extending of civilization the ingenuity of the inventor has been directed in a great measure toward the development of vehicles for rapid transportation of men and material, and though speed has been the aim, safety has been the paramount factor. Yet much risk is indulged in by over-anxious and reckless persons who would stake everything on chance.

And while it may often appear that rapid progress has been made regardless of care, yet it has been proved that where caution and temperate action has been exercised the greatest success has been attained.

RAPID TRANSPORTATION

The principal agents of commerce today are the railroads. By them goods and persons are transported great distances in an amazing short space of time, but often travel is interrupted and the delivery of goods is delayed in arriving at destinations by the intervention of accident. The destruction of life at times has been appalling, while the financial loss has been incalculable. And why? Because some one had neglected to apply caution in the prosecution of their work, or had for a moment probably allowed their mind to wander from the thing upon which it should have been concentrated, or recklessly took a chance and lost out.

Within the past twenty years there has taken place a wonderful change in the character of vehicles commonly used by man on the highway. The ox cart and the horse-drawn vehicle have been superseded almost entirely by the gas motor vehicle, which is constructed for comfortable and rapid travel. And because of these advantages over the primitive vehicle travel, transportation by automobile has grown rapidly in favor until our roadways teem with pleasure and commercial cars.

Improved roads permit of fast driving without hardship, which is an incentive to indulge in speeding. Therefore, travel on our highways has become extremely hazardous. Accidents by which persons have suffered bodily injury or death have been so numerous the public has become seriously concerned with the problem of preventing them. Laws have been enacted restricting the use of the roadways and regulating the operation of vehicles on them.

Such measures have been taken because the public has demanded that reckless driving on the public highways shall cease, and the slaughter of human beings from that cause shall be stopped.

We have investigated many so called accidents, and I can safely say that 80 per cent of them were not accidents but were the result of recklessness, carelessness or willful distraction, and could have been prevented. An accident we cannot prevent. I may be severely technical in defining the word "accident," but when the casualties on our highways have outnumbered by three to one those occurring in our army on the battlefields of France, is it not time to become exacting?

When we come to consider that the bodies of those persons killed in vehicular accidents on our highways in this country in one day, if laid side by side, would form a line over one mile in length, does it not require of us that we be more technical in the determining of what occurrences are accidents. I am inclined to insist that in every case where the facts will prove that an occurrence could have been prevented, it be reported as a preventable occurrence and the responsibility for it fixed.

Now it often happens that some one besides the principal in an occurrence may have done something indirectly which contributed to the cause of a casualty: For example; If one who deals in or uses dynamite or gun

or blasting powder, carelessly leaves such explosives where they may come into the possession of persons ignorant of their character, or if an inexperienced person is permitted to drive a locomotive or an automobile, or if an employer encourages or compels an employee to work until he becomes over-fatigued, or without sufficient light when operating machinery in a factory; and loss of life or property results, can such occurrence be termed an accident?

Let us not be too much inclined to condone lack of caution, for so long as we do, accidents (so called) will multiply.

FIRE PREVENTION

Little attention is given to accidental fires, except by the insurance companies; the average citizen never gives a thought to the matter of the cause of a fire, except when an appalling loss of life has resulted. The financial loss, he seems to think, is borne by the insurance companies, which is not the fact. All business men do or should know that every person who carries insurance on his property is one of the guarantors against loss by fire and helps to pay the loss. The people at large suffer in proportion to the extent of the interruption to business, of the unemployment and the poverty brought about by such occurrences.

Fire prevention is essentially a public duty, and if assumed and carried on in the proper spirit, 80 per cent of the fire loss of the present day can be saved; this estimate I am sure is not excessive. Why then delay the enactment of laws penalizing carelessness in the disposal of rubbish, hot ashes, oily rags and waste; and the storage of highly combustible materials; and providing for a board of fire investigators whose duty will be to discover, if possible, the cause of fires, fix the blame and suggest measures for prevention of the reoccurrence of happenings, resulting from neglect of caution.

Accidents in the home are numerous and are due in nearly every instance to lack of caution and are therefore preventable, but it seems that some serious mishap must occur now and then, in order that we may be brought to a realization of the necessity for caution. The match box, carbolic acid, the hot poker and sharp knife have not been put out of reach of the babies, and open stairways and windows are left unguarded. Mothers should practice the doing of these preventive things constantly, until it becomes a habit, then household accidents will become rare and much pain and sorrow will be averted.

APPLY THE GOLDEN RULE

A review of the causes of accidents convinces us of the necessity for the devising of methods of prevention which will be effective in constantly keeping before the people that fact that we are seldom, if ever, where we can be considered safe from accidental injury or death. Those who are careless of their own safety and that of others seem to be everywhere. Everybody at some time or other indulges in recklessness hoping thereby to win applause or gain some selfish end or advantage over his fellow man, and occasionally failing, not only loses all for himself but brings injury,

sorrow, and suffering to his neighbor. It is imperative, therefore, that in accident prevention work, the golden rule shall apply. Always keeping in mind the rights of our neighbor, conceding, if need be, some of our own rights, if by so doing we may avert a disaster.

When making up your committee, therefore, let the personnel represent the family, the school, the employer and the worker, an attorney, a doctor, and a clergyman, who will consult and advise with a public safety committee appointed by the Mayor of a City. Such a committee will, I think, represent every phase of interest, and having official powers, may be able to compel strict observance of safety rules.

In this short paper I think I have shown that persons in every walk of life and of varied interests should become concerned in safety work, and if I may be permitted to say so, it is a duty which no one can justly avoid and yet claim to be a good neighbor, a considerate employer, a faithful employee, a cautious parent, or a good citizen.

Caution should be the watchword of all; in planning be cautious and do not hazard too much for the sake of haste or excessive production; be content with reasonable accomplishment and you will become a true apostle of safety.

DISCUSSION

CHAIRMAN TALBERT: In view of the fact that Chief Quigley is not present this morning I will say a word in this connection.

The entire committee of the Public Safety Section has endeavored during the past year, to work out a comprehensive plan of public safety, and that work had been tried in three cities. It was tried first in St. Louis to a certain extent, carried a little further in Pittsburgh, and now is being tried out in Cleveland. The coördinating of the matters found in those three cities has brought us to a fairly definite program for public safety work, and we have on the table here copies of the program which I will be glad to give to those who are interested. We will set two o'clock as the definite time to discuss the traffic question. Inasmuch as we have thirty or forty minutes left this morning, I would suggest that we go on with our informal discussion and continue this as a business meeting.

MR. COFFIN: I believe that the plan proposed by Mr. Crum is altogether too complicated to put into practical use. It is all right to get these statistics, but the simpler they are, the better.

CHAIRMAN TALBERT: At my suggestion, Dr. Vitt, the Coroner of St. Louis, in conjunction with the public safety campaign has made a thorough study in regard to the matter of statistics, and has developed a lot of information we didn't know could be had from his records. I asked him yesterday if he would not take up Mr. Crum's paper and make a study of it and then give us the results of his study during the past 24 hours. I am going to ask him now to give us his idea of what it contains and its value.

FORM FOR REPORTING ACCIDENTS

DR. R. S. VITT (Coroner, St. Louis, Mo.): It certainly was quite a pleasure to review with Mr. Crum and Mr. Ryder the work they had been

doing for months. I was amazed how thoroughly they had covered all the accidents and deaths. I do not believe that the form they have presented is too complicated. I rather think additions will be made. The only difficulty that I see in connection with the use of the form, and I don't think that is a serious one, is the question of locating the proper person in each locality to whom to make these reports.

CHAIRMAN TALBERT: The only question in my mind, Mr. Crum, is whether or not the report might be too complicated for the use of the average policeman or traffic officer who has to fill out the report?

MR. CRUM: I think you are under a misapprehension if you think the form is too complex. If you will go into the latter part of the report, it may appear complex, but accidents only find a place for tabulation in certain parts of the report. Policemen are intelligent people and know how to make reports. It is really very simple. If all the information is not given on the report a member of the Police Board, some clerk or assistant should follow the thing up and go right back to the man who made the report and get the information wanted. That information should be gotten immediately while the matter is hot, and not several weeks afterwards or a year afterwards when the thing is forgotten.

DR. VITT: I think we ought to decide where these reports should go. I think Mr. Crum's office would be the logical central bureau.

CHAIRMAN TALBERT: Does your scheme, Mr. Crum, provide for the codification of these statistics after they are received? What method would there be for accumulating this information?

MR. CRUM: They should go to some central organization, either one supported or organized by the National Safety Council, or to some voluntary agency to start with. I doubt that those forms will be in use next year in more than a half dozen large cities. I am quite sure that if no one else will do it, that our company will finance the printing of the forms and take care of the mechanical end of coding and tabulating it. I don't see how we could possibly spend money in a more serviceable way.

CHAIRMAN TALBERT: I will ask the committee then to devise some way, before leaving, of getting the reports back to some central point where they can be compared and tabulated.

FREDERICK S. CRUM: We may not be able to decide it here, but we will take care of that question.

INSPECTOR MAY: It seems that everything finally winds up in the standardization of accident reports and laws, and so I advocate standardization.

I have just finished a tour of the principal cities of the United States for the purpose of trying to learn what could be done to make Cleveland safer for the pedestrian and the careful driver.

One of the questions I went into was the use of accident reports used by the various cities. A good many cities follow the New York plan, but some of them have a form which doesn't mean anything. I think New York uses a good form, but Coroner Hoffman of Chicago gave me the best I saw. It all resolves it into this, that the fellow who makes the report is the one who makes the guess. Sixty-five per cent of automobile accidents are due to carelessness of the pedestrian. Some say 55 per cent and others 75 per cent, and it is a question of whether one can guess better

than the other. The man who makes the report should have certain things to answer. In fact, everything should be in there, as Mr. Crum has said.

CHAIRMAN TALBERT: Mr. DeArmand, the chairman of the publicity committee of the public safety section, will now make his report.

REPORT OF PUBLICITY COMMITTEE

LOUIS G. DEARMAND (Commissioner of Public Safety, Davenport, Ia.): The Publicity Committee assumes that we have a commodity to sell, safety to the public in public places. There is no need to go into details as to the methods to be used.

We carried on an investigation during the last three or four months in some thirty of the largest cities throughout the United States, and found that Detroit, St. Louis, Pittsburgh and Cleveland have done constructive work in publicity. That is, they have gotten what they went out to get, which was publicity without paying for it. It was found however that a great number of towns had no idea of how to get publicity on public safety work.

Now it is our idea that this committee should formulate a plan just as some manufacturer, department or retail store would do in advertising.

We are going to give equal attention to free publicity and paid publicity, with the idea that if a community is sincere in its endeavor to make the streets and highways and other public places safe for the public, that it ought to be sufficiently interested to raise money with which to pay for part of the publicity.

CHAIRMAN TALBERT: To my mind, that is one of the biggest things we have to work on. I am sure that a great many of you have some very definite ideas on publicity and how best to get it, so I am going to ask Mr. DeArmand to select three or four men from among you who will act as a sort of an advisory committee and coöperate with him during the year. The men selected should be fairly well scattered throughout the country. Mr. H. W. Mowery has a paper to read on the pedestrian hazard.

MR. MOWERY (American Abrasive Metals Co., New York City): Measured in terms of fatalities, the automobile or vehicular hazard is unquestionably in a class by itself. It surpasses all the other causes of casualties in its number. Closely following is the pedestrian hazard, which is due to the conditions of the walkways, and those two so far surpass any other form of casualty in public safety work, which are worthy of particular attention. Last year this committee prepared a paper on pedestrian hazards which was entitled "Making Walking Places Safe." This paper was presented to the meeting. The committee subsequently appointed to investigate pedestrian hazards met just once, the appointment being made only about six weeks ago, and that left us no time in which to do a great deal of work. However, reference was made to the paper presented last year, and upon reviewing it, it was the consensus of opinion in the committee that nothing better could be reported than to refer again to that paper and the recommendations with which it was closed. I will repeat.

(See Proceedings, Seventh Safety Congress, St. Louis, 1918, p. 385.)

We have gotten to that point in this work where some real constructive action is necessary. I think it would be well if some definite constructive action to enforce those recommendations could be taken.

CHAIRMAN TALBERT: I want to say that Mr. Mowery presented last year, one of the most exhaustive papers that it has been my pleasure to hear or to read, and it was included in last year's proceedings in full. Unless there is something else to come up now I am going to suggest that we adjourn.

(On motion made and duly seconded, the meeting adjourned.)

Adjournment.

FRIDAY AFTERNOON SESSION

THE meeting was called to order at 2:30 P. M., Mr. C. M. Talbert presiding.

CHAIRMAN TALBERT: Here is the particular thing for this afternoon, the question of considering whether the Traffic Code put out by the National Council of Defense and the publication called their Code should be adopted

NATIONAL TRAFFIC CODE

by this body. The code has been prepared by Mr. W. P. Eno of Washington, D. C. Mr. Eno is probably the best informed man on the traffic situation in the country, being the first man to take it up as a serious matter and to systematize it and to put it into effect. He wrote a number of pamphlets on it and made a trip or two to London and Paris where his lines of traffic control were adopted. He has never, however, to my knowledge, affiliated himself with this organization or any organization of this sort.

I say this at the outset, because we ought to give to Mr. Eno all the credit we possibly can for being the originator and the first in the field to attempt to put into definite form, traffic rules and regulations. This work of his dates back over the last ten or twelve years.

Some six months ago the National Council of Defense sent out a number of letters to a list of organizations, among which was the National Safety Council, suggesting taking up the matter of traffic regulations with the idea of formulating some that might be taken as a national code. They asked us to criticize this letter and return it to them. It happened at that time there was a meeting of the Executive Committee in Washington and I was not able to be there. Mr. Cameron was designated to represent the Council at that meeting and I emphasized to him the things that ought to be taken up in connection with this proposed regulation. Unfortunately Mr. Cameron wasn't there for some reason and that left the Council without representation. Having missed the first meeting it is rather difficult to get in touch with the question again, and, of course, no criticism was sent. This particular letter which I am going to read to

you now from Mr. Eno will give you the present status of the case, so far as the Council is concerned.

"COUNCIL OF NATIONAL DEFENSE

"Highways Transport Committee

"Washington, September 26, 1919

"Mr. S. J. Williams,

"National Safety Council,

"168 North Michigan Avenue,

"Chicago, Illinois

"My Dear Sir:

"I am sending you herewith my file of correspondence with you, dating from April until the present time. I am also enclosing a self addressed franked envelope for the return of this correspondence when you are through with it. I thought this would be the easiest way to bring the matter before you so that you could see at a glance where we stand. I am sorry I can not be at the meeting this year and therefore take this other method of again bringing to your attention the desirability and necessity of standardized Traffic Regulations.

"From the time we began our work last November, the National Safety Council was kept posted by circular letter of all our activities but did not apparently interest itself in doing anything towards assisting us either by suggestions or recommendations although from all over the country we received suggestions and recommendations and letters of approval in our efforts to bring about safety on the roads.

"I am also sending you a dozen of the General Highway Traffic Regulations adopted for standardization by the Council of National Defense on May 8th together with a dozen pamphlets which were sent out with these Regulations. These I send you for the use of your committee and would beg of you to approve of the regulations as they now stand.

"I think I explained to you before the plan of the Council of National Defense was to annually invite suggestions and recommendations and to pass upon whether they should be adopted or rejected.

"This has been a most strenuous campaign, involving continuous labor from November until the Regulations were adopted on May 8th. I hope I am not asking too much when I earnestly request your prompt coöperation at the present time.

"I deeply regret that I am not able to be present at the meeting this year. I shall never forget the conference I attended in Detroit some years ago and I am a great admirer of the good work your Council has been doing.

"Very sincerely yours,

"(Signed) W. P. Eno."

You observed in his letter he states particularly— "These I send you for the use of your committee and would beg of you to approve of the regulations as they now stand." The question is, shall we approve them as they stand?

Mr. COFFIN: I have had a copy of these General Highway Traffic Regu-

lations, for some time, and I cannot in justice to everything, vote to accept these regulations as they stand. They are not applicable to all parts of the country, in the first place. In the second place, some articles are rather antiquated. The State of New York follows these suggestions of Mr. Eno, and we used them to a large extent in drawing up the new State law of Oregon. I am heartily in favor of a standardization of traffic laws throughout the country. But I think it should be left to a committee to go over the existing conditions throughout the country, take them all into consideration, report back to the National Safety Council, and then through the various Legislatures ask that it be adopted as a general program.

LIEUT. LEWIS: As far as that Code goes, it is all right, but it doesn't go far enough. I think it would be foolish for this Council at the present time to approve something we are bound to change within a year or six months. We should go further into the matter and get a more complete code before we approve anything at all.

MR. MAY: I don't think we ought to flounder on this thing at all. I think we ought to take up each article separately and see whether it is practical for the whole country. We have to have certain regulations in certain places to cover special conditions.

CHAIRMAN TALBERT: In taking up these discussions, we must take them up by section; if we need a license law that question would become an argument by itself. The question now is, whether or not we approve them as they stand.

INSPECTOR MAY: I don't see any provision here for a license law, but Mr. Eno and his committee assume that there should be such a license law. I don't see anything in Section 1, that is not practical and wouldn't be a good thing.

CHAIRMAN TALBERT: The question is, is this traffic regulation a proper one?

INSPECTOR MAY: I move that Section 1, of this Article be adopted.

SERGEANT BLECKE (Cleveland): I second the motion.

MR. DEARMAND: I don't think we ought to adopt Section 1, on account of that last clause—"When for any other reason not competent to drive properly." We don't state what the reason is to drive properly, whether every driver should be licensed or only employed drivers, in other words chauffeurs.

LIEUT. LEWIS: Before we go any further, what would be the effect of the adoption by this Council of these regulations? Does that make the foundation of all traffic laws?

CHAIRMAN TALBERT: No, it is merely an endorsement of that particular part of the code as devised by the Council of National Defense. There is no official connection with that, as I know of. I don't see the connection between the National Council of Defense, which was a war measure, and the standardization of traffic regulations throughout the country. Nevertheless, they have undertaken it and it is a question whether we adopt their plan.

MR. COFFIN: I believe that a Committee should be appointed of the best men available in this country to take up the general rules and regu-

lations, and any other rules and regulations that may come before them, and draft a suitable standard code that can be brought back to this National Council next year. If this is done we will have a year to study this thing over and put it into practical shape. If we start to take and endorse this by section, it will take us a month of discussions as to whether it is proper or not. If we leave it to a committee which we know has the qualifications to draw up a suitable proposition we will get suitable and practical results.

CHAIRMAN TALBERT: It seems quite evident there will be opposition on this. Mr. Eno in his letter asked for a unanimous approval, and it is evident it is not the unanimous opinion of those here that we adopt at once the code proposed to us.

MR. C. HOWARD STEWART (LaCledé Gas Light Company, St. Louis): I have had the opportunity to glance through this code, and I can see no objection to approving it.

I heartily approve Mr. Coffin's suggestion, however, that a permanent committee be appointed to work out a code. Mr. Eno has simply asked us to endorse the work as far as it has progressed, that doesn't obligate the National Safety Council to take this code and accept it in its entirety.

CHAIRMAN TALBERT: Yes, that is what it would mean. We endorse it or we don't. If we do endorse it we become a part of it and endorse it as our code. Now, if we don't do it that way, we may on the other hand, accept it and offer to coöperate with them and endeavor to devise one that we will endorse. Certainly from the tone of the talk now and this morning, we are all for a standardized code. Then a theory of a standardized code we can approve, and we can take this one here and modify it in some way or make a new one entirely.

MR. L. J. SMYTH (Kansas City): I think this question is far too important for any snap judgment. The traffic situation in every large city is such that experts should give it at least a year of very thorough study before any uniform code is formulated. I would like to endorse Mr. Coffin's plan to adopt a committee to go into this question, give them all the time necessary so that they will finally be able to make recommendations that will really solve the traffic problem.

MR. R. N. HEMMING (Fort Wayne): I agree with Mr. Coffin, a committee ought to be appointed.

CAPT. JACK ROBBINS (Windsor, Canada): Speaking for Canada, I am one of the representatives and I think something should be done today, but as Mr. Smyth says, not on snap judgment. We come so close to Detroit it is going to interest us greatly, and we are going to work in co-operation with the United States laws.

MR. R. B. MORLEY (Toronto, Canada): I have talked with various members of the Toronto traffic squad and they are firmly of the opinion that traffic laws should be, that is certain fundamentals should be, uniform for the whole continent. I think it is also the feeling of the Police Department in other centers.

CHAIRMAN TALBERT: It is extremely difficult for a body of men to formulate in its entire detail, a code applicable to every town. A system

in one town will not answer for another, and yet we do know there are certain general principles of traffic that are by common consent recognized throughout the country, but they are only elemental. We can not attempt to devise a complete code at this time, that would undoubtedly entail long discussions, a great deal of work, committee meetings, and personal contact to thrash out those minor points. We are all committed to the general policy of standardization in our principal rules.

There are two things we can do today. We can appoint a resolution committee who can carefully consider Mr. Eno's letter—because their work should be recognized and the end they intend to attain should be recognized—and make it clear we are heartily in sympathy with that scheme; that we are willing to cooperate with them and work with them. We should attempt in that resolution to show how we can do that. We might at this time present certain definite, general basic rules of traffic that we would recommend be included at once in a national traffic code and that these rules be added to from time to time. As an example, we have in several States a rule that a vehicle on the right has the right of way. I don't know whether there is any national law upon that or not, in the United States. But that is the first simple elemental rule we have, drive to the right and yet it is only by common consent and by common usage that it is done. The vehicle on the right has the right of way, that is the rule practically everywhere, it is a State law in Missouri, and it may be in other States. There are two examples which are fundamental. We might add that we are willing to go on record in favor of a few fundamentals like that and to take on others from time to time.

I doubt if there is a man here who doesn't know the time it takes to get one board of aldermen to settle on a traffic law. How much more difficult would it be to formulate a law for the whole United States? It is a process of building up to it, not of days or weeks but of months and years. We could formulate certain rules which we may add to and make that the foundation upon which we build from time to time.

If we don't take any action on it, on the other hand, we can start up with these other things and build up from them. Having our policy started it will be much easier than to formulate a perfect regulation at the outset and have that adopted. I would like to have a discussion on that phase and particularly as to whether we should appoint a resolution committee to consider Mr. Eno's letter because it deserves all the courtesy that we can give.

MR. MOREY: It is a big problem for any one community to get into, and I think appointing a committee—we have never had a committee on that subject—would certainly be a good idea. Surely this body isn't ready to adopt a code, and I don't see how it can be approached in any other way than to appoint a committee of careful selection, men who will work and produce a definite report to be gone over and adopted in whole or in part and I surely will move the appointment of a committee to work on this.

CHAIRMAN TALBERT: What do you think of a resolution committee to answer his letter?

MR. MOREY: I would simply refer that to this committee who would immediately acknowledge receipt of the letter and tell Mr. Eno the matter

was referred to a committee and the results would come from it.

INSPECTOR MAY: I will withdraw my motion, and I think it will be all right for a committee to be appointed, but I really can't see the necessity of a year's wait for a report.

MR. J. H. HANSON (Rochester): I think this committee ought to take some action, say three months, or ninety days, that would be time enough.

MR. A. RYDER (New York): I agree with Inspector May, usually if you give a committee a year's time they will let nine months go by and then do it all in three months.

In this public safety education we are starting with the children. Why can't we look ahead ten or fifteen years on this thing? For instance, if you didn't have grade crossings you wouldn't have many of the problems that you are talking of today. I don't see why this same committee can't look into that question so that we can look forward to fool proof crossings at every busy section in the United States.

MR. CARL L. SMITH: I think we ought by all means appoint a committee to reply to Mr. Eno's letter. He has written us several times to get some definite suggestion from the National Safety Council and we ought to reply as soon as possible one way or the other.

It occurs to me that he mentioned sometime back in his correspondence that the revision of this code would be somewhere around January 1, that next January they are going to issue the new code with amendments and modifications and improvements that they have been receiving from all over the country. I, however, think that as far as a code is concerned, the National Safety Council is big enough and has representatives enough in States and practically all large cities, that we should prepare our own code and I think that if we appoint a committee here to take up this matter of code we should either write Mr. Eno or telegraph him before the Congress closes. In that telegram state that we have appointed a committee on the traffic situation that is going to work out a code, and then give that committee the power to work out a code along the lines we have been discussing. Don't wait until the next Congress to have them report, have them report in sixty days, or ninety days. The Executive Committee can get together perhaps in some future time and receive that report.

MR. MOREY: I think it vitally important that no confiction enter these things and a proper committee should be appointed and get in immediate touch, not only in acknowledging that letter, but in conference with that National Council of Defense, and these other bodies, the Automobile Clubs, etc., and be the medium to get a uniform code.

CHAIRMAN TALBERT: I have very distinctly in mind that we must do one of two things; either refuse any advice or suggestion from Mr. Eno, or get into it and do something. We must not come in and talk about a committee and then let it drift. If we acknowledge this letter in any way then we must follow our action, without which we would be stultifying ourselves. There is a motion made and seconded that the Chair appoint a committee to draft a reply to Mr. Eno's communication, that maybe in the form of a resolution, telegram, or whatever they think best. Those in favor say "Aye"—Contrary "No." The motion is carried.

COMMITTEE APPOINTED TO ANSWER MR. ENO'S COMMUNICATION

The Chair will appoint Mr. Carl L. Smith, Mr. H. P. Coffin, and Mr. Louis G. DeArmand to be the committee to draft that communication to Mr. Eno.

There is another matter brought up by Mr. Roemer, that is the manner in which this traffic committee shall carry out its work. He offers a suggestion that we should formulate certain definite things and then transmit them to the different communities and ask them to criticize them before we finally decide upon them. Do you think that is feasible?

MR. H. SPROEHRER (St. Louis): Before answering that specific question, my thought was that we have so much conflicting legislation on our books at the present time, if you are going to attempt to unify those laws in the various States then it is absolutely ill advised to adopt this code, because some of the States would immediately accept that endorsement and begin to found new laws on this code. The matter of appointing a committee and getting immediate action is the proper procedure.

As to the matter of submitting those opinions to the practical people, I think that is also highly advisable.

CHAIRMAN TALBERT: What is your idea, Mr. Morey? Is it feasible for the committee to formulate different rules and send them to the different communities and organizations?

MR. MOREY: I would say, to a certain extent that would be according to the amount of money, and the amount of time that can be put into it. I think if we had the money and we had the time, as to getting results from that sort of thing you would be getting opinions that would be almost invaluable.

MR. MORLEY: This matter has engaged the attention of the National Safety Council so long, I know the headquarters in Chicago will give all the necessary assistance in canvassing that this committee will want. I think it is a very important thing and as far as the expense, and time, and work, are concerned, I am sure the headquarters will help you.

MR. MOREY: I think we are agreed what the motion should be and I move you that the Chair appoint a committee, and leave it to his judgment as to how many, to consider this entire matter and get results.

(The motion was seconded.)

CHAIRMAN TALBERT: If I am empowered to appoint that committee I would take it up on the basis of the person; what the men could do and would do; their geographical location; and their ability to cooperate with other organizations on the same line. There are several organizations working on this and very much interested and we would give that very careful consideration.

MR. RYDER: The United States is engaged today, and will be engaged for the next five or ten years in building roads, mail roads all over the country. These roads are going to be permanent. I don't see why we shouldn't interest ourselves that those roads are built along the best lines for accident prevention work.

MR. ROEMER: This committee's work isn't building roads, it is conduct-

ing the traffic of those roads. I don't believe that it is within the scope of this committee to interfere with the building of roads.

CHAIRMAN TALBERT: I will say for Mr. Ryder's benefit that the matter mentioned by him was proposed in another meeting and will be given consideration. It is fairly certain that the Council will establish within the next six months, a separate division of engineering which will consider that phase of the work, e. g., the type of road that will be safest, but which would be entirely distinct from this committee's work. Road building has technical features entirely different from the regulation of traffic.

Are there any objections to the Chair appointing a committee of not less than seven members, bearing in mind what I said as to geographical location, etc.? Our Traffic Committee on the Safety First Federation consisted of twenty-one or twenty-two men. We held three or four different meetings, and we gave two or three days of discussion at each time, and I think we can have some of those men work on this. We will get the benefit of their work and ideas and also the cooperation of the American Automobile Association.

TRAFFIC COMMITTEE TO BE APPOINTED

The motion is made and seconded that the Chair appoint a committee to take up the phases of traffic as discussed.

(The motion was carried.)

CHAIRMAN TALBERT: Now shall we at the present time take up any further detailed discussion of this particular phase, or shall we leave that to the first report of that committee?

MR. STEWART: I move that the details of that traffic code be left to that committee to be reported on within ninety days, and a copy of that report be mailed to each member.

(The motion was duly seconded and carried.)

MR. MOREY: As Chairman of this Section the Chairman should put himself on that committee.

I move that Mr. Talbert be Chairman of this Committee.

(The motion was duly seconded and carried.)

CHAIRMAN TALBERT: I have been in considerable correspondence and I do know a good many men who are in the automobile business and the American Automobile Association. I am sure we can get their cooperation.

Now I want to bring up a matter Mr. Roemer and I were discussing.

MR. ROEMER: The question I would like to bring up this morning, Mr. Morey brought the first thought to mind, is the statement that manufacturers were trying to cooperate with the legislators and were to be complimented as to what they had done. The legislators were trying to get information, and in order to get legislation the manufacturers were spending money for these devices. The legislatures are willing to act if they can get the right information, but the proposition isn't submitted properly until some organization like the safety first organization goes behind the thing and approves it.

Now the one thing I have particularly in mind is a law that was just

passed in the State of California making it compulsory to put on the rear end of every closed automobile such a safety signal as would warn the man behind of your intentions. If you will look up statistics on accidents you will find an alarming percentage are rear end collisions, and these are due to faulty signals.

I would like to have this body, if it is possible, to do one of two things the same as the National Traffic Officers' Association did, on the Coast. Either to endorse such a proposition, or appoint a committee to investigate the points I have tried to bring out. That committee can report back to this section with a view of legislation and I am sure the manufacturers of any of these signal devices will aid you and the ultimate purpose will be gained and we will avert these accidents.

MR. HEMMING: I am interested in tail end signals. Some rear end signals are in the center of the car and some of them off to one side. I recall several accidents both rear end and front end, also side smashes because of lack of signal. We can greatly eliminate that class of accidents by defining a definite position for tail lights. To my mind, that should be on the left rear guard on top; red to the rear; green to the front or any combination of colors, for the reason that the approaching car has a gage line of clearance. That is very important, especially when one of the headlights is out on either car. The headlights being out is the cause of many head-on collisions or side swipes.

That is one important thing that the committee on standardization of rules should take into consideration. It is important not only in connection with automobile driving, but in every kind of traffic, especially on narrow streets where vehicles left on the curb are sometimes left out to such extent they are hit by the electric cars. If the signal were on the dash it would signify instantly what the clearance line is and accidents would be avoided.

CHAIRMAN TALBERT: Let us try to close, if we can, in the next ten or fifteen minutes.

Two or three years ago we had considerable discussion on uniform signals, or signs on the public highway. To my mind those signs undoubtedly should be uniform so that when a man is traveling he doesn't have to stop to read the sign. We are getting many national highways now, and we ought to have standardized signs. That question should be given fair study. We have three types of signals for the motorist, those on the roadside; those given by the traffic officer; and those on the car itself. Are not those three sufficient to ask for special consideration? In other words, ought they not be taken up separately from the traffic committee?

MR. MOREY: If one committee handles it you will get information from the same parties and there will be no duplication, and questionnaires, and letters, and all that.

CHAIRMAN TALBERT: We might appoint a subcommittee of the traffic committee.

MR. MOREY: I would suggest a subcommittee.

CHAIRMAN TALBERT: Mr. Coffin, what do you think of appointing a general traffic committee and dividing it into subcommittees?

MR. COFFIN: That is a very good idea, I am sure. The Chairman spoke

about standardized signals. We made a full set about five years ago which are now in the Museum in New York. This shows you the idea. As we adopted it in Portland, and I believe St. Louis has it, the green in the center denotes safety and carries the words: "Safety First". The ring outside is bright red, and on that you can print anything you wish. "Caution"—"School"—"Slow Down"—"Dangerous Corner"—"Keep to the Right"—"Steep Hill Ahead". That is mounted on a regular standard sign, or fastened to a telegraph pole. Signs where black lines are used don't show up at night.

MR. HEMMING: In the next six months we will be swamped with questions from all these committees. I suggest the committees be so mapped out, that they do not run at cross purposes.

CHAIRMAN TALBERT: My suggestion is that the Chicago office receive all this correspondence and tabulate the information. If these committees will do the investigation work the necessary clerical work will be done at the Council's office and that will simplify the committee work and get better results. These committees might formulate the questions and indicate the people to whom they should be sent, and the Chicago office will take care of it.

MR. SMITH: We beg to submit the report of the Resolutions Committee, and suggest that this telegram be sent to Mr. Eno tonight.

REPORT OF RESOLUTIONS COMMITTEE

"Mr. Wm. P. Eno,

"Your letter of September 26, 1919, was read today before a special session of the Public Safety Section of the National Safety Council, and it was unanimously agreed that the subject matter being of such vital importance to the country, your code was referred to a special committee for consideration, with instructions to report not later than January 1st, 1920.

"We thoroughly agree with you that a national traffic code should be adopted throughout the country.

"Mr. Charles M. Talbert, Director of Streets and Sewers, St. Louis, Missouri, and Chairman of Public Safety Section, National Safety Council, will advise the personnel of this committee.

"(Signed) Carl L. Smith

"Secretary Public Safety Section, National Safety Council, Chicago, Ill.

"H. A. Coffin

"Executive Secretary Public Safety Commission, Portland, Ore.

"Louis C. DeArmand

"Commissioner of Public Safety, Davenport, Iowa."

CHAIRMAN TALBERT: It has been moved and seconded this telegram be approved and forwarded to Mr. Eno tonight by night letter. Any discussion?

MR. RYDER: Any work that is done by the committee is absolutely free from Mr. Eno, is that the idea?

MR. COFFIN: This is only the committee on resolutions. We have no power to tie the committee to Mr. Eno, or any policy. We thought we would leave that to the committee.

CHAIRMAN TALBERT: I will send him a personal telegram telling him it is our purpose to cooperate with him just as fully as we possibly can. I will outline the purpose as discussed here this afternoon, stating that we thoroughly believe in a national code, we thoroughly agree with him in the necessity for it, and that this committee will expect to cooperate with him. If that is agreeable to the body, I will put this to a vote for approval. Those in favor of sending this to him signify by the usual manner. I will send them then. If there is nothing further we will adjourn until tomorrow morning.

Adjournment.

SATURDAY MORNING SESSION

THE meeting was called to order by Chairman Talbert at 9:30 A. M. CHAIRMAN TALBERT: The program this year made no provision for a business session. We have on our program this morning three papers, two of which I know can be covered in a general way in a very few minutes, but Mr. Crum's paper will probably take more time. It seems to me to be more worth while to discuss our general problems and how to carry them out, than to read those detailed statements. I suggest therefore, that the two papers be read by title, with a synopsis of what they contain, with the understanding that they will be published in full in the proceedings where they can be read by anyone interested, and that the time saved be given to a discussion of the matters of our work during the year and our program for the next convention. I would like to ask you what you think of that procedure?

(Suggestion unanimously approved.)

ESSENTIALS AND NON-ESSENTIALS, AND COST OF CONDUCTING A SAFETY WEEK CAMPAIGN

CARL L. SMITH, PUBLIC SAFETY FIELD SECRETARY,
NATIONAL SAFETY COUNCIL

In presenting this paper, I am asked to state, as briefly as possible, a few things that constitute essential things to be done in a Safety Week campaign, and their cost, as well as the things that might be done to help in the campaign and that could be classed as non-essentials. Our purpose in conducting a Safety Week campaign is obviously that we want to reach every man, woman, and child in the community and impress upon them the importance of Safety. To do this it is necessary that we have some avenue by which we can reach, without a great deal of trouble, the majority of the people in the city.

ESSENTIALS

Publicity—Our first thought, therefore, is plenty of publicity, and the services of a high-grade publicity man or woman should be secured to follow up and keep before the people the fact that there is to be a Safety Week and to secure the coöperation of every one, and have published daily all meritorious items of news. It depends entirely upon the community as to the cost of a publicity expert. He should be secured at least two months prior to the time the Safety Week is to be held. However, a fair average would be an estimate of \$400.00 for two months' work.

Schools—Another avenue that is, perhaps, more effective than any other, is the schools, and the first thing to do is to reach the parents of the children with an effective message on Safety. The method used in Rochester, St. Louis, and Cleveland is to send a letter—signed by the president of the Local Council or the president of the Chamber of Commerce—by the children to the parents, stating clearly the accident situation in the city, and asking their coöperation in the Safety Week campaign to help eliminate these accidents. On the reverse side of the letter a bulletin is compiled, giving the things that the parent should teach the child, together with a picture of a crippled child and the figures as to the number of children injured annually in the United States. At the bottom of the letter is a pledge which the parent signs, stating that the window card which accompanies the letter will be hung in a window of the home. After the card has been hung in the window and the pledge signed by the parent, the child then returns the pledge to the teacher, and the teacher gives the child a ticket which carries free admission to several rallies which will be held in the community. At these rallies Safety motion pictures are shown, with speakers on Safety; also community singing as well as special entertainment. This is essential No. 2 and is by far the most effective means of enlisting the support of the citizens that has ever been tried in any Safety Week campaign. A conservative estimate of the cost of this publicity for such cities as St. Louis and Cleveland was \$1,800.00, including distribution.

Stickers—The third essential and a preferable means of publicity and enlisting the support of citizens is through the coöperation of the automobile clubs. I say clubs because in some cities there is more than one club. In St. Louis, as well as in Cleveland, a sticker of the same design and wording as the window card in the homes was pasted on the wind shields of every automobile. This did three things:

1. It enlisted the support of the driver in the Safety Cause.
2. It educated him as to the things he could do to help eliminate accidents.
3. It advertised to the public that he was willing to drive safely, and kept before him, as a constant reminder for the week, that it was Safety Week, and that he was expected to drive safely.

The stickers for Cleveland were contributed by the Automobile Club, which took full charge of securing permission to paste them on the automobiles and arranged with the Boy Scouts for their distribution. The average cost for them was \$150.00.

In this connection, in St. Louis a letter was sent to every automobile owner, visualizing to him the number of fatalities caused by automobiles, and the sticker and the letter were sent through the mail at a great expense. As there was an average of 35,000 automobiles in St. Louis, and during the war the cost of postage was two cents per letter, it can be readily seen that using the mail was rather expensive. It was decided to eliminate this expense in Cleveland and depend upon the Boy Scouts to placard the majority of the automobiles. They distributed 40,000 stickers.

Safety Sunday. Setting aside the Sunday of Safety Week as Safety Sunday, and having the ministers and the priests in the city devote part or all of their time to a sermon on Safety, has proven to be a convincing way of arousing the church-goers' interest in the safety of the community. A large portion of the ministers are very enthusiastic and give all of their sermons to this subject, others devote a part of it, and, of course, some pass it by altogether. A booklet has always been prepared in all of our campaigns, setting forth just a few things that a minister should know to deliver properly a Safety sermon. Distribution of the book was made through the Secretary of the Church Federation, who, after securing the endorsement of the Board of Directors, sent a letter to every minister who was a member of his organization, asking him to preach on this subject Safety Sunday. The same thing can be said for the priests of the Diocese, and it has been found advantageous to have in the booklet a letter signed by the Archbishop and by the President or Secretary of the Church Federation. Accompanying the letter and the booklet on Safety Sunday, it has been found well to include another booklet, known as the Plan for Safety Week, containing a résumé of all the activities to be conducted Safety Week. The cost of the two booklets, letters, and distribution, averages \$200.00.

Cooperation of City Officials. The fifth essential which I might speak of would be the cooperation of all city officials, especially the Police Department, in holding a mass meeting of Police at which time Safety speakers would talk to them on what they could do to eliminate accidents during Safety Week, such as enforcement of the traffic rules and regulations; daily demonstrations by the Fire Department to show their interest in the Cause; and cooperation of other city officials, such as Superintendent of Streets, Judges of the Police Courts, Coroner, etc.

Cooperation of Street Car Company. I would deem getting the cooperation of the street car company in a city an essential part of the program and one which can be easily accomplished. In the two campaigns held in St. Louis and Cleveland, buttons of the same design as the window card and automobile sticker were distributed to the police and to the motormen and conductors of the street car company. Large posters of the same design as the window card were used on the front of the cars in St. Louis, and in Cleveland on the windows inside and outside and on some of the strap hangers. In Cleveland, the Cleveland Street Railway Company generously assumed all of this expense, amounting to \$350.00.

These six points that I have mentioned constitute really the founda-

tion of the campaign, and are the essential things that should be done, and must be done, in order to have in the smallest way an effective campaign, at a total cost of \$2,900.00.

NON-ESSENTIALS

As to the non-essentials, I will say that, of course, it is desirous to have as many things to interest the people as possible during the week in order to have sufficient momentum to arouse the interest of every one in the community and have them know that there is a Safety Week demonstration being held. The following are some of the attractions that contributed to the success of St. Louis' and Cleveland's Safety Weeks:

Parades. Now that the war is over, and people have had a rest from parades, these might well be included as a splendid way to draw the attention of the public. The schools (including any military organization), industrial bands and the drum corps of private concerns and organizations, can be mustered into service with little cost. In Cleveland every school held a parade in the vicinity of the school, and it proved a splendid way of interesting not only the child but also the parents as many of the mothers turned out to see their children parade.

Accident Clock. An effective way to interest citizens is to have something spectacular, such as the accident clock used in St. Louis and Cleveland, and banners to be placed on all vehicles of the city.

Circulars. Circulars on home and street safety, to be inserted in bundles by all department stores, reach many people, and 100,000 of these were distributed in Cleveland at a cost of \$210.00.

Teachers' Meeting. A mass meeting of all school teachers in the city is a splendid way of securing publicity and the proper propaganda on Safety, especially as regards school safety. Out-of-town speakers on this subject can be easily secured and this can be done at a small expense.

Complaint Cards. Complaint cards may be run in the newspapers during the week, giving the citizens a chance to report careless practices they see occurring on the streets, these complaints to be followed up by the Police Department by letter, calling the attention of the offender to an infraction of the traffic rules and regulations. In 99 cases out of 100, people will reply, apologizing and pledging their support and cooperation to make the city safe.

Safety Supplement. Sunday supplements in newspapers, as given in Cleveland by the Cleveland News-Leader, are far reaching in the interest aroused among the citizens.

Slogans on Milk Bottles. All milk companies can be enlisted to run slogans on the caps of the milk bottles, such as was done by the Telling-Belle-Vernon Company and others in Cleveland, reaching 200,000 people every day with a Safety message. This without cost.

Window Displays. Department stores will be glad to arrange for window displays providing that material for such displays is furnished them.

Slogans on Menus. Hotel and restaurant menus are splendid mediums for slogans, drawing the public's attention to Safety Week. These were successfully used this week in Cleveland at practically no cost.

Slogans on Bills. Telephone, Gas and Electric Light Companies will be glad to run the same slogan on all their monthly bills provided you interview them early in preparing your plans for Safety Week, as most of these companies have their printing done sixty to ninety days in advance. The City of Cleveland used a slogan on all letters and bills sent out.

Safety Speakers Before All Clubs, Organizations, High Schools. All clubs holding noon-day luncheons during Safety Week will be glad to have men who are of national prominence in safety work speak before their organizations. The high schools and normal schools are always glad to cooperate by having speakers talk to the students.

Demonstration of Boy Scouts. It is interesting to have the Boy Scouts give demonstrations and exhibits of First-aid Work at some central point in the city during the noon hours. The boys like to participate in this movement for they feel they are doing something worth while. These demonstrations also give good material for publicity and a great many homes are reached in this way.

Welcome Cards. The Retail Dealers' Association is glad to help in the arrangements for Safety Week in attending to such matters as arranging for the stores to exhibit Welcome Cards in their windows.

Advertising Club. The Advertising Club of St. Louis appointed an advisory committee to assist the secretary and general arrangement committee in all matters of publicity. In Cleveland the Advertising Club assumed entire charge of the out-door advertising, such as posters, bulletin boards, pennants for trolley wires and lamp posts, etc. They also prevailed on the members in the Club, who had contracted for advertisements in the newspapers during the week, to insert in the advertisement a slogan regarding Safety Week.

Motion Pictures. The Ford Motor Company of Detroit and the local motion picture people in Cleveland arranged to take motion pictures of all things that were done during the week. The local motion picture agency will distribute their films in every theatre in Cleveland following the week, showing the people the full story of Safety Week.

Slides in Theatres. Slides in theatres are effective. A week previous to Safety Week a black and white slide was run in all theatres of Cleveland, announcing the coming of Safety Week and asking the people to observe all rules of Safety. Two hundred slides were distributed in Cleveland at a cost of \$300.00. One hundred slides in three colors, of the same design as the window cards, showing how to make Cleveland safe from accidents, were run during Safety Week.

Prizes for Cartoons. In Cleveland and St. Louis prizes were offered for the five best cartoons published during Safety Week, as follows:

First prize	\$ 50.00
Second prize	30.00
Third prize	25.00
Fourth prize	20.00
Fifth prize	10.00

\$135.00

Notice was given to the cartoonists through the city editors of all newspapers. News items were published about the contest and letters were addressed to cartoonists personally inviting them to participate.

COST OF SAFETY WEEK DRIVE

The total cost of a Safety Week drive in cities the size of Cleveland and St. Louis can be safely estimated at \$3,000.00 for the necessary and essential things, and \$2,000.00 for the non-essentials, making a total cost of \$5,000.00, which does not include any entertainment when the Safety Week is a part of the plans for the holding of a National Safety Council's Annual Congress.

From the results achieved from Safety Week demonstrations we can safely assume that the National Safety Council has now a plan that will get results. In almost everything attempted, the idea has been to pledge those concerned to do their part. The result has been that we have secured coöperation, and it takes the coöperation of every man, woman, and child to have community safety.

I think we all realize that while a Safety Week demonstration does good and is far-reaching in awakening a community to the importance of Safety, it is only a start and is only intended to create the proper impetus for the establishing of a Public Safety Committee with a definite program of activities for a year's work—which will be explained to you in detail by the next speaker.

I think we are to be congratulated on the results obtained in Cleveland. As a result of the work done on public safety, we decreased the number of fatalities in Cleveland since the first of August, fifty per cent. Inspector May of this city who was present yesterday questioned that statement, so he went back to his office and on investigation found it to be true.

(Mr. Smith read Mr. Talbert's paper.)

ST. LOUIS PLAN OF PUBLIC SAFETY

C. M. TALBERT, DIRECTOR, DEPARTMENT OF STREETS AND SEWERS,
ST. LOUIS, MO.

There are three distinct and common causes of deaths in the United States today, viz., sickness, public accidents, and industrial accidents.

In the past five years splendid reduction has been made in fatal accidents in industry, due principally to the fact that the National Safety Council being an organization composed almost entirely of industrial men has focused its attention chiefly on the prevention of industrial accidents.

This demonstration has been fine and it has proved conclusively what can be done to control the human factor in industry. Managers of industries all over the country are now beginning to see that public accidents have a direct bearing on their business, just the same as industrial accidents. It is claimed by some that we cannot hope to reduce industrial accidents to the minimum that we should until something is done in the way of controlling careless habits of the employee on the street. For il-

illustration, it hardly seems good business to spend so much time and money educating an employee to be careful while he is working in industry if when he leaves the shop he forgets all that has been taught him, and on the way home is struck by a street car or automobile and fatally injured.

It matters little whether an employee is killed in the shop or on the street—it is obvious that the loss of a valuable workman to the employer is just the same. It is no consolation to the wife and children that their protector and provider was killed in a public accident, nor can industrial safety men feel that they have done their duty.

It is indeed encouraging to know that fatalities in industries the past five years have been decreased from 35,000 to 22,000; that serious injuries have been reduced from 750,000 to 500,000. It is rather discouraging to think that 80,000 people lose their lives every year in public accidents (6,000 of which are children under ten years of age), and that so many thousands of people are seriously injured that we hesitate to estimate the figure.

INDUSTRIAL SAFETY WORK SUCCESSFUL ONLY IN SPOTS

Factories all over the country have done efficient safety work but this success has been entirely individual, and in spots. Before the formation of the Central Mississippi Valley Division of the National Safety Council in St. Louis only 5 per cent of the factories in St. Louis were doing anything like efficient safety work. As a direct result of the work of this division during the past year all large manufacturing plants that are members of the National Safety Council are doing constructive work, and a great many of the smaller ones.

A liability manager for the largest insurance company in St. Louis recently stated that the safety work among his assureds had been increased 50 per cent the past year, and that this was due to the employing of a permanent secretary in the district who could give all of his time to the work, and the adopting of a permanent program with such activities as School for Safety Supervisors, when fifteen lessons on the fundamentals of safety were taught; each lecture being given by a high grade speaker. Over five hundred students were enrolled in this school with such men in attendance as managers, superintendents, safety engineers of plants, coroner and his deputies, insurance factory inspectors, and state factory inspectors. Two hundred and twenty-six of these students who had attended 75 per cent of the lectures were graduated and each received a diploma.

Other activities were monthly meetings for foremen and superintendents with an average attendance of 1,500 to 2,000; meetings for managers with an attendance from 200 to 400; motion picture shows in plants and safety instruction given to the children of the public schools.

SAFETY MUST BE PART OF COMMUNITY LIFE

This proves, does it not, that safety to be successful must be a part of

the community life, and an integral part of every man, woman, and child's life. People must come to respect safety just as they do pure milk, pure food, or pure drinking water.

We know the fundamental fact of safety work proven by the experience in industry is that only one-third of accidents can be eliminated by mechanical guards and that two-thirds must be eliminated by educational methods. What is true in industry is likewise true in public safety. Not more than one-third of the causes of fatal accidents on the streets can be taken care of by such installations as safety zones, crosswalks, proper signals, clearances, etc.

SAFETY WEEK IN ST. LOUIS

Can any definite results in public safety be shown by educational work? I think you will agree with me that this was conclusively proved by the demonstration of Safety Week in St. Louis last Fall which synchronized with our Seventh Annual Congress. Only one death occurred—a case of a drunken man falling from a wagon—notwithstanding the fact that previous records show that for several years there had been one to four deaths every day. The corresponding week in September, 1917, there were twenty-four deaths and the corresponding week in September, 1918, ten deaths occurred. Does this not prove that the human factor can be gotten hold of in a city with a population of 800,000 and that every man, woman, and child can be made to think Safety?

PERMANENT ORGANIZATION

Following the Seventh Annual Congress and the Safety Week demonstration in St. Louis steps were taken by the executive committee of the Central Mississippi Valley Division of the National Safety Council to appoint a permanent safety committee and to adopt a definite program of procedure to reduce the amount of public accidents in the city of St. Louis.

To begin, there were two fundamental questions to be considered: First: What steps should be taken to produce results; second, who were the logical men in St. Louis to do the work?

The committee decided to name a temporary chairman and they selected Mr. Arthur T. Morey whom most of you know because of his wide experience and intensive interest in safety work, and the fact that he was past president of the National Safety Council. The committee felt that by having a strong industrial man at the head of the General Public Safety Committee it would insure the permanency of the chairman, whereas if some one were named in public life, such as a director of public safety, a change in the administration might occur and the head of the committee would then be lost.

It was realized that no organization could expect to achieve the cooperation of all the citizens unless enough momentum was given the movement to arouse the public to the necessity for unanimity of action on the part of all the leading organizations of the city, so a public

meeting was held to which were invited representatives from all the leading organizations, such as the Automobile Club, Chamber of Commerce, City Club, Retail Dealers Association, Advertising Club, Team and Truck Owners' Association, Women's Clubs, representatives of the municipal government such as the mayor, coroner, chief of police and fire departments, police commissioners, director of streets and sewers, circuit attorney, prosecuting attorney, director of public safety, complaint board, health commissioner, comptroller, judges of all courts affecting traffic, superintendent of schools, etc.

PUBLIC MEN MUST BE INTERESTED

It was obvious that if we were to succeed in any plan it was necessary to interest the men who by reason of the office they held should necessarily be members of the committee. For instance, it would be rather foolish to organize a committee and not include the men whose duty it is to look after the welfare of the citizens. Imagine how ridiculous it would be to have an industrial man as the head of the statistical committee, whereas it is logical that the coroner would be the proper person by reason of the office he holds.

A personal visit was made to all of these men by some representative of the executive committee of the council and they were told of the proposed plans and sold the safety idea, just as it is necessary to sell a manager of a plant before you can expect to install any spirit of safety in the works.

PUBLIC MEN NOT FAMILIAR WITH SAFETY

To prove further the necessity for this personal contact, would it surprise you to know that the coroner of St. Louis, Dr. R. S. VHL, who is one of the most ardent safety supporters in our city, did not know previous to the holding of the Seventh Annual Congress in St. Louis last fall that such an organization as the National Safety Council existed, and what is true of the coroner of St. Louis is true of 95 per cent of all the public office holders in our large cities today.

As I said before this general meeting of public men was held, at which time the general chairman outlined the reasons why we should take some definite steps to form a public safety committee with a definite plan of action. All present were asked to submit suggestions regarding things that should be attempted and the names of the men in St. Louis who should naturally undertake the work, also what committees should be formed to correct the present careless condition.

Figures were given by the coroner's office showing the number of deaths occurring last year, their causes, etc. All newspapers were represented by reporters.

After all had gone on record as to their willingness to support the idea of a public safety committee, it was moved and seconded that a general chairman and a general secretary be elected and the general chairman be empowered to appoint a committee to select men to serve

on the various committees and to outline the tentative duties of these committees, and at the next meeting these committees appointed should form and elect a chairman and secretary of their committee and then submit to the general committee their plan of action for approval. This was done and the following is the plan as adopted:

THE PLAN

AUTOMOBILE AND LEGISLATION COMMITTEE: It was obvious that it was necessary to have a strong committee to look after the many activities that would naturally come under this heading, such as parking problems, traffic regulations, hazard of pedestrians, speeding, head lights, slowing-down at crossings, etc., and the following committees were named. Please note the official connection of the men on this committee: C. M. Talbert, superintendent of streets and sewers, chairman; J. C. Josse, superintendent Continental Portland Cement Company, secretary; F. S. Pingree, president St. Louis Automobile Club; Howard Siderer, prosecuting attorney; J. A. Bruner, secretary Lawton-Byrnes-Bruner Insurance Agency; Louis Nolte, comptroller; Lawrence W. Daniel, assistant attorney; Patrick Kelleher, general superintendent Columbia Transfer Company.

SUB-COMMITTEE ON AUTOMOBILE PARKING: H. E. Engel, secretary, Team and Truck Owners' Association; T. B. Wirtke, attorney; K. F. Niemoeller, secretary, St. Louis Retail Credit Company; A. E. Martin, Martin-Breitt Real Estate Company; Dr. W. H. Bruner.

SUB-COMMITTEE ON TRAFFIC LAWS AND REGULATIONS: Howard Siderer, prosecuting attorney; T. B. Wirtke, attorney.

SUB-COMMITTEE ON PRIORITY FOR PEDESTRIANS, WOMEN, AND VEHICLE DRIVERS: F. S. Pingree, president St. Louis Automobile Club; J. A. Bruner, secretary, Lawton-Byrnes-Bruner Insurance Agency.

RECOMMENDATIONS ADOPTED BY COMMITTEES

1. Licensing of professional chauffeurs and teamsters.
2. Regulations for pedestrians, such as adopting of city ordinance to compel pedestrians to cross the streets at the crosswalks and refrain from crossing in the middle of the block.
3. Parking laws to be revised in the congested district for the limit of thirty minutes on some streets and one hour on other streets; also, that certain streets be kept entirely free from parking and be used exclusively for heavy hauling for teams and automobile trucks.
4. Additional traffic police to be provided on busy intersections and between crossings, and to enforce traffic regulations pertaining to both pedestrians and vehicles.
5. Effort to be made to have all pedestrians at intersections follow the signal of the traffic officer and move with the traffic.
6. School to be held for licensed chauffeurs. Suggested subjects to be taught:

- a. Traffic rules
- b. Safe operations of automobile and truck.
- c. Hazards on the streets
- d. How accidents occur
- e. Dangerous curbs and corners
- f. Proper signals

Other subjects to be selected and speakers for these subjects to be secured and pamphlets provided on each subject by the headquarters staff of the National Safety Council.

VIGILANCE COMMITTEE

Were you to ask me what is the one thing most needed in every city to promote public safety, I should unhesitatingly say the enforcement of the present traffic laws. Police are handicapped in making arrests and securing prosecutions in the courts because there has been no united effort on the part of the citizens, or on the part of any organization to cooperate with the judges in securing this end. What arrests are made usually result in no conviction in the courts because of the fronting done by the friends of the arrested one.

I dare say that a great many men in this room have passed through this experience. Most everyone has some friend that will say a quiet word to the judge. When the judges were asked about this condition they said: "What is the use of convicting or fining one offender when there are hundreds doing the same thing every day who are not molested. If any united effort is made to stop men who are infracting the law, we will do our part." So a vigilance committee was formed to give special attention to this need. This committee is at present composed of one hundred and fifty prominent men.

First, five men were appointed on the committee, viz: Major Roy F. Britton, attorney, chairman; William Dover, deputy coroner, secretary; Herman Spoehrer, secretary and treasurer Union Electric Light and Power Company; C. M. Talbert, superintendent of streets and sewers; Cline Finnell, president Junior Chamber of Commerce.

The chairman selected was a man who had charge of the four hundred and sixty secret police during the war. These five men met and adopted a pledge card that every member of the committee must sign before becoming a member, as follows:

PLEDGE

As a member of the vigilance committee of the St. Louis Safety Council, I realize the importance of eliminating needless traffic accidents and promise that I will faithfully endeavor to note all instances of hazardous violation of traffic regulations coming under my observation on "Chance Taking Reports," and forward same promptly to Secretary E. G. Marsh, Complaint Board, City Hall, St. Louis, Mo.

I have read the ordinances of the City of St. Louis and the laws of

Public Safety Section

1051

Missouri relating to motor vehicles and traffic regulations and consider myself competent to report violations.

Name

Address

Telephone No.

He is then given a number and thereafter is known not as Mr. John Brown, but as number 23, 24, etc., and is supplied with a number of report cards on which he is pledged to report careless practices occurring on the streets, as the following sample complaint card:

REPORT OF CHANCE TAKING

Month.....Day.....191.....Time.....M.

Location

License No.

(X opposite violation, or write in blank space)

-Recklessly drove in front of moving car.
 -Recklessly passed car while taking on or off passengers.
 -Pulled in front of approaching car when parking.
 -Passed car to left on double track.
 -Created hazard by excessive speed.
 -Did not slow up on nearing pedestrian at crossing.
 -Did not give way to right for faster moving vehicle.
 -Passed another vehicle to right.
 -Failed to signal change of direction, slow down, stop.
 -Started from curb into traffic without giving notice.
 -Front; rear lights out.
 -Did not sound horn or slow down nearing crossing or curve with obstructed view.
 -Did not show license as required by law.
 -Driver continued on after accident.
- (Write particular not covered above)

Witness(Name)

Address

Car No.....

Signature.....

These cards when filled out are sent to the secretary of the Complaint Board who takes the matter up either personally or by letter with the person concerned. Complaint card is filed by license number of the car.

Should a second offense be reported more severe measures are taken and in case of a man being tried in court for careless practices, such as speeding, etc., the judge will look up his record at the Complaint Board and see if he has had previous complaint made against him. Imagine if you can what chance a man would have of being acquitted by a safety judge when a judge finds there are three or four complaints filed against the offender for carelessness.

Each one of these five men agreed to name five more men and be responsible for their instruction. This made a total of twenty-five men. These twenty-five after they had signed the pledge card and had a little experience named five more men, making a grand total of one hundred and fifty men.

The idea was taken up slowly until the results could be demonstrated. As stated before the names of the committee are held entirely secret; the secretary being the only one who has the file showing who these men are. It is not necessary for them to sign their name in making complaint, they simply sign the number by which they are known. You never can tell but what the friend you are driving around on Sunday afternoon in your car is one of these special police.

As an example of the public's willingness to coöperate, here is a sample of the many letters received in answer to letter sent out by the Complaint Board calling attention to the violation of traffic laws:

BROWN PLANING MILL COMPANY

Manufacturers of

SASH, DOORS, AND BLINDS

3100 Salena St.

St. Louis, Mo., March 29, 1919.

Mr. E. G. Marsh, Secretary, Complaint Board,
Municipal Courts Building,
St. Louis, Mo.

Dear Mr. Marsh:

Referring to your letter of complaint calling attention to the reckless driving of our truck driver on Grand Avenue, regret exceedingly this inexcusable offense. We have reprimanded him severely and will let him out if further complaints are received.

We certainly do not approve of these reckless tactics, and will be glad at any time to coöperate with your office to reduce these violations.

Thanking you for your kind letter, we are

Yours very truly,

(Signed) A. R. BROWN.

COMPLAINT COMMITTEE

Lewis B. Tune, superintendent of Bradstreets, chairman; E. G. Marsh, secretary of Complaint Board, secretary.

The specific duties of this committee are to follow the complaints that are received from the Vigilance Committee. We have found that em-

ployers of labor and business men are very considerate and courteous about replying to a letter calling their attention to infractions of traffic regulations. The records show that only two people out of one hundred and fifty to whom letters were sent calling attention to complaints received failed to answer the letter sent them by the Complaint Board. In cases like this the secretary of the Complaint Bureau gives the complaint special attention, and should further reports be received against such individuals the matter is called to the attention of the judges of the police court and summons are issued for their appearance in court and they are tried on the last complaint filed against them. In special cases like this it is sometimes necessary for the man filing the complaint to appear as a witness. This they are willing to do.

COURTS

C. B. Hardin, president, Central Mississippi Valley Division, N. S. C., chairman; C. L. Smith, secretary, Central Mississippi Valley Division, N. S. C., secretary; Chauncey I. Krueger, judge Court of Criminal Correction; Calvin Miller, judge of Criminal Court; George E. Mix, judge City Court No. 1; Anthony F. Ittner, judge City Court No. 2.

The purpose of this committee is to adopt a uniform method of dealing with traffic violators and to cooperate with the police and other committees. You will be interested to know that this was the first time the judges of the courts of St. Louis got together on a problem of mutual interest. With every judge a safety judge, changes of venue for the traffic violator will be a thing of the past.

STATISTICS

Dr. R. S. Vitt, coroner, chairman; W. L. Patterson, St. Louis Motor Service Company, secretary; M. W. Doyle, American Automobile Insurance Company; Barney Verheyen, assistant to chief of police.

One of the greatest helps in tackling an accident condition is to have a thorough analysis and study of causes. To understand such problems as the automobile problems and for the use of various other committees, it is necessary to have a statistical committee that could give a statistical analysis of all automobile and vehicle accidents, advising for instance: Ages of victims; ages of drivers; condition of drivers, whether intoxicated, etc.; whether drivers were owners, members of family, or employees; location of accidents; description of accidents; cost of accidents, such as property damage; personal property and personal damage; what laws, rules, or cautions were violated; adoption of proper form to report accidents; analysing causes of accidents; securing pictures of all wrecks and furnishing a statement of the accident. This to be used as propaganda matter for bulletins, etc.

POLICE

C. H. Stewart, assistant treasurer, Laclede Gas Light Company, chairman; Barney Verheyen, assistant to chief of police, secretary; C. W.

Mansur, president, Board of Police Commissioners; Wm. A. Giralдин, member, Board of Police Commissioners.

This committee is to assist the police department and help them realize that in their hands lies a large part of the solution of this automobile situation, and to procure for the police the necessary backing of public opinion and the police courts.

The following recommendations were adopted by this committee:

Safety code for patrolmen

Proper report form for accidents

School for police—suggested subjects to be taught.

1. Handling pedestrians
2. Statistics
3. Automobile and truck hazards
4. Hazards of children playing on the streets
5. Parking problems
6. Enforcement of traffic regulations
7. Proper safety equipment

SCHOOLS

Dr. John W. Withers, Superintendent of Instruction, chairman; George Platt Knox, assistant superintendent of instruction, secretary; Dr. E. George Payne, principal, Harris Teachers' College; Carl G. Rathman, Assistant Superintendent of Instruction; Henry J. Gerling, Assistant Superintendent of Instruction; W. J. S. Bryan, Assistant Superintendent of Instruction; Rev. J. P. M. Murray, Supervisor of Instruction Parochial Schools.

It is obvious this committee's work has to do with the safety education of children which involves instruction covering such items as: Roller skating in streets; bicycle riding in streets; playing ball in streets; "hitching" onto vehicles; unsafe coasting in and across streets; playing tag in streets; simple rules as to crossing streets safely; secure proper material for instruction of children.

The plan for instruction of children has been well worked out by Dr. E. George Payne, principal of the Harris Teachers' College, St. Louis. Dr. Payne has written a syllabus covering the teaching of safety to the children, and the matter of school safety will be taken up in detail at one of our general sessions.

STREET CARS.

Bruce Cameron, superintendent, United Railways Company, chairman; Homer Hodson, safety engineer, East St. Louis & Suburban Railway, secretary; George Fisher, assistant to manager, Illinois Traction System.

This committee adopted the following on which to focus their attention: Constant education of motormen and conductors; safety slogans inside and on front of cars; special lectures to motormen and conductors; backs of transfers to be utilized for safety slogans.

BULLETINS AND PUBLICITY

Carl L. Smith, secretary, Central Mississippi Valley Division, N. S. C.,

chairman; Anita Moore, publicity expert; H. J. Krusz, Ludlow-Saylor Wire Company, secretary; H. C. Davis, assistant treasurer, Wagner Electric Company.

This committee will give their attention to the following items: Publicity, such as all items of interest to newspapers, house organs and trade magazines; establishment of standard bulletin boards in all garages and gasoline stations, using public safety bulletins of the National Safety Council monthly; designing monthly bulletins regarding home accidents which are distributed into the homes by the school children; cooperation with other committees and especially Women's Committee in regard to bulletins for the home.

WOMEN'S COMMITTEE

The members of this committee should consist of the prominent members of the various Women's Clubs of the city, such as Women's Council of National Defense, Federated Clubs, etc.

The duties of this committee will consist of taking charge of the distribution of bulletins in the home each month by school children; to arrange for speakers to talk before all women's societies, parents, teachers' organizations, etc., and such other work as they see fit.

CLUBS AND ORGANIZATIONS

Dr. E. George Payne, Principal, Harris Teachers' College, Chairman.

This committee is organized solely for the purpose of supplying speakers on Industrial, Home, and Street Safety. Its duties consist of: Organizing Speakers' Bureau and training men, women, boys, and girls for speakers to hold themselves in readiness to speak as they may be assigned; to supply speakers for all clubs and organizations upon request.

PLAYGROUNDS

Nelson Cunliff, Park Commissioner, Chairman; T. P. Chapman, Chairman, Parks and Recreation Committee, Chamber of Commerce, Secretary; Martin Collins, President, Papa Club.

This committee is primarily for the purpose of establishing safety in connection with all playgrounds. Their activities are as follows: Playground safety; motion picture shows on playgrounds during summer months; utilization of streets for playgrounds.

FEW COMMITTEES DESIRABLE

The mistake has often been made in organizing a Public Safety Committee to have too many sub-committees, so that the committees become burdensome. In the outline that I have given you there is but one committee—a General Committee. All of the sub-committees are a part of the General Committee and meet when the General Committee meets at a regular monthly meeting. In this way should a member of any sub-committee desire information an opportunity is given to any member of the other

the papers in detail. That will allow us more time for questions and discussion, because every man who comes into this meeting should be allowed, and even requested to give us his ideas.

DISCUSSION

MR. ROEMER: I think that inasmuch as the time allowed for the various meetings is very short, that the plan you have suggested is the proper one, especially so since the real good out of any particular subject is gained through the discussion and questions. That was shown on several different matters yesterday. I think your plan is the best.

H. B. ADAMS (A. E. & C. R. R., Aurora, Ill.): I believe we will save a lot of valuable time in adopting your plan. Time is very valuable; when we come a thousand miles to get to one of these conventions we ought to conserve it.

MR. DEARMAND: I move that the plan as outlined by the Chairman be adopted and submitted to the Executive Committee, for approval.

Motion seconded by Mr. R. N. Hemming, Fort Wayne, Ind.

CHAIRMAN TALBERT: It is moved and seconded that this Section request of the Executive Committee that at the next annual convention it be assigned a definite room for the entire period of the Congress, with a Secretary or Assistant Secretary who will be in charge during the entire time, and that the place assigned be at some point commensurate with the work we have in charge.

(Motion unanimously adopted.)

MR. SMITH: I think the idea is a good one. I think that can be worked out very easily. I will certainly give it my attention and I will see that the details are carried out according to the plans adopted.

PROGRAM SUGGESTIONS FOR 1920

CHAIRMAN TALBERT: Before we start on the next paper I want to ask for suggestions as to the character of the program for next year. The work this year has been carried on by six committees, the Traffic, Statistical, Educational, Elevators, Publicity, and Pedestrian Hazards. Next year's program should be taken up largely with the reports of these committees and their discussions.

MR. DEARMAND: I suggest that we have a paper by some street railway man. Also it seems to me to be a good idea to have some member of a teamster's union present the teamster's side of the proposition of public safety as it relates to vehicles and pedestrians.

CLAIR BOWERS (Goodyear Tire & Rubber Co., Akron, Ohio.): I would like to recommend that we have four papers presented, one by a policeman or traffic man who is outside and sees the accidents, one by a postman, and one each by a teamster and an automobile man.

MR. MORLEY: What we want to get at is essentials. We want to find out exactly what people in the different modes of locomotion on the streets and highways think of the other fellow. We want to give their attitude to the public at large, and if we can take these four classes and can get

someone who will come and give us their ideas on the subject, we will evolve something a great deal better than if we had them tell us what they think they do is right.

CHAIRMAN TALBERT: A suggestion was made yesterday that next year we hold a joint meeting of this section and the Educational Section. Mr. Hemming, what is your opinion of that suggestion?

MR. HEMMING (Chairman, Public Utility Section, National Safety Council): I would like to see it go one better. Inasmuch as the electric railway field is so closely allied with the public safety proposition, I would like to see a joint session combining the three, public safety, transportation and public education. I think the two Sections would be deeply interested in the educational feature, and that is the thing we are all driving at. If we can get the Public Safety Section to meet with us jointly, I think we would be able to thrash out in a very short time problems the solution of which otherwise would take a period of from three to five years.

CHAIRMAN TALBERT: We will ask the Executive Committee for a joint session of the Public Safety Section, the Educational and the Electric Railways' Sections.

DR. PAYNE: It seems to me that there is a little bit of duplication there. You have an Educational committee of this Public Safety Section, and you also have an Educational Section. It seems to me that the Educational Section really belongs to the Public Safety Section as a part of its work, and therefore the program should be merely a part of this Section's program.

MR. VIRT: There are two subjects which we have discussed very little here, which I would like to see taken up at our next year's convention, and they are Vigilance Committees and the police judges' attitude with reference to traffic violations. I believe that traffic violations play a very important part in large cities' relations to public safety, and we should have a freer discussion at our convention next year as to what large cities are doing to the traffic violators, and the attitude of the police judges.

MR. TALBERT: We found that was one of the best plans we could get hold of, because the judges go back to the bench with the public attitude toward these accidents. The question now is whether we should have a paper from some judge or traffic court dealing with that point of public safety. (There were remarks of approval.)

MR. JOSSE: Mr. Chairman, for the benefit of those gentlemen who are not from St. Louis, I suggest that you outline the coöperation we have received from our two police judges since they joined our committee. When a man comes up before either of those judges, it doesn't make any difference whether he has a "fixer" or not, he gets it, that is all. Our State Headlight Law went along for 18 months without any prosecutions at all; but when these two judges got in they notified automobile drivers that they were going to start enforcing that law on a certain day, and they started too. They had six hundred violators the first day and every one of them was fined. That has a very salutary effect on a fellow. Out of some eleven thousand men who came up before these two judges in

three months' time for violations of automobile laws, only two repeaters were reported, and they won't repeat again.

MR. TALBERT: I remember Judge Mix apologized at one of our meetings because he was only 98 per cent pure, saying he had let two people off. So far as the judge is concerned, the moral support of somebody back of him is the greatest possible thing you can have in enforcing your traffic regulations.

Then I have added to the prospective papers for next year, one by some police magistrate on his view of traffic violations and hazards of that nature.

DR. S. DANA HUBBARD (Supt. Division of Industrial Hygiene, New York City): I would suggest for a paper of that nature that you select a man who is Secretary of State.

MR. SMITH: The question arises there whether the Secretary of States is really sold on the question of safety as strongly as a judge is?

MR. HUBBARD: In New York State the present law gives him the power to abrogate a license, and he is now sitting as a magistrate.

MR. SMITH: Yes, but I see he has almost taken the punch out of the law by saying that he is going to modify the power of the law, and is not going to compel automobile drivers to become licensed, except in the cases of new ones.

DR. HUBBARD: I don't think you quite understand it. His plan is this. In licensing new drivers, men who have never driven before, he is going to require a physical examination. My complaint was that there were some 35 or 40 narcotic addicts who were driving up to the clinics on trucks and getting their dope, and it was my opinion that a physical examination should be required, as both a snuffler and a needle man could be recognized. Mr. Hugo stated he would not require a physical examination of every person, nor a road test. Mr. Hugo is sitting as a committee magistrate, and any man who repeatedly violates the law is brought before him, and if it is a question of intoxication, reckless driving, incompetency, moral deficiency, etc., he immediately stops his license.

MR. TALBERT: Mr. Smith suggests that we have a paper outlining the methods followed by Vigilance Committees in the various cities. Do you think that question is worthy of a paper and discussion?

MR. SMITH: Four Vigilance Committees are working now, one in St. Louis, Pittsburgh, Kansas City and Cleveland.

LOUIS G. DEARMOND (Davenport, Ia.): What success have they had in St. Louis?

MR. VITT: I think they have had very good success. I know that on some days they send in as high as fifty and one hundred reports of violations of Ordinances. The reports are sent in to Mr. Marsh, who is Chairman of the Complaint Board, and he in turn writes them a letter calling attention to the violation which has been reported. He reports that 95 per cent of the answers to his letters are courteous and apologetic. From eleven or twelve hundred reports from the Vigilance Committee, he probably has a half dozen repeaters, which shows that some attention is being paid to the letters from the Complaint Board. To those who do not answer he writes a second letter and refers the names of the parties

to the Chief of Police, who sends for them and talks to them in rather a corrective manner. There are no fines or other methods used. It is merely a corrective plan.

CHAIRMAN TALBERT: I am going to ask our Secretary, Mr. Carl Smith, to bear this topic in mind and during the year collect all data he can from all cities having Vigilance Committees, and then present a digest of the results. We can then go on record as to whether Vigilance Committees are desirable. We will now proceed to Mr. Crum's paper.

FREDERICK S. CRUM (Prudential Insurance Co., Newark, N. J.): I will not read the report in full, but will run over it and pick out the more important points and elaborate on them a little, and then the report will be printed in full in the proceedings.

PUBLIC ACCIDENTS AND THEIR COST

FREDERICK S. CRUM, PH. D., ASSISTANT STATISTICIAN, THE PRUDENTIAL INSURANCE COMPANY OF AMERICA, NEWARK, N. J.

Accidents to persons may be conveniently divided, or classified, into three main groups—namely, INDUSTRIAL, or those arising out of industry or employment, HOME, or those occurring in and immediately about the home, and PUBLIC, or those met with in public places. This grouping is not entirely satisfactory but if it can be generally adhered to, a beginning will have been made in clearing up what is now a very chaotic condition in the statistics of personal accidents.

We are all familiar with these three types of accidents, but no one can say definitely what proportion each type forms of the grand total of personal accidents. Almost nowhere, in the various and numerous official reports of accidents, is there a sharp differentiation made of these three classes of accidents. Fairly satisfactory distinction is made in the Interstate Commerce Commission reports between accidents to employees (industrial accidents) and accidents affecting passengers and trespassers (mostly public accidents) but even here there is an overlapping. A commercial traveller, for illustration, must use trains in the pursuit of his occupation. If killed in a train accident, the death can quite logically be classified either as an industrial or a public accident. Similarly, if a driver of a truck is killed in the street as a result of collision, or other accident occurring while in the pursuit of his regular work, the death is very likely to be classified both as an industrial and as a public accident. In other words, public accidents are quite likely to include or affect a very considerable number of industrially employed persons who are in the pursuit of their vocations when the accidents occur.

One of the most laudable recent attempts to separate persons killed as a direct result of their employment from persons killed otherwise is that made by The Metropolitan Life Insurance Company.¹

¹See *Mortality Statistics of Insured Wage Earners and Their Families*, by Louis I. Dublin, Ph.D., Statistician. New York: 1919.

In this mortality experience—limited to white males, ages 15 and over, and for the period 1912-1916—out of 14,151 deaths from sixteen specified causes or forms of accidents, careful inquiry revealed the fact that only 28 per cent were definitely assignable to occupation or were of occupational origin. If weather agencies, such as lightning, excessive cold, excessive heat (insolation) and certain other forms or types of accident had been included, the percentage would have been smaller. Again, it must be remembered that this experience embraced mainly the industrially employed, or wage-earners. If the professional, commercial, and other largely non-wage earning classes had been as fully represented as in the general population, the effect would have been still further to reduce the percentage of accidental fatalities of occupational origin. In only four types of accidents in this experience traumatism in mines and quarries (91.4 per cent), traumatism by machines (80.9 per cent), crushing—other than vehicular and in mines and quarries, by machines and by falls (64.9 per cent), and electricity—lightning excepted (61.9 per cent)—were the percentages of fatalities of occupational origin in excess of fifty. On the other hand for drowning accidents the percentage of occupational origin was only 6.2 and for falls the percentage was only 6.3. For railroad accidents the percentage assignable to occupation was only 35.2. Obviously if females had been included in this experience these percentages would have been further and quite materially reduced.

If we assume that one-fourth the total accidental fatalities in the general population of ages 15 years and upward are due to occupation the estimate is probably a liberal one. Three-fourths of the deaths by accident, ages 15 and over, would then be assignable to either PUBLIC or HOME accidents. Here, however, we are left without any very definite knowledge of what percentage or proportion belongs to either class. From general knowledge and experience, however, it seems reasonably certain that fully one-half of all the fatal accidents in the United States are chargeable to public accidents. It is quite probable that the true proportion considering all ages is nearer 60 than 50 per cent, but to be conservative, this argument will be based upon the assumption that 50 per cent of all accident fatalities in the United States are of the public type.

In the registration area of the United States during the calendar year 1917, which then embraced about 73 per cent of the total population there were 65,644 accidental deaths, so reported. For the whole population and area of the continental United States the total of accidental deaths must have been close to 90,000 during 1917. On the basis of the above assumption 45,000 of these may be considered as having been of the PUBLIC type. Of this total (45,000) about three-fourths were males and one-fourth females.

Considering the age factor, we know that in the registration area during the ten years 1907-1916, 12 per cent of the decedents by accident were of ages under 5 years, 9 per cent, ages 5-14 years, 44 per cent, ages 15-44, 20 per cent, ages 45-64 and 15 per cent, ages 65 and over. The age distribution of those killed by accident are quite different for the two sexes, however, as the following table clearly shows:

AGE DISTRIBUTION OF ACCIDENTAL DEATHS

U. S. REGISTRATION AREA, 1907-1916

Ages	Total Deaths		Male Deaths		Female Deaths	
	Number	Per cent	Number	Per cent	Number	Per cent
Under 5.....	56,613	11.9	31,562	8.6	25,051	22.9
5-14	43,100	9.1	31,739	8.7	11,361	10.4
15-44	209,172	44.0	185,509	50.7	23,663	21.6
45-64	95,823	20.1	80,233	21.9	15,590	14.2
65 and over.....	70,926	14.9	37,072	10.1	33,854	30.9
All known ages.....	475,634	100.0	366,115	100.0	109,519	100.0
Unknown	2,777		2,608		169	
All ages.....	478,411		368,723		109,688	

Among females a much larger proportion of fatal accidents occur at the extremes of life, that is at ages under 5 and at 65 and upward, than is true of males and, conversely, the proportion of ages 15-44 is much smaller for females, or only 21.6 per cent as against 50.7 per cent for males.

Returning now to the fatal accidents which occurred in the United States during 1917—the total was estimated at 90,000 for the continental United States during 1917, or 1,730 per week, and the public accidents, constituting fully one-half of the total, were estimated at 45,000, or an average of 860 per week. These 45,000 deaths distributed by age and sex on the basis of the reported total accidental deaths in the registration area, 1907-1916, can be tabulated as follows:

ESTIMATED DISTRIBUTION BY AGE AND SEX, OF 45,000 FATALITIES BY PUBLIC ACCIDENTS IN THE UNITED STATES DURING 1917

Age	Total	Males	Females
Under 5	4,993	4,046	947
5-14	4,051	3,094	957
15-44	20,537	14,960	5,577
45-64	9,243	6,834	2,409
65 and over.....	6,176	5,066	1,110
Total	45,000	34,000	11,000

Assuming further that the approximate average economic loss by these deaths was on the following basis:

APPROXIMATE AVERAGE ECONOMIC VALUE PER ANNUM OF HUMAN LIFE IN THE UNITED STATES BY AGE AND SEX

Age	Males	Females
Under 5.....	\$350	\$150
5-14	600	200
15 and over.....	750	300

We arrive at the following estimate of the total economic loss involved in the 45,000 deaths by public accidents in the United States during the calendar year 1917.

Age	Total	Males	Females
Under 5.....	\$ 73,517,000	\$ 66,557,000	\$ 6,960,000
5-14	88,438,000	79,825,000	8,613,000
15-44	338,567,000	291,720,000	46,847,000
45-64	52,634,000	46,130,000	6,504,000
65 and over.....	4,133,000	3,800,000	333,000
Total'	\$557,289,000	\$488,032,000	\$69,257,000

MALES

Age	Number of Deaths	Expectation of Life to Age 72	Total Number of Years of Life Lost	Average Economic Value per Life per Annum	Total Loss
Under 5.....	4,046	47	190,162	\$350	\$ 66,557,000
5-14	3,094	43	133,042	600	79,825,000
15-44	14,960	26	388,960	750	291,720,000
45-65	6,834	9	61,506	750	46,130,000
65 and over.....	5,066	1	5,066	750	3,800,000
Total	34,000		778,736		\$488,032,000

FEMALES

Under 5.....	947	49	46,403	\$150	\$ 6,960,000
5-14	957	45	43,065	200	8,613,000
15-44	5,577	28	156,156	300	46,847,000
45-64	2,409	9	21,681	300	6,504,000
65 and over	1,110	1	1,110	300	333,000
Total	11,000		268,415		\$69,257,000

Enormous as these figures are they represent but a fraction of the economic loss involved in public accidents for they refer only to fatal accidents while accident insurance and workmen's compensation experience shows that there are approximately 125 non-fatal but more or less disabling injuries to every fatal injury. Assuming that these in the aggregate involve an economic loss three times that of the fatal accidents, we have it that these estimated 5,625,000 non-fatal injuries by public accidents during 1917 involved an aggregate economic loss of \$1,671,867,000 which added to the former total of \$557,289,000 gives a grand total of \$2,229,156,000. Even yet, however, the total economic loss has not been

¹The method of estimation. In brief, is as follows: From the life tables prepared by the United States Bureau of the Census and based upon the population of 1910 and the mortality for the three years, 1909-1911, we find the approximate normal expectation of working years of life to age 72 separately for the males and females who are estimated to have been killed in public accidents during 1917. It is assumed that age 72 years marks the period when life ceases to have an appreciable economic value. The number of deaths by age and sex multiplied by the expectation of life factor (average number of years normally lived through to age 72) gives the total number of years of life lost as the result of public accidents. These years when multiplied by the estimated net economic worth to society of these lives, as shown in the previous table, gives the aggregate net economic loss by age and sex. The table in detail is given above.

accounted for, as we have only considered the loss involved in the human wreckage to which must be added untold and unknowable losses from wreckage and destruction of property values resulting from the destruction of all kinds of material wealth such as buildings and other structures, crops, rolling stock, including vehicles of all kinds, goods, chattels, etc. Then to all this there must still be added the unmeasurable but none the less real and enormous physical and psychological loss involved in the physical pain and mental anguish of the victims, their dependents and friends.

From the foregoing statements it must be patent to every reasonable person that public accident prevention is a worth-while undertaking and that organized effort should be put forth on a nation-wide scale to abate the present criminal negligence and recklessness which is so characteristic of Americans. In no other civilized country is life held so cheap. To emphasize this point some tables have been prepared which will form an appendix to this statement. Also the toll of life in the United States in disasters and sports have been itemized for several years as a part of this paper. When these are placed before you I am sure that you will agree with me that it is high time that a more definite and resolute course of action be adopted by the National Safety Council and other official and public organizations to check these enormous and largely preventable losses of lives and property due to public accidents.

A good beginning will be to place the facts before the public in a clearer light. This cannot be done effectively until public accidents are more completely reported, more intelligently classified and more clearly differentiated from industrial and home accidents. To this end the Committee on Statistics (Public Safety Section) of this organization of which I have the honor to be Chairman is trying to develop blank forms for the better reporting and recording of public accidents. When these are perfected we may hope to get information before the public, the truth of which will be undeniable and the significance of which will be so truly startling that a much wider cooperation of government and public for the prevention of public accidents must be the sure result. Then and only then can we hope to see a reduction in public accidents similar to that which is now being effected in industrial accidents and in certain diseases such as pulmonary tuberculosis, typhoid fever, malaria and diphtheria.

APPENDIX A

DISASTERS

Some of the more important public accidents involve such loss of life that they may properly be designated as disasters. Many of the land transportation or vehicular accidents fall within this class and a large proportion of serious accidents at sea, as also many navigation accidents on rivers and other inland waters fall within this group. In the following lists drawn largely from the annual summaries of the Chicago Tribune I have included the more noteworthy disasters of all kinds within or near the United States during the period 1908-1918. Only

accidents involving a reported loss of twenty or more lives have been included in these lists.

RAILWAY DISASTERS

		Lives Lost
1908	Sept. 25, Collision, Northern Pacific R. R., Young's Point, Mont.	21
1910	March 21, Derailment, Chicago, Rock Island & Pacific, Green Mt., Iowa	50
	April 21, Collision, Ft. Wayne & Wabash Interurban R. R.	43
	Oct. 4, Collision, Interurban R. R., Staunton, Ill.	36
1911	Aug. 25, Derailment, Lehigh Valley R. R., near Manchester, N. Y.	28
1912	March 18, Locomotive Boiler Explosion, San Antonio, Tex.	32
	July 4, Collision, D. L. & W. R. R., Corning, N. Y.	41
	July 5, Collision, Ligonier Valley R. R., Wilpen, Pa.	21
1913	July 31, Collision, Ore train, Duluth, Minn.	21
	Sept. 2, Collision, N. Y., N. H. & Hartford R. R., Waterford, Conn.	21
	Oct. 19, Derailment, Mobile and Ohio R. R., State Line, Miss.	26
1914	Aug. 5, Collision, Kansas City and Southern R. R., Tipton's Ford, Mo.	40
	Aug. 15, Derailment, St. Louis & San Francisco R. R., Lebanon, Mo.	27
1915	Nov. 22, Collision, Georgia Central R. R., Columbia, Ga.	24
1916	March 29, Collision, Lake Shore R. R., Amherst, Ohio.	26
	Aug. 12, Collision, Electric Cars, Johnstown, Pa.	25
	Nov. 8, Elevated R. R. Accident, Boston, Mass.	54
1917	Feb. 27, Collision, Pennsylvania R. R., Mt. Union, Pa.	20
	Sept. 28, Collision, St. Louis and San Francisco R. R., near Kellyville, Okla.	23
	Dec. 20, Collision, Louisville & Nashville R. R., Shepherdsville, Ky.	45
1918	June 22, Collision, Michigan Central R. R., Ivanhoe, Ind.	53
	July 9, Collision, Nashville, Chattanooga & St. Louis R. R., near Nashville	89
	Nov. 1, Derailment, Rapid Transit R. R., Brooklyn, N. Y.	98

MARINE DISASTERS, U. S. AND CANADA

1909	April 5, Steamer "Oak Branch", Pacific Coast	20
	May 11, Sinking of launch "Pittsburgh"	23
	Dec. 10, Marquette & Bessemer No. 2 Ferry Boat, Lake Erie	38
1910	Oct. 1, Drowning Accident, Hudson River	47
1911	June 24, Explosion, Steamer "City of St. Joseph", Memphis, Tenn.	20
1912	April 14, Sinking of Steamship "Titanic"	1,517
	June 23, Drowning Accident, Niagara River	39
	Dec. 22, Steamer "Florence", New Foundland Coast	22
1913	Aug. 18, Steamer "State of California", Alaskan Coast	40
	Nov. 10, Steamer "Bridgeport," lost at sea	42
	Nov. 10, Steel Freighter "Regina", Lake Huron	20
	Nov. 10, Steamer "Wexon", Lake Huron	20

Public Safety Section

1067

	Nov. 10, Steamer "Charles S. Price", Lake Huron.....	28
	Nov. 10, Steamer "James Carruthers", Lake Huron.....	25
	Nov. 10, Steamer "John A. McGear", Lake Huron.....	23
	Nov. 10, Steamer "J. P. Hutchinson", Lake Huron.....	20
1914	Jan. 4, Steamer "Oklahoma" off Sandy Hook.....	27
	Jan. 29, Steamer "Monroe", Virginia Coast.....	41
	April 2, Steamer "Newfoundland", Newfoundland Coast.....	77
	April 2, Steamer "Southern Cross", Newfoundland Coast.....	173
	April 15, Steamer "Kite", Newfoundland Coast.....	65
	April 18, Barge "America", Alaskan Coast.....	50
	April 29, Steamer "Benjamin Noble", Lake Superior.....	30
	May 29, Steamer "Empress of Ireland", St. Lawrence River.....	1,027
	Sept. 19, Steamer "Frances A. Leggett", Oregon Coast.....	80
1915	April 4, Steamer "Prince Mauritz", Virginia Coast.....	49
	July 24, Steamer "Eastland", Chicago River.....	811
	Aug. 17, Steamer "Maroigne", Gulf of Mexico.....	96
	Nov. 13, Steamer "Charles A. Luch", Lake Superior.....	20
	Dec. 12, Steamer "St. Kilda", Newfoundland Coast.....	29
1918	July 4, Sinking of Steamer "Columbia", Illinois River.....	85
	? Steamer "Florizal" off Cape Race.....	92
	? U. S. Collier "Cyclops" lost at sea.....	293
	? Steamer "Princess Sophia", Alaskan Coast.....	343

FIRES AND CONFLAGRATIONS

1908	Jan. 13, Theatre, Boyertown, Pa.....	172
	March 4, School house, Collingwood, Ohio.....	178
	Oct. 16, Forest, Michigan.....	50
1909	Jan. 20, 71st Street Crib, Chicago, Ill.....	55
1910	Aug. 21, Forest, Idaho.....	80
	Oct. 9, Forest, Northern Minnesota.....	30
	Nov. 25, Factory, Newark, N. J.....	25
	Dec. 24, Stockyards, Chicago, Illinois.....	24
1911	March 25, Triangle Waist Co. Factory, N. Y. City.....	142
	Aug. 25, Theatre and panic, Canonsburg, Pa.....	87
1913	Feb. 23, Dewry Hotel, Omaha, Neb.....	20
	July 22, Binghamton, N. Y.....	32
	July 22, Jackson, Miss.....	35
	Dec. 3, Arcadia Hotel, Boston, Mass.....	28
	Dec. 24, Fire and panic, Calumet, Mich.....	72
1914	March 8, Athletic Clubhouse, St. Louis, Mo.....	30
1915	Oct. 21, St. John School, Peabody, Mass.....	21
1917	June 14, New York City.....	20
1918	April 13, Norman, Okla.....	37
	Oct. 12, Forest, Minnesota.....	1,000

EXPLOSIONS

1908	Feb. 20, Dynamite, Berkeley, Cal.....	30
	Nov. 20, Gas, Brooklyn, N. Y.....	25
1910	Oct. 1, Dynamite, Los Angeles Times Office, Los Angeles, Cal.....	21

	Dec. 27, Dynamite, El Paso, Texas.....	20
1911	Feb. 1, Dynamite, Jersey City, N. J.....	35
1913	March 7, Dynamite, Baltimore Harbor, Md.....	50
1915	Sept. 27, Gasoline, Ardmore, Okla.....	47

STORMS AND FLOODS

1908	Jan. 13, Cyclone, Mississippi.....	20
	April 24, Cyclone, Louisiana.....	108
	April 24, Cyclone, Alabama.....	31
	April 24, Cyclone, Mississippi.....	229
	May 13, Cyclone, Louisiana.....	42
	June 6, Cyclone, Nebraska.....	23
	June 20, Storm, Oklahoma.....	100
	Aug. 28, Flood, Folsom, N. Mexico.....	20
	Aug. 28, Flood, Georgia.....	60
	Aug. 28, Flood, S. Carolina.....	26
	Nov. 25, Cyclone, Northwestern Ark.....	27
1909	Feb. 5, Cyclone, Arkansas and Mississippi.....	23
	April 7, Storm in Northwest.....	58
	May 29, Cyclone, N. Dakota and Oklahoma.....	22
	May 30, Cyclone, Texas.....	32
	July 21, Hurricane, Galveston, Texas.....	38
	Oct. 15, Storm, Tennessee and Georgia.....	93
1911	April 4, Cyclone, Missouri, Kansas and Oklahoma.....	28
	Sept. 30 Flood, from burst dam, Austin, Pa.....	74
1912	April 4, Flood, Mississippi River.....	20
	April 18, Flood, Boliver Co., Mississippi.....	200
	April 21, Cyclone, Illinois and Indiana.....	75
	April 22, Cyclone, Georgia and Alabama.....	25
	April 27, Cyclone, Oklahoma.....	60
	May 9, Flood, Louisiana.....	75
	June 16, Storm in Missouri.....	26
	July 18, Cloud burst, Seven Tvaughs, Nev.....	29
	July 23, Cloud burst, Western Pennsylvania.....	65
	Sept. 2, Storm, Western Pennsylvania and W. Virginia.....	40
1913	March 14 Cyclone, Middle West and South.....	338
	March 22, Cyclone, Mississippi Valley.....	220
	March 28, Floods, Indiana and Ohio.....	736
	Dec. 4, Floods, Texas.....	500
	Dec. 4, Storm, Colorado.....	24
1914	May 3, Storms in Southwest.....	20
1915	April 23, Floods and Cyclone, Texas.....	40
	May 4, Tornado, Louisiana.....	41
	July 7, Cyclone, Middle West.....	58
	Aug. 2, Cloud burst, Erie, Pa.....	35
	Aug. 16, Hurricane, Texas Coast.....	375
	Aug. 20, Storm, St. Louis, Mo.....	20
	Sept. 29, Hurricane, Louisiana.....	500
1916	Jan. 28, San Diego, Cal.....	100
	Jan. 28, Floods, Arkansas.....	29

	June 5, Storm in Southwest.....	150
	July 6, Storm, Alabama and North Carolina.....	80
	Aug. 3, Cloudburst, Tazewell, Tenn.....	38
	Aug. 9, Cloud burst, W. Virginia.....	94
1917	Feb. 22, Cyclone, Georgia and Alabama.....	20
	March 24, Cyclone, New Albany, Indiana.....	36
	May 25, Cyclone, Andale, Kansas.....	36
	May 26, Cyclone, Illinois.....	94
	May 26, Cyclone, Kentucky.....	70
	May 27, Cyclone, Alabama.....	48
	May 27, Cyclone, Tennessee.....	34
	May 30, Cyclone, Missouri.....	79
	June 1, Oklahoma and Kansas.....	21
	June 6, Cyclone, Missouri.....	22
1918	Aug. 21, Cyclone, Tyler, Minn.....	35

MISCELLANEOUS DISASTERS

1910	Feb. 23, Snowslides, Montana.....	118
1912	June 11, Volcanic Eruption, Alaska.....	200
1913	Jan. 23, Fall of building, McKinney, Texas.....	35
	May 24, Collapse of Municipal pier, Long Beach, Cal.....	39
1916	July 24, Water tunnel accident Cleveland, Ohio.....	23
1918	June 29, Collapse of store, Sioux City, Iowa.....	41
	Nov. 9, Asphyxiation Accident, Pittsburgh, Pa.....	25

These disasters may be summarized as follows:

Years	Railway	Marine	Fire	Explosion	Storms and Floods	Miscel- laneous	Total
1908	21		400	55	691		1,167
1909		81	55		286		402
1910	129	47	159	41		118	494
1911	23	20	229	35	102		414
1912	94	1,578			616	200	2,488
1913	68	218	187	50	1,818	74	2,415
1914	67	1,570	30		20		1,637
1915	24	1,005	21	47	1,069		2,166
1916	105		20		491	23	639
1917	88		1,037		454		1,579
1918	240	813			35	66	1,154
Total	864	5,332	2,138	223	5,562	481	14,605
(1908-1918)							

In these lists of the more important disasters, and not all are included, there were 14,605 reported deaths during the eleven-year period, or an average of 1,328 deaths per year. By kinds of disasters, storm and floods and navigation easily lead in importance. Fires, too, are shown to be responsible for many disasters, those listed causing a reported loss of 2,138 lives. Railways are a less frequent cause of disasters today than a few year ago, although 1918 was a particularly bad year.

The above lists and summary furnish striking evidence of the importance of disasters in swelling the grand total of lives lost in public accidents and they emphasize the importance of devising more efficient preventive measures. With the possible exception of deaths in storms and floods there would appear to be great possibilities for the saving of lives which now are lost by thousands in needles fires, explosions, collapse of buildings, etc., and in transportation both by land and water.

APPENDIX B

FATALITIES FROM SPORTS

Probably few of us realize or even stop to think of the toll of lives which Death takes in Sports in the United States every year. The most interesting figures on this interesting subject are to be found in the annual summaries of the Chicago Tribune. No pretense is made that these data are complete or entirely accurate, but they will serve when totaled for a number of years to attract attention to a series of public hazards many of which are preventable and all of which are indicative of American recklessness. During the eight-year period, 1911-1918, inclusive, there were no fewer than 4,143 fatalities as the direct result of sports, hunting, celebrations, etc., according to the records of the Chicago Tribune. It is not likely that this total is anywhere near large enough to express the whole truth, and it does not contain the fatalities due to ballooning and aviation, but it is significant of the accumulative results of many small numbers. By specific causes or methods of death, bicycles and motorcycles is at the head of the list with 1,769 fatalities; hunting is second with 1,105; and Fourth of July and other celebrations is third with 303 fatalities. It is interesting to note that this class of fatalities has been rapidly reduced with more rational community action in the regulation of the sale and use of fireworks, firearms, and other dangerous display and noise makers. In 1908 the Chicago Tribune reported 178 deaths due to Fourth of July celebrations, when ten years later in 1918 only 8 such deaths were noted. Here is a most significant lesson in the value of rational accident prevention work.

The danger of careless handling of firearms is clearly set forth in the data collected under the caption "Didn't know it was loaded." During the eight years, 1911-1918, no fewer than 298 fatalities were reported by the Chicago Tribune as the result of this fatal excuse of ignorance; it is a record which in disastrous results is now more important than celebrations. During the last five years, 1914-1918, this cause was responsible for 177 fatalities against 149 from celebrations.

In eight years 198 deaths have been charged against baseball and 134 against football. Even golf is charged with 7 deaths and tennis with the same number, also basketball. Coasting has cost 71 lives, roller coasting 34; roller skating 24; prize fighting 19; boxing 17; wrestling 18; horse-racing 31; and polo 6. The record of fatalities from auto racing does not seem to be complete, but it has become a real menace not only to the drivers but to the spectators as well.

Rocking the boat may be an interesting diversion, but is charged with

45 fatalities, which probably does not express more than a fraction of the truth. Scenic railways have caused 13 deaths during the period under review. In this connection it is interesting to recall the recent (August 10, 1919) disaster at a Montreal resort in which seven passengers on a scenic railway were dashed into a fire and their bodies burned beyond recognition. Merry-go-rounds have caused one fatality per year, on an average. The other specific causes of sport fatalities as listed by the Chicago Tribune are of minor importance, but for convenience the data have been tabulated in the following table by order of the relative importance of the causes specified:

Death Toll of Sports in the United States—Data Rearranged from Annual Summaries in Chicago Tribune, 1911-1918

Sport	No. of Fatalities	Sport	No. of Fatalities
Bicycles and Motorcycles.....	1,769	Scenic railway	13
Hunting	1,105	Merry-go-round	8
Fourth of July and other celebrations	303	Golf	7
Didn't know it was loaded.....	298	Tennis	7
Baseball	198	Basketball	7
Football	134	Polo	6
Coasting	71	Pole vaulting	3
Rocking the boat.....	45	Disc throwing	3
Prize fighting	35	Foot racing	2
Roller coasting	34	Hammer throwing	1
Horse racing	31	Putting the shot.....	1
Roller skating	24	Tobogganing	1
Wrestling	18	Hockey	1
Boxing	17	Trapeze	1
		Total	4,143

APPENDIX C

MORTALITY FROM ACCIDENTS IN THE REGISTRATION AREA OF THE UNITED STATES 1907-1917

(Rates per 100,000 Population)

Year	Males	Females	Total

*On the assumption that there has been no increase or decrease in the accident rates which prevailed in 1917.

MR. CRUM: The automobile question as regards public accidents, probably is today the most important. There are in this country over eight thousand fatalities from automobiles annually and that is a real serious problem because the number is increasing rapidly. The intensive effort in the safety work ought to more than offset the increase in the number of automobiles. That is an enormous problem, and the States are getting after it. Massachusetts is going to enact some drastic legislation.

Here is a little report on fatalities in the one borough of Manhattan. In one year there were 712 fatalities due to automobile accidents.

CHAIRMAN TALBERT: I want to extend the Section's sincere thanks for the time Mr. Crum has put on this work and the two wonderful papers he has presented.

DISCUSSION

DR. S. DANA HUBBARD (Division of Industrial Hygiene, New York City, N. Y.): I would like to say that we publish a weekly and monthly bulletin in which we give our figures carefully studied and carefully analyzed, and also comments by the various public officials. We also publish in this bulletin a scientific paper prepared by a publicist on some particular subject such as health. When you figure there are fifty thousand industrial establishments in New York, and that Manhattan is only twenty-five square miles, you can readily understand what it means. It is like dealing with contagious diseases, the greater the congestion the greater the danger of the diseases. For instance, I am told that 125,000 people pass out of the Equitable and Woolworth Buildings in a day. The subway in the city of New York with less than fifty miles of track, carries

pretty close to 3,000,000 people a day.

New York City is an island. On one side the river is a mile and a quarter wide, and our bay on the east side is about five miles wide. Last year a canoeing party crossed the river for a picnic. A storm came up and forty-six persons were drowned. This year we forbade any such canoeing in groups.

The same thing is true about motor boating. You may recall a fishing expedition off of Seebright, in which fifteen motor boats sank at one time with a loss of 116 lives. The Park Place disaster was a question of a cigarette. The Ireland Building fire had similar origin. When you have 50,000 industrial establishments it is impossible to be in those places all the time. A State Factory Department and an Industrial Commission can't be everywhere, and the result is, that where there is a large number of people the police power will not do the trick, and you have to educate the people by concentrated instruction.

FREDERICK S. CRUM: It was not my intention, Dr. Hubbard, to criticise Manhattan.

DR. S. DANA HUBBARD (New York City, N. Y.): That is all right. We need it and deserve it.

FREDERICK S. CRUM: If those figures were posted where they could be seen by everyone in New York, I think it would help some.

DR. S. DANA HUBBARD: We are glad to have those facts brought out and we want them made public. We appreciate where the negligence is, and I think to a large extent it is due to a lack of knowledge of the English language. I came here for the purpose of learning safety, with the idea of taking it back to the city of New York in a comprehensive report, in order to show the citizens of New York, who are contemplating a campaign on industrial health promotion and safety, just what is being done. We don't want to steal anybody's thunder or patent their devices, but we do want to know about the best methods of educating the people of New York to this work. We have forty-five inspectors who have just been appointed at a salary payroll of \$65,000, and we have a publicity payroll of \$20,000, making pretty close to \$100,000 we are spending a year to prevent accidents. Now if we are going to tax our tax payers for that money, we have to give them something for their money.

CHAIRMAN TALBERT: That concludes the papers to be presented this morning. I wish those who were in the Public Safety Section work last year at the St. Louis Congress would please raise their hands. (Only five hands were raised.)

Now you can see for yourselves how radically these assemblages change from year to year. On the other hand, if you will go to the industrial sections you will find men there who have been there for years. They are able to tell pretty accurately about how many of their members will be present next year, but in our work it is extremely difficult to get in touch with those on whose cooperation we can count, and upon whom we can rely for committee work. That condition is not due to any fault of the members, but to the fact that most of them are public officials, people who are interested from one cause or another outside of the industrial relation.

We are now in position to carry on actively our propaganda work. That is, the National Safety Council has financed us to the extent of employing a most excellent Field Secretary, Mr. Carl Smith, who will carry on this work during the coming year. Mr. Smith has had a good deal of experience in this work. During the next twelve months he will be at the service of this Section.

MR. SMITH: We have at Headquarters, two men who will coöperate with these committees. The committees appointed this year will be expected to continue their work through correspondence as far as possible. The Chairmen of those committees will communicate directly with this Section and with the Chicago office. The mailing of questionnaires or circulars of information, or the printing of reports, will be done by the Chicago Office. In other words, as far as possible the headquarters staff and field staff will take the detail work from these committees. We want the committees however, to outline what is to be done, and then entrust to us the work of carrying out the details.

COMMITTEES

CHAIRMAN TALBERT: I am going to ask the chairmen of committees to furnish a list of all members selected by them. It was agreed upon at our first meeting that two or three of the chairmen of this year's committees should continue through the next year. Through the assistance of the National Safety Council we are now in position to do some real work, and these men should be allowed to continue their work under these advantageous conditions. With that understanding Mr. Crum has been asked to continue on the Committee on Statistics, and I believe you will agree with me that that is a good appointment and should be continued. Mr. DeArmand has been reappointed as Chairman of the Committee on Publicity. I am asking him to select such men as he thinks will be of most service to him, but I am going to suggest that Mr. Morley would be a very valuable man on that committee.

MR. DEARMAND: I have selected the following members to work with me on the Publicity Committee:

R. B. Morley, Ontario Safety League, Toronto, Can.

W. N. Fitch, B. F. Goodrich Co., Akron, Ohio.

Clyde R. Miller, Hicox Bldg., Cleveland, Ohio.

Marshall Dana, Portland Oregon Journal.

CHAIRMAN TALBERT: Next we have the Committee on Pedestrian Hazards of which Mr. H. W. Mowery was chairman.

We have a Committee on Elevators of which Mr. Dana Webster was Chairman, but Mr. Webster suggests that someone else be appointed as Chairman for the coming year, bearing in mind that he will act as a member of the committee.

MR. WEBSTER: I would suggest the name of Mr. Geo. W. Greenleaf as Chairman of the Committee on Elevators.

CHAIRMAN TALBERT: Then we have the Committee on Education. I would like Dr. Payne to say a word on that. Last year we appointed Dr. George Platt Knox who is an associate of Dr. Payne's in St. Louis, as Chairman of that Committee. While I have the highest personal regard

for Dr. Knox, it seems to be the logical thing for Dr. Payne to take that committee for this Section. However I would like to have an expression from some of the other delegates from St. Louis.

MR. JOSSE: Dr. Knox was very unfortunate in having a rather severe accident which kept him from attending the meetings of the Executive Board for three months. I think Dr. Payne is the logical man for the committee.

DR. PAYNE: Dr. Knox is probably as much interested in public safety work as any man I know of in the country, and we don't want to lose him to that movement. I would be perfectly happy to work with him on the committee, and I would suggest if possible, that we hold that matter over until you and I and Dr. Knox can get together in St. Louis and talk it over.

CHAIRMAN TALBERT: It happens that all three of us are from St. Louis, so if the members here will permit me, I will consult with the two gentlemen after we return to St. Louis, and we will arrange for the chairmanship of that committee, bearing in mind that it will be either Dr. Knox or Dr. Payne.

MR. CRUM: I move that Mr. Talbert be authorized to talk this matter over with the two gentlemen in St. Louis, and there select the chairman for the Committee on Education.

(Motion seconded by Mr. Hodson, and unanimously adopted.)

MR. CRUM: Is there any By-Law or Rule governing the Section as to the size of committees, and what has been the practice in the past in that respect?

CHAIRMAN TALBERT: The idea has been to confine the committee to as small a size as you can and still get good results. So far as getting information is concerned, I want you to follow your own judgment. You can feel perfectly at liberty to circularize men in various towns to act as committeemen and to care for that town. You are authorized, if you desire, to ask any man in any town to act as your representative or your committeeman for that particular city, and to furnish you such information as you want.

A. W. WHITNEY (National Workmen's Compensation Service): I think the idea of allowing the various chairmen to select as large a committee as they desire, is a good one, because public safety work is a little different, in that it reaches out and strikes all cities, and you have to create the machinery for getting hold of them.

CHAIRMAN TALBERT: We still have the Traffic Committee to deal with. I made the suggestion that the Traffic Committee be sub-divided, and that one section be made to cover signs and signals. It developed that there were three different characters of signs and signals as controlling traffic, that, by the officer at his station in the highway; signs adjacent to the highways, and signs on cars. I appoint Mr. Harry P. Coffin of Portland, Ore., and who is a member of the Public Safety Commission of that State, as Chairman of the Traffic Committee. He has taken a deep interest in this matter, and has made a thorough study of it. In addition I appoint on the Traffic Committee Lieut. Lewis of Portland, Ore., who is in charge of the traffic work in Portland, and who I understand is in direct com-

munication with the entire Coast situation; also Inspector H. May of Cleveland, who has traveled rather extensively under the auspices of the Cleveland Chamber of Commerce, studying the traffic situation.

Before we adjourn I want Mr. R. B. Morley, General Manager of the Ontario Safety League, of Toronto, Canada, to say a few words to us. I am going to ask him to prepare for us as a part of next year's program, a resume of the Canadian situation.

ONTARIO SAFETY LEAGUE

MR. MORLEY: Nearly six years ago the Ontario Safety League was created, largely because of the reports received by the Ontario Railway and Municipal Board dealing with electric railway accidents throughout the Province. The original intention was that we would deal with traffic accidents only. About three months after we started our campaign in 1914, we came to the conclusion that traffic accidents were only a small portion of the work, and that we had to extend our activities into the industrial field. We have used bulletins, pictures, buttons, blotters and practically all the approved methods of publicity. That is to say, that nearly everything we have done has been done in some form or other by someone else.

Our organization is represented throughout the Province. We have an excellent Executive Committee, composed of men who take a real interest in the work. We have devoted a large portion of our time to the education of the children through various channels of publicity. We have lately created a new organization to be known as the Canadian Safety League, by which we intend to encourage the formation of Provincial Leagues in the other provinces, leagues similar to the Ontario Safety League. We are now, through the Canadian National League headquarters, in communication with five of the other provinces, and I believe at least two will line up and form provincial leagues before 1920. We expect to work out some sort of a proposition for affiliation with the National Safety Council. If there is anything at all that I can do to help things so far as any of your committees go, I will be only too glad to do it.

There is one thought I want to leave with the members of the committee, namely that as a source of funds, you cannot beat public safety work. Nearly ninety per cent of the people who have contributed to our work in Canada have done so through a succession of years, largely on account of Public Safety work. Public Safety is the big end of it and is really the tent under which all the others will ultimately come.

CHAIRMAN TALBERT: The other day I asked Mr. Hodson of E. St. Louis, Ill., to present to us a resume of the conditions under which his Boy Scout was designated to come to this convention. I want to express my appreciation to him for the help he has been, and the gentlemanliness and manliness in which he has carried out those things left for him to do. I am going to ask Carl to stand so that we can all get a look at him.

(Carl E. Wiemken, Boy Scout from E. St. Louis, Ill., stands up and is applauded.)

DR. HUBBARD: I move that the Public Safety Section of the National Safety Council thank E. St. Louis and its representative for their work.

and that we extend to E. St. Louis and their Boy Scouts the thanks of this Section for the work they have done in sending this young man, and that we thank Carl Wiemken of Troop 9, for coming here.

(Motion duly seconded and unanimously adopted.)

HOMER J. HODSON (E. St. Louis, Ill.): I have made a short report showing how this Boy Scout was selected, and this report will be put in the record.

REPORT ON SELECTION OF BOY SCOUT DELEGATES TO NATIONAL CONGRESS

Each troop in East St. Louis, Illinois, was asked to submit the name of a Scout who had successfully passed an examination in his individual Troop and had proven to be the best speaker on the value of scouting and safety. The scout chosen from each Troop then appeared before the Court of Honor (of which I am a member), which selected the best scout who could deliver the best five-minute talk on scouting and safety. The reward was a trip to the National Safety Congress, with all expenses paid.

I think that one of the greatest things which we could do for the Scout movement, with regard to its safety work, would be to suggest to all local Boy Scout Councils that they put on this same competition next year and that the reward for the winner shall be a trip to the Annual Safety Congress. It might be well, and I think it would be an ideal movement, for the National Safety Council to establish a Boy Scout Section.

You will recall that the Council was instrumental in arranging with the Boy Scouts of America to establish a Merit Badge Examination in Safety First. The questions which a Scout must answer before he is entitled to a Safety First Merit Badge are as follows:

1. State four or more dangerous conditions in the average home and indicate what steps should be taken to correct these conditions.
2. Produce satisfactory evidence that he is personally responsible for the application of at least two constructive Safety First principles in his home town.
3. Name the most serious violation of public safety principles which has come under his observation and produce satisfactory evidence that he has done all within his power to correct the same.
4. State in writing at least six of the most important regulations covering street safety to meet the conditions of the neighborhood in which he lives.
5. State in writing at least six of the most important regulations covering street safety to meet the conditions of the school he last attended.
6. Submit in writing an outline of his own plan for a school fire drill, and explain the method of properly carrying it into effect.
7. State in writing at least six violations of Safety First principles which are responsible for accidents in connection with railroads.
8. Stand a satisfactory examination, showing a knowledge of the importance of the Safety-first Movement, and the most important principles it involves, and satisfactorily demonstrate his ability to assume leadership in case of a fire, panic or other disaster.

Surely after a scout has successfully passed such an examination as that given above, he would be a great booster for the Safety-first Movement, and if it were possible to have a delegation of Boy Scouts at the next

Annual Conference, they would go home so enthusiastic for safety work that it would be a great help in getting all of the Scouts to cooperate in this valuable movement.

I have a promise that this idea of sending a Scout to the Congress will be given wide publicity by the National Headquarters of Boy Scouts of America in their weekly magazine, which reaches every Troop in the United States, numbering, I believe, about 450.

I do not believe that there is any one in this audience who is not interested in the Boy Scout movement, and especially to the part the Scout plays in the Safety-first work.

As I explained to Mr. Barclay, after his valuable paper at our session yesterday morning, I would be very glad indeed to explain this idea, which is suggested to all the Boy Scout organizations throughout the United States.

Respectfully submitted,

Homer J. Hodson.

Safety Engineer, E. St. Louis Ry. Co., E. St. Louis, Ill.

INSPECTOR MAY: There is one thought I would like to send back to the various communities represented here today. It seems to me that in many cities the aim is to move traffic quickly. Every man here should go back to his community and advocate the slogan, "Move it safely".

CHAIRMAN TALBERT: The question has been asked as to whether the Chairman of this section should appoint the sub-committees of the Traffic Committee. I believe it would be better for Mr. Coffin to appoint his own sub-committees.

LIEUT. LEWIS: I would like to get a list of the members on that committee for use at the National Traffic Officers Convention. They are going to appoint a committee for the nationalization of traffic laws themselves, and I would like to have that list with me.

CHAIRMAN TALBERT: We are not trying to assume to ourselves the right to say what these things shall be. We want to cooperate and offer this Association's machinery for doing that. You will express to them our attitude and tell them that what we want to do is to cooperate. If they will appoint a committee to work with us we will be very glad to meet them. We will ask you as a member of this traffic committee to take that up in detail and keep us fully posted in regard to the situation. Is there anything further to come before the meeting at the present time?

CARL E. WIEMKEN (Boy Scouts of America, E. St. Louis, Ill.): Mr. Crum quoted statistics showing that about seventy-five per cent of all accidents involved the male population. The Boy Scouts have a merit badge system which teaches them "Safety First", and if you gentlemen, when you go back to your respective communities, will look up the Boy Scouts and interest yourself in their organizations, I think you will be able to reduce the accidents to the male population through the Boy Scouts. I think you will find out things you never knew before if you will just put yourself in a place where you can help the Boy Scouts.

CHAIRMAN TALBERT: If there is nothing further, this meeting will stand adjourned to meet next year.

Adjournment.

Public Utilities Section

October 3 and 4, 1919

C. E. PAIGE, Chairman

Manager, Malden and Melrose Gas Light Company, Malden, Mass.

WILLS MACLACHLAN, Vice-President

Electrical Engineer, Consultant Employees' Relations, Toronto, Canada

SAMUEL H. REID, Secretary

Bureau of Safety, Chicago

FRIDAY MORNING SESSION

CHAIRMAN PAIGE: The meeting is scheduled for 9:30 and, although all the delegates have not come in yet, I think we have enough here to listen to the report of the Chairman.

REPORT OF CHAIRMAN

This section has before it possibilities that were but vaguely appreciated at the time of its inception.

More and more we are brought to realize that *business*, large business and small business, has given up Safety First as a fad, but has taken it up as a practical necessity.

It has now become so intimately related to operation, both in production and distribution, that many companies have well and carefully planned departmental organizations to work coöperatively with the other branches of the enterprise.

But the smaller companies, who are not in position to have definite organizations to work out this matter, must and are giving it attention. They may not have a corps of inspectors, or "safety staff." They must look to the National Safety Council for the highly-specialized knowledge which their particular problems require.

This section must function as a clearing house for ideas and preventive equipment, for the handling of accident prevention and for methods of dealing with accidents peculiar to public utilities.

The key-note of this convention is struck by the phrase—Employees' Relations.

Its various phases have formed the subject of many discussions here, formal and informal. Utilities are not unfamiliar with the term. Public relations have been an important feature of our operations, and it is but a step to private or better named employees' relations.

No matter what a company may believe with regard to the merits of various theories in the matter, we have one point on which we must all agree.

Accident prevention interest can not come from the top down, it must permeate the whole structure, bottom and top, and to this extent all must recognize that satisfactory work can be accomplished only by developing a relationship which acknowledges unreservedly that this effort is indeed for mutual benefit. There are many things which are closely related to this matter. They go into the methods of employment, questions of physical examination, vocational differentiation and questions of company policy with regard to protecting employees' interests.

All these things are so closely related to our work that they indeed are a part of it.

If these subjects are to be worked out as part of the program of this section we must prepare ourselves.

If this Section is to be considered a valuable asset to the National Safety Council and to the industries we represent, we must go to work.

At times like this we find no difficulty in getting up enthusiasm and making plans. Plans do not mean much if they are not executed. By all means let us have our plans, but when you have returned to your everyday occupations, and are expected to do something for the Section as an officer, or a member of a committee, or as an individual, recall the enthusiasm you now feel and make your effort count.

The various committee reports will give you information as to the status of the section, past and present.

The program is before you. Let us make the most of it, and let every man here leave with a sense of obligation to the Section, and remember his duty until we meet again.

We will now have the report of the Secretary.

SECRETARY'S REPORT

The secretary was not privileged to attend any of the meetings of the Public Utilities Section during the year and his report will therefore be brief.

According to the best information available, 25 member companies canceled their membership during the year and 13 new ones were added, resulting in a net loss of 12. The total membership at the time of this report is 224.

It is significant that most of those who cancelled are small companies, and some are isolated from the great center of population and Council activities and it is evident that they withdrew their memberships because of a feeling that they were not getting the worth of their money.

The service rendered by the National Safety Council is largely general and the need of members of the Utilities Section, particularly the small companies, is special service designed so far as possible to meet local and individual problems. In view of this fact and the obvious necessity for a close study of the problems of member companies, the following recommendations are submitted:

(1) The adoptions of a prearranged policy governing the activity of the Public Utilities Section during the coming year and strict adherence to that policy..

(2) That more meetings be held and a special study be made of the needs of the member companies.

(3) That efforts be made to make this section of the National Safety body of, by, and for its members.

(4) That special attention be given to the smaller companies, particularly those far removed from the center of activities of the National Safety Council and the local councils of the larger cities.

(5) That all helpful information gathered from time to time be promptly distributed to the members.

(6) That more attention be given to the gas, ice, and water interests, and that these interests be given a place on the programs of the Annual Congresses.

(The report was accepted and filed.)

MR. HERMANN SPOEHRER (Union Electric Light & Power Co., St. Louis): I would like to inquire why some of the larger companies have withdrawn their membership.

SECRETARY REID: In each instance, the company withdrawing stated the reasons and if the members want to take the time to go over them, I shall be glad to do so.

MR. SPOEHRER: I would like to say that I imagine resignations of some of the smaller ones are due to consolidations, but I can hardly conceive of such a large company as the Newark, N. J., Company withdrawing their membership.

MR. H. A. JOHNSON (Omaha Gas Company, Omaha, Neb.): Some of the smaller companies gave reasons, but as for the Newark Company, I have this question up with their main office and they plan to take it up again. Does that answer the question, Mr. Spoehrer?

MR. SPOEHRER: Yes, sir.

CHAIRMAN PAIGE: Mr. Rosseland of the headquarters staff is here and as his time is limited, he has asked for the privilege of speaking at this time.

MR. ROSSELAND: I want to ask for some help and suggestions. The first proposition is to urge that members be a little more free in sending in bulletin material. Send in suggestions for bulletins. I don't know whether you all appreciate it or not, but it is difficult to even attempt to cover adequately the public utilities field and when, as in the case of the Council, we are entirely dependent upon the membership for suggestions and for material you may realize how important your part is in the work. Please send us bulletin material, pictures if possible, if not, simply a clear, concise statement of what you think should be in the bulletin. If it is impracticable to send a picture, please tell us what you think the picture should contain, then possibly we can arrange through some of the other members to secure the pictures.

Then I want to ask that you consider whether you wish the Staff to work with such of your officers as you may select in the preparation of a Safe Practices pamphlet. Other sections have prepared pamphlets

during the year and if you decide that you want one, and will appoint officers to work with the Council's staff in the preparation of the pamphlet, you shall have it. I also wish to refer to the use of the Council's Information Bureau. You are probably rather tired of hearing us tell how much information we have in our files. We have a lot of it. It is in the form of reports and letters, but we feel, keenly, that the information is of no value in the files. We know from conversation with members who come into the Council Headquarters and through correspondence, that there are many subjects upon which we have information that members desire to have. What can we do to encourage the use of the Information Bureau? —

I should like very much, if your Chairman will permit, to have some discussion of the several points that I have brought up. I don't want to delay you, but I want you to feel that the Council is yours.

MR. C. E. MORRISON (Utilities Mutual Insurance Company, New York): The subject of bulletins is mentioned. I think possibly there has been a little feeling in this section that some of the information submitted to the Council has not been accepted and recognition has not been placed upon the bulletin and it has not been shown that the information came from the Public Utilities Section. We are very glad to cooperate and I know those who have no bulletins on hand are more than anxious to get such information through the Council. I don't know whether we have assumed that we have a right to more space than we probably are entitled to, but that matter ought to be cleared up so we won't be laboring under a misapprehension.

MR. ROSSELAND: The Public Utilities section has received during the past year, without exception, one special bulletin each week. Inasmuch as this section includes several industries, we have tried to divide the subjects of the bulletins so as to give at least three of them something during the year, that is, the gas plants, the electric light plants and the telephone and telegraph companies. So much for that. We are constantly at some pains to maintain the sectional bulletin service so that it will cover the specific hazards of the industry that we are trying to serve. I can't speak, of course, for the years prior to my connection with the staff of the Council but since that time, much of the material that has been sent in for sectional bulletins has been very general, and really not suitable for sectional bulletins which should cover a specific hazard peculiar to the industry. Please understand, however, that material that is not used immediately is not lost, it may not be desirable or practicable to place it in the general bulletin service immediately because of other material possibly already printed.

As to crediting the member companies that send in material, I know personally of instances where credit was not given where it should have been. That again is another illustration of human element, men working under pressure, and trying to do the best that they can. I know of two companies each of which provided twelve pictures but they asked that their names be not shown on the bulletins. Does that answer your question?

MR. MORRISON: Yes, sir.

MR. SPOEHRER: Do the suggestions come through the officers of the section or are they sent to the Council headquarters for approval?

MR. ROSSELAND: That is a question your officers must decide. It makes no difference to us unless it is something that requires immediate attention, in which case we should like to have them sent to the Council and copy sent to sectional officers. If the sectional officers are ready and willing to care for such matters as may be brought to them by correspondence, we prefer to have them do so, but remember, we are on the job to try to relieve them of as much of the detail work as we can.

MR. F. W. FISHER (Rochester Railway & Light Co., Rochester, N. Y.): I would like to urge a little better coöperation on the part of the gentlemen here and the member companies in sending in bulletins. I have been somewhat responsible for helping collect them and it is very discouraging to write a lot of letters to your friends and acquaintances and get promises and have them stop with that. If we want bulletins, we all must get into the work or see to it that somebody has the time and means and money to make a special study of it and work up new bulletins. There is plenty of material that has been used and it isn't the easiest thing in the world to re-hash it and work it up to make it look like new so I urge you to coöperate next year to do all you can.

MR. ROSSELAND: I want to second Mr. Fisher's remarks. He was chairman of the committee having the bulletins in charge. I know how discouraging it is not to get material from Bill and Jack who are good friends, upon whom you depended when you accepted the office. There is no secret about safety bulletins. I don't believe that there is a single member of this section who couldn't provide at least six bulletins and the photographs to illustrate them, each year.

CHAIRMAN PAIGE: Has anybody anything further to add to this discussion? If not, we will proceed to the regular order of business.

REPORT OF THE MEMBERSHIP COMMITTEE

There are at present a total of 210 companies in the Public Utilities Section. This includes 44 companies who are also operating electric railways and are therefore counted in the Electric Railway Section as well as in the Public Utilities Section.

According to the 1918 report of this committee there were 198 members, so it appears that there has been an increase in membership of 12 new members during the past year.

At the request of this committee a letter enclosing a folder explaining the activities of the National Safety Council was mailed to each company member of the Iowa District Gas Association by their Secretary, Mr. H. R. Sterrett, of Des Moines, Iowa. This letter was written on their stationery and heartily endorsed our organization. Only one new member was obtained by this effort, and I believe it shows that it is very difficult to obtain members through correspondence.

As this Association grows and adds Field Secretaries, I think great results could be obtained by having a representative of the National

Safety Council attend the large annual conventions of the American Gas Association and similar societies, at which time short talks could be given and membership booths established.

The Membership Committee wishes to express its appreciation of the hearty coöperation of the Headquarters of the National Safety Council.

The Membership Committee, H. A. Johnson, Chairman.

(The report was accepted and filed.)

CHAIRMAN PAIGE: The next is the Program Committee, Mr. John Bailey of Philadelphia, Chairman.

REPORT OF PROGRAM COMMITTEE

MR. JOHN BAILEY (Bell Telephone Company of Pennsylvania, Philadelphia): The Program Committee has no special report to make. Its duties, I believe, were finished when they presented the program for this meeting. When I was elected Chairman of this Committee I supposed there would be other members of the committee but I was surprised to find that the Chairman was a whole committee. I want to take this occasion to thank the Chairman of the other committees for the assistance they rendered me in preparing the program. I would like also to make the suggestion to the Section that I think it would be well in the appointment of a Program Committee if there would be other members named, selecting those members from the various utility bodies that are members of the section in order that you may be able to get good representative selections for people to present papers. It is pretty hard for a telephone man or electric light man or gas man to be conversant with the proper people and the proper subjects for all the various utilities and I think it would very materially aid my successor in selecting a program for the coming year.

CHAIRMAN PAIGE: You have heard Mr. Bailey's report and I am sure the logic of his suggestion will appeal to you.

MR. W. L. BRUCE (Westchester Lighting Co., Mt. Vernon, New York): I move you, Mr. Chairman, that the report be accepted and filed and as a suggestion, I would offer that at the next meeting of the Council next year, the Program Committee arrange to have on possibly the second day, as that will not interfere with our arrangement of program, a get-together dinner, as this seems to be the arrangement here that different sections have their meetings and informal gatherings and I think it would be a good idea to get something among ourselves at some specified evening. I offer the suggestion for the next Program Committee.

(Motion seconded and carried.)

CHAIRMAN PAIGE: The next is the Safe Practices Committee, Mr. F. W. Fisher, Rochester.

REPORT OF SAFE PRACTICES COMMITTEE

MR. F. W. FISHER: The Safe Practices Committee collected several hundred bulletins, the majority of which were sent on to the Council and most of them were used. In my remarks a few minutes ago, I covered practically all that the Committee has to report. I especially

urge that in coming here, information on what we call "stunts", "short cuts", unsafe tools or safe methods which are not standard and not on the market, information on those things be sent in. They have been particularly valuable in our own Company and I feel that they will be equally valuable in other companies. The work on preparation of special Safe Practices pamphlets has been held in abeyance pending some action of this body.

(The report was accepted and filed.)

MR. J. B. DOUGLASS Mr. Chairman, it seems to me it would be interesting to hear something of the relation between the work of our Safe Practices Committee and the work of the individual or department of the home office which has to do with safe practices. It seems to me we should get a little closer together there. Speaking entirely without reference to this Section but in the attitude of the Executive Committee of the Council, it seems to me that the Safe Practices pamphlets can be better handled by the home office. I have never known any good results to be had from a Safe Practices pamphlet put out by the Safe Practices Committee. In fact, I don't know of a safe practice committee which is putting out any pamphlets. It seems to me that the relations of our Safe Practices Committee should be more clearly defined. Of course I think that the question of whether we haven't been assuming something that we shouldn't assume is embodied there. I don't know but that the retiring chairman feels the same way.

MR. F. W. FISHER: A year or two ago I inquired of the home office what the practices of the Safe Practices Committee were and the information was given me that the work was limited almost entirely to collection of bulletin material, and I may say that is all the committee has tried to do this year.

MR. J. B. DOUGLAS: Then, Mr. Chairman, may I ask would it not be well to change the name of our Committee to Bulletin Committee as it used to be known as it seems to me that is expressive and to the point. It doesn't comprehend anything that we are not responsible for.

MR. ROSSELAND: If I may be permitted to say so, I think that would be highly advisable. The fact of the matter is that the securing and preparation of the bulletins is enough for one committee to handle as it is. In so far as the headquarters is concerned, if the membership decide that they wish one or more safe practices pamphlets and will so indicate, the staff is prepared to assign a member, one of its engineers, to work with an individual or a committee appointed by the section in the preparation of a safe practices pamphlet.

MR. F. W. FISHER: I think the record will show that we have already made recommendations to the staff for Safe Practices pamphlets. As retiring Chairman of the Safe Practices Committee, I would like to make a recommendation that we abolish that committee and substitute in its stead a Bulletin Committee, and that the former recommendation relative to preparation of Safe Practices pamphlets on our industry by the Staff be renewed. I make that as a motion.

(Motion seconded and carried.)

CHAIRMAN PAIGE: The next order of business is the appointment of the Nominating Committee. On that committee I have appointed Mr. F. W. Fisher, Chairman, Mr. John Bailey, and Mr. Charles B. Scott. This committee is to report tomorrow morning and should get together in the meantime.

CHAIRMAN PAIGE: We will now proceed with the reading of papers. The first paper is on the subject of "Preventing Accidents in Gas Plants," by Mr. J. F. Conner.

MR. J. F. CONNER: I feel that I must make an explanation in regard to the brevity with which I have treated this important subject. The fact is that had I gone into it in detail it would have consumed more time than that at my disposal for its presentation, so I have therefore taken it up in a general manner hoping that the detail part of it would come out in the discussion that would follow.

PREVENTING ACCIDENTS IN GAS PLANTS

J. F. CONNER, SAFETY SUPERVISOR, THE UNITED GAS IMPROVEMENT
COMPANY, PHILADELPHIA, PA.

In view of the fact that during the past several years all phases of the accident prevention problems have been broadly and ably discussed by men and women who, in serious interest, have given much of their time and thought to the questions involved, there appears to be left little or no opening for further amplification, and in addressing you on the subject "Preventing Accidents in Gas Plants" I fear that my remarks may not carry with them any new or constructive suggestions.

The title may lead persons unacquainted with the operation of gas plants to assume that employment in such plants is an extra hazardous occupation, fraught with unusual danger. Let me at this point make it clear that with few exceptions, the accident hazards met in gas plants do not materially differ from those found in other industries where mechanical and construction operations are the rule.

My conclusion in this respect is based on experience gained from a close acquaintance with such operations, receiving reports of accidents and investigating their causes, and from making accident hazard inspections of many gas plants.

HAZARDS PECULIAR TO THE INDUSTRY

The industry has, of course, inherent hazards. There are certain zones in gas works where in the course of operation pockets of gas may accumulate and, with the admixture of air, serious explosive hazards may form. Precautions should be taken against such conditions arising. The ventilation, and the lighting system of such zones are questions for consideration. Such places should be as well ventilated as conditions will permit. In the lighting system, approved types of keyless socket, vapor proof globe electric lamps with remote switch controls should be used, to guard against the possibility of the gaseous atmosphere being fired by an electric arc. Warning signs of size sufficient to attract attention cau-

tioning against smoking and the carrying of naked flames in such zones, should be posted in conspicuous places.

Like precautions should also be taken to guard against dust explosions in coal crusher rooms and pits where the air may be heavily charged, especially while the crushers are in operation, with minute particles of carbon which may be ignited and exploded by contact with an exposed flame. Dust explosions, while infrequent in gas plants, have been known to occur frequently in other industries with disastrous results.

It may be unnecessary to state that all warning signs should be kept in clear, legible condition if any benefit is to be derived from their posting. The writer has found, in the course of inspections, instances of lettering on painted wooden signs having become illegible from exposure to weather, and enamelled metal signs covered by accretions of smut and dust.

Emergency conditions may arise which will require working against live gas. In such instances, the workman should be protected by a suitable type of respirator. The same precaution should be taken when a workman is required to enter any gas-charged atmosphere and in every instance he should be under the clear observation of a person outside the danger zone, who should be prepared to render immediate assistance. Oil and other tanks in which gases are present should, where conditions will permit, be first purged by steam and well ventilated before entrance is made to such enclosure. Life lines can in such work be used to advantage.

Generally speaking, gas plants are usually well guarded mechanically. Occasionally, however, accidents occur on machinery due to guards being temporarily removed during repairs and failure to replace guards before putting the machines in operation again, or possibly to an exposure being considered too remote to warrant guarding.

A review of cases reported shows that the causes responsible for the greater number of accidents are due to the simple hazards found in all industrial establishments such as tripping, falling, slipping, and lifting, protruding nails, to the use of defective hand tools, ladders, scaffolds and makeshift supports that give insecure footing, and other like minor hazards, and to disregard of instructions to wear goggles when engaged in work in which the eyes are exposed to flying particles or splashing liquors.

The safeguarding of machinery and the installation of other mechanical devices for the prevention of accidents is unquestionably a necessary measure in any well-ordered plant, but in many cases the guards cannot be made absolutely fool-proof, so that in the final analysis, the greater reliance for preventing accidents must be placed on the human agency.

GREATER EFFORT MUST BE MADE TO EDUCATE WORKMEN

If we are to continue to look forward to a reduction in the accident frequency, greater efforts must be made to educate the workman to know the dangers that beset him, and others, from carelessness, thoughtlessness, and inattention on his part, and to arouse and maintain the accident prevention spirit in him.

How we shall best reach the workmen by educational propaganda is a

question of personal opinion. Reasoning with the men collectively is usually attended by good results. In obdurate cases, however, resort to individual approach brings the best results. We should not, however, be too hasty in censure of the workman for apparent indifference to safety. He possibly may be influenced by environment and be reflecting the attitude of his superiors to this important question. The problem, to my reasoning, should first be brought convincingly to the attention of the man higher up, the man directly in charge of the operation. If he meets it, as he should, in a spirit of serious interest and by precept and example sets the standard for his subordinates, lets it be known that he is keenly alive to any failure or disinterestedness on their part to shoulder their duty, the indifference, if any, of the foremen and sub-foremen will quickly vanish and those in positions of responsibility will, figuratively speaking, be standing on their toes and showing greater activity toward preventing accidents. The interest they show is bound to be reflected in the workmen and with the environment of good housekeeping, a place for everything and everything in its place, which must of necessity be part of the program, there will come a subconscious awakening of the prevention spirit in the workmen and that is the dominating factor in preventing accidents.

The company with which I am connected is one of the pioneers in the first aid and prevention field. Its activity in this regard dates back some fifteen years. The education of its employees in accident prevention has been carried on by means of safety rallies including motion pictures, shop meetings including lantern slides, a house organ under the title of "Safety News", the use of bulletins, buttons and other measures that tend to instill, attract, and maintain an interest in accident prevention and in holding down the accident occurrences.

Team work as outlined means coöperation. When the force of coöperation is behind the punch for safety, the fight for accident prevention is soon won.

MR. J. F. CONNER: It has been my experience time and time again that the safety engineer or supervising inspector in going through a plant greets the superintendent or manager and his presence is accepted more as a matter of fact, something that they have to bear with and their attitude toward safety is not such as would reflect on their workmen and I believe, as I have stated in my paper, that if we are to get the results from the safety movement, our efforts must first be directed towards the men above and bring them to a realization of what our work consists and get them to fall in line with us.

CHAIRMAN PAIGE: Mr. Conner has given us a real contribution. Before opening the discussion, I wish to announce that Mr. Scott has given me an adequate reason for not serving on the Nominating Committee and the name of Mr. H. A. Johnson of Omaha is substituted. The discussion on Mr. Conner's subject will be taken up by Mr. A. O. Mitchell.

DISCUSSION

MR. A. O. MITCHELL (Adjuster, Northern Indiana Gas and Electric Company, Hammond, Indiana): Mr. Chairman and fellow members, I

also wish to apologize for the brevity of this discussion, feeling that it was better, possibly more practical, to treat a few of the points rather than go into it in a general way.

In my discussion of Mr. Conner's paper I cannot hope to offer anything particularly original or new along the lines of accident prevention in and about gas plants, but rather to view the subject in the light of my experience, in the investigation of such accidents. These investigations with few exceptions, disclose no especially dangerous conditions, after, of course, the machinery and equipment contained therein has been protected with guards, as most of them are at this time.

The possibility of explosion brings to mind a case wherein the blast line of a water gas plant was literally blown to pieces by the ignition of gas which it contained. Investigation developed the fact that the valve from the generator was leaking and certain quantities of gas entered the blast line; when the generator was next opened the gas in the blast line was subjected to the heat of the burning coke, a terrific explosion resulting. Fortunately no one was injured, the accident taking place in the early hours of the morning when comparatively few workmen were about the premises. The remedy for blast main explosion requires that the blast valves be kept clean and in good repair and that the blast main be purged continually by a strong current of air.

ILLUMINATION AN IMPORTANT FEATURE

Illumination is an extremely important feature, not only in the plant itself, but in the yard where men are called upon to attend valves and around the coke and coal dumps where employees have regular duties at night. Good light shows up the tripping hazard if any there be due to construction or unusual maintenance about the works; it exposes the up-turned shovel, nail, fork or other tool in the passageway, thoughtlessly laid down by fellow workers.

Warning signs have a wholesome effect on accident prevention. They are handicapped somewhat in plants where a number of different nationalities are employed and where it does not seem practical to have them printed or embossed in the several languages. I have noted, however, that the foreign workman, though not being able to read our language, has learned that a sign indicates something special, usually a danger, a place not to enter, a piece of machinery or apparatus not to touch and in many instances will bring from him an inquiry as to its full meaning.

GAS PLANT ELEVATOR, A SOURCE OF ACCIDENTS

I have found the gas plant elevator an enemy of the safety inspector and a source of numerous accidents to the workmen. Many of the accidents attributed to the elevator, however, are due to the men who operate them. They persist in tying or fastening the safety gates so that they cannot function. Elevator platforms are left above or below building platform levels causing severe strains, and bumps from coke and coal buggies. Simple adjustments will usually remedy this condition. Within the past thirty days I have investigated a case wherein an elevator

chain broke inside of the stop weight, permitting the chain and weight to fall inside and on the elevator platform narrowly missing a workman who had placed a coke buggy thereon. Had this weight fallen on the workmen most likely another fatality would have been added to our gas plant records. This condition has been a difficult one to compete with. Daily inspection by the foreman is possible, but this does not always suffice—the guards and gates being tampered with as soon as the foreman's duty requires his attention elsewhere.

Disciplining employees for failure to abide by safety regulations or for tampering with guards is a matter worthy of our deepest consideration. It is a very simple matter to discharge a man, but not nearly as simple to bring another to the point of efficiency gained by experience of the man going out. Hence it would seem that our duty is to get the confidence, the respect of the trifter or meddler, to win him over to the safety side. This may require persistent effort, which perhaps may be attended by some little unpleasantness, but it is being done every day and in several instances of my own knowledge has been well worth the effort expended. These men frequently develop into our best inspectors, calling to the attention of their foreman or superintendent dangerous conditions and practices that had seemingly been overlooked. I am a firm believer in inspections made jointly by the workmen and the safety inspector. The interest the former will show is surprising, especially when he is convinced that his suggestions are being given the consideration to which they are entitled. He has in mind hazards which may not have been considered as such by the foreman or inspector and can usually tell you how Bill or Tom was cut, bumped, or bruised due to the conditions he will point out.

COMPANY OFFICIALS DISREGARD SAFETY RULES

The safety example set by a Company's officials has either an effect beneficial or detrimental upon the employee personnel. To illustrate this point, I wish to call attention to an action brought by an employee to recover for personal injury received while employed in a building where gasoline was used. Smoking was prohibited in this building; large "No Smoking" signs printed both outside and inside the building in addition to which the employees had been personally warned against smoking. Regardless of these warnings the employee caused an explosion while lighting a cigarette. In the trial of the cause he testified that it was the practice of the manager and superintendent to come into the building with a lighted cigar and that he (the employee) did not think it dangerous. In this testimony he was supported by the shop foreman and the evidence injured the Company's case to a considerable extent.

Education is of course a feature for serious consideration. The method of teaching, I believe, should differ as the conditions are different. A method that will avail in one plant may be a failure in another; hence, it falls to the lot of the individual directing the work to figure out and to observe a method that will give the best and the quickest results. Many communities offer night schools to the foreigner, which, for no other ex-

pense than the pencil and paper he uses, give him the opportunity to learn the rudiments of our American grammar, mathematics, etc. These classes invariably start out with a large attendance; the percentage completing the work or of finishing the first year, I am not in a position to state.

I would like to hear a discussion of the elevator question, one that is a serious question with me.

THE ELEVATOR QUESTION

MR. J. F. CONNER: I think there is only one answer to that question, that all elevators should be properly guarded, not only the casing of the shaft but the gate should be high enough to prevent a person leaning over the top and should extend to the floor level to prevent any material from falling into the shaft. The platform of the elevator should have fence guards, and the sides of the platform used for entrances should have gates. The top of the elevator car should have a heavy screen guard over it to prevent any material falling into the shaft from above and injuring the operator. The gates should be constructed so that they cannot be operated from the outside. They should also be arranged so that when the gate is opened, the elevator is locked at that landing. Of course the counter weights should also be guarded. The machinery overhead should have a substantial bar grating or ceiling underneath to prevent any broken parts from falling and it goes without saying that the cables should be frequently inspected. There should be adequate space left at the foot of the shaft in event of any repairs being made there to guard against the platform descending on the man at work. In fact there should be landing posts or trestles put in the bottom of the shaft if any work is being done there.

MR. A. O. MITCHELL: I wish particularly, Mr. Conner, to have you deal with the method of trifling, or prevention of trifling with the elevator gates, weights, etc.

MR. J. F. CONNER: If the ropes, chains, or cables on the elevator gates are properly housed to prevent a person from getting hold of them, that will eliminate one source of danger. If the gates are of such construction that when they are closed they are locked on the inside, that prevents any one from meddling from the outside.

CHAIRMAN PAIGE: The discussion will be closed with the announcement that those interested in elevator hazards have at their disposal Safe Practices pamphlet, No. 15.

The next paper is the "Inspection of Plants of Gas Companies," by Mr. Alvin E. Bliss.

MR. BLISS: I am in hearty accord with the previous speakers that twenty minutes is a very short time to deal with a subject so large as "Accident Prevention in Gas and Electric Companies." I have tried to touch the high spots as the previous speakers have done and after listening to those two very valuable papers, I feel, Mr. Chairman, that mine might well be dispensed with. I have dealt with mine a little more on a personal style than general.

INSPECTION OF PLANTS OF GAS COMPANIES

ALVIN E. BLISS, GENERAL SUPERINTENDENT,
CHARLES H. TENNEY AND COMPANY, BOSTON, MASS

The spirit of victory which has become so much a part of our lives since the eleventh of November last, can only be maintained by a spirit of safety and this "Spirit of Safety" must be followed by each individual in order to establish the solid foundation for the constructive element of the future.

About five years ago the companies which I represent became interested in the subjects of Inspections and Safety First and appointed me as official inspector.

At the end of my first visit to each plant I sent in this report: "Safety first is almost unknown in some of our plants so far as signs, guards, fire traps, etc. are concerned. I could not begin to relate the number of small defects which might mean tremendous loss and possibly serious accident. Belts and dangerous places should be properly guarded and signs placed conspicuously about all plants calling attention to the fact that no trespassing is allowed."

From that time on, our managers became aware of the importance of safety first and coöperated with me by explaining the merits of safety first and accident prevention to employees at each meeting of their department heads.

During the past five years the improvement has been remarkable. It is impossible for an industrial plant to be "accident-proof," but I believe that some of our companies nearly approach that mark.

There is so much to be said on my subject: "*The Inspection of Plants of Gas Companies*"—that I hardly dare get in too deeply as time will not allow it.

HAZARDS OF A GAS PLANT

A gas plant is particularly hazardous. The first item is perhaps the coal pile where some kind of accident happens almost every day. A man hauling coal in a wheelbarrow stubs his toe; gets a cinder in his eye; the coal pile slides too rapidly burying him; beyond this many companies have a high trestle or perhaps low trestle, with railroad sidings where coal passers are at work and everywhere you look is an accident hazard. Next comes the man at the retorts; under a constant and intensive heat, liable to burns of all kinds. Then we have acids, by-products, etc., of inflammable nature, not to mention asphyxiating gas. In fact, we could easily recite:

"Accidents to right of them
Accidents to left of them
Accidents all around them"

when speaking of plant employees of gas companies.

How then can you attempt to overcome the danger of accident? There is only one way—and that is by a process of education. In other words

safety first must be driven and pounded again and again into the heads of the employees.

Realizing the *human element* is the vital factor in safety first and that the human equation must be reckoned with at every turn, how should we proceed to educate the employee in regard to *his* safety?

We know that the school teacher has to go over the A B C's many hundreds of times before the pupil can begin to form words, so our foreman must keep everlastingly at the rules for Safety First. Eternal vigilance is the price of liberty and it is also the price of safety.

There is no subject with which a man is so familiar as himself, so if we could put through a systematic campaign of safety by compelling each man to put himself into accident prevention—we should go a long way toward improving conditions in an establishment or plant.

Even now, it would be interesting if each employee would take stock of himself; check up on the items of precaution which he has used since the campaign of Safety First has been in force. I believe it would be helpful information for any plant.

HINT OF SAFETY ON PAY ENVELOPES

It is the custom in one or more of our companies to have a hint of safety on the pay envelope. One that I have seen has Safety First in bold type printed on the envelope flap. Across the back of the envelope: "Did you ever stop to think—that you, yourself, are the one who should be most interested in our accident prevention work? You and your family suffer more than any one else if you are injured. **THINK FIRST—BE CAREFUL ALL THE TIME.** Let's cut out all accidents."

Another one is as follows:

If you are HURT, say so.

Report all accidents, no matter how trivial they seem.

Do not neglect small cuts.

Don't take chances.

Be Careful.

Further, we think we have obtained some results by using the safety bulletin which we try to issue each month. Many of these are actual accidents which have been photographed around the plant showing the right and wrong way of handling switches, valves, manhole covers, etc.

COPY OF SAFETY BULLETIN GIVEN EACH EMPLOYEE

A copy of the bulletin is sent to each employee with instructions to take it home. In this way, we feel that the family will become interested and by talking it over in the home, the workman is more thoroughly impressed.

This process of education is more or less unsatisfactory as many of you have proved. One of the greatest difficulties to overcome is the utter disregard of instructions. For instance: Goggles are always provided where there is danger of accident, but it is very rare that the employee uses them—his excuse being that they are a bother and he is unable to see while using them. Only a few days ago, one of our em-

ployees got a cinder in his eye. It troubled him, of course, but he thought it was too trivial to report, so kept on working. He suffered all night and the next morning went into the superintendent's office and asked him to remove it. The superintendent immediately took him in an automobile to the doctor, who, after many attempts covering a period of several hours, removed the cinder. The eye was badly inflamed which meant a great deal of pain to the employee, expense and loss of time for the company, and all this because the employee failed to obey instructions.

This clearly shows the lack of cooperation on the part of the employee by not reporting the accident. Analyzing cooperation—the first and most important thing to accomplish is the manager's interest; then the foremen; and the employees. As stated before this is often a slow process, but once the germ of Safety First is inoculated, it spreads rapidly.

Our experience has proved that another good way to get results is by the formation of a Safety Committee in each of our organizations. Right here I would call attention to the report made by a committee on accident prevention which is published in the *Proceedings of the American Gas Institute*, Vol. X, 1915. This report goes into the subject in a very exhaustive manner and is well worth the careful attention of every

RECOMMENDATIONS OF COMMITTEE ON ACCIDENT PREVENTION

manufacturing institution. It recommends the appointment of one or more employees, of whom at least one should devote a large portion of his time to the work of looking after safety details. Care should be taken in making these appointments as the men chosen should be proficient in their own work and should command the respect of their fellow workmen. Unless every man is made to see that his work is closely related to that of the other fellow, success will not follow. Each and every accident should be referred to this committee and the committee should consider all the details in connection therewith and make a report as to whether or not it was preventable, and see that conditions are remedied so that a like accident cannot occur.

It is the custom to send a copy of the report of each accident to me.

EMPLOYEES' REPORTS OF ACCIDENTS

On the back of this report is written a remedy if possible; suggestion for precaution against a similar accident; and finally, whether or not the accident was unavoidable. Some of these suggestions are very amusing, as follows:

"While about work some sand fell down the neck of one of the other employees and he, thinking it was a fellow employee who threw it, hit him over the head with his shovel.

Remedy: Employees have been warned not to get too vicious—and we do not know of any safety appliance that would have prevented this accident."

"Employee was washing the floor and he used his knee to push the

mop causing it to swell and become inflamed.

Remedy: He will be instructed to leave out the use of knee in mopping."

"Injured party was putting new pin in stoker and tried to use his finger as a drift pin. Finger was caught in the hole and slightly jammed.

Remedy: This man should not have used his finger in the manner he did and he has been cautioned and instructed not to repeat the performance."

Most of the remedies are very helpful however, one of which is described as follows:

"Employee was laying 6-inch gas main and fellow employee pushed a length of pipe into place and it caught employee's forefinger on his right hand.

SAFETY BULLETIN

No. 3

June, 1919

Step ladders are furnished for work of this kind. This man, for some reason or other, preferred to take chances. Fortunately no accident resulted from this carelessness.

WHY TAKE SUCH CHANCES?

ACCIDENT PREVENTION COMMITTEE

CHARLES H. TENNEY & CO.

SAFETY BULLETIN

No. 7

October, 1917

This man stood up on the back of a chair placed against the wall to work on a meter—

The chair slipped out and the man was painfully injured by the fall.

If you would avoid
accidents you must

If he had used a step ladder the accident would not
have happened.

THINK SAFETY

ACCIDENT PREVENTION COMMITTEE
CHARLES H. TENNEY & CO.

Report: Cause was carelessness on the part of fellow employee together with careless handling by other man."

Employees are continually cautioned to use a perfect step-ladder, but occasionally, owing to laziness or in the hope of saving time, he will resort to any and all kinds of make-shift with the result that the accident occurs—See illustration from "Safety Bulletin," No. 7 (Reduced). Another lazy-man contrivance is shown in "Safety Bulletin," No. 3 (Reduced).

A LAZY-MAN CONTRIVANCE

Another glaring case was where a step-ladder had been utilized for some time as a means of getting into and out of a sub-basement. After attention had been called to this condition, the proper steps were provided. (See illustration on page 1108).

In one of my discussions at a convention of our companies I told them that I could write a book about the chairs, tables, ladders, benches, etc., which I had condemned in my inspection and which had been destroyed in my presence. At that time I urged each one present to condemn and destroy everything that was hazardous.

Just as a side incident, I should like to state that our medical friends are cooperating with us to the extent of inventing complete first-aid kits which are very necessary for any industrial plant if kept in a complete condition. Only recently another very valuable remedy for burns came to our attention.

HOT WAX TREATMENT

One of our employees was badly burned by receiving an electric shock on a 33,000-volt circuit. By the persistent use of the hot-wax treatment, this man is slowly recovering and my latest report is that he has been dismissed from the hospital and expects to report back to the company for very light work, the last of this month. He owes his life, however, to the fact that his fellow-employees acted promptly and intelligently, which points out the absolute necessity of always having somebody accompany a man who is working around dangerous places and back of all this, the importance of instruction regarding all kinds of first-aid work.

REQUIRES CONSTANT CARE TO PREVENT ACCIDENTS

We have proved then that it requires constant care to rid us of the menace of accidents and their followers of pain, sorrow, grief, disfigurement and despair, a combination of enemies far more insidious than those that face nations, because they lie so stealthily in wait for each individual.

I have felt obliged to be more or less personal in this paper, but I believe that these experiences, even in "testimonial form" will meet the conditions of some of our delegates.

The best slogan in the world today is—*BE A GOOD AMERICAN* and one of the best ways to be a good American is to *PREACH, TEACH, and PRACTICE "SAFETY FIRST."*

MR. J. B. DOUGLAS: Before the formal discussion of this paper takes place, I would like to make a few remarks. I have listened to Mr. Bliss'

BEFORE

AFTER

A STAIRWAY IS NOT ONLY A SAFETY MEASURE BUT IT INCREASES EFFICIENCY

paper with much interest, but there are certain points at which I am not absolutely of the same opinion. Mr. Bliss refers to a gas works as being particularly hazardous. He considers conditions around a gas works as being dangerous but I question whether many of you feel that either of those statements apply. As Chairman of the Accident Prevention Committee of the American Gas Association, I am at work on some statistics. Our committee got into action in August at which time I sent out a letter soliciting accident reports. My greatest trouble is a lack of accident reports on which to make suggestions. I have also on file in my office from a number of companies, letters stating that the first six months of 1919 did not produce an accident to report. It seems almost impossi-

ble. Now in having made an analysis of some ten thousand cases some time ago during our investigation, purely gas cases, as I recall, the percentage peculiar to the industry amounted to two or three per cent or less. In other words, the accidents we have in gas industry are pretty much the same that are met with in other industries and I have been informed that certain insurance companies which thought that accidents

ARE GAS PLANTS EXTRA HAZARDOUS?

were more or less extra hazardous, are beginning to change their viewpoint entirely. I don't know whether Mr. Fisher is in the room, but I understand he has practically no accidents in his gas works. If he isn't here, Mr. Morrison can tell you the wonderful record that the Rochester plant has. No doubt Mr. Van Doren can tell you of the small number of accidents in New York and I know many plants around the country where they go for months without any accidents. I am just stating this because I don't want those who are not familiar with gas plants to think that they are extra hazardous. Mr. Bliss has made a very helpful contribution but I don't think it should be allowed to stand without some statements on those two points. I would be interested as to whether other men from their experience, think that a gas works is extra hazardous.

CHAIRMAN PAIGE: Is Mr. Fisher in the room? Mr. Morrison, have you any thing to say?

MR. C. E. MORRISON: In a measure, Mr. Douglas is correct. There is not as great a hazard in the gas industry as a good many people are inclined to believe. I think that possibly the reason for that is that the nature of the personnel of the employees is such that it doesn't very frequently change as it does in normal industries. You have the same people year after year, particularly in the smaller plants, old trusted employees who know how to take care of themselves. One point that has not been touched upon, I think reflects the accident frequency: Is the attitude of the employer right? I don't mean the manager necessarily, but the president and perhaps the owner. I am firmly and absolutely convinced that if the employer and owner have the right attitude, the proper concept, they can instill into the employees the idea of safety which will prevent accidents. We have frequently come across very serious structural conditions which one naturally concludes would result in many accidents, and yet the record of accidents is absolutely nil. Another hazard that hasn't been touched upon is that occurring when men are digging a trench for the laying of gas mains, which I think is very important. We find very frequently that these trenches are not shored in sufficiently to protect the workmen from the dirt which may fall into the trench. The class of workmen you get there are casuals, the drifters who come in and work for a week or a month, or during the open season and then leave. To my way of thinking, much more stress should be put upon that than perhaps in the gas plant itself.

MR. V. R. HUGHES (Pacific Gas & Electric Co, San Francisco): We have about the same number of accidents in our gas department that

we have in the electric. Some of them are not quite so severe because, as you say, they don't need to fall off a pole to be injured, but the gas men will go under a house once in a while with a match or candle and blow the house to pieces. The electric man will get on a pole and short circuit something or get against a wire. Talk about your old employees, they are the hardest ones to convert that there are. The old gas men have an idea that they know how to make gas and that is all there is to it, but we have gradually got away from that and got the men to clean up a little, take up the dirt, and not sweep it into corners and under things. Our electric departments are pretty well cleaned up but our gas plants were in bad shape. There is another item which has just occurred to me, speaking of valves. I have an article in "Power", February 25, 1919, on this subject. I talked it over with Mr. Jones, Chief Engineer of the Gas Department, and he said they devote a large amount of time to the inspection of valves but very little time as to where they are going to put them, up high, in the ground, with the stem sticking out in the way, some back of a pump or back of shafting where

EXPERIENCE WITH SIGNS

they are either hard to get at or right in the way. There is also another item of signs mentioned in these papers. My experience with signs has been very poor. I went into a warehouse with the superintendent of supplies one day to put some supplies in and I asked him about the signs and he said they were no good. And yet right near us on a shaft, was a sign reading "No Smoking" and he was smoking himself. The only accident we have had, fatal accident, this year, was the case of a man crushed against a sign which read "Look Out for the Cars".

MR. G. R. RINKE (Utilities Mutual Insurance Company, New York): I haven't any statistics in my hand but I think you will find just about as many accidents in gas as in electric plants. The reason you do not have as many fatalities in gas is that there is not the electric hazard. I have been very much interested in the point raised several times about Americanization. I believe there is one point not touched on and that is that gas makers or men handling gas machines should be American-speaking people. So frequently you will find that they are Italians or other foreigners. They are naturally badly handicapped in case some unusual condition is met. Quite frequently, too, you will find that there are machines installed and in operation and the people who are operating them do not have complete instructions as to what to do or the proper procedure to go through in starting a set up. I have in mind an accident where one man was killed and two others horribly burned. The man instead of controlling the draft through the ash pit doors, endeavored to control the draft through the clinker doors; the result was gas pockets formed. There is a question as to whether they formed under the grates or in the fuel bed itself, but it was a fact that the fuel was thrown out on the men. These men had been operating the sets in that plant probably since their employment and no accident had occurred but they weren't doing it the right way. There is a little question in my mind also as to whether the manufacturers of the equipment aren't

somewhat at fault because of the fact that they do not give sufficiently definite instructions as to just what the procedure should be in operating the equipment. That question of accidents seems to show that in an organization such as you have around a gas works, you usually have more foreign-speaking people around than in an electric station. Quite a number of laborers are necessary to take care of outside work and those people seem more prone to accidents than the others. I think the electric hazard makes the electric plants really more dangerous than the gas plants.

CHAIRMAN PAIGE: The discussion on Mr. Bliss' paper will be handled by Mr. H. A. Johnson.

DISCUSSION

MR. H. A. JOHNSON (Adjuster, Omaha Gas Co., Omaha, Neb.): I have read Mr. Bliss' paper with a great deal of interest and not only has he touched on the subject of "Inspection", but referred in a general way to the prevention of accidents in the Gas Industry.

Mr. Bliss states that a gas plant is particularly hazardous, but, although one would expect that the greatest number of employee personal injuries in the Gas Industry occur at the Works or Manufacturing Department—on account of the machinery, boilers, generators, etc.,—it has been our experience that we have less accidents in this branch of the work than in others. This probably is due to the fact that the men are under a closer supervision than those men who have to work in dark basements of consumers' homes or on the street.

With very few exceptions, the hazards of the gas plant are similar to those of other industries. We have found that the best plan to reduce these hazards is by inspections at regular intervals, which work I have been doing for some time. I usually make an inspection of our plant about once every month. This inspection covers all our departments including the Commercial Office. Fire risks as well as accident hazards are noted and a report, giving location, nature of hazard—together with a recommendation to remedy it is referred to the Manager for his approval—after which the person in charge of each department is expected to take immediate action reporting back what is done in each case.

Very good results have been obtained from these inspections owing, especially, to the fact that we have the coöperation of manager and foremen, which Mr. Bliss says is the most important thing to accomplish. The foremen are especially interested in reducing these hazards because most of them are caused by poor housekeeping, and by adopting the policy of putting everything in its place immediately after completing each job, it is quite easy to eliminate several items on the report.

Owing to the responsibility placed on employers by Workmen's Compensation laws, the Company of course is quite interested in providing the necessary guards for machinery, stairways, footwalks, etc., and it is important that the Company does its duty before asking the coöperation of the employees.

I agree with Mr. Bliss that the only one way to overcome the danger of accidents is by a process of education. As Mr. Bliss says, there is no better and easier way to educate the workmen in accident hazards than through safety committees.

ORGANIZATION OF SAFETY COMMITTEES

We organized a Safety Committee in our Works last March, similar to that outlined by the Accident Prevention Committee of the American Gas Institute, and mentioned in Mr. Bliss' paper, and we have found that it pays. We also expect soon to organize them in other departments. While there hasn't been any reduction in the number of accidents over last year during the same period of time, there has been a reduction in time lost by employees on account of accidents—amounting to 25 days; and the cost of holding the Safety Committee meetings, plus compensation paid injured employees, together with medical expense, was less than that paid for accidents in the Works last year during the same period of time.

The Superintendent of Works acted as Chairman of this committee for six months and six workmen were appointed to serve on the committee with him. Each workman serves 90 days, and at the end of every 30 days two men are replaced with 2 new men and by this plan we hope soon to give every employee a chance to serve on the committee—in this way educating every person. At the expiration of his time each member is given a gold-mounted safety button which he wears with much pride.

The Committee meets every two weeks and spends about two hours time. Part of the time is spent on an inspection through the plant, after which a round-table discussion is held on working conditions in general. I have been acting as Secretary and occasionally accompany the men through the plant, and I have been surprised to find the number of important recommendations the men make. Most of the suggestions made would probably never appeal to an inspector who did not happen to see certain work being done.

This Committee does not confine its meetings to Safety, but talks about other conditions which help to reduce operating expenses so it is impossible to place a value on the work of such a committee. Each accident that occurs in the plant is discussed by the Committee and in this way considerable publicity is given on accidents, at the plant.

REPORT OF AMERICAN GAS INSTITUTE COMMITTEE

I am glad that Mr. Bliss referred to the report made in 1915 by the American Gas Institute Committee and hope that every member, if he has not already done so, will secure a copy of this report and study it. It is based on the experience of several gas companies, and covers in detail most every hazard in the Gas Industry.

In this connection I would also like to refer to some work now being done by the Accident Prevention Committee of the American Gas Association of which Mr. James B. Douglas of the United Gas Improvement

Company is Chairman. This Committee is asking for a report of all accidents in Gas Companies wherein the injured person is disabled over one shift. I think this section ought to coöperate with this Committee so that every Company can get the benefit of the other's experience.

As Mr. Bliss states, much can be said on the subject of "Gas Plant Inspections", but I should like to point out some of the things I consider most important in this kind of work. Any plant can select a man to devote a few hours each month to this work. He need not be a safety engineer nor a graduate of a technical school, but he should be a man who is not daily on the ground—as he will be more alert and notice the little things, which, left unchanged, might cause serious injuries.

INSPECTION TOUR THROUGH GAS PLANT

I recently had the pleasure of accompanying an inspector on a tour through our Gas Works, and the first place he advised going was to the top of our large gas holder, or highest point near the Works. He said he could usually tell from this point if a plant was paying much attention to safety, by the appearance of the yard, in general, and he also stated he could plainly see loose pieces of slate or other defects on roofs of buildings. I was glad to hear him say our yard was very clean, but he did notice some loose pieces of slate. We have great difficulty in preventing the last hazard owing to continued Western winds which usually find their way under the pieces of slate.

In making these inspections, I try not to be too critical, and oftentimes correct small things at time of inspection by calling the attention of the person whom I feel is responsible for the condition, and in this way I think the foremen will not be apt to consider the report too critical.

It is necessary, around a Gas Works, to have several valve pits with wooden covers, and I find it quite important frequently to inspect the cover and if it becomes cracked or rotted, recommend repairs at once. This hazard appeals to me particularly owing to the fact that while making an inspection, I stepped on a cover over a pit which was located in one corner of a holder yard, and my leg immediately went through. Fortunately, however, I was not injured. Upon close examination I found that the material had become so rotted that it was nearly like paper, but to look at it one would have thought it quite strong.

Wooden stairways, wooden passageways, or ladders exposed to the weather, should receive the most careful attention.

Some of the most common hazards around a Gas Works are oily waste on floor or work benches, clothing or other combustible material in bottom of lockers. Frequently tools are found with mushroomed heads, nails protruding from boards, and pieces of coke on runways. It is necessary to have several foot-walks around a Gas Works, and the proper guard rails should be provided, also toe-boards on sides to prevent accidents from falling objects. It is important to provide sloping tops on all lockers and small cabinets to prevent the storage of material on top of

same. Lockers may be purchased with sloping tops and it is well to so specify when ordering.

Our storeroom and distribution shop is located in a six-story building away from the plant, and there are several conditions to be watched here, such as nails protruding from boards near place where stoves and other material are uncased, and we have also had a few accidents caused by trucks running over loose nails on floor causing the head of same to become wedged in floor and injuring workmen by striking foot against point of same.

Shelves used in storing glassware and other material should have uprights to prevent material from falling; fixtures should be suspended from hooks and not nails; passageways should be kept clear.

In our storeroom we have a sprinkler system, and we have had considerable difficulty in getting our men to realize the importance of not piling material closer than 18 inches to the sprinkler heads. It is quite important to provide ample fire protection in meter repair shop such as sand pails and Tetrachloride Fire Extinguishers on account of oil fires.

DANGER FROM EXHAUST PRODUCTS OF AUTOS IN A CLOSED GARAGE

We also have our own Auto Repair Shop where we have tried to provide suitable fire protection, and I should like to mention at this time the danger of workmen being made sick by the exhaust products of autos in a closed garage, especially during the winter. Two years ago our distribution superintendent installed three or four pipe connections leading from the inside wall of the garage to the outside of the building, and in the cold weather the cars being repaired are backed up to the wall and a hose is connected from the exhaust pipe of the car to pipe in wall. This has helped us to eliminate the disagreeable and dangerous condition in the garage when the engines of two or three cars are running.

I have tried to touch only on the most common hazards of the gas industry, and hope I have covered at least a few conditions which might be new to some of the members—or at any rate renewed their importance in your minds.

Mr. A. E. BLISS: I am very glad that this matter of particular hazards of gas companies has been brought up. Our employees must report everything and I think that I am safe in saying that the serious accidents are no worse in the gas companies than in the electric, but cinders in the eye, cutting fingers, or slight accidents of that kind that do not lay the men up, are very common in the gas plants and that was what I had reference to in bringing out the large number in gas plants over electric.

CHAIRMAN PAIGE: The next paper is on "Effective Means of Focusing the Responsibility for the Prevention of Accidents upon Foremen" by Mr. J. W. Easley, Kansas City Home Telephone Company, Kansas City, Missouri.

**EFFECTIVE MEANS OF FOCUSING THE RESPONSIBILITY
FOR THE PREVENTION OF ACCIDENTS UPON FOREMEN**

J. W. EASLEY, KANSAS CITY TELEPHONE COMPANY, KANSAS CITY, MO.

A discussion of effective means of focusing the responsibility for the prevention of accidents upon foremen naturally leads to an investigation of the foreman's relative position in industry, and to the methods by which can be secured his supervision to cover prevention of accidents to the end that such supervision will be a matter of assigned routine and not optional. The problem is a constructive psychological problem; a problem to secure a realization and acceptance of responsibility.

FOREMAN THE MOST POTENT FACTOR IN ACCIDENT PREVENTION

In the organization scheme of the telephone industry the foreman, because of his functional duties is probably the most potent factor in accident prevention. To a more or less extent this is probably true in all industries, but particularly so in the telephone industry because of the necessary wide-scattering of the working units; the foreman's direction is final; his judgment conclusive; he is the controlling element relatively absolutely responsible for the efficiency of his unit and the correct performance of its duties. If properly organized the foreman and his crew are working under well-defined instructions, each operation covered by standardized specifications. To make proper progress in prevention work accident prevention must be made an integral part of the operation of the unit; safety practices and safety standards must be made part and parcel of construction specifications and construction methods—and the foreman must be brought to a realization of his responsibility in this regard—then will accident prevention receive relative consideration. Definite instructions must be issued for every operation of the crew, instructions estimated to provide for the completion of a given operation without accident, and the foreman's duties must be clearly defined to cover supervision in that direction. Output should not be a controlling factor. It should not be optional with the foreman whether a workman do this or that which may be safe or unsafe, even to hasten production. He should be specifically charged that his directions must be along the line of the fewer hazards regardless of output. As the human equation is a controlling factor in accidents, and as the mental attitude of the workman has much to do with success of prevention work, the matter of hiring and discharge should be delegated, with restrictions, to the foreman. He is in a position to judge motives and should not be hampered with workmen who are antagonistic to the safety idea. The problem of the new man on the job and his relation to accident prevention is one for the foreman's particular study. Much thought and energy have been concentrated upon improvement of method without a single new idea as to the

man on the job. The foreman should be as responsible for correct instruction of safety practices as for operating methods, and this responsibility applies particularly to the new employee. Foremen should not tolerate indifference.

Necessarily all employees should be required to inspect and test for efficiency, strength, and safety, all equipment and tools used by them. They should be instructed to do nothing contrary to their judgment with reference to their personal safety, and that when in doubt they must consult their foreman and be governed by his instructions. The foreman must be cautioned not to accept an instruction or put it into effect if in his judgment it will lead to unsafe practices. He must be encouraged to question the correctness of instructions as affecting safety. He must know that working conditions can be improved largely through his suggestions and that it is his moral obligation to make such suggestions and that such suggestions would be of benefit both to the employee and the employer. Inspection and correct instruction for use of tools and materials should be made a part of the foreman's duty. He should be made responsible for the condition of tools.

If foremen or workmen are fined, laid off or dismissed for violation of operating rules, why should they not be fined, laid off or dismissed for failure to follow safety practices if these are to be a part of the operating rules? Dismissal of employees for unsafe practices should be delegated, with restrictions, to the foreman and there should be a well-defined penalty for accidents resulting from improper supervision.

UNSAFE PRACTICES CHECKED UP TO THE FOREMAN

Safety inspectors should report failure to observe safe practices as carefully as the output inspector reports faulty output, and the same penalty should apply. Faulty output is checked up to the foreman, why not unsafe practices? In our plant we have tried the scheme of plant inspectors. They are appointed from the rank and file of the employees, to serve for a term of three months. Their reports are transmitted to our committee and are treated confidentially. The results have been very gratifying. The foremen are continually on the outlook to prevent unfavorable reports. But foremen must not be made too dependent upon inspection for improvement, as it hampers their initiative.

The economic loss resulting from an accident should be brought forcibly to the foreman's attention; the detrimental effect upon morale, the resulting confusion and tendency to uncertainty. The foreman should be required to make a detailed written report of all major accidents to members of his crew. He should be kept informed of the condition of the injured person. The foreman must know intimately the effects of the accident upon the workman and his family, really to appreciate what it means. The foreman must realize his moral obligation.

The foreman must be informed of the principles of common law as they relate to his position. He should know that an employer is bound to use ordinary care to prevent injury to an employee; that the degree of diligence varies with the character of the work and that for this reason the

degree of diligence in utilities is very high; that the employee, to recover damages must be free of continued negligence; that reasonable rules and safeguards must be formulated and adopted by the employer and that the responsibility rests upon the foreman to see that they are enforced and that any neglect on the part of the foreman in not carrying out the orders of his employer subjects the employer to full liability in case of injury to the employee, for reason of such neglect; that if the foreman is sues proper instructions and urges caution they will tend to mitigate the damages. The foreman must realize his legal obligation.

The foreman should be well-informed as to Compensation laws that may be in effect. For instance, in Missouri: he should know that compensation will not be allowed for an injury or death due to the employee's or another's willful misconduct including failure or refusal to use a safety appliance or perform a duty required by statute or failure to obey any reasonable rule adopted by the company for the safety of the employees. He should especially know that the burden of proof rests upon the employer; that it is an accepted principle in compensation that neglect on the part of a fellow workman does not prevent recovery of compensation. If a compensation law is in effect, foremen and all other persons in supervisory positions should be furnished with a copy of the law and with the notations and explanations as issued from time to time by the Commission, and they should be encouraged to discuss them at the various meetings. The foreman should be in a position to see that justice is done as relating to compensation.

The study of accidents and their causes, by the foremen, is very important. We find a very good method is to submit the circumstances and conditions leading up to an accident to each foreman for suggestions as to how the accident could have been prevented. If accidents occur the details should be given wide circulation among employees. We are employing for this work a personal letter to the employees as we question the value of the collective method—the use of the bulletin board. An effective method also of securing the coöperation of the foreman in accident prevention work is to make the discussion of accidents an important feature of the foremen's meetings. In these meetings accident prevention should be considered equally important with the discussion of other plant matters, and topics for discussion should be assigned in advance.

CHAIRMAN PAIGE: Mr. Easley has given us a new slant on this question and the discussion to be taken up by Mr. H. C. Lucas will be interesting.

DISCUSSION

MR. H. C. LUCAS (Secretary-Treasurer, Philadelphia Electric Company, Philadelphia): To those who have studied safe practices in large utility companies, the question of focusing the responsibility for prevention of accidents upon foremen has been answered in the admirable paper you have heard read.

There are two classes of foremen to be considered: The foremen properly instructed to the necessity of doing work well and as expeditiously as possible, who carries out his orders, always keeping in mind

safe practices while so doing, he is known as a safe man. To such a man fully realizing the importance of safe practices, and the responsibilities of the company as relating to his position, no accidents are chargeable. Accidents may and do happen under him, but they are few. There is the other foreman, just as intelligent, just as safe in some particulars, but who insists on the work being done expeditiously, safely if possible, if it does not interfere with getting it done quickly. This is the man we must consider. There is a lack of earnestness when he talks of safe practices to his men. He neglects frequently to call the attention of his men to safety. Labor conditions of the past few years brought new men in each gang every week. These men he neglected to instruct in safe practices.

There is another class of foreman I have not considered. He is out of the pale. Intelligent or otherwise, safe practices have no place in his composition. He simply will not consider them, and therefore should not be retained.

In considering the responsibility of the foreman—it is fair to begin with the assumption that if proper attention be given to laying out the work and if proper tools are supplied to do a given task, and instructions on safe practices given to the men, a very large portion of the proper duty of a foreman has been complied with.

Where this has been done, only a direct violation of orders, or gross carelessness on the part of the worker is likely to result in an accident. At first glance, it does not seem fair to charge the foreman with responsibility for such accidents. Nevertheless, the foreman who tolerates careless methods, who permits any deviation by the worker from the recognized and safe practices of work which have been explained to him, must in all fairness be held responsible for such carelessness and disobedience, particularly if the worker is not an entirely new employee.

Too many foremen close their eyes to chance-taking, simply because they have seen so many chances taken and gotten away with safely, that they unconsciously acquiesce in rule disobedience, rather than take the time to censure and discipline infraction of the safe though narrow way of performing the operation.

How to get the foreman to realize his responsibility for the waste and sorrow incident to accidents, is indeed no easy matter, but one that requires plain talk from the management. Such realization can only be expected after man-to-man talks with him—only after he has become an honest-to-goodness safety man himself. Like many other things, it is a matter of education, and no man should be a foreman if he cannot be brought to a realization that a job is not well done if there is any sort of accident entering into the performance of the work.

EDUCATE THE FOREMAN

Talk to the foreman; show him that the accident cost is part of the job; show him that a foreman that turns out jobs with an accident cost tag attached is a luxury that cannot always be tolerated. Show the indifferent foreman that he cannot compete with a real production man

who insists that all work that he in any manner has supervision over, must be done, not only accurately and expeditiously, but free from the stain of any accident overhead. Show the foreman the record of accidents in the plant, and how many he is responsible for in his division. Create an incentive for him to make his division 100 per cent accident free. Fail not to let him know you are interested in this record.

Every foreman if he is honestly and earnestly interested in safety will find his men the same way. It is the foreman tolerant of careless and unsafe methods who finds his men reflecting his attitude. Such a foreman must be talked to earnestly; told positively if unsafe practices continue he will be discharged. While the bulletin board is effective, the personal letter to the foreman, as Mr. Easley says, is the most effective. A weekly letter to all the foremen in his department by the head of that department calling their attention to the accidents that have happened during the week, the persons responsible, analyzing the causes, and determining if avoidable; discharging those foremen and men whose record is continuously bad; laying off for a few days those responsible for avoidable accidents, and encouraging all to strive for a clean monthly record.

One of the most effective means for focusing the responsibility for prevention of accidents upon foremen is the safety engineer. In season and out, every time they meet, he continually boosts SAFETY. His position, however, does not empower him to fine or discharge the careless foreman, but it is his duty to report to the head of that department any infractions of the rules he may observe, or that may be brought to his attention. The head of the department is the man with authority to fine or discharge, and if his attitude is strict, the observance necessarily will be.

A trained foreman is the logical instructor of every man working under him—he is the creator of dozens of safety enthusiasts where only one existed before.

All this he can obtain by tact—by friendly coöperation. The good foreman should not quarrel with nor unduly censure his men—win them the other way—make them realize that accidents are not only unnecessary, but economically wrong, that they, too, somewhere along the line have to absorb part of the cost, and that when they help to minimize or wipe out entirely such wastes in operation, they are doing real things, and are surely headed for financial advancement.

The foreman who makes excuses for accidents occurring within the division of work he supervises, rather than train his men in safe practices, *cannot be considered as a good foreman*, and therefore should not be considered as in line for further promotion.

Safety talks were all right when we started the safety campaigns. We have passed that stage. What is needed now is safe practices; safe practices enforced by reprimand, fines, lay-offs, and dismissal.

Mr. J. B. DOUGLAS: Mr. Lucas' remarks on discipline are rather new in this day when men are so scarce, and I would like to ask what peculiar plans the Philadelphia Electric Company has for making men safe

to their employment in case they are fined or laid off for a while. If we did that in the same town, they would never come back. It seems to me in this time of labor shortage it has been felt very generally that it would be rather disastrous for others to try that idea.

MR. J. W. EASLEY: I brought this proposition up just to see what you folks thought about it. This was our experience as I have outlined it, that when we fined or laid off or disciplined one employee or one foreman who failed to observe safe practices the news scattered so quickly that we weren't required to lay off many more. The result was to boost the standard of our work.

MR. H. C. LUCAS: The superintendent in one of our plants gets out weekly letters to his foremen on such points as may seem best. We are so scattered, occupying probably one hundred and twenty-eight square miles of territory, that while we work more or less out of one store there are foremen who report at the station fourteen or fifteen miles distant or other parts of the city.

MR. B. F. DAY (The Philadelphia Electric Company, Philadelphia): It seems foolhardy to let a man go in these times of difficulty in getting foremen but we have found that it is difficult to penalize foremen to the extent of letting them go if they will not size up as a safety man and we have never lost permanently any men that we have desired to retain as foremen through that fact. Probably the answer is that the service of the Philadelphia Electric Company is more desirable to foremen than many other companies. In other words, it may be to their advantage to pay the penalty rather than seek employment with the competing company. We try to use men and foremen like men should be used. Our employees are not paid entirely under compensation if they are absent on account of accident, but, in addition to state compensation, they are allowed an amount sufficient to bring their wages up to their full amount and the instances in which we have discovered malingering have been very few indeed. Personally, I believe that penalizing is a process which must be used very cautiously. We have tried to be diplomatic in the matter and so far have not incurred any permanent hatred or lack of cooperation from the foreman who has been penalized.

BENEFIT ASSOCIATIONS

MR. J. B. DOUGLAS: One feature Mr. Day omitted when speaking of the features offered by his company to employees is their beneficial association. As far as we can learn from our employees, their connection with the United Gas and Improvement Company is very satisfactory and attractive to them but you take two companies in the same city with working conditions being equal as far as they can be, if one company has a pension and beneficial system, it is natural for a man, if fined, to think the second time before he kicks out and loses what rights he may have in that system, whereas with the other employer having no such welfare plan, the employee does not give the matter the same concern. I have no doubt that the very excellent welfare that Mr. Lucas has among employees there in Philadelphia has a great deal to do in

causing employees if fined to submit to the fine and return to their work because from what my friends have told me and from what I know of other ordinary employers, I know that in this day it is almost impossible to dock a man or fine him or penalize him and expect him to come back to his job unless you have some unusual hold such as beneficial association or something unusually attractive.

MR. H. C. LUCAS: I don't believe the beneficial association is one that will pay full pay for any accidents for practically unlimited time, especially for accidents on duty. I don't think that has any bearing on this at all, neither do I think the service annuities or anything else matters to that extent. Of course, I think that with the older foremen it is different as Mr. Day and myself are placed in position where we do take care of them irrespective of beneficial association or anything else because their records of years and years entitle them to that. I think it is the man, the foreman. Any foreman that is just and strict will keep his men the same way and they will realize that when they are laid off, they are laid off for a cause and that cause was their own. I don't think there is a bit of difference between Mr. Douglas' men and the other company's men and I don't think the beneficial association makes a big difference but the average employee when you lay him off says that he'll get a job somewhere else. I think it is the foreman and when you settle it, as Mr. Easley says, focus it on that man and make him liable for it, you have struck the nail on the head.

MR. WILLS MACLACHLAN: In connection with the placing of blame for accidents, one method that we have used is to have the safety committee, as you call it, go over the accident and see who was to blame and what was the cause. If the blame is placed by fellow members, there isn't the sting to it of the blame being placed by the company, but the matter of laying off or firing for cause has been used for years by all railroad companies quite successfully, in fact the only successful system.

CHAIRMAN PAIGE: We have had some very interesting papers and very interesting discussions and in behalf of the Section, I want to thank those who have put so much effort into making this program so successful. The next session of this section will be tomorrow morning at 9:30 A. M.

The Section then adjourned.

SATURDAY MORNING SESSION

THE meeting was called to order at 9:00 o'clock A. M., Mr. Wills Maclachlan, Vice-Chairman, presiding.

VICE-CHAIRMAN MACLACHLAN: The first item on the program is the report of the Nominating Committee. As Mr. Fisher, the Chairman of this Committee, had to leave last night, I will ask some one else on the Committee to present the report.

REPORT OF NOMINATING COMMITTEE

Mr. JOHN BAILEY (Bell Telephone Company, Philadelphia, Pa.): Mr. Fisher asked me to present the report of the Nominating Committee. The following members were nominated:

Chairman: Wills Maclachlan, Electrical Engineer, Consultant Employees' Relations, Toronto, Canada.

Vice-Chairman: Charles E. Morrison, General Manager, Utilities Mutual Insurance Company, New York City.

Secretary: H. B. Harmer, Philadelphia Electric Company, Philadelphia, Pa.

We recommend that the various sub-committees be appointed by the incoming Chairman.

(These candidates were elected.)

CHAIRMAN MACLACHLAN: I appreciate very greatly the honor you have paid me in this, and possibly after I have had a little time to think it over I will try to lay before you some of the policies of the incoming administration.

The next order on the program is a paper by Mr. H. J. Burton, Consumers' Power Company, Jackson, Michigan, on "Working Safely on Live High Tension Lines."

Some of us who have known Harry Burton for the past five years appreciate what he is doing in the instruction work and the developing of the men in his Company to carry on the technical work for that Company. I think that a paper on this subject by Mr. Burton will be appreciated by all of us. Mr. Burton.

WORKING SAFELY ON LIVE HIGH TENSION LINES

H. J. BURTON, CONSUMERS' POWER COMPANY, JACKSON, MICH.

Ordinarily live, high tension conductors are dangerous to touch or approach, and they can only be handled safely by those who have been properly trained and equipped for the work. Energized electric light and power circuits should be handled carefully under all conditions, and in no circumstances is greater caution required than in the installation and repair of high tension lines and equipment.

HAZARDS NOT ONLY ELECTRICAL

Some causes of accidents are common to most industries, and the danger to the electrical worker is not only due to shocks and burns, but also to falls from towers, poles, or other elevated structures. Many conductors are placed underground, in conduits and in tunnels, and there is sometimes danger from explosive or inflammable gases. The question of asphyxiation of employees must also be taken into consideration. Coal or coke dust, or any deposit on the insulators, in the nature of a conductor, or partial conductor of electricity, increases the chances of flash-overs and danger to the worker. The weather affects operating conditions—rain, snow, wind, sleet, and lightning generally mean work for the trouble man, and quite often the most dangerous work to be done is during or imme-

diately after a storm. "As there is always a possibility of danger from lightning, induction or live conductors swinging into and energizing the lines to be worked upon, no lines should be treated as "dead" or not energized unless they are short circuited and thoroughly grounded.

EDUCATING THE PUBLIC

The use of electricity is daily becoming more general, and a network of electric wires extends over and under the streets of our cities and across the fields of our country. The number of injuries due to the public wittingly or unwittingly coming in contact with live conductors is unnecessarily high. Experience teaches us that most accidental injuries can be prevented by education. Persistent instruction to the public would tend to decrease some of these accidents.

In this paper an attempt will be made to outline some of the precautions to be observed for the safe handling of live or energized lines and equipment. It will deal more particularly with electrical hazards rather than those common to most industries.

SELECTION OF MEN FOR LINE WORK

Records show that linemen and patrolmen, that is, the men who handle distribution circuits and transmission lines, sustain a large percentage of the fatal accidents to employees of the electric light and power companies and particular attention should be given to the selection of men for this work. In dealing with the problem of safety to linemen, it should be realized that most of the accidents are due to mistakes, lack of instruction or the incompetence of employees. Such accidents can be prevented by education. Very few of the accidents are due to mechanical or physical conditions of the property.

CONSTRUCTION OF LINES

If the construction of the lines is of a temporary nature, the clearances and other physical conditions should be checked up. If it is essential that such lines be worked on while energized, it may be necessary to build special platforms and barriers before any work can be done.

Electricity is sometimes generated and distributed at from 2,300 to 7,500 volts. In other cases it is generated at from 2,300 to 7,500 volts and it is then stepped up by means of transformers to from 30,000 to 150,000 volts and transmitted long distances and then stepped down again and distributed at lower voltage. On account of the great difference in voltage between distribution lines or circuits, and transmission lines, two distinct safety problems are presented. Methods and practices that would be safe when considered in connection with distribution circuits, would be out of the question for the higher voltage transmission lines.

Live distribution circuits can be worked upon safely in good weather when the poles are dry without any intervention between the worker and the live conductors, except a good pair of rubber gloves or other comparatively thin insulating guard. When work on high tension transmission lines is to be done, long insulating rods, tongs, or similar appliances that isolate as well as insulate must be used.

TRAINED MEN ESSENTIAL

A competent crew of trained men is essential if work on live lines is to be performed safely. Too much care cannot be taken in the selection and training of the foreman who has to take immediate charge of the work and all of the men must be instructed as to the character of all lines and equipment on or near which they are to work. Employees should not be left to learn their work by the "absorption" method, they should learn by the "intentional" method, that is, it should be the duty of some competent person to instruct them. Some foremen consider their duties fulfilled when they have briefly outlined to the men under them the work to be performed, but in order to insure safety they, or some authorized instructor, must give repeated and detailed instructions. Sometimes men do not fully understand or they forget their instructions. The foreman should satisfy himself that all of his men are competent and their knowledge of line conditions and hazards should not be taken for granted.

PROTECTION FOR THE MEN

In addition to being properly qualified to perform their work employees must be equipped with suitable insulating appliances for the safe testing and handling of live equipment and lines. All insulating tools and appliances must be inspected and tested regularly and they must be properly stored or taken care of when not in use.

Rubber gloves, when not in service, should be stored in a dry and cool place where the temperature does not exceed 75 degrees F. The gloves should not be exposed to the light and each pair should be kept in a separate box. If rubber gloves have to be stored for any length of time, it is a good practice to take them out periodically and roll or crumple them with the hands. They should then be straightened out and laid away again. This practice seems to revive the rubber and lengthens the useful life of the gloves. It should be borne in mind that a perfect pair of rubber gloves can be rendered useless for work on live conductors if subjected to rough usage. They should not be worn while climbing as a splinter or a slight abrasion or puncture will destroy or lessen their insulating value and render their use a hazard instead of a protection. Special care should be exercised to avoid puncturing the gloves when making a wire splice. It is advisable to wear leather gloves over the rubber gloves to protect them.

Linemen's shields or protectors should always be used when work is to be done in tight places on distribution circuits. These shields which are of rubber, or some other insulating composition, are for placing over live conductors that are in close proximity to the lines on which the work is to be done. These protectors are guaranteed by the manufacturers to withstand all ordinary distribution circuit voltages. They are of great help to linemen and their use should be encouraged. When not in use, shields should be placed in and carried to and from the place where the work is to be done, in substantial boxes. If this is not done, they are liable to be damaged by contact with the other tools in the line-wagon.

Linemen's spurs are necessary for climbing wooden poles, and they

should always be kept in first class condition. The gaffs should be kept sharp and should be replaced when they are so short that they will not puncture into the wood far enough to hold safely. The straps and buckles should be inspected frequently for defects. Spurs should only be worn when they are actually needed for climbing. They should not be worn while traveling to or from work. Fooling and scuffling among linemen while wearing their spurs has been the cause of many accidents.

Safety belts are essential for preventing accidents to linemen, and yet quite frequently they are not used. The materials used in the manufacture of these belts should be the best obtainable and the workmanship should be of the best. They should be inspected frequently to make sure the straps, rings, snaps, rivets, and buckles are in good condition. When using a belt, care should be taken to see that the straps and buckles, are properly secured before weight is brought to bear on them.

Rubber boots and coats are now used quite extensively, by linemen, their use being especially valuable when work is to be done during or immediately after a storm where broken lines or falling wires have to be handled.

The ropes used in connection with the work on high tension transmission lines should be impregnated with paraffin and kept in a canvas bag. The insulating rods should be thoroughly treated with paraffin. A drying room or oven should be provided where the tools can be thoroughly dried and then treated. This should be done at regular intervals.

Insulating tools and appliances should be of the best obtainable and employees should be instructed that they must not use anything else as a substitute. The insulation commonly placed around the handles of pliers, screw drivers and other tools used by linemen serves to keep static away but should not be relied upon for complete protection. Rubber gloves, in fact, all insulators may lose their insulating qualities and become incapable of resisting high voltages by wear or by deterioration. If they are not inspected and tested periodically, their use may prove a hazard instead of a protection.

INSTRUCTING EMPLOYEES

First: Employees should be instructed how to avoid shocks and short circuits when working on or near live conductors. Before starting any work they should be informed by the foreman which conductors they are to handle and which to avoid. The employees should be acquainted with the fact that if they are thoroughly insulated from the ground and all other conductors, it is comparatively safe to touch a single conductor, but that contact with two conductors or one conductor and the ground is dangerous and may result in injury. The foreman should caution his men to keep all parts of their body, as well as feet and head, away from live conductors. The insulation on high tension wires cannot be relied upon as a protection against shock and this also should be explained to employees.

Second: Linemen, before climbing, should be satisfied that the pole or tower is in good condition and strong enough to bear additional weight.

Poles may be tested near the ground line for decay with a bar or screw-driver, and sounded for decay at the center of the pole by rapping with a heavy tool or block of wood. When poles or crossarms are apparently unsafe, they should be properly braced or guyed before any dependence is placed upon them for personal safety. No employee should go among any wires until he knows their condition and voltage, and knows that it is safe to do so. Leaning over and crowding through unprotected wires should be avoided.

Third: Sometimes because of leaking insulators, defective transformers or broken ground wires caused by storms, or other unusual conditions, poles or towers may be energized or "hot" and difficult or even dangerous to climb. If it is necessary to do work upon a line or circuit and conditions are such that pole cannot be mounted or climbed without danger, the circuit should be made "dead" at least until protection shields, barriers, or other safeguards are in place. Employees should be instructed not to work immediately above unprotected live lines or equipment, as a tool, rope, or branch of a tree dropped across a high tension line might result in a flash with serious consequences. The rule—"work from below"—is a good one and should be enforced whenever practicable.

Fourth: Underground electrical workers are exposed to special dangers. There is always the possibility of gas in tunnels, conduits, and manholes, and employees should be cautioned not to smoke and to keep all open or exposed flames away from manholes. They should report to their superior officers unusual evidences of gas and should not enter a manhole opening if the slightest danger is evident. The use of a plumber's torch should be avoided as far as possible.

Fifth: Numerous accidents have occurred to linemen when working on new extensions to distribution feeders, due to the fact that the extension has been connected or tapped on to the energized circuit before the new work was completed. New work should be finished and all of the crew engaged on the work notified before the "hot tap" is made.

What has been said in the foregoing applies more particularly to distribution circuits. The following will apply to transmission lines.

TRANSMISSION LINES NOW HANDLED ALIVE

A few years ago working on live, high tension transmission lines was considered foolhardy and out of the question except in rare cases and under extremely dry climatic conditions. Today, insulating rods, tongs and similar appliances have been so developed that 140,000 volt transmission lines can be handled alive with no greater hazard than accompanies the handling of 2300-volt distribution circuits with the protection afforded by rubber gloves.

By means of the improved appliances, the insulators on live, high tension lines can be tested while in position and the defective insulators weeded out and replaced with good ones.

LONG INSULATING RODS USED

Several different methods are used to test and change the insulators, the fundamental principle of them being that there is always a long

insulating rod or other appliance between the man and the live part that is to be worked upon. Various patented devices in the shape of tools are used on the ends of insulating rods for removing and replacing tie wires on pin type insulators and for removing and replacing cotter pins on suspension type insulators. Special long handled testing poles for picking out defective insulators are also on the market. In testing insulators on live lines advantage is taken of the fact that a difference of potential exists between the cap and pin of a disc insulator. A wire fork on the end of an insulating pole is used in some cases for making the test, placing the wire across the insulator between the cap and pin. If the insulator is good a static spark is obtained and the absence of spark or a weak spark shows that the insulator is defective.

The following is a brief description of one of the methods used to change defective insulators on high tension lines. The insulators are first tested and the defective ones noted, a record being kept of the pole, or tower and the position of the insulators. A crew generally consisting of six men and the foreman do the work of changing the insulators. First, long insulating rods are attached to the wire and the line secured in position and held so that it cannot swing into the poles or towers. By means of rope blocks the rods are made to force the wire upward and away from its regular position. The insulator is then disconnected from the wire after which the insulator can be removed and replaced or any necessary changes made. With proper tools it is not necessary for any of the workers to approach or place their hands or any part of their body within dangerous proximity of any live conductor. Methods of working on transmission lines with lines alive were described in the June 10 and May 10, 1916, numbers of the "Electrical World."

SPECIAL PRECAUTIONS TO BE OBSERVED IN CASE OF LINE TROUBLE

Noise and static on telephone lines, discharging lightning arresters or an unusual amount of static on or around lines and insulators indicates trouble and it may be due to defective insulators or to an "arcing" ground, on the high tension lines. Foremen should instruct their men to work with extreme caution at such times. It is generally advisable to stop the regular work of changing insulators until the cause of the trouble has been located. This precaution should always be heeded on systems with a grounded neutral.

Before any work on high tension transmission lines is undertaken, for the first time, a careful analysis should be made of the job. Each operation should be considered and men should be selected and trained for the different operations they have to perform.

It is interesting to note that linemen who have tried both methods of changing insulators would rather work on live lines with insulating rods between them and the line, than on "dead" lines without this protection. The dangers incident to the accidental energizing of lines that are supposed to be "dead" are eliminated. Emergency or rush work which always adds to the hazard is to an extent avoided and the work can generally be done in the daytime when the light is good.

Telephone, telegraph, signal, and other lines that parallel high tension

lines are always liable to be more or less energized and dangerous to handle. This fact should not be overlooked in instruction given to linemen.

TO SUM UP

The prime requisites for safe working on high tension lines are: Safe construction, a good foreman, competent workmen equipped with proper tools and insulating appliances.

VICE-CHAIRMAN MACLACHLAN: Mr. Burton, would you come up and take the Chair?

DISCUSSION

MR. MACLACHLAN: We have just heard, and I am sure you will all agree with me, a very admirable paper by a man who is thoroughly competent to give some of the best advice that could be given by anybody in the Utilities gang in the United States.

In connection with the question of educating the public to the danger of fallen wires on the street, one plan that we have carried out is to prepare a letter to school children pointing out the danger of fallen wires on the street. This is a mimeographed letter and is sent to the Superintendent of the Board of Education and distributed through their regular channels to the various school boards and teachers.

We only tried to touch the one point: The danger of fallen wires on the street. Later on possibly we will touch other points. Another way that we are drawing the attention of the public to the danger on the street is by using the standard danger emblem that was prepared some few years ago by the National Safety Council on our poles and substations. We have also prepared a slide that is to be sent to various moving-picture houses which points out that wherever you see this emblem it means danger.

NECESSITY FOR INSTRUCTION OF LINEMEN

All through Mr. Burton's paper there was one thought brought out and that was the absolute necessity of education or instruction for the linemen as to the dangers of working on live lines. That is absolutely essential and I do not think that enough attention has been paid to it in the past. We have been too prone to hire a Bill Smith because he is a lineman and then put him on high tension work and let him go. I think instruction to linemen is absolutely essential and it also applies to the work of our sub-station men.

Another danger that we are up against in working on live high-tension lines or on primary lines is the danger of the ground wire on the pole. Our men, in general, are depending upon the pole for a certain amount of insulation and they forget at times about the ground wire being there. One or two fatalities that we have looked into have been partially due to the presence of the ground wire on the pole.

I will not go into the details of the testing of rubber gloves, the testing of linemen's shields, blankets, and standardizing the belt question, because I think most of you have seen the work that has been done by

the N. E. L. A. Accident Prevention Committee in this line. They have out at the present time standard specifications for rubber gloves for work on lines of not more than 3,000 volts. They are working at the present time on the standardized belt for linemen. The preliminary standard has been in operation with linemen now for two or three months and is working out very satisfactorily.

WORKING ON LIVE TRANSMISSION LINES

The point that I wanted to touch upon more particularly was this new phase that we are getting into—the working on live transmission lines. Very few companies have had experience in this and without a word of warning I think that we will have fatalities, due to the carrying out of the work originated by the Georgia Company, as I understand.

It is quite practical and perfectly safe for the skilled, trained surgeon to carry on an operation in a perfectly equipped operating room. It is perfectly safe for a skilled, trained lineman with the use of these tools to change insulators, but it must be remembered that this does not apply to all linemen, all types of tools and all types of construction. Where you have to change an insulator above a live line, I think you are simply juggling with your life.

I think the companies should instruct their men as to the best ways of grounding the line and short circuiting, because I think we have all come to the point where we have very little confidence in the ground chain and very little confidence in our present method of grounding because a number of us have had fatalities, or near-fatalities on lines supposed to be grounded.

I think these two will have to go hand in hand for a few years:—the old method of short-circuiting the line, grounding it, tagging it at your substations at both ends, and carrying on work on a dead line, and that of changing insulators by trained crews with special appliances, and I would like to reiterate that statement on certain types of construction.

After the meeting is over, if you wish to see it, I have a report on the changing of insulators on 44,000 volt pole construction by this method with about forty photographs showing the different details. We tried it as an experiment. We do not believe it is generally applicable to our lines and we intend to carry on our present methods as the standard routine for special work.

I would like to have a general discussion on this subject because it is one of the most important that we have before us.

GENERAL DISCUSSION

MR. HERMANN SPOEHRER (Union Electric Light & Power Co., St. Louis, Mo.): Mr. Burton's paper was most complete and interesting. There are one or two questions I would like to submit.

To begin with, I notice the National Line and Safety Bureau has been getting out circulars from time to time and I took occasion to write to Chairman Paige on the subject because I noticed they showed the linemen not wearing gloves, and in another instance where he was wearing

buckskin gloves without any rubber gloves, and whether it was intended or not, it would tend, I am afraid, to encourage unsafe practices among the linemen.

We have the county division and the city division in our company. The county division made it a practice to put their gloves on after they reached the top of the pole for fear they would snag them in climbing the poles. In the city they made it a practice to put the gloves on before climbing the poles. If you climb the pole without gloves and pass the safety strap around the cross arm of the pole after you get up there, it is rather hazardous to do that without the use of gloves, for, of course, you have to have a safety belt in order to put the gloves on. I would like to know the general custom in that respect.

Mr. Burton also referred in his paper to the matter of educating the public. Notwithstanding the precaution you take and the efforts to reach the public, we still have repeated accidents. It is practical to use motion pictures in pointing out to the public the danger of handling dangling wires, and probably a newspaper advertisement should be resorted to. I would like to know what experiences other companies have to offer in that respect.

MR. F. B. VAN DOREN (Utilities Mutual Insurance Company, New York): I would like to know if Mr. MacLachlan had reference to the distribution system or high tension.

MR. MACLACHLAN: Distribution.

MR. VAN DOREN: I have come across, in my experience, another bad hazard: that is fire-alarm contact. In this instance, companies covering the fire alarm had taken the apex of the pole and run the wires down about a foot or a foot and a half from the top of the iron conduit, from the iron conduit to the fire-alarm box and from the fire-alarm box to the ground. Several men working on the distribution system have come in contact with this wire and have been seriously injured.

Another thing, Mr. Burton spoke about linemen's belts. I think every company should make an exact inspection of these belts. It has been brought to my notice lately, in three different instances, where the linemen's belts apparently were in good condition but where the snap seemed to be working very easily and I took the belts and by giving them a slight twist they would come unhooked every time. That is something that should be watched very closely.

CHILDREN AND FALLEN WIRES

MR. H. A. JOHNSON (Omaha Gas Company): I don't happen to be connected with the electric industry but this hazard of the children coming in touch with fallen wires has come to my attention several times during the past summer. In driving through our city, especially after a storm, I have seen children gathering around electric wires that have fallen and it seems to be a common thing for them to do. I have never seen a motion-picture reel on this subject. It seems to me there is a chance for some of the electric companies to get up such a reel which could be

shown, especially to the school children, and also in the motion-picture houses.

I also think that during the school season if there happens to be any severe electric storm where this hazard is to be found, that the school teachers would be glad to cooperate with the electric companies if they get in touch with them over the telephone and have them make some announcement just to call the attention of the children to this hazard.

Mr. SCOTT: The thing that is on my mind in connection with Mr. Burton's paper is this changing of insulators on transmission lines and the danger connected with it. The tendency seems to be now on the part of the operators to work on live transmission lines wherever they have an execution for continuity of service and this is going to be very popular in that connection. They don't want to kill the lines. They don't want to shut off the current so they rely upon this new method. Recently this matter was put up to our safety organization for approval or disapproval.

I must confess that I am afraid of the thing, afraid something is going to happen and yet after going over it with those who are in charge of the work and being assured that the instructions are carried out, I feel that it is probably safe. I am afraid, although this has been confined to a trained crew, that there will be a tendency to ignore that in a little while; they will say, "Well, Frank is sick; we will take John today." I want to know how many trained crews Mr. Burton has on his properties for this special purpose and if there has been a tendency towards breaking the rules and regulations that were especially provided for that work.

Mr. BURTON: We have two crews.

Mr. W. H. MULLIGAN (Hydro-Electric Power Commission of Ontario, Toronto, Canada): There is one point that I would like to bring out and that is the education of the man.

A few years ago in our Company, on a duplicate circuit, 110,000 volt lines, we undertook to change insulators with one side dead. We had trained crews and trained men, yet, in that summer, within two weeks, we had two men killed; they climbed the poles and thoughtlessly walked into the live side. We can't impress that point too much on the men.

One thing Mr. Burton said was that gloves must not be worn when climbing. Gloves must be worn when climbing. We do not allow any man to wear rubber gloves without leather covers.

Another point mentioned was the inspection of belts and spurs. In our Company we have monthly inspections of these things.

Mr. BURTON also said that gloves must not be relied on as complete protection. I would like to ask Mr. Burton why. All of our gloves are tested. They receive monthly tests. The men have to use gloves very often when standing on the ground when the poles are wet and in stormy weather. If they cannot rely on the gloves as ample protection, what else have they?

Another question is, how does he recommend keeping open flames out of manholes especially when it is necessary to tap joints?

The matter of educating the public cannot be put too strongly. Just recently at one of our safety meetings a man said a line was down the other day and Mr. So and So came up to him and said, "I noticed this wire. I knew it was a live wire and I just took my umbrella and shoved it to one side." It was an iron umbrella.

CHAIRMAN MACLACHLAN:—Is there any further discussion on this point? Mr. Niesz, have you anything to say on this?

MR. H. E. NIESZ (Commonwealth Edison Company, Chicago): I haven't any discussion to contribute, but since I have been called upon, I would like to express, on the occasion of my first convention of the National Safety Council, three things that impressed me the most: One is the large number of people in attendance; another is the caliber of the men here, who are mostly either practical or technically-trained men, and third, the wonderful enthusiasm that each and every man has for his work, and if that enthusiasm, that ability is carried along the lines of the safety organization down to the ultimate worker, we can't help but do the things that we are to do to make work safe for the men and to conserve human life.

CHAIRMAN MACLACHLAN:—I will ask Mr. Burton now to wind up the discussion on his paper.

MR. BURTON: I agree with Mr. MacLachlan regarding the working on high tension lines. It can only be done where the construction is right. Some types of construction, that is high tension lines, cannot be worked upon alive. There are also some types of construction that cannot be grounded safely and worked upon. For instance, if it is in close proximity to other circuits, it isn't safe to ground the circuit you are working upon. You are liable, if you are close enough, to get against the other line and the hazard is greater with the grounded line than with the line not grounded. It is safer in that case, if it is at all possible, to work the line alive and handle it from the end of long poles or sticks, or other insulating appliances. Sometimes it is safer to ground the wire and sometimes it is safer to work it alive. It is a question of the construction.

DEPENDENCE ON RUBBER GLOVES

Regarding putting on rubber gloves, after climbing the pole: The rubber gloves are lessened in their insulating value if they should get the slightest abrasion and if you use them for climbing you are liable to do that and such gloves are not worth much after you get up to the top of the pole. I think the circuit should be killed until the man gets to the top of the pole and then he could put on his protectors and other paraphernalia and go to work.

Regarding not placing complete dependence on rubber gloves: Rubber gloves are tested, it is true, for 10,000 volts or 20,000 volts or whatever it may be, but it isn't necessary to place complete dependence on them. For instance, if a man has a wire that is of 2,300 or 5,000 volts and he is standing on the wet ground, he should put a board on the ground. Rubber gloves may be used safely there but he should not

base complete dependence upon them. He has just one factor of safety if he puts complete dependence on the rubber gloves. He should put the board on the ground, keep away from the ground wires, use a pole wherever possible, keep away from all other conductors, then use his rubber gloves.

A man had tested rubber gloves and said, "They are good for 10,000 volts." He asked a man to stand on the ground and ground the circuit on one side and let the other side take on the voltage and then test the gloves by putting his hands on there. You know what it would do. I wouldn't do it. They may be safe while they are on the testing machine but not immediately afterward.

Regarding the education of the public. You may be interested in knowing that we had a 5,000 volt circuit on the top of a pole—about a fifty foot pole—perfectly straight, with no steps on it and we thought no one could climb up it except the lineman. An eight-year-old boy climbed to the top of this pole, thinking there was a bird's nest up there, and was killed. It seemed impossible that an eight-year-old boy could climb up there but if you had seen the boy you wouldn't wonder at it. I went to see him at the hospital; he was burned so badly that he soon died.

CREWS FOR WORKING ON HIGH-TENSION TRANSMISSION LINES

Regarding the crews for working on the high-tension transmission lines: The company I represent has two crews at the present time. We only do work under favorable conditions. We don't use substitutes when we don't have a complete crew. The beauty of this work is that it doesn't have to be done on short notice. It is not emergency work. We do not wait until the work gets that bad before we do it. As soon as we know it is in any way defective, we go ahead and change insulators.

Some time ago we were testing out a line and when we got close to the cross station we found some insulators in a very bad condition. I think nine out of ten poles were defective and the tenth was holding up the line. Now the operator had occasion to operate around this line. Due to "hot line" testing we found that place and remedied it before an accident occurred. That is one of the things to say in favor of working on "hot" lines, you can find the trouble and remedy it. The work does not have to be done, therefore, you can wait for the men on the crew. I wouldn't attempt to change an insulator on a high tension line until all my main men were there.

Regarding open flames in manholes: Open flames in manholes should not be used where there might be explosive gas. It is hard to tell sometimes whether there is gas; it is more or less of a guess method. There are some devices on the market, I believe, for testing for gas in manholes. I don't know how logical they are.

CHAIRMAN MACLACHLAN: I am sure we are very grateful to Mr. Burton for his paper. It has opened up a point that is being discussed in a

great many companies at the present time and needs to be carefully gone into.

We will now hear from Mr. Walter Wagner on the question of "Practices of Operators and Tagging of Switches, Markings, and Barriers."

TAGGING, BARRIERS, MARKINGS, AND PRACTICES OF OPERATORS

WALTER C. WAGNER,

PHILADELPHIA ELECTRIC COMPANY, PHILADELPHIA, PA.

Safety is a cogent word these days, and there is no activity in which its powerful appeal to determine the course of action is more strongly felt than in the Central Station industry.

Safety measures in stations serve not only the local station men, but this protection, with its corollary insurance of continuity of safe service, involves, directly or indirectly, the safety of the community dependent upon electricity for light, heat, and power. The use of equipment of greater capacities, the concentration of greater power demands in limited areas due to unprecedented growth of load, and increased voltages, have individually and collectively tended toward greater hazards; but, due to the introduction of safety measures, an equal or greater degree of safety has, in general, paralleled these changes.

Under the stress of the war's demands for the maximum and continuous production of electric power, safety measures were given all possible consideration, but the application and further development of proper methods and devices were necessarily somewhat restricted.

Now, confronted in this new era of peace by increasing demands for power from industrial activities, by the assimilation of untrained men in the industry, and with the difficulties of the general labor situation with its attendant great increase in turnover of employees, those who are responsible for Central Station safety today require the guidance from an active and extended discussion of the subjects of this paper. With such guidance, they will be assured of tried practices, which will make for the greatest practicable degree of safety and efficiency.

Another potent factor requiring an adequate development of these subjects at this time, is the fact that the revision of the 1916 edition of the National Electrical Safety Code is now in progress. The United States Bureau of Standards is concerned with the development of a code of minimum requirements, and while an effort should be made here, by papers and discussion, to present the very best practice and design for electrical safeguards found in the industry today, many of these elements of general progress will serve, through their incorporation in the safety code and by its distribution, better to guide those concerned with safety in central stations throughout the entire country.

An adequate presentation of all the important features is obviously not possible here, and it will, therefore, be assumed that descriptions of the more common safe practices in general use throughout central

stations need not be included. This will permit the presentation of some of the more recent safe practices in large electrical systems using high voltages of distribution. In many instances, the methods used by The Philadelphia Electric Company will be submitted as being productive of good results.

TAGGING AND OTHER BLOCKING OPERATIONS

In the natural growth and development of electric power systems from

PL. 1. STATION PANELS-LOAD DISPATCHER'S BOARD

one to many stations, and with the increasing extent of conductor networks, the control by the station operator has given way to the direction of system activities by a load dispatcher. He, as the central authority responsible for the successful control of the entire system, directs the general machine and switching procedure at all stations. The extent of detail with which the load dispatcher is concerned, as compared with details delegated to the station operator, can best be shown by a comparison of their respective dispatch panels. See Plates Nos. 1 and 2. It is evident that the load dispatcher's field is limited to the major elements of control, leaving the station operator responsible for those details of switching and miscellaneous control which come within the jurisdiction of the individual stations.

On Plate No. 2 is shown a system of marking switching locations by means of colored enameled tags hung on small hooks. In stations, this is the method used to reinforce the operator's memory. The same principle is carried out on the station panels of the load dispatcher's board,

PL. 2. GENERATING STATION DISPATCH BOARD

but substituted for the enameled tags are miniature electric lamps, capped with glass bull's-eyes and controlled by jacks located on the dispatcher's desk. No illumination indicates that the switch is open: when illuminated, a green cap placed over the lamp denotes the switch is closed, and a red cap that the switch is blocked. Manually-operated metal plugs

PL. 2. LOAD DISPATCHER'S OFFICE

fitting into recesses are used for switching at the less important points.

A reproduction of the entire system, with stations and feeders in relative position, is shown in Plate No. 3. The panel lights and emergency room illumination can be supplied from a battery at the rear of the dispatch board.

Cycle of Tagging (Blocking) Operations. The circuit or apparatus upon which work must be done is examined by an authorized representative of the department which is to do this work. He reports to the load dispatcher the amount of equipment involved, the nature of the

Immediately upon completion of the work notify Operator in Charge by returning Permit, properly signed. Operator will then notify Load Dispatcher, repeating carefully Permit Number and nature of work for absolute identification.

PL. 4. REVERSE SIDE OF CARD
BLOCKING PERMIT CARD

FIG. 5. MECHANICAL BLOCKS FOR BLOCKING TYPES OF HAND-OPERATED AND REMOTE CONTROL OIL SWITCHES

work, and its probable duration. With the reproduction of the system before him, the load dispatcher determines the necessary blocking procedure on the equipment to be worked upon, and enters this information on a permit card bearing a printed serial number. This card is shown on Plate No. 4. When it is time to start the work, the load dispatcher directs the operators at all stations involved to do the necessary blocking. The operator at the station where the work is to be done makes a copy in duplicate of the load dispatcher's permit, using the same serial number. This operator gives the original of the duplicate permit to his assistant. This assistant, accompanied by the man in charge of the work, blocks the necessary equipment and the permit is handed to the workman. The operator makes the corresponding changes on his circuit dispatch panel. Then, assured that all stations have properly blocked the circuit involved, and making the corresponding changes on his dispatch board, the load dispatcher directs the operator at the station

where the work is to be done to proceed with the work authorized by the permit.

Where oil switches are involved, these would be opened by the usual remote-control mechanism, having the usual pilot lamps to indicate the operation, and the control and power circuits and equipment blocked mechanically and electrically, as follows: A conspicuous and substantial mechanical block—of which No. 20 block on Plate No. 5 is an example—is placed as a guard over the control switch to prevent accidental closing. The positive and negative knife switches supplying the control circuit

DANGER

PL. 6. REVERSE SIDE OF TAG

are opened and tagged with a red blocking tag by the operator's assistant. Potential transformer fuses on the voltmeter and synchronizing circuits of the apparatus are opened and tagged to prevent the energizing of the apparatus through the insertion of a plug in a voltmeter or synchronizing receptacle.

In one present station design, all station compartments are locked, and but one key will open the compartments of any circuit. The operator then supplies this key to his assistant for access to the proper switches. His assistant and the man in charge of the work then go to the necessary disconnecting switch compartments, which are plainly marked with the equipment designation and its phases, and looking through the clear wire glass panels of the compartment door, observe if the green indicating lamp is burning. This is an incandescent lamp

PL. 7. TRIPLE POLE REMOTE-CONTROL DISCONNECTING SWITCH
OPERATING MECHANISM

placed at all disconnecting switch points in a low voltage circuit positively controlled by the oil switch mechanism, and it burns only when the oil switch is in open position. It is placed at all disconnecting switch compartments where switches may control conductors connected to the oil switch. As the lamp must be burning to indicate when the discon-

PL. 8. MECHANICAL BLOCKS FOR BLOCKING VARIOUS AND REMOTE-CONTROL TYPES OF HAND-OPERATED OIL SWITCHES

necting switch may be safely pulled by a hook with an insulated handle, it is an additional precautionary measure to prevent a mistake in the operation of a disconnecting switch. With this green lamp burning, the compartments are opened, the disconnecting switches pulled, and red blocking tags (see Plate No. 6) are attached at all points where the equipment to be worked on can be made alive. Where necessary, the further precautions of grounding or short-circuiting are used, and these would also be noted on the permit. Types of remote-control mechanism that have been recently developed, open and close the disconnecting switches on all the phases of a circuit simultaneously; this absolutely prevents the accidental opening of a phase of an adjoining circuit. One of the means is shown on Plate No. 7. In the closed position, the link-

ages are on dead center, holding the blades in position, and the operating lever can be locked with the switches either open or closed.

Where work is being done on remote electrical control oil switches, the workmen are further safeguarded from accidental tripping of the mechanism by opening a small knife switch in the control circuit at the oil switch, and by the use of special mechanical blocks, such as is indicated by No. 10 Block on Plate No. 8, to prevent movement of the switch parts.

In case more than one department or outside firm is working on the apparatus, or is exposed to hazard by the possible re-energizing of this blocked apparatus, separate permits must be issued, and as many red blocking tags as there are permits issued must be placed wherever the equipment may be made alive. No tag is to be removed until all departments have signed their permits and have reported "clear," and the work and equipment are checked by the operator's assistant to make certain that everything is clear for service. The operator, upon receipt of this advice, signs the permit, then informs the load dispatcher, and restores the switch indications on his dispatch panel. Whenever he considers it necessary, the load dispatcher may require the additional approval of the district supervisor. When all departments have reported "clear," the load dispatcher orders the removal of all blocks, and after having directed the making of the necessary tests and restored the equipment to service, he then corrects the switching indications of his dispatch panels. The equipment with tags removed is then ready for service.

Special tagging of circuits and apparatus for the purpose of identification and tabulation of apparatus and cable condition data is in common use. In some instances, these are for permanent service, an example being the use of a stamped non-corrodible metal tag wired to the lead cable sheaths. Others are designed for temporary use, as, for example, the attachment of an oil tag to apparatus until its case is properly filled with oil. —

BARRIERS (INCLUDING COMPARTMENTS)

Barrier walls are designed to give separation for conducting parts at different potentials and, when provided with covering doors, form complete isolating compartments, which give protection to those in the vicinity from all arcing, shock, and mechanical hazards. Unlike warning signs, they form a physical protection against thoughtless or accidental movements. This construction is superior to insulation in that equipment so enclosed is generally supported on separate insulators or connected to a permanent ground, is easily inspected and accessible for repairs and changes, and incurs no possible shock hazard from deteriorated materials. Simplicity of arrangement of conductors and apparatus, and the less room space required, also serve to render conditions safer for station men. —

Confining this discussion to concrete construction, the following characteristics of this material may be noted. It cannot be considered in any

sense an insulator, nor is it a good conducting medium. It serves to isolate live parts, which are otherwise insulated, and to support casings and frames, which must be grounded by other means, even should the concrete be reinforced with steel.

As a rule, barriers should not support live busses or apparatus subject to stress due to electrical disturbance, and, where isolating live parts, should have a minimum of reinforcement consistent with mechanically safe construction. Doors cover the openings between the barriers, and are designed to be readily removed for access to the compartments covered. Such doors may be painted white pine frames, paneled with impregnated asbestos where they enclose conductor runs and instrument transformers; paneled with clear wire glass in front of disconnecting switches; and built of heavy wire screening where heat radiation necessitates this construction, as in front of reactance coils. Such doors

PL. 9. FEEDER AND LIGHTING. ARRESTER COMPARTMENTS

must be of small size, light weight, not easily damaged in handling, and rugged in construction. A pair of handles for detachable wall doors, and detachable hinge supports, allow ready removal. Where covering ceiling runs, the doors are permanently hinged, with latches to fasten them in place. A door having a special panel in which a spring-hinged panel is inserted is placed in front of locked current transformer and oil switch compartments, where an electrical breakdown might cause a sudden formation of gases.

The standard practice is not only to isolate circuits of different classes—such as power feeders and station-use conductors—but also to separate the individual phases, as shown in Plate No. 9. In this illustration are also shown the special barriers isolating the lighting arrester, through which cords pass which operate the charging mechanism.

MARKINGS (IDENTIFICATION)

The general identification of the character of equipment by those concerned in the maintenance and operation of electrical stations, is based on a knowledge of the nature of the construction—namely, the method of isolation, type of barrier, support, and insulation—and of the general characteristics of the apparatus connected thereto. In a system where unvarying practice in arrangement of equipment exists, as a fixed order of phases and number of compartments and apparatus, the relative positions are a further means of identification, especially when clear and adequate, yet simple, wiring diagrams showing physical arrangements of units, apparatus, and circuits are at hand, and where the more hazardous situations are, in general, made inaccessible by elevation or enclosures.

For example: The Philadelphia Electric Company establishes the same definite reference point at all stations, and all groupings of units, apparatus, circuits, and conductors have their sequence of numbering or lettering determined by this point. Special exceptions are definitely indicated.

Experience has shown that further insurance of safety is absolutely necessary, especially in large stations. To make a complete identification a certainty, markings in the forms of well-illuminated color arrangements, signs, tags, and markings of a permanent nature on surfaces of walls or equipment must be used.

The danger of placing too few or too many signs is obvious; insufficient guidance makes men uncertain, and too numerous signs tend toward possible confusion. In the latter case, for example, if signs were placed at every possible hazardous spot and its absence led a workman to conclude that the location was safe because not marked alive, the accidental removal of a sign might be a serious matter. *It is now the general practice for authorized persons having access to hazardous locations to assume that everything is alive unless marked otherwise.* Such rule, together with wisdom in distribution and in placing warning and identifying markings, makes for the greatest practicable degree of safety. The markings or symbols must be permanent, easily distinguished, legible, concise, simple, and absolutely accurate in legend; and the marking system must supply a distinguishing number or symbol for every part of the circuits and apparatus.

The key to the markings of electrical equipment in a station is given on the station dispatch board, mounted, with a single-line wiring diagram with symbols indicating the nature and designation of the lines and apparatus, and with the provisions for manipulating switch indicators. See Plate No. 2. Such indicators are changed simultaneously with operation affecting the indications.

The standardization of switchboard panels, with their markings showing control characteristics and indicating operating conditions, and also the use of mimic wiring to indicate the relative positions of circuits and apparatus, are too well known and extensively used to be described

PL. 10. BUS SWITCH COMPARTMENTS

in this paper. Special attention should, however, be directed to the requirements of simplicity in designation and maintained legibility of symbols and legends, and their good illumination with the absence of glare.

Markings, either portable or painted upon permanent surfaces of contrasting color, may be used for general identification throughout the hazardous parts of electrical stations. Entrances should have warnings—in several languages where necessary—to unauthorized persons, which

will also serve as a general guide to workmen. For those who must move about in these rooms or enclosures, markings and signs are placed to indicate the hazards which should designate the highest voltage concerned, and the electrical apparatus and circuits and phases of circuits must have their character clearly identified.

Portable signs serve well in some instances, especially where special or temporary conditions exist. For permanent construction lettering and symbols are painted, stenciled, or stamped on every accessible side of enclosures and equipment. Care should be taken to see that these markings are so placed that the removal of a part, such as a compartment door, does not result in the entire loss of identification of the equipment concerned. Plates Nos. 9 and 10 show some of these markings used in a high-tension switch-room. The broad, dark band covering the edges of wall and ceiling barriers is bright red in color on a light surface, and furnishes a division marking between the sets of three single-phase compartments of three-phase circuits. In addition to this identification of circuit divisions, special metal red tags with white letterings project from the barrier walls, which are more plainly shown in Plate No. 10. A workman standing before any set of compartments containing the three conductors of a circuit has this tag facing him on either side, with the circuit designation clearly marked thereon in contrasting colors. This permanent tag has been recommended for use by the sub-committee on accident prevention of the National Electric Light Association.

Where wire glass or wire screen doors are placed over apparatus, they serve to facilitate inspection as to condition, but their use is no excuse for laxity in maintaining the necessary identifying markings.

PRACTICES OF OPERATORS

It is not without pride that we can say that no other activity has given the matter of safe practices more study and intelligent application; and today many instances can be pointed out which make work in an electrical station, even with its more complex and higher voltage conditions, far safer than in the earlier stages of development.

This has, in a large measure, been due to increasing vigilance in the early detection of hazards arising from the use of new operating methods and equipment. Guided by the experience of the departments and the work of the laboratories, the safety engineers have produced safeguards and inaugurated methods of practice and courses of education, which have proven fully adequate to meet these new situations. So interfused is this factor of personal safety with other elements of company organization that the measure of success in the proper application of its principles is, to a large degree, determined by the success of the company's management in general. In turn, every successful effort to make safety more certain is reflected in raising the whole tone of the organization.

"Standardization" and "coöperation" are the key-words in the application of general station safety organization methods. There must be, of

course, a clear understanding of the principles involved; a familiarity with practices for efficient action, especially in times of emergency; and a realization and assimilation of the spirit of loyal coöperation with others. All this must be furthered through frequent get-together meetings for conference, study, and general social activities.

Special reference should be made at this time to the importance of Safety First courses at the stations, to secure the presence of all the station men, and teach prevention and first aid in familiar surroundings.

A fixed order of routine according to approved methods—in general, in the form of published operating rules—is essential to maintain this standardization and coöperation.

In addition to the protective practices, which have heretofore been described in this paper, the following are worthy of comment at this time:

Rubber Gloves: A study of the specifications of manufacturers and practices of operating companies, and an extensive series of tests on the various makes of rubber gloves, have enabled the accident prevention committee of the National Electric Light Association to prepare and recommend specifications for the purchase, testing, and care of rubber gloves for service on high-tension apparatus not to exceed 3,000 volts to ground.

Insulating Stools: An insulated wooden stool having extended corners to prevent stool from tilting.

Fuse Puller: A fuse puller with wooden handles, for use around high-tension apparatus, requiring the use of both hands (protected by rubber gloves) on the fibre insulators of the two handles.

Lamp Guard: A lamp guard with a wooden handle and fibre guard for the globe.

Pliers with Insulated Wood Handles: Ordinary pliers with straight oak wood handles about eight inches long, which can be placed on gas or wire-cutting pliers.

Wooden Nozzle: A wooden nozzle, made of oak, with a guard, for use in cleaning around electrical apparatus.

Safety Rod: A wooden rod with an attachment at one end to engage the handle of a D. C. railway feeder switch, keeping the operator at a distance, and preventing hazard from poor operation of the feeder circuit breaker.

Permanent Ground for Station Bus: This feature of station bus design dispenses with the unsafe practice of trailing grounding cables throughout rooms, and eliminates the use of all temporary ground connections. Permanently-mounted disconnecting switches in compartments, with grounded blades, are arranged to ground positively any station bus. A test for possible potential on a bus supposed to be disconnected from sources of energy is provided as follows: A double-throw knife switch, carrying a small-capacity expulsion fuse in the grounded blade, is thrown down to a clip which places it in series with a test lamp in a lighting circuit. The burning of the lamp indicates fuse integrity. The blade is then swung up to the clip connected with the station bus, which

enforce the rule that was to be put into effect on that particular job, or did it in such an off-hand way that the fellow didn't know that it was an order but thought it was a suggestion.

I think if we get to work on these three things we can boost up the work we are trying to do. Those of you who followed this paper closely will agree with me that it was a presentation of a perfect system of guarding against those dangers which may be guarded by tagging and marking and practices in the ideal central station.

I can't conceive of saying anything that would add to the admirable arrangement presented here. It would be impossible for me to do so. I doubt if the highly-trained technical men could suggest anything to improve the points brought out but all the time I was thinking of this paper, following it, I was thinking of the large central station in the large city, then my mind would go to the little plant away down in the country that wouldn't know what this was if they read it, wouldn't know what a plant was like this if they would see it and I am thinking about their getting the thought that is expressed in this paper and applying it in these stations that are not able to put in this sort of construction and follow these ideas and when I get through that is one point I would like for Mr. Wagner to touch on and help me out on as to how the problem that is unsolved here may be answered for these small companies.

LOCKS EQUIPMENT AND HOLDS FOREMAN RESPONSIBLE FOR ENERGIZING THE CIRCUIT

Now you always think the company you are connected with has it on the other fellow just a little bit and I am thinking now of the Commonwealth Edison Company. Mr. Wagner's plans for killing the circuits would appear to be ideal, and could not be improved upon, but the Commonwealth Edison Company has gone just one step farther than the thoughts presented in this paper. In addition to all the things that have been pointed out here with reference to killing circuits, the Edison Company provides a padlock and locks the equipment. The key to this lock is carried by the foreman of the men who are doing the work, or who are at work on these lines, and the lead dispatcher who attends to energizing the lines here couldn't energize the lines until the foreman who has the key comes back and unlocks the block that controls the switch, so that the responsibility for energizing the circuit, instead of being left with the operator or the dispatcher, is placed upon the foreman, the man who is in charge of the men doing the work. In the case of more than one crew doing work, two locks are provided and two keys are provided for the separate foremen. I don't know whether that would be practical in all instances or not but it is one of the things that this Company has adopted.

The Edison Company also is trying out a leather coat for the operator to prevent injury from flashes. This coat is made without sleeves and has a hood that comes up over the head and the operator wears that coat to prevent being injured by flashes. Perhaps it wouldn't appeal to you

so much but it goes to show how far you can go in getting absolute protection, making assurance doubly assured. I think that spirit in an organization to do that sort of thing is a mighty good spirit to have, even though some of the things that are done seem to be going a little bit too far

CHAIRMAN MACLACHLAN: I would like to hear a full discussion on this paper. It is a paper that applies very closely home. Mr. Scott has pointed out the question of the smaller company; the application of these ideal conditions that are in the larger company to the smaller. Mr. Rinke, can you let us have any information on this?

GENERAL DISCUSSION

MR. G. R. RINKE (Utilities Mutual Insurance Co., New York): It is rather a difficult point to cover the smaller company as the smaller operators are very badly handicapped and they haven't had the opportunity to get in touch with the larger proposition.

So far as protecting the plant is concerned, there is an awful lot to be done. It is surprising to see how fully guarded they are when you get around to them. There are a few ways you can reach those people. Quite a few of them, it is true, read technical magazines of some sort, but they seem to lack the incentive to go ahead and do the things that they realize are well worth while doing.

MR. W. L. BRUCE (Westchester Lighting Company, Mt. Vernon, New York): I would like to hear whether or not some of the men here have had any accidents in connection with employees coming in contact with the metal guards. When I talk to my engineers about it they laugh at me. I am satisfied to be a clown if it stops any one from getting hurt. Why they make guards out of metal I don't know. Just as an illustration: When I went up to Sing-Sing Prison in our district about fifteen years ago there were guards in uniform with muskets and rifles and here about two years ago when I went up there I didn't see any guards. They kept those prisoners in check with a league called the Mutual Welfare League. You wouldn't think you were in a prison. Now I believe there ought to be some other method of guarding sub-station apparatus.

MR. MULLIGAN: I will state that in one company with which I am familiar they formerly had iron-clad doors in front of their buses. I am not aware whether or not they had an accident, but due to the possibilities of an accident these doors were replaced with asbestos board doors.

In one of our stations we have had a number of near-accidents to men who went to examine the oil rings in the barriers and at the same time a flash-over occurred. I have spoken to several men who have missed these flash-overs by a second. I am wondering what protection Mr. Wagner has in the examination of oil rings.

CHAIRMAN MACLACHLAN: I have asked Mr. Wagner to make a note of these points. Mr. Davis, have you something to add to this?

MR. DAVIS: At the sub-stations we lock the switches, as Mr. Scott stated, and the key is carried by the foreman in charge of the work. One other point was brought out in Mr. Wagner's paper with reference to the foreman turning the work off to the leading operator in the station, as I understood his paper. The foreman does not turn the work off to the operator but the operator, after he has reported that the work is completed, checks over the work that has been done to make sure that it is O. K., then the foreman goes to the booth and calls up the load dispatcher and turns the work over to him, seeing that everything he had to do is complete. Immediately after that the load dispatcher checks up with the operator to verify that the work has been completed and is O. K. and put in service. The same way when the foreman starts on the job, the permission is given him through the load dispatcher to start on the work after the dispatcher has checked with the operator in the station to make sure everything had been properly attended to. The foreman goes around and watches every movement that is made by the operator to make sure that everything is O. K. so that when he goes to the load dispatchers and gets the orders to proceed with the work he is absolutely sure that there is no chance of the line being made alive before he starts to do the work.

In grounding the more modern sub-stations after pulling the disconnect from the live side of the bus, we have it fixed so that we can insert that disconnect in the ground bus and then after that has been done we close the oil ring to the ground and the oil switch is closed and the foreman carries the key to that lock.

OIL RINGS

MR. SPOEHRER: I want to say a word in regard to oil rings. During March, of 1919, I had a letter from Mr. Paige and I sent him some photographs showing how it is practiced in St. Louis and those photographs were for bulletin purposes. The photograph to which I refer shows a small mirror at an angle of forty-five degrees over the opening which permits the man to see whether the oil ring is turned without the necessity of placing his head in a dangerous position over this opening or the machine in operation.

MR. F. N. LEONARD (Public Service Company of Northern Illinois): There isn't much that I can add to what has already been said except one point in connection with reaching the small properties. Now none of our small stations are isolated from our system of transmission lines but we have that class of men whom you call service man whose duties are to operate the sub-station, read the meter, control the high tension lines, and do all the general work in his small community. Our method of reaching him and giving him the information to carry on these various combinations is through our safety meetings. We do pay particular attention to that class of men. We give them all the detailed information we can by discussing the different phases of this work at our meetings.

MR. BURTON: Regarding the question of oil rings: The man knows when the cars are near the station and he can watch his opportunity to

look at the rings which would prevent his getting in such a position that he would be in line with the flashes.

Regarding metal guards: I happen to know to what guards the gentleman refers because I was present at the meeting the other day when he brought it up, and I would suggest that the ammeter be more carefully guarded; it should be grounded to make it safer. If the metal guard was so close that the man couldn't go in between, it ought to be placed farther away. The metal guards are better to use because wooden guards would add to fire risks and if it is asbestos it would have to be reinforced with something else. If it is anything else but metal it is liable to be injured and soaked with the rain.

Regarding the difference between the smaller stations and the larger ones. If the smaller station didn't have the apparatus they couldn't guard the same way as the larger stations. It seems to me it would be easier to guard the small station than the big one. The small stations are not guarded as well as the larger ones because they think the power is less. We are coming to a point where we have to take more pains in guarding them.

CHAIRMAN MACLACHLAN: I will ask Mr. Wagner to close the discussion and answer those points that have come up.

MR. WAGNER: I believe I am in the happy situation of having most of the questions answered.

Regarding the little fellow: I was a little fellow for about twelve years myself. I really think, if I were a little fellow today, I would guard the small station not directly connected with a larger station in any way. I would keep in touch with all the developments regardless of how ideal they may be so far as concerning their own equipment because the experiences that have been brought out in the National Safety Council meetings are nationalized in character; no item is over-estimated. I do not think that too much emphasis can be placed upon the fact that the little company should keep in touch with the larger things that are happening as indicated in this Council.

With respect to the Commonwealth Edison Company, I believe that particular improvement regarding locks is very good. One company goes up one way and another, another and possibly a complete investigation of the intricacies would show the same percentage of safety for both companies. I won't be satisfied until I know more about that particular locking plan.

With respect to oil ring examinations, that has been answered the way I would answer it.

With respect to substation guards: Where the screens were so close that umbrellas could be poked through we moved them back so this condition would not be so hazardous.

With respect to the plan of checking up the work: We place the direct responsibility upon the station operator, the foreman of the job being directly responsible for him in practically all instances.

CHAIRMAN MACLACHLAN: I am sure we are all glad that we had Mr.

Wagner here. We hope that in the future he will give us further papers and come and enter into the discussions.

The Nominating Committee dodged their full duty and I think they have taken some of the ideas out of the army and learned how to "pass the buck" along. I got the incoming Vice-Chairman and the incoming Secretary together and discussed with them the Chairman of the various committees that are to be appointed. I wish the appointment to come right from the Secretary. In suggesting to you these names, we have had in mind the fact that we have electricity, gas, and telephone, and also that the Chairmen of these committees should be appointed from various sections of the country.

With those remarks I suggest to you, for Chairman of the Membership Committee, Mr. H. E. Niesz, of the Commonwealth Edison Company; Chairman of the Program Committee, Mr. Hermann Spoehrer, of the Union Electric Light & Power Co., St. Louis; and for the Safe Practices Committee we suggest that we will communicate with the headquarters of the A. T. & T. Company and ask them to suggest a man from their engineering department to fill that position.

If this meets with your approval, I would like to hear a motion from the floor appointing these men to fill the office of Chairmen of the various Committees.

MR. C. HOWARD STEWART (Laclede Gas Light Co., St. Louis): I move you that the gentlemen mentioned be placed in nomination for the positions that you have mentioned.

(The motion was seconded and carried.)

CHAIRMAN MACLACHLAN: I declare these gentlemen elected as Chairmen of the various Committees and I would ask the gentlemen who are present to wait for a few minutes after this meeting so that we can hold a preliminary Committee meeting.

We are now going to have the pleasure of hearing from Mr. Webber, of Chicago, on that most important point, "Spasmodic Safety Efforts and the Harmful Results." We have all had them and I am sure Mr. Webber can give us a great deal of information.

SPASMODIC SAFETY EFFORTS AND THE HARMFUL RESULTS

H. M. WEBBER, SUPERINTENDENT, DEPARTMENT OF CLAIMS, CHICAGO
TELEPHONE COMPANY, CHICAGO

To the experienced safety man this subject is practically answered at the start. On the very face of it, the real, honest-to-goodness safety man knows that no possible good can come from occasional efforts to bring before the employees or the public the value of accident prevention.

Whether the safety work is of the public or industrial type, the need of forceful, intensive, persistent, and systematic efforts is necessary and should be of the "hammer and tongs" variety. No one can or ever will make a success of accident-prevention work who does not continually follow it up.

To my mind there is nothing more harmful to the general safety movement than spasmodic efforts, and this is one of the primary reasons why so many companies entering into the safety work make a failure of it.

To make a start today with a blare of trumpets and possibly continue for a few weeks or a month and then forget the work for the next six months, is a decided waste of effort and a source of danger to the great safety movement. In every line of endeavor the success of the movement is conditioned by the degrees of effort that are obtained. Thus it is that the unsatisfactory results or lack of results which follow spasmodic efforts may end in the dropping of the effort on the part of the employer and will have a tendency to discourage others who may be contemplating entering into this work. We all know that properly conducted safety work in a plant means the saving of both lives and limbs, and this is true not only in our industrial plants but in public safety work as well. It means the possible prevention of an accident or death, not only to strangers to us but possibly to the members of our families.

With so much at stake in the maiming of thousands of people each year, as well as numerous deaths caused through accidents, and with the knowledge we have, that by persistent efforts in properly presenting to the employees, their families, and the public the value of the safety movement, it can be plainly seen that it must be constructive, not destructive. Spasmodic safety efforts are destructive and will tear down all of the beautiful plans you may have prepared before the movement was started.

Does any one believe that the National Safety Council, with all of its wonderful and glorious success in the safety work, would have been any where near as effective today had the officers and management made only occasional efforts to interest the employers, employees, and the public in this work? "The proof of the pudding is in the eating" and the results attained by the National Safety Council have been secured only by hard and persistent efforts on the part of the entire and most efficient management. In other words, the National Safety Council did not go to sleep on the job. They knew that the subject was a live one and accordingly went out to make the best of it. It was their persistency and belief in the value of the work in hand that helped toward the final brilliant success which they are now receiving; and only by such efforts will the safety movement be a success.

SUCCESS MAY BE TURNED INTO FAILURE UNLESS PROPERLY FOLLOWED UP

Would the railroads and other public utility companies, the steel industries and our large manufacturing plants that have made such wonderful strides in accident-prevention work have been able to make such a showing in the reduction of the number of accidents in their industries if they had not kept the work alive by constantly keeping the movement before the employees in such a manner as to keep them interested? No one man can make a success of the safety or accident-prevention work without the cooperation of every man, woman and child in the industry in which he is engaged, and this must include the officials and the entire supervisory force. When he has secured this cooperation and all thoroughly believe that safety is a real live issue and that lives and limbs can be saved by

following out its dictates, and that the continued success of the movement depends upon each individual's efforts, then and then only will the safety work in any industry become a success; yet, this success may be turned into a failure very quickly if it is not properly followed up.

Consider for a moment what would have been the results if only occasional efforts had been made on the part of the Allies to stop the great German army in its progress during the period of the war. Does any one believe for an instant that the final success gained by the Allies could possibly have been gained in any other way than by dogged persistency and determined efforts to make their entire campaign a success?

If after a brilliant start we then rest on our oars, hoping what we have done will bring forth results, we might just as well have not started, and the harmful results of such spasmodic efforts will unquestionably be shown in the lack of interest which the employees take when we again try to put the matter before them. You can't just say to employees or the public that the safety movement is a good thing; that you thoroughly believe in it and you want them also to believe in it. You have got to show them that there is something behind the movement. You must let them know that you are not alone interested in it from the Company's standpoint, but that you know it is for their own individual good and for the good of their families.

One of the fundamental principles of the safety movement is education. It is much more simple to teach a child than an adult, for the child's mind is always in a receptive mood and is constantly seeking information. "Train up a child in the way he should go" is an old and true saying. And in teaching safety, we must train the men the way we want them to go. It is hard, however, to teach an old dog new tricks, and so it is with the presentation of safety work to the workmen. You must put it before them in such a manner as to impress them, not only with the seriousness of the subject but in such a way that they will realize that they will be the gainers by accepting it. Show them that it is not from the standpoint of saving money for the organization which you represent that you urge them to prevent accidents, but that it is for the general interest of the individual and his fellow employees. Teach each man to be a real safety man. Show him how he can assist himself and his fellow workmen by preventing accidents, and that your interest in the work is wholly in his behalf; but that in order to make a real success you must have his individual help. Every employee has a vital interest in his fellow employee whether he knows it or not, and it is only through education that he can be brought to see the real assistance that he personally can render in the prevention of accidents.

SPASMODIC SAFETY EFFORTS PREJUDICE EMPLOYEES

Spasmodic safety efforts will result in the lack of appreciation of the importance of safety ideals in the plant where such spasmodic efforts are made, and cause the employees to feel that this is only one of the numerous fly-by-night fads which are constantly cropping up from time to time, so that when the real safety campaign is finally put under way, the safety man will find that he is up against a much harder job than would have

been the case had the movement been started originally in the proper manner. It will be necessary for him to convince the men that the movement is one for their good, and he will be compelled to put forth greater efforts to put it across and overcome the serious prejudice which the men will have by that time taken to the entire question.

When once the employees have become prejudiced against a movement of this kind, it will be necessary for the safety man to use a much greater amount of tact and diplomacy. He will have to start a propaganda in the plant in favor of the idea before he will be able to secure their confidence.

I believe that where one company in a group has made only superficial efforts to interest employees in safety work, especially if that company has a large number of employees, the prejudice that will enter the minds of the employees of that plant will in time permeate the minds of employees of other plants in the immediate vicinity and cause great harm to the entire safety work in these plants. We all know that the greatest influence in making a shop or job safe is careful work, and hence it is that accident-prevention work is a constant battle against habits. All of us are constantly and persistently fighting bad habits that are easily formed and difficult to break. On the contrary, we are constantly trying to teach good habits that are hard to form and easy to break. However, the habit of being careful is not self-sustaining. When you start your automobile the engine roars and sputters, and every evidence of the vast amount of energy being expended is given, and yet, once the engine is started it gets under way and quiets down; but there must be a constant supply of power, and fuel, and a level head if the automobile is to be kept going. In conducting accident-prevention work a similar condition exists. In instilling habits of safety work there must be a constant supply of power and fuel in the form of inspiration, supervision, and direction. If the supply of fuel is interrupted, the accident-prevention work is bound to slow down, and may even stop, and much energy will be wasted in getting it started again.

SAFETY MOVEMENT ONE OF CONSTANT ADVERTISING

Success in safety work is comparable somewhat to the success which some of the large concerns of this country have made through the efforts in advertising, and the success in their line was not made by the placing of an ad today and again in six months, but by constant and persistent advertising. Think for a moment of the best-selling merchandise that you know of. Some of the following, no doubt, come to your mind: Heinze's 57 Varieties, Ivory Soap, Waterman's Fountain Pens, Wrigley's Gum, Cream of Wheat, etc. These names occur to you at once because of the steady and persistent manner in which the advertising was placed. You may also be able to recall articles that were extensively advertised for a short period, which are no longer on the market, and you probably can recall these names only with an effort. The purpose of advertising, then, from a sale standpoint, is to impress the name so firmly and so fixedly in the minds of the public that the name will become synonymous for that particular class of articles; so that when a purchase is contemplated the name will instantly leap in the mind of the prospective purchaser.

People readily forget, however, and if advertising is not kept up the advertiser soon loses the advantage gained, and we no longer think of this particular article but simply ask for those articles as a class. The safety movement is one of constant advertising; the more the better.

During the great world war strenuous efforts were made not only by the National Safety Council but by all of the various industries throughout the country and more especially in the shipyards and munition works, to impress upon the employees the necessity for safety in order to preserve the man power of the country and thus assist in preventing the slowing up of production.

Today, with our men returning to their various vocations after spending many months in preparation for and in actual warfare, we should not relax in any way in the education of the workmen along safety and accident prevention lines. On the contrary, we should use, if possible, greater efforts to prevent loss of life and limb, for production is needed now as much as during the war to help in the reduction of the high cost of living and thus assist in overcoming the general unrest among the working classes.

In starting the safety movement in the company I represent, we began in a small way and have kept it constantly before the minds of the employees. It was started some seven or eight years ago by first presenting the idea to our supervisory force at one of our Monday luncheons, having for the speaker a man who had been interested in the work for some time. From that time to the present we have never omitted a single day to do something to keep it alive and to keep the employees interested. Our company publishes each month a magazine devoted to the employees, which is mailed to their homes, and from the time we started the Safety Campaign there has not been a month that data of some kind pertaining to the safety work has not been published under the heading of "Safety and Accident Prevention." The articles are not limited to Accident Prevention, but also touch on subjects pertaining to the general health of the employees and their families. Our pay days are twice each month and the checks are mailed to the employees at their homes. On the first pay day a bulletin on Accident Prevention or Health accompanies the pay check, and on the last pay day the check is accompanied by a small calendar blotter on which appear short, snappy, up-to-date Accident-prevention or Health slogans. These calendars are never sent out in the same general form, but changed to attract attention, and we are advised that the employees and their families have come to watch for them so as to see what new thought or suggestion they contain. We have, of course, held the usual meetings on Accident Prevention, First Aid, Welfare, etc. These we call only occasionally, not frequently enough to tire the employees, but simply to keep up their interest.

Having had charge of the accident work for my company for the past twenty years, I have had occasion to study the question from all its angles and to appreciate most fully what the safety movement means and what it would have meant to the numerous employees and their families years ago, in the saving of life and limb, and how much needless suffering might

have been prevented had we then had the present-day efficiency in the safety work.

From the experience in my own field of endeavor, I know that the continuous, persistent efforts we have made to keep the employees interested and advised on questions of safety have paid, and paid big, and that the results accomplished could not have been secured had we made only half-hearted or spasmodic efforts.

CHAIRMAN MACLACHLAN: This is the type of paper that we all need at practically all times. I would like to hear what Mr. Lucas has to say in connection with the danger and bad features of spasmodic efforts.

- DISCUSSION

MR. LUCAS: If you slow down your campaigns you will find that your accidents will immediately start to crawl up. You have got to keep going all the time, month after month and year after year. I do feel, as I said yesterday, that we have had an awful lot of safety talks. I do not mean to let up on safety talks. I mean to continue the safety bulletin and the safety meetings of all kinds.

You can talk to some men until doomsday and it would produce no effect on them, but take it out of their pay and you will see them wake up immediately.

MR. V. R. HUGHES (Pacific Gas & Electric Co., San Francisco): I do not believe in antagonism and when you are fighting and lay him off you antagonize him. When I find a man a little lax on the movement I talk to him, and I have gotten a good deal of work out of such men, who were indifferent to start with. Some of our best men today are the ones who were indifferent on the start.

CHAIRMAN MACLACHLAN: Due to the fact that I had in my hand the second edition of the program instead of the final, I have inadvertently made an error and I will now call on Mr. Buchaca to carry on the discussion on this subject.

One thing, I would like to ask those who discuss in the future to stick to the subject under consideration and after we have taken that up we will revert to the subject that was under discussion yesterday, which is extremely important.

MR. E. J. BUCHACA (District Engineer, New York Telephone Company, Syracuse, New York): Leading the discussion I presume means starting the discussion, and perhaps the best way to start something is to disagree as much as possible with the other fellow, and also call attention to points upon which there may be difference of opinion.

Mr. Webber has cited a number of cases to show that best results come from hard and persistent efforts. He refers to the endeavors of the National Safety Council of public utility companies, the steel industry, manufacturing plants and to the doggedness of the Allies that won the war. Certainly we must agree with him in this.

He says that the unsatisfactory result, or lack of result, which follows spasmodic safety effort, may end in the dropping of the campaign on the part of the employer and the discouragement of those who have been

promoting the safety work. This is indeed true, for it seems to be human nature to start something new with enthusiasm, gradually lose interest, and finally drop the matter altogether, unless there is a will behind the movement to keep it going without regard to obstacles. However, even the will to do safety work opposed by great pressure from other sources may result in spasmodic rather than continuous effort, leaving the question still open whether such effort is better than none at all. There was a great deal of such pressure during the war, and many managers who would have liked to have kept up the safety work found it impossible to do more than put on an occasional campaign. Don't you think they accomplished some good?

The influence on the employee is mentioned as a harmful result. It is stated that as a result of spasmodic effort he will show lack of interest the next time that the matter is put before him; that he will not appreciate it but will consider it one of the numerous fly-by-night fads which are constantly cropping up, and that this feeling will spread to other plants in the immediate vicinity and cause great harm to the entire safety work in these plants. I can hardly agree with this, for I have found that if when the safety work is revived, it is dressed up in new clothes and approached from a different angle with a good selling campaign to present it, employees grasp the idea as enthusiastically as they did the first time, and often show a new and stronger interest. They welcome it as an old and helpful friend who works in their behalf.

Now we come to the subject of education and training, and here is where I hope to make my stand in favor of the proposition that the net result of spasmodic safety effort may be good, that it is better than nothing at all.

Surely we agree with Mr. Webber in his statement concerning the value of training both the child and the adult in the value of safety, and in its ways.

May I develop this thought a little further from the psychological viewpoint?

If a manufacturer, for instance, puts on one advertising campaign and does nothing further, he is soon forgotten, but nevertheless he has made a few sales as a direct result and has made an impression upon the minds of all those who have come in contact with his campaign which cannot be entirely eradicated by time, and should he put on another at some little time afterwards the old impression will be revived and the purchaser will feel conscious of having heard of the thing before, which in advertising is an advantage, giving the article a certain standing. If he continues these occasional campaigns he will make a deeper and deeper impression and his goods will become more and more familiar. There is a mathematical relationship between spasmodic and continuous. If the periods between the spasmodic efforts were shortened and shortened, these efforts would tend to become continuous and the results would multiply until we got the well known results of Heinz's 57, Ivory Soap, etc., as mentioned by Mr. Webber.

TRAINING EMPLOYEES TO RECOGNIZE RISKS SUBCONSCIOUSLY

In much the same way as with advertising, the purpose of the safety movement is to make such an impression on the mind of the employee that when an unsafe act is contemplated the safety idea will instantly leap into his mind and cause him to do the safe thing. Putting this same thought into other words, accident prevention training is not so much for the purpose of "educating" workmen or keeping employees from being careless, or even of arousing enthusiasm, as it is for training them to recognize risks subconsciously and without hesitation to decide on the safe way and proceed in that manner. This sort of training is particularly necessary in public service work where men work singly or in small groups without close supervision, often at some distance from city or village, and where the chances of accident through carelessness and lack of foresight are great. It is a branch of education just as advertising and schooling are, and for the best results has for its object the training of the subconscious mind.

This is particularly necessary if accidents are to be prevented, since more than 80 per cent of all accidents according to statistics are due to risk-taking, which the employee may or may not be conscious of, and less than 20 per cent are due to structural or mechanical defects, risks of employment, acts of God, or physical deficiency. The employee's own mind, conscious and subconscious, must be his chief guardian against accident and injury.

If the initial safety campaign were well staged, it "sold" safety to the employees at that time and made an impression. It is reasonable then to believe that some accidents at least, with their pain and sorrow, were avoided as the direct result of that first campaign. In view of what has been said about advertising and safety work and the similarity of the objects to be accomplished, is it not clear that each succeeding safety effort, even though infrequent, tends to revive the impression made by the initial campaign and deepen it and stir the employee's self-interest in avoiding accident, at least for a short time afterward? Surely some accidents will be avoided as the direct result of each campaign and some from the lasting impressions carried by many of the employees. Can the possible harmful results that might come from spasmodic effort outweigh this saving of life and limb?

FOR SAFETY EFFORT WHETHER OCCASIONAL OR CONTINUOUS.

In conclusion, I would like to say that while I may seem to disagree with Mr. Webber on some points, I agree with him heartily in this, that continuous, persistent effort saves life and limb, pain and sorrow, out of all proportion with the effort expended, dividends that cannot be estimated in terms of dollars and cents. However, I am for safety effort whether occasional or continuous, and wish to leave it with you to decide whether there isn't some net good resulting from even spasmodic efforts.

CHAIRMAN MACLACHLAN: Is there any further discussion on this paper? I would like to hear some one speak who hasn't spoken this morning.

MR. M. C. GOODSPEED (General Electric Company, Erie, Pa.): I just have one item to add. The gentleman who just spoke covered these points very fully. Although I agree that spasmodic efforts never can give us the results that continuous efforts will give and that continuous efforts are by all means to be desired, still I am fully convinced that the spasmodic efforts must give us some beneficial results. The man who is in charge of the spasmodic efforts, because they are spasmodic, may tend to become discouraged. You may think you have harmful results because he becomes discouraged, but you will find that while one man may have been discouraged, hundreds of others may have been encouraged for the time being. I will increase that to thousands that may have been encouraged, as shown by the safety rally here in the city of Cleveland this week. It is a spasmodic effort for safety for one week. We don't expect it to be extended for the entire year but you are getting results in the city of Cleveland from the spasmodic effort and you expect to get further results when the city of Cleveland and its Safety Council go ahead with the work, on probably different basis perhaps, and present that work to the city and utilize the results and enthusiasm of this spasmodic effort to obtain definite permanent results in the increase of safety in the city.

MR. BURTON: I think this question of spasmodic effort depends upon the question of labor turnover in the labor industry. For instance, you may come back next week or next month and find you have an entirely different set of men.

MR. A. O. MITCHELL (Northern Indiana Gas & Electric Co., Hammond, Ind.): The question of spasmodic effort brings to my mind a peculiar situation in which I work, arranging safety committees, going to the property and calling all the foremen together from every department and outlining the plan which we are to follow, telling them what we intend to do, then during that day, having those men select two men from their department to complete the committee from that department, and then having a meeting the next day of all the committeemen. I think in this particular case they numbered 26 out of 150 employees. We had meetings every week and I went every day during that week with the different foremen, half-day or quarter-day with each one, making a complete inspection of the division over which they had control, inspecting all of the line wagons, the gas wagons, the push carts and all the tools and appliances that they contained. We wound these meetings up with a general safety rally to which the women and children were invited and a great many, in fact a larger percentage than we expected, responded, and giving some little entertainment and luncheon for that night. During that time we took the opportunity of telling the women what we were intending to do and urging them to use their influence in the work.

I left and was gone about two months before getting back. When I came back I asked the man who was made President of this safety organization how they were getting along and he said, "We are doing pretty well, we haven't had any meeting since you left though." It was vacation time. I said, "When do you expect to have a meeting?" He

said. "We are going to take it up now, right away." This was the first of September.

I got around some of those foremen and found they were practicing safety although they were not having any meetings. That was a spasmodic effort that I know had no harmful results, and I know the work will be taken up again this fall and they will get into it during the winter and have their meetings.

We completed an organization in another section employing about 250 men some two years ago. It started out, not with a cry of a horn or any big spill or noise but now they have a very complete organization. During their first six months, as I recall it, their efforts were very spasmodic. They had no regular plan to follow but now they have gotten on a solid foundation and the work that they have done there has been worth the time and effort, not only in the prevention of accidents, the saving of money and the conservation of funds but it has brought the men closer together: it has made them sort of a family, and I find that, in that particular place, the labor turnover has been cut down to a very fine point. In fact, there are men there who have been there now for two years and previous to that time they worked possibly two weeks or a month, thinking that nothing was being done for them and nobody seemed to care anything about them. That has been changed and it started out spasmodically.

I have been with this Company for about nine years and I know of no harmful results that have come from a spasmodic safety movement.

CHAIRMAN MACLACHLAN: Is there any one else who wishes to talk on this?

MR. T. D. RAMSEY (Kansas City Gas Co.): The thought just occurred to me: What is the reason for the spasmodic effort? I was just wondering if it is in the man who starts the campaign. He may have the idea that it is absolutely necessary for him to do all the talking and all the leading. My idea in starting a campaign or in starting a movement would be to get the others interested and get them to do the work. I think that should be the manner in which the leader should lead;—get the other men to do the talking and the acting and let the leader assist them and counsel with them.

CHAIRMAN MACLACHLAN: Mr. Rosseland is here and wishes to speak to you for a few minutes.

MR. F. M. ROSSELAND: First, I want to refer to the discussion of Mr. Webber's paper. It suggested to me that there is a considerable difference in the various definitions of "spasmodic efforts." When I first heard Mr. Webber's paper I had in mind the spasmodic effort which opened up with a blare of trumpets, and then stopped, not the work such as Mr. Mitchell described, which is the usual work, the usual method of conducting safety work in a large company. I think you will agree with me in that.

As a matter of fact, the large companies seldom have a safety man out on the job who sees each man and talks to him, they have a safety meeting about once a month and the safety engineer or the safety inspector

gets around and leads the meeting and talks to the men. I wouldn't call that spasmodic safety work. I think we should consider the other angle as spasmodic safety work, that is where it starts up and dies down absolutely.

I have had it thrown up to me time and again in starting out work of that kind, "Oh, yes, they started some of that work two years ago. I didn't hear anything more about it at all." At any rate, it is a decided handicap in getting the interest of those men. In some instances, I never did succeed. We had some men who absolutely required discipline.

REGARDING PRINTING CONGRESS PAPERS IN ADVANCE

Turning to the subject of printing Annual Congress papers in advance—for some time there has been a demand for this, so that the papers might be placed on the registration desk and elsewhere for members to get and read. The objection to that is, as has been made by some of the sectional officers, the fear that the members will get the papers, look them over, put them in their pockets, and then not attend the sessions.

On the other hand, there is a decided advantage that the people who attend the sessions may get the papers, read them over, and come prepared to discuss them more intelligently than they could otherwise.

The National Safety Council is anxious to give the maximum service. We are not anxious to print the papers, however, unless you want them as it entails quite a bit of expense that could be diverted to some other good work for the Section. I should like to know what you think about it.

MR. SCOTT: I move you that it is the sentiment of this meeting that the papers be distributed in advance.

(After discussion, the motion was carried.)

CHAIRMAN MACLACHLAN: I will now give Mr. Webber the floor to wind up the discussion on his paper.

MR. WEBBER: I don't believe that there is much more that can be said. It seems to me that spasmodic efforts speak for themselves. I have no doubt that there have been cases such as some of the gentlemen spoke of where they have started a movement on safety and the result of that particular movement did sink in and that it did carry along with those who were interested and impressed them for the time being. Mr. Rosseland covered that point, however, that it must not stop permanently, that it must not stop for six months even.

I don't believe that, unless you do persistently keep after this question of safety and the accident prevention and keep it before the individual workman, you can possibly get the results that are desired.

MR. SCOTT: I move you that it is the sense of this Section that we recommend to the Program Committee that at the next Annual Congress we have a paper presented in this section on the subject of "Fixing the responsibility of penalizing the foreman and superintendent who are responsible for accidents."

The motion was seconded and carried.

MR. MULLIGAN: I would like to suggest that copies of the proceedings

of this Section be distributed among some of our superintendents. We are not interested in a whole bound volume.

CHAIRMAN MACLACHLAN:—It is the sense of this Section that the Section's proceedings be bound separately that they may be available to the members of this Section.

(The motion was seconded and carried.)

CHAIRMAN MACLACHLAN:—Now it is just seventeen minutes to one. Is it your wish that we go on with the discussion of various matters, or should we adjourn within a few minutes, or do you wish to carry on this afternoon?

MR. MORRISON: I move that we adjourn.

(The motion was seconded by Mr. Lucas.)

CHAIRMAN MACLACHLAN:—I want to thank you for the honor of being elected Chairman of the Section.

During the year to come, I hope, with the assistance of you all and with the assistance of those you have elected with me, to present possibly some other phases of the work as they apply to the Public Utility Company.

The work of the Utility Company in regard to pensions, benefits, employees' representation and other such schemes is entirely different from the work of a company having thousands of employees in one spot, and I think that we could, with profit to ourselves and to our employees, go into this question from the standpoint of public utility.

MR. ROSSELAND: I wonder if I might just add a word about the printing of the proceedings of the sectional meetings. It will be done and sent to the membership at cost. We don't like to go to the expense of printing a lot of unused copies and I would request that you who want them write in and tell us so that we may have some idea of how many to prepare.

CHAIRMAN MACLACHLAN:—It has been moved and seconded that we adjourn and I now declare the sectional meeting for this Congress adjourned.

Rubber Section

October 4, 1919

MINUTES

THE meeting was called to order at 9:30 a. m. to consider the advisability of forming a Rubber Section. Mr. E. H. Fitzgerald of the Federal Rubber Company acted as Chairman pro tem. The advisability of forming this section was discussed by Mr. W. N. Fitch of the B. F. Goodrich Company, R. N. Watson of the Goodyear Tire and Rubber Company, S. M. Shott of the Morgan and Wright Company, Dr. Horan of the Hood Rubber Company, and Mr. Rosseland of the National Safety Council. All spoke in favor of the section, and a motion that a Rubber Section be formed was offered, seconded, and carried by an unanimous vote.

The Nominating Committee consisted of W. N. Fitch, Dr. Horan, and Harold T. Martin. This committee nominated S. M. Shott, Chairman, E. H. Fitzgerald, Vice-Chairman and R. N. Watson, Secretary. Report of the Nominating Committee was accepted and motion was made and seconded that the nominees be elected unanimously.

The following men were in attendance at the meeting: E. H. Fitzgerald, The Federal Rubber Company, Cudahy, Wis.; Harold Martin, T. J. Dwyer, H. T. Greene, and E. Forand, the Fiske Rubber Company, Chicopee Falls, Mass.; P. B. Martens, T. S. Petty, C. G. Dimcombe, A. L. Weyand, E. S. Hoener, N. A. Shepard and M. F. Letzel, the Firestone Tire and Rubber Company, Akron, Ohio; R. N. Watson, and P. A. Belden, The Goodyear Tire and Rubber Company; W. N. Fitch, W. L. Schneider, J. C. Howard, E. P. Raiford, A. C. Mack, W. G. Oberholser, E. K. Davis, G. A. Knofler, and R. B. Howe, The B. F. Goodrich Rubber Company; H. G. Pushee, The General Tire and Rubber Company, Akron, Ohio; A. L. Rose, The Kelly Springfield Tire and Rubber Company, Akron, Ohio; S. M. Shott, the Morgan and Wright Rubber Company, Detroit, Mich.; R. W. Fogerty, U. S. Rubber Company, Mech. Goods Div. Cleveland, Ohio; A. C. Peterjohn, The U. S. Rubber Company, Mech. Goods Div., Cleveland, Ohio; W. H. Larkin, Jr., J. W. Towsen, Lycoming Rubber Company, Mech. Goods Div., Passaic, N. J.; R. L. Gould, The U. S. Rubber Company System; M. Klein, The Federal Rubber Company, Cudahy, Wis.; C. F. Horan, The Hood Rubber Company, Watertown, Mass.; Mr. Rosseland, National Safety Council, Chicago.

Mr. Rosseland of the National Safety Council was requested to inform

the Section of the committees to be appointed, their duties, and method of operation. He suggested the formation of the following committees: Program, Bulletin, Membership, and Standardization.

No papers having been prepared for reading in the section, a general round-table discussion was held on the subjects on the program.

The first subject discussed was that of washers, crackers, and mills. Mr. S. M. Shott of the Morgan and Wright Company stated that their men were not allowed to start rubber through the washers or crackers with their hands but that small wooden paddles were used to push the rubber into the rolls. Also the blocks of rubber are cut into a wedge shape to further facilitate starting.

Mr. Fitch of the B. F. Goodrich Company stated that all of their mills have been placed high and holes were cut in the floor in front of those already installed in order to bring the top of the rolls nearly as high as a man's shoulders.

Mr. R. N. Watson of the Goodyear Company reported that bars had been mounted across the front of the washers in a bearing which allows them to revolve, the rubber being run over these bars while washing, and the men are instructed to keep back of the bar.

Mr. Horan of the Hood Rubber Company reported that individual clutches are used on all washers and crackers and that the inspectors have each man try out this safety each day and that the men are trained in the proper operation of the safety. Foot treadles just under the edge of the pan have worked out very satisfactorily and are the only means of stopping the mill in case a man gets both hands caught. Mr. Horan also stated that automatic reversing devices were used on a great many of their mills and work out much better than the dynamic brake.

Mr. Snyder of the B. F. Goodrich Company stated that a special screw is being designed by the Farrell Machine and Foundry Company, for opening mill rolls.

Mr. Hoener of the Firestone Tire and Rubber Company stated that their company was using a signal from the motor pit before starting up a mill line and that an answering ring was received for each mill before the line was started.

Mr. Belden of the Goodyear stated that switch boards are mounted over the motor pits with a platform at least six feet from the floor, giving a clear view of the line and assuring the electrician starting the line that no men are near the mills.

Mr. Shott of the Morgan and Wright Company brought out the point that reports of mill line safety tests did not only report that the line stopped O. K. but also showed the distance traveled by the rolls before stopping. He further stated that these reports should go to the Master Mechanic and Safety Department signed by the mill room electrician and inspector.

It was further suggested that a "Safe Practices" pamphlet be published on the subject of washers, crackers, and mills.

The next subject discussed was calenders.

Mr. Petty of the Firestone stated that on all calenders having an opening center and lower rolls, special gears had been provided and rolls had been lowered so that the opening was at least $2\frac{3}{4}$ inches, this opening being wide enough to clear the hand in case it came near the opening of the rolls. The calenders at the Firestone are also equipped with electrical clutch and brake.

Mr. Shott of the Morgan and Wright Company reported that they are using successfully a triangular-shaped casting at the opening between the rolls, $\frac{3}{4}$ -inch clearance being provided between the casting and the rolls. This prevents a man getting near the opening in the rolls and the only danger is in getting the tips of the fingers squeezed between the castings and the rolls.

On fabric calenders the casting is split and a one-inch slot provided for the fabric to pass through.

Mr. Watson of the Goodyear reported the use of a 1-inch bar across the calenders in front of the opening in the rolls, this bar being connected with the bell crank on each end to trip the switch which operates the dynamic brake on the calender so that as soon as a man's hand strikes the bar the calender is stopped. The point was also brought out that many calender accidents were caused by slipping and that the floor when surfaced with carborundum was not slippery and provided an effective means of eliminating this hazard.

The next subject was the handling of material.

Mr. Rose of the Kelly Springfield Tire and Rubber Company inquired if there were any automatic systems of opening molds after curing. Mr. Hoener of the Firestone reported that it was done with some degree of success on a conveyor system with a hydraulic opening device but that the operation was too slow and they had gone back to a special opening bar with increased leverage.

Mr. Shott of the Morgan and Wright advised that molds and cores were not being rolled in their factory, but that a special track was provided for hauling same.

The proposition of getting men to use respirators in the handling of compounds or on dusty jobs was brought up and it was the general consensus that the men would not wear them and that some other means should be provided to remove dust.

Mr. Fitzgerald of the Federal Rubber Company reported that milk was being furnished men in the compound and mill rooms twice per day.

Several companies reported that their mills were hooded and that a strong suction was used on them so that there was no danger of injuries from compounds.

Poisonous hazards in the rubber industry was next brought up.

Mr. Martin of the Fiske Rubber Company called attention to the hazards connected with the use of benzole reporting one fatality among the women engaged on this work. Some women are more susceptible than others.

Dr. Horan of the Hood Rubber Company brought out the point that

the accelerator Eurotropine causes a rash on the hands, arms, face, and neck—blondes being more susceptible than others. This rash can be eliminated by neutralizing the sweat with borax and this has been done in the Hood Rubber company by the application of 20 per cent gum arabic solution saturated with borax to the hands and arms. This forms a shellac-like coating and prevents the chemical from attacking the skin.

The meeting then adjourned.

A special meeting of the officers of the Rubber Section was held at 2:00 p. m. October 4, 1919, for the purpose of appointing committees as follows:

Bulletin Committee: W. N. Fitch, The B. F. Goodrich Company, Chairman; P. B. Martens, The Firestone Rubber Company; H. G. Pushee, The General Tire and Rubber Company.

Program Committee: H. Martin, The Fiske Rubber Company, Chairman; H. E. Gilson, U. S. Rubber Company, General Laboratories, 11th Ave. and 58th St., New York, N. Y.; Dr. Quinby, The Hood Rubber Company.

Membership Committee: E. H. Fitzgerald, The Federal Rubber Company, Chairman; A. L. Rose, The Kelly-Springfield Rubber Company; Frank Scott, The Hamlin Company, 21 Cedar St., N. Y.

Steam Railroad Section

October 2-4, 1919

R. C. RICHARDS, Chairman

Chairman, Central Safety Committee, Chicago and North Western Railroad, Chicago, Ill.

JOHN T. BRODERICK, Vice-Chairman

Supervisor of Special Bureaus, Baltimore and Ohio Railroad,
— Baltimore, Md.

F. WHITEMORE, Secretary

Superintendent, Safety Department, Nashville, Chattanooga and St. Louis Railroad, Nashville, Tenn.

IN ATTENDANCE AT SECTIONAL MEETINGS

Alabama & Vicksburg—

D. H. Beatty, Superintendent of Safety, Southern R. R., Washington,
D. C.

Atchison, Topeka & Santa Fe—

Bert Bertram, Safety Agent, Arkansas City, Kan.

R. E. Blok, Safety Agent, Amarillo, Tex.

Isaiah Hale, Safety Agent, Topeka, Kan.

C. A. Judd, Safety Agent, La Junta, Colorado.

Geo. Moore, Safety Agent, Kansas City, Kan.

Asheboro and Southern—

D. H. Beatty.

Atlanta & West Point—

J. A. Barnette, Supervisor of Safety, Atlanta, Ga.

Atlanta & Yodkin—

D. H. Beatty.

Atlanta, Birmingham and Atlantic—

J. A. Barnette, Supervisor of Safety, Atlanta, Ga.

Atlantic Coast Line—

John R. Adams, Supervisor of Safety, Wilmington, N. C.

J. V. Miller, Supervisor of Safety, Wilmington, N. C.

Robert Scott, Superintendent of Insurance and Safety, Wilmington,
N. C.

Augusta Southern Railroad—

W. O. Wall, General Safety Agent, Augusta, Ga.

Baltimore & Ohio Railroad—

John T. Broderick, Superintendent, Safety and Welfare Dept., Baltimore, Md.

W. J. Head, Safety Agent, Northwest District, Cleveland.

Wm. D. Lenderking, Safety Agent, Baltimore, Md.

W. A. Mitchell, Safety Agent, Grafton, W. Va.

J. C. Morgan, Safety Agent, Baltimore, Md.

T. J. Reagan, Safety Agent, Southwest District, Cincinnati, Ohio.

E. R. Scoville, Supervisor of Safety, Baltimore, Md.

Bangor and Aroostook—

M. F. Dunn, General Safety Agent, Portland, Me.

Big Four—

T. R. McCampbell, Safety Agent, 719 Majestic Bldg., Indianapolis, Ind.

Bingham and Garfield—

C. H. Wilson, Safety Engineer, Garfield, Utah.

Blue Ridge—

D. H. Beatty.

Boston and Maine—

A. A. Stebbins, Assistant to General Secretary, Safety Department.

Buffalo, Rochester & Pittsburgh—

John S. Rockwell, General Agent, 155 Main St., W. Rochester, N. Y.

Carolina & North Western—

D. H. Beatty.

J. W. Chamberlain, Safety Supervisor, Knoxville, Tenn.

Carolina, Clinchfield & Ohio—

J. W. Chamberlain, Safety Supervisor, Knoxville, Tenn.

Charleston & Western Carolina—

J. A. Barnette, Supervisor of Safety, Atlanta, Ga.

Chicago & Eastern Illinois; Chicago, Terre Haute & Southwestern; Evansville & Indianapolis—

J. F. Lord, Supervisor of Safety and Fire Prevention, Evansville, Ind.

John O'Brien, Switchman (C. & E. I.), 227 Lincoln Ave., Dolton, Ill.

Walter D. Smith (C. & E. I.), Supt. Shops, Danville, Ill.

Chicago & North Western—

Geo. R. Campbell, Train Dispatcher, Eagle Grove, Ia.

Wm. H. Copp, Machinist, S. Kaukauna, Wis.

Fred Curtis, Conductor, Huron, S. Dakota.

S. M. Galaty, Safety Inspector, 226 W. Jackson Blvd., Chicago, Ill.

John W. Herrington, Telegraph Foreman, Baraboo, Wis.

H. C. Lenter, Switchman, Chicago, Ill.

C. F. Mabie, Freight Conductor, Chicago, Ill.

H. Nelson, Brakeman, Chicago, Ill.

J. A. Peabody, Signal Engineer, Chicago, Ill.

M. A. Schuster, Air Foreman, 285 24th Ave., Milwaukee, Wis.

James Sullivan, Safety Inspector, 4423 Washington Blvd., Chicago, Ill.

Chicago & Western Indiana —

V. R. Walling, Principal Assistant Engineer, Chicago, Ill.

Chicago, Burlington & Quincy—

E. M. Switzer, Superintendent of Safety, Chicago, Ill.

Chicago, Cleveland, Cincinnati & St. Louis.

B. G. Chamberlain, Safety Agent, 719 Majestic Bldg., Indianapolis, Ind.

E. B. Goodart, Safety Agent, Mattoon, Ill.

C. H. Lentz, Safety Agent, Bellefontaine, Ohio.

A. L. Mason, Conductor, 2362 Adams St., Indianapolis, Ind.

Wm. Van Gorder, Safety Agent, Springfield, Ohio.

Chicago Great Western—

L. C. Espersen, Claim Agent, Clarion, Ia.

O. P. Larson, Chairman Oelwein Shop Committee, Oelwein, Ia.

G. O. Perkins, Superintendent, Telegraph and Signals, Chicago, Ill.

Chicago, Indianapolis & Louisville; Chicago, Indianapolis & Western—

J. H. Holloway, General Safety Supervisor, LaFayette, Ind.

Chicago Junction—

T. F. Barry, Safety Supervisor, 837 Exchange Ave., Chicago, Ill.

Chicago, Rock Island & Pacific—

W. L. Bradley, Supervisor, Safety and Fire Prevention, El Reno, Okla.

W. P. McGuire, Supervisor, Safety and Fire Prevention, Des Moines, Ia.

L. F. Shedd, General Supervisor, Safety and Fire Prevention, Chicago, Ill.

Wendell H. Stillwell, Supervisor, Safety and Fire Prevention, Des Moines, Ia.

Floyd P. Wilson, Supervisor, Safety and Fire Prevention, El Reno, Oklahoma.

Chicago, St. Paul, Minneapolis & Omaha—

F. F. Reed, Inspector Safety Bureau, St. Paul, Minn.

F. F. Whaley, General Mail and Baggage Agent, St. Paul, Minn.

Geo. L. Wright, Superintendent, Safety Bureau, St. Paul, Minn.

Delaware & Hudson—

R. C. Helwig, Safety Agent, Albany, N. Y.

J. E. Long, Superintendent of Safety, Albany, N. Y.

H. G. Stevens, Safety Agent, Albany, N. Y.

A. V. Rohweder, Supervisor of Safety, Duluth, Minn.

Duluth & Iron Range—

W. N. Henry, Engineer, Two Harbors, Minn.

F. W. Hiller, Conductor, Two Harbors, Minn.

B. R. Moore, Superintendent, Motive Power, Two Harbors, Minn.

Duluth, Missabe & Northern—

W. A. Clark, General Car Foreman, Proctor, Minn.

M. J. Dixon, Locomotive Engineer, Proctor, Minn.

A. V. Rohweder, Supervisor of Safety, Duluth, Minn.

D. C. Sullivan, Conductor, Duluth, Minn.

Elgin, Joliet & Eastern and Chicago, Milwaukee & Gary—

O. F. Gnadinger, Supervisor of Safety, Elgin, Ill.

El Paso & Southwestern—

L. H. Trimble, Superintendent of Safety, El Paso, Tex.

Florida East Coast—

William W. Scott, Safety Agent, St. Augustine, Fla.

Great Northern Railroad et al.—

C. L. La Fountaine, General Safety Supervisor, Room 705 Railroad Bldg., St. Paul, Minn.

Georgia Railroad—

J. A. Barnette, Supervisor of Safety, Atlanta, Ga.

Great Northern Railroad—

Geo. F. Buehler, Machine Foreman, St. Paul, Minn.

Gulf and Ship Island et al.—

W. P. Withers, in Charge of Safety, Hattiesburg, Miss.

Gulf Coast Lines and Gulf, Colorado and Santa Fe Lines—

J. G. Fitzhugh, Superintendent of Safety, Galveston, Tex.

Gulf, Mobile and Northern and Meridian and Memphis—

J. O. Gaither, Supervisor of Safety, Laurel, Miss.

Hawkinsville & Florida Southern—

D. H. Beatty.

Illinois Central—

S. S. Morris, Chairman, General Safety Committee, Chicago, Ill.

Indiana Harbor Belt—

E. G. Steineck, Examiner and Safety Agent, Gibson, Ind.

Kansas City Southern—

D. B. Daley, Superintendent of Safety, Kansas City, Mo.

Lake Erie & Eastern—

William J. Foster, Conductor, Youngstown, Ohio.

Long Island—

T. P. Brennan, Safety Agent, New York City.

Lehigh Valley et al.—

A. E. O'Dea, Supervisor of Safety, Bethlehem, Pa.

Louisville & Nashville, and Louisville, Henderson and St. Louis—

R. L. Pilling, Supervisor of Safety, Louisville, Ky.

J. P. Hamilton, Chief Clerk, Supervisor of Safety, Louisville, Ky.

Clifton Lock, Louisville, Ky.

T. B. Lockart, Safety Agent, Louisville, Ky.

Minneapolis & St. Louis—

O. F. Johnson, Safety Supervisor, Minneapolis, Minn.

Minneapolis, St. Paul & Sault Ste. Marie, et al.—

L. P. Green, Superintendent of Safety, Minneapolis, Minn.

Missouri, Kansas & Texas, et al.—

J. W. Butz, District Superintendent, Smithville, Tex.

C. F. Colby, Safety Agent, Dallas, Tex.

J. L. Walsh, Superintendent of Safety, Katy Bldg., Dallas, Texas.

Missouri Pacific et al.—

M. McKernan, Superintendent of Safety, Room 2160 Railway Exchange Bldg., St. Louis, Mo.

Mobile & Ohio—

Vester J. Thompson, Supervisor of Safety, Mobile, Ala.

Monongahela—

V. D. Pringle, Train Master, Brownsville, Pa.

New York Central Lines—

W. L. Boslooper, Safety Agent, Detroit, Mich.

A. R. Cooper, Safety Agent, 611 Thayer St., Toledo, Ohio.

F. L. Diehl, Shop Safety Agent, 320 Aspenwold Avenue, Elkhart, Ind.

Marcus A. Dow, General Safety Agent, New York City.

H. W. Ferrel, General Foreman, McKees Rocks, Pa.

C. B. Floyd, Assistant to General Safety Agent, New York City.

D. J. Hackett, Division Superintendent, Jackson, Mich.

C. W. Hammond, Division Safety Agent, 831 E. 156th St., Cleveland, Ohio.

A. C. Hartley, Supervising Safety Agent, Detroit, Mich.

J. W. Johnston, Safety Agent, Chicago, Ill.

R. E. Laidlow, Superintendent, Terminals, Detroit, Mich.

E. M. Mann, Chief Safety Agent, 814 Columbia Blvd., Cleveland, Ohio.

F. P. McGirr, Shop Safety Agent, Buffalo, N. Y.

F. P. Neesley.

G. E. Parks, Mechanical Engineer, Detroit, Mich.

F. E. Pfeifer, Superintendent, Chicago, Ill.

W. E. Pusey, Safety Agent, Columbus, Ohio.

H. M. Ready, Jr., Safety Agent, 905 E. So. Union St. Bay City, Mich.

W. H. Siufe, Division Superintendent, Bay City, Mich.

M. H. Scheib, Buffalo, N. Y.

E. P. Spangler, Safety Agent, Jackson, Mich.

J. P. Tinley, Division Safety Agent, 525 Lake St., Ashtabula, Ohio.

E. R. Webb, Division, St. Thomas, Ont.

Nashville, Chattanooga & St. Louis—

F. Whittemore, Superintendent of Safety, Nashville, Tenn.

New York, New Haven & Hartford—

Frank A. Barrows, Inspector of Transportation, New Haven, Conn.

J. A. Clancy, Safety Inspector, Boston, Mass.

F. W. Mitchell, Supervisor of Safety and Examinations, New Haven, Conn.

E. G. Wride, Chief Clerk, Department of Safety, New Haven, Conn.

New York, Ontario & Western—

N. L. Satchell, Safety Agent, Middletown, N. Y.

Norfolk Southern et al.—

J. B. Robinson, Supervisor of Safety, Norfolk, Va.

Northern Pacific—

Fred M. Metcalfe, Superintendent of Safety, St. Paul, Minn.

E. W. Griffin, Safety Representative, Duluth, Minn.

Oregon Short Line: Los Angeles & Salt Lake—

C. T. Bailey, Safety Agent, Salt Lake City, Utah.

J. C. Clark, Assistant to General Manager, Salt Lake City, Utah.

D. K. Rawlings, Safety Agent, 625 West 1st North Street, Salt Lake City, Utah.

Pennsylvania Lines—

T. H. Carrow, Supervisor of Safety, Philadelphia, Pa.

E. S. Chapin, Jr., Safety Inspector, Insurance and Safety Department, Philadelphia, Pa.

T. E. Crosson, General Yard Master, Buffalo, N. Y.

A. L. Cunningham, Division Safety Agent, Pittsburgh, Pa.

W. H. Fassett, Vice-Chairman, Safety Comm., Philadelphia, Pa.

J. J. Henry, Safety Agent.

H. E. Meginness, Safety Agent, Indianapolis, Ind.

E. G. Otto, Altoona, Pa.

H. B. Reynolds, Superintendent, Safety Bureau, Pittsburgh, Pa.

J. H. Stadelman, Assistant Engineer, Wilmington, Del.

J. W. Warwick, Special Clerk, New York, N. Y.

H. C. West, Safety Agent.

E. J. Wilson, Safety Agent, New Castle, Pa.

Pittsburgh, Cincinnati, Chicago & St. Louis—

W. Conner, Division Safety Agent, Pittsburgh, Pa.

Pittsburgh & Lake Erie et al.—

F. H. Babcock, General Safety Agent, Pittsburgh, Pa.

W. A. Dean, Signal Supervisor, Pittsburgh, Pa.

A. G. Dunlop, Ticket Agent, Monessen, Pa.

J. W. Holsinger, Assistant Yardmaster, Aliquippa, Pa.

Pittsburgh & West Virginia—

R. M. Mall, Principal Assistant Engineer, Pittsburgh, Pa.

Reading System—

S. B. Zartman, Superintendent, Safety and Labor, Philadelphia, Pa.

Richmond, Fredericksburg & Potomac—

D. P. Browder, Safety Supervisor, Richmond, Va.

St. Louis & San Francisco—

G. L. Ball, Superintendent of Safety, St. Louis, Mo.

C. H. Baltzell, Division Superintendent, Fort Smith, Ark.

Southern Railroad Lines et al.—

J. W. Chamberlain, Safety Supervisor, Knoxville, Tenn.

Southern Pacific Lines—

R. M. Glover, Division Superintendent, Lafayette, La.

H. M. Mayo, Superintendent of Safety, Houston, Tex.

Southern Railway and Associated Lines—

D. H. Beatty, Washington, D. C.

C. R. Staples, Safety Supervisor, Lexington, Ky.

Terminal Railroad Association of St. Louis—

H. E. Watkins, Supt. of Safety, St. Louis, Mo.

Toronto, Hamilton & Buffalo—

W. J. Orr, Safety and First Aid Officer, Hamilton, Ont.

Union Pacific—

Chas. Finlayson, General Car Inspector, Omaha, Neb.

P. Groome, General Safety Agent, Omaha, Neb.

H. H. Hawes, Engine Foreman, Council Bluffs, Ia.
F. C. Hunter, Assistant Safety Agent, Omaha, Neb.
C. W. Moats, Safety Inspector, Omaha, Neb.
David More, Assistant Safety Agent, Omaha, Neb.
F. B. Olds, Brakeman, Oxford Hotel, Denver, Colo.
C. E. Olson, Locomotive Fireman, Rawlins, Wyo.
W. L. Richards, Locomotive Engineer, 217 W. 5th St., North Platte, Neb.
J. W. Taylor, Conductor, Kansas City, Mo.

Wabash Railroad—

D. J. Bailey, Chief Clerk, Superintendent of Safety, St. Louis, Mo.
J. A. McNally, Safety Inspector, Room 1423 Railway Exchange Bldg., St. Louis, Mo.
F. Meyers, Superintendent of Safety, St. Louis, Mo.
V. M. Packwood, Safety Inspector, St. Louis, Mo.

Washington Terminal—

J. O. Tatton, Chief Clerk to Superintendent, Washington, D. C.

Wheeling and Lake Erie—

J. T. Briggs, Supervisor of Safety, Canton, Ohio.

United States Railroad Administration—

J. M. Hoy, Safety Agent, Potomac District, Hagerstown, Md.
M. McGovern, Statistician Secretary, Safety Section, Washington, D. C.

Regional Supervisors of Safety—

H. A. Adams, 1205 Burlington Bldg., Chicago, Ill.
C. M. Anderson
H. J. Bell, Chicago, Ill.
C. W. Gregg
R. S. Jarnagin, Eastern Region, 3623 Grand Central Terminal, New York City.
A. Kirkendall, Allegheny Region.
F. A. Wightman, South West Region, 2002 Railway Exchange Bldg., St. Louis, Mo.

Asst. Chief Inspector of Locomotives—

J. M. Hall, Interstate Commerce Commission, Washington, D. C.

Chief Inspector of Locomotives—

A. G. Pack, Interstate Commerce Commission, Washington, D. C.

THURSDAY MORNING SESSION

THE meeting was called to order by Mr. R. C. Richards, Chairman, at 9:45 A. M.

CHAIRMAN RICHARDS: The eighth annual session of the Steam Railroad Section of the National Safety Council will come to order.

(The roll was called by roads, alphabetically.)

CHAIRMAN RICHARDS: The next order of business is the report of the Chairman of the Section. It goes without saying that the Chairman feels highly complimented that the Section should have turned out such a fine attendance at this Congress. I believe that we have the largest representation of any Section at the Congress. It certainly speaks well for you men, who are interested in safety work, that you are all ready and willing to leave your jobs and come here to get what inspiration and assistance you can and to give what inspiration and assistance you can to others who are engaged in the same line of work that you are engaged in, that is, in conserving that priceless thing, that one thing which we hold most dear—life. If we can just carry on during the next year as we have during the past year, and I am very sure that we will, with the assistance and enthusiasm and active coöperation of the Manager of the Safety Section of the United States Railroad Administration, who has done so much to assist us in adding to the membership of this Section, nobody knows how large a representation we will have at our next Congress and how much good we will be able to do in the meantime.

There is one thing that I want to say to the members of this Section as I said to you when you were kind enough to elect me your presiding officer at the last meeting. The Section is yours. It doesn't belong to the Chairman; it doesn't belong to the Secretary; it doesn't belong to the members of the Executive Committee. Whether or not the Section is going to be a success depends upon you just as much as it does upon them. Last year, too many of you left everything for "George" to do. I am very sorry to say that I got very few suggestions and no advice, and nobody stood in more need of advice than did I from the members of the Section as to what we ought to do. I hope that the presiding officer next year, will get more active assistance and coöperation from you all.

You may be interested in knowing that a year ago, we had 103 railroad members of the Section with 171,700 miles. This year, we have 127 railroad members with a mileage of 206,222. The increase in mileage and the increase in number of roads represented in this Section, of course, is largely due to the active assistance of Mr. Duffy and the Regional Supervisors of Safety. I am sure that we all appreciate very much what they have done to help us.

The Chairmen of the various Committees of the Section will be called upon for reports of the activities of their committees. During the progress of this meeting, we are to have some very interesting papers from some very distinguished gentlemen, some of whom are members of this Section, some of whom are outsiders. We owe it to these men and we owe it to ourselves to show some appreciation of the fact that they have been willing to give their time and thought to the matters that are before us.

I don't think I have anything important to say to you except that I hope that now we have gotten started, we will continue to have a very interesting Congress.

The next business on the program will be the report of the Secretary, Mr. Whittemore.

REPORT OF THE SECRETARY

SECRETARY WHITTEMORE: There is nothing of particular interest that your Secretary has to report at this meeting. The usual duties of the office have been fulfilled. The News Letter has been issued with regularity, and other routine matters have been attended to in the usual form.

CHAIRMAN RICHARDS: I want to say for the benefit of the members of the Section who are not acquainted with the work, that Mr. Whittemore has been one of the hardest working, most industrious, most enthusiastic men connected with the Executive Committee, and he has done more work than all the rest of us put together. I am sure that if you men knew how much work he has done and how much he has been called upon to do and how little assistance he has had from you fellows to do it, you would appreciate more than you do what he has accomplished.

The next report will be from the Accident Causes and Remedies Committee. Mr. Carrow is the Chairman of the Committee.

REPORT OF ACCIDENT CAUSES AND REMEDIES COMMITTEE

T. H. CARROW, CHAIRMAN, SUPERVISOR OF SAFETY, PENNSYLVANIA
RAILROAD, EASTERN LINES

J. T. BRODERICK, SUPERINTENDENT OF SAFETY AND WELFARE BUREAU,
BALTIMORE AND OHIO RAILROAD

L. G. BENTLEY, GENERAL SAFETY AGENT, CHESAPEAKE AND OHIO RAILROAD

The pamphlet published by the Interstate Commerce Commission entitled "Rules Governing Monthly Reports of Railway Accidents, 1918 Revision, Effective October 1, 1918", contains a set of causes which will be used in the future by the Interstate Commerce Commission for classifying train accidents and train service accidents, the causes having been developed for the Commission by a Committee representing the American Railway Association.

At the first meeting of the Accident Causes and Remedies Committee it was decided to call upon the statistician of the Interstate Commerce Commission with a view of obtaining a statement showing the accidents which occurred during a given period, classified in accordance with the revised causes. The Committee accordingly called upon Mr. M. O. Lorenz, Statistician of the Interstate Commerce Commission, who agreed to furnish a statement covering the month of January, 1919, which is attached and will be embodied in the printed report of your Committee.

The American Railway Association Committee in developing the causes above referred to made careful study of the accident statistics used by the large railroads in the United States and foreign countries and while experience will probably suggest certain alterations and addi-

Code No.	Cause.	Number of train accidents.	Damages to Railway property.	Total non-trespassers Killed. Injured.
1400	TRAIN FLAGGING:			
1401	Total failure to flag.....	11	7,270	16
1402	Failure to flag promptly.....	1	150	---
1403	Failure to go back a sufficient distance	7	14,140	2
1404	Torpedoes, failure to use or to place properly	3	2,520	3
1405	Fusees, failure to use or to place properly	1	640	---
1406	Failure to carry flagman's equipment	---	---	---
1407	Other improper flagging.....	4	5,340	10
1408	Total disregard of flag.....	4	6,980	---
1409	Failure to be on lookout or to regard flag in time	1	570	---
1410	Torpedoes, failure to regard.....	---	---	---
1411	Fusees, failure to regard.....	---	---	---
1412	Other failures to regard flagging..	---	---	---
1400	Not reported	---	---	---
	Total	32	37,610	31
1500	AIR BRAKES:			
1501	Insufficient air pressure, failure of engineman to observe	2	4,730	---
1502	Improperly releasing air brakes.....	1	160	---
1503	Emergency application, unjustifiable	6	2,910	2
1504	Other improper handling by engineman	1	410	---
1505	Failure to test.....	1	200	---
1506	Application from train other than from locomotive, unjustifiable....	1	230	---
1507	Retaining valves, failure to set sufficient number	---	---	---
1508	Failure to have proper percentage in service	4	17,590	4
1509	Other improper handling.....	2	3,550	---
1500	Not reported	---	---	---
	Total	18	29,780	6
1600	HAND BRAKES:			
1601	Failure to control by.....	55	14,500	10
1602	Failure to secure by.....	20	13,670	4
1603	Failure properly to test.....	---	---	---
1604	Other negligence	---	---	---
1600	Not reported	---	---	---
	Total	75	28,170	14
1700	SWITCHES:			
1701	Switch set in wrong position.....	28	18,900	9
1702	Switch thrown under locomotive or cars	14	5,670	---
1703	Wrong switch thrown.....	6	4,100	---
1704	Failure to latch or secure lever....	3	770	---

Steam Railroad Section

1183

Code No.	Cause.	Number of train accidents.	Damages to Railway property.	Total non-trespassers Killed.	Injured.
1705	Failure to see that switch points fit up properly.....	1	170	---	---
1706	Switch thrown before car cleared derail	---	---	---	---
1707	Switches run through.....	6	1,560	---	---
1708	Derail-running off	11	9,670	2	3

MR. CARROW: Now I shall endeavor, as quickly as I can, to explain the system of statistics previously referred to. The main division in the statistics is between train accidents and train service accidents. There are a number of headings under which are shown certain details. Train accidents have involved the use of train orders, but so far as I know, there has never been any separation as between specific misuse of train orders. I have often wondered if, in the last fifty years, let us say, there had been an accumulation of information of this character, our system of train dispatching, our system of rules, would not have been more rapidly developed.

Under train orders, for example, I will mention one or two details in order that you may carry in your mind the scheme of the thing.

1. Error in transmission of copying, telegraph.
2. Error in transmission of copying, telephone.

One might inquire as to what the difference is. The difference is just this: Many railroads in the United States operate by the telegraph system. Others operate by the telephone system. Suppose it would come up for consideration to install a telephone system in train operation on one of your lines. The first question that would arise would be whether or not it would be safe. In two years after we have established these causes, you can go to the Interstate Commerce Commission and ascertain specifically whether operation by telephone is as safe as it is by telegraph or vice versa.

Speaking for our own road, we have telephones in use almost exclusively. I recall very distinctly, in the early stages of the game, there was very much uncertainty as to whether or not it would be safe.

The next cause under that heading might properly be: Meeting point, overrunning. We all know about the disastrous accidents that have occurred as the result of overrunning meeting points. Here we have accidents not summarized but in specific detail. A year from today when these statistics are classified, we will be able to put our finger on specific causes of accidents. In other words, we have endeavored to take it out of the realm of uncertainty and put it into the realm of science.

The next classification is fixed signals. There are as many systems of signals in the United States as there are characters and types of men here today. As to which is the best system, nobody seems to know. Yet there are certain fundamental principles which are accepted as being satisfactory and safe. I will read the first detail under that. While there are a number, I can't go into very much detail, but I will mention enough to give you the scheme of the thing. The first cause is: Clear signal displayed for occupied block. You men who are familiar with the train operation all know what that means. We all know what it would mean if we should see in the United States, for example, an epidemic of accidents from clear signal displayed for occupied block. Would it not suggest that we take steps on our respective railroads to put in motion some scheme to correct the trouble?

The proverb that impressed me strongest, perhaps, in my young life was "knowledge is power," but most knowledge is so generalized that it is not susceptible of application. It has been my opinion, ever since we undertook to work in this safety field, that our knowledge was too general.

The next general heading to which attention is called is Air Brakes. All of us know the danger of improper application of air brakes. We know about the danger that arises from improper maintenance of brakes. We know about the danger that arises from insufficient air pressure. We know all about the dangers that are related to the air, but we do not know about it specifically. Our boys who were formerly with the Interstate Commerce Commission are more familiar with that than we are, but wouldn't it be a fine thing if we knew exactly what the record had been in the United States for the last ten years?

I can tell you frankly that I have developed for specific purposes at the cost of much time and effort much information that these statistics would provide without any effort.

Those of you who are familiar with that subject know that car inspection at loading points is one of the most indefinite things on the railroad. Put your Safety Committees on that particular thing, and you will find out that some stations have inspection very carefully done; you will find that at others it is not so good. If we can develop statistics, over a series of years, of accidents that are attributable to faulty inspection, then we will have the knowledge that will lead us to understand what to do in connection with the loading of cars.

Then under miscellaneous we have malicious acts or other misbehavior of outsiders, and other ascertained causes which are quite numerous and which you can all get from the Interstate Commerce Commission's classification.

What I have said thus far relates entirely to Train Accidents. I want to direct your attention just a few more moments to Train Service Accidents, the ones with which the Safety Committees are probably more frequently bothered, but not by any means the most important.

We have eight classifications under what we call Train Service Accidents. The first heading is Coupling and Uncoupling Cars. Under this heading we have fifteen causes arranged to the best of the ability of the Committee and giving every detail which will enable the safety committee men and the safety agents to lecture or talk on the subject.

For example, there were nine killed and 149 injured during the first month of the year, which would make 108 killed and about 1,800 injured during the year. Of that number, some were due to:

1. Adjusting coupler, unexpected movement of cars due to slack.
2. Adjusting coupler, unexpected movement of cars due to other causes.

The next would be operating locomotives, under which heading there are a considerable number of accidents.

You have been sympathetic in listening to me. All I want to say is this: We do want to put safety on a practical basis. We want to make everything that we do just as reasonable, just as scientific, just as businesslike, as we can. We want to refrain, as far as possible, from unnecessary work. We want to educate also ourselves, our committees, the superintendents, and everybody else.

I recommend particularly that young men who are taken into the service be first instructed to study and master the causes of accidents. In that way, I fully believe that in the course of a few years we will arrive nearer to a satisfactory solution of the safety work than in any other way.

CHAIRMAN RICHARDS: I am sure we have all been very interested in Mr. Carrow's address. He said something about knowledge being power. Somebody said, a great many years ago, that we get knowledge from other people's experience and from books but that we get wisdom from our own experience, and wisdom is what we want.

Possibly, if this information, which has been set forth so intelligently

by Mr. Carrow, can be disseminated among all the members of this Section and the other sections of this great Council, we will all have a chance to get not only knowledge but wisdom.

The next report that we have is from the Program Committee, of which Mr. Clark is the Chairman.

REPORT OF PROGRAM COMMITTEE

MR. J. C. CLARK (Oregon Short Line): I don't believe that the Program Committee has any particular report to make. We tried to pick out subjects for discussion at this meeting that would be comprehensive and would catch the vital points in connection with safety work. We thought that you would come here to get a certain amount of information and inspiration and also to impart a certain amount of information and inspiration to others. We picked the subjects that we thought would cover the field most thoroughly, but to get the full benefit of your attendance here and to make this meeting thoroughly interesting, it is necessary for every one of you to speak your mind with regard to each subject when it comes up for discussion. In the discussion of the various subjects and in the benefit received by exchanging ideas is to be found the chief benefit of this meeting.

I hope the program will speak for itself.

CHAIRMAN RICHARDS: I am sure that this Section appreciates the work that has been done by the Chairman of the Program Committee. We gave him one of the hardest jobs we had because we knew he was one of the best workers in the organization, and he certainly has turned out a fine program which you will come to realize as it proceeds.

The next report we would like to hear is that from the Publicity Committee. Mr. Dow.

REPORT OF PUBLICITY COMMITTEE

MR. MARCUS A. DOW (New York Central R. R.): I think that the bulletins that have been distributed during the past year ought to serve as a report of this Committee. However, for your information, I will state that this Committee has held three meetings since it was appointed a year ago, and material has been prepared and submitted to the Council for seventy-five separate bulletins. Five of those were bulletins that have previously been issued which were reissued during the year. Seventy of them were new bulletins.

Your Chairman has employed the services of a professional photographer, and we have taken over 200 specially-posed photographs for the purpose of illustrating bulletins, so that every bulletin that has gone out during the past year has been illustrated with from one to three illustrations.

The Council now has on hand material for enough bulletins, furnished by this Committee, to carry them through, issuing one bulletin a week, until the end of March next year.

CHAIRMAN RICHARDS: I do not think that any of you gentlemen realize the amount of splendid work that has been done by the Publicity Com-

mittee and the amount of time and thought that has been given to the matter. I am very sure that if this Section will be a little more generous in furnishing suggestions and photographs and ideas to the Publicity Committee, the service that will be performed by that Committee will be as useful and beneficial to the Section as that of the present Committee.

I want to say again in this connection that if you have some specific accident that you want to illustrate or call attention to, something that may be new or unusual, and will furnish that information to the Chairman of the Publicity Committee, he may be able to illustrate it in a way which will be very beneficial to all the members.

The next report will be from our old friend Blakemore who served so many years valiantly as the Chairman of the Membership Committee.

REPORT OF MEMBERSHIP COMMITTEE

The Committee as formed this year consisted, in addition to myself, of the following gentlemen:

G. L. Ball, Superintendent Safety, St. Louis & San Francisco

D. H. Beatty, Superintendent Safety, Southern Railroad

C. L. LaFontaine, General Supervisor of Safety, Great Northern

L. F. Shedd, General Supervisor of Safety, Chicago, Rock Island & Pacific to whom I now wish to express my grateful appreciation for the coöperation they have given.

During previous years, by the most strenuous effort, we had raised the membership of the Railroad Section from its initial roll of 27 members to 63, then to 87, then to 103 and this year, as the United States Railroad Administration had given its approval to affiliation with the Section, I anticipated no difficulty in bringing into the fold all those other lines yet outside, but I was surprised to find still a certain indifference to our appeals; many of the lines approached being reluctant to join because of the increase in dues, which had been made absolutely necessary by reason of the higher cost of labor and supplies, so that withal the membership campaign did not resolve itself into the sinecure which I thought it would probably be. However, results have been produced of which we are very proud, the following lines having been brought into the ranks:

Arizona Eastern Railroad Company,

Atchison, Topeka and Santa Fe Railroad,

Belt Railroad of Chicago,

Boston and Maine Railroad,

Brooklyn Eastern District Terminal,

Central Vermont Railroad,

Charleston & Western Carolina Railroad,

Chicago and Alton and C. E. and St. L. Railroads,

Chicago and Western Indiana Railroad,

Duluth, South Shore & Atlantic Ry. and Mineral Range Railroad,

Duluth, Winnipeg and Pacific Railway,

Fort Worth and Rio Grande Railway,

Georgia, Southern and Florida Railroad,

Grand Rapids and Indiana Railway,

Grand Trunk Lines in New England,
 Green Bay and Western Railroad,
 Gulf, Colorado and Santa Fe Lines
 Gulf, Mobile and Northern Railroad,
 Kansas City Terminal Railroad,
 Louisville, Henderson and St. Louis Railway,
 Louisville and Nashville Railroad,
 Macon, Dublin and Savannah Railroad,
 Maine Central Railroad,
 Minneapolis, St. Paul and Sault Ste. Marie Railroad
 Norfolk Southern Railroad,
 Northern Pacific Railroad,
 Northwestern Pacific Railroad,
 Pennsylvania Railroad (Western Lines),
 Pittsburgh and West Virginia Railroad,
 Sioux City Terminal Railroad,
 Southern Railroad Lines,
 Terminal Railroad Association of St. Louis,
 Toledo, Peoria and Western Railroad,
 Toledo Terminal Railroad,
 Ulster and Delaware Railroad,
 Union Terminal Railroad Co.,
 Virginian Railroad,
 Waterloo, Cedar Falls and Northern Railroad,
 Wheeling and Lake Erie Railroad,
 Wichita Valley Railway,

a total of forty new members.

At the close of last year's work 103 railroads appeared upon our roster, but during this year 14 of them withdrew, reducing the number to 89 as the actual basis for calculating the beginning of the year's work. Today there are 129 members, an increase of 40, or 45 per cent. One year ago the memberships represented about 171,000 track miles. Today they represent nearly 216,000 track miles, an increase in mileage of more than 26 per cent.

One of the most important factors contributing to the success of this campaign was the assistance given us by the Regional Supervisors of Safety, not in urging that memberships be taken, but in helping us to fairly present our cause, and I take this occasion to make record of my sincere appreciation.

Now just a word about the future: It takes a bolder man than I am to forecast the railroad situation for next year, but I think we may safely assume that there will be changes, both in sentiment and in practice, and amid these new aspects may come dangers to this organization which has been so carefully built up. I, therefore, strongly urge that during the coming year each one of you give to your Membership Committee your utmost support. When your membership expires, hasten strongly to recommend its immediate renewal, and lose no opportunity to use your personal influence further to build up the Section, for thus,

and thus only, can we feel assured that your organization will come safely through what promises to be the most trying year of its existence. Remember that it is *your* organization and that upon *you* largely depends the continuance of the association which all of us have found so pleasant and profitable.

C. H. BLAKEMORE,

Chairman Membership Committee.

MR. D. P. BROWDER (Richmond, Fredericksburg and Potomac Railway): The administration, as I understand it, has authorized the railroad companies to take membership in the National Safety Council, but it affects us in this way: The authority they have given is limited to miles; a railroad of 100 miles can have but one membership. We have a very prosperous little railroad. In fact, we have three that I represent, and the total mileage is 116 miles. I think if Mr. Duffy or somebody could get a new way of allotting memberships based on earnings rather than on miles, it would help us considerably. We require more than one membership to get bulletins.

CHAIRMAN RICHARDS: Every member of this Section knows that regardless of any membership or any number of memberships they may have in the Council, they can purchase all the bulletins they desire at cost price.

MR. BROWDER: As I understand the rules of the Council you have to take membership to get bulletins.

CHAIRMAN RICHARDS: That is a matter that might be brought up at the round table discussion, Friday afternoon or Saturday, when everybody will have an opportunity to thrash out these questions.

You have heard the reports of the Committees. They were received in an informal way. There was no motion made that they be adopted and placed on file. That is in order now.

(On motion the reports were adopted.)

CHAIRMAN RICHARDS: The first paper that we have this morning is that by Mr. Duffy, Manager of the Safety Section of the United States Railroad Administration. Last night, we were told by Mr. Lee that he had known Mr. Duffy for twenty-five years, that during that time he had grown very fond of him and had great respect and admiration for his ability and for his manly qualities. The members of this Railroad Section came to that conclusion very much quicker than did Mr. Lee, because we have only known him about two years but we found that out about the first time we met him. I know you will all be very glad to hear from Mr. Duffy.

AIMS AND PURPOSES OF THE SAFETY SECTION OF THE UNITED STATES RAILROAD ADMINISTRATION

A. F. DUFFY, MANAGER, SAFETY SECTION, UNITED STATES RAILROAD ADMINISTRATION, WASHINGTON, D. C.

We are living in the greatest period of the world's history. The war, which as an armed combat, ceased slightly less than a year ago, has

changed many of the important fundamentals upon which this country was built. The entire industrial structure was altered to meet war conditions, and now must be again changed to meet situations resulting from the victorious peace accomplished largely through the indomitable will to win of our Army and Navy. We owe a real duty to those men who returned and to all people who in even a small measure contributed to this achievement, but we are everlastingly obligated to those men and to those women who did not come back from foreign service and to their families and dependents. The war taught the people of this nation as nothing else could have done that the most precious thing in the world from a humanitarian standpoint, and the most valuable economically, is human life—this greatest of all assets of individuals and of the country itself. I take as a matter of course the fact that our duty as safety men and women in the national developments is clear cut and without equivocation or reservation. I subscribe firmly to the belief that Safety is more than the conservation of life and limb, that it will do more than any single agency of which we now have knowledge to create industrial conditions and practices and principles which will render the employment of the man who works not only safe, but satisfactory and economically just from every standpoint.

Safety is basic in any business where physical hazard is involved, for if you will look about you, I venture you will perceive that the best railroad is the safest railroad and the most efficiently and satisfactorily operated from the standpoint of the people, the Government, the owners of the property and last but very important, the men who work on that railroad and who have it in their hands to make it a successful organization or a mediocre enterprise. No right-thinking student of current national events can fail to discern these indisputable facts.

I can best respond to the subject assigned for my address "Aims and Purposes of the Safety Section of the United States Railroad Administration," therefore, by stating with all the force and honesty of purpose and sincerity in my command that these facts as I have stated them by way of prefacing my remarks will be so intensely and indelibly impressed on the minds of railroad men and women that the transportation industry will be so humanized, and that our work will be conducted with so much intelligently applied energy, that we shall reach the high attainment which the Director General of Railroads had in view when the Safety Section of the Division of Operation was created, whereby avoidable casualties in railroad employment will be mere history.

And, my friends, this is not the mere theory of an idealist. I have been a practical railroad man during all of my working life, and I predict, without qualification, that when once the railroad men of this country thoroughly understand what we are endeavoring to do, why it is necessary, and what are the possibilities of this work—and they are rapidly reaching that understanding because of the activities of the Safety Section and the admirable assistance afforded by you Safety officers and employees—they will take hold of this subject in such a manner as to accomplish results which will startle the railroad fraternity.

The President of the United States has called a conference of representative citizens of the country, to be held in the National Capital on October 6. It is significant that this Safety Congress should be held just preceding that important gathering, because Safety is definitely related to every phase of industrialism. And perhaps out of this Congress in Cleveland and the Conference at Washington, there will come an awakening on the part of the public generally to the need for constructive, systematic, well ordered Safety in every branch of industry and in every aspect of life. Safety on railroads has been advanced many years by virtue of the recognition which has been given it by the United States Railroad Administration, and I believe that contrary to the opinion that some of you perhaps hold that this work has but a temporary existence, its permanency is already assured; it has demonstrated its capabilities and is now at the crucial time when a realization of its fullest possibilities is all but at hand. Safety today is a real, live, good-business, energetic force for good on every railroad under Federal control, and any officer or employee who does not believe in it, who does not think it is sincere, who does not give it every support and coöperation which might reasonably be expected, is so outstanding an exception that he had better be careful that some one does not find him out!

REDUCTION OF ACCIDENTS DURING PERIOD OF SIX MONTHS

So that you may understand some of the accomplishments which are now a matter of official record, I desire to call your attention to the fact that during the six months ended June 30, 1919, as compared to the same period of 1918, there was a reduction of 656 deaths and 18,554 injuries to railroad employees on Federally controlled roads; that for the same period there was a reduction of 435 deaths and 1,745 injuries to passengers, highway travellers, and trespassers; that during this period of six months a total of 95,365 conditions and 38,015 practices reported by Safety Committeemen and other employees of the railroads have been corrected and disposed of. And that each railroad under Federal control has now an officer or employee devoting the necessary time to this work with a total additional force of about 150 field assistants whose sole duty it is to supervise, instruct, and educate railroad officers and employees to understand that there is a safe way to do all work and that it must be done in that way. It will be of interest to you likewise to know that on railroads under Federal control there are today approximately 2,000 committees with a total membership of 32,282 officers and employees, devoting their best thought and effort to Safety. When I say that I am proud of that record I have in mind that each of you men should also feel gratified with these accomplishments to the extent that you have done your work efficiently and well.

I give it as my unbiased opinion that railroads—like many other industrial organizations—have not, up to a comparatively recent time, given due consideration to the human factor in industry by recognizing the fact that men and women are infinitely more important than machines, structures, or appliances of any description. When we contrast the de-

gree of care which is exercised in the purpose, use, and maintenance of locomotives with the employment, service, and training of the average employee of the average railroad we are disappointed to learn the inequality which exists as between the machine, which can be replaced with money, and the life, which is absolutely irreplaceable, and which, when once gone, can never be brought back.

Some of us are disposed to be altogether too conservative and reactionary in the activities we employ in conducting this work, and sometimes we are apt to under estimate the value which comes from the financial expenditure required to carry it on. I do not subscribe to the theory that within intelligent and reasonable limitations it is possible to become overzealous or to overdo in a matter of this kind. We must, from the very nature of the work, consistently and continuously develop new plans and methods for creating and sustaining the interest of railroad employees, and of all persons subject, directly or indirectly, to the hazard of railroad operation. It is just as good business, if we must for the moment regard the matter from a monetary standpoint, to expend money for Safety activities as it is to make investments for approved devices which will conserve fuel, increase car loading, improve efficiency, or reduce maintenance cost. It is a great deal more important, and, as a rule, will pay materially larger returns.

In deliberating these matters, however, I urge you not to lose sight of the fact that the aim and purpose of the work of the Safety Section is not to save money, but always has been and always will be to conserve human life and limb. If any saving of money is made by reason of a reduction in casualties,—and we all know that a properly managed Safety Department does save money,—surely that result is not subject to criticism, for in order to save money we must first avoid the casualties themselves.

RECOGNITION OF HUMAN ELEMENT, THE MOST IMPORTANT FACTOR IN RAILROAD SERVICE

The recognition of the human element, then, is the most important factor in railroad service, and its training and education in Safety is the foundation upon which are built the aims and purposes of the Safety Section. And, since the whole scheme of things revolves around the Safety Committee organizations it is to this phase of our work that the greatest attention must be given. There is no more honorable position today on a railroad than that of Safety Committeeman. His is a real service to mankind, and he can be proud of that service, if he is doing all that may reasonably be expected of him. If he is not measuring up to his responsibilities—and they are very real responsibilities, too—it is probably because he has not been properly instructed and trained in his work. Our Safety Committee meetings must be so regulated that the members thereof will be not merely interested in their work, but enthusiastic about it. To this end it is essential that Safety officers or their assistants attend committee meetings frequently in order to insure

their proper functioning and to sustain the interest which is so necessary on the part of Safety Committeemen.

If I were the General Manager of a railroad I would regard the meeting of a general or central safety committee as the most fruitful opportunity, with a minimum expenditure of time and effort, to improve the regularity and efficiency of operation. So it should be with the Superintendents, Master Mechanics, and other line officers in respect to the monthly Safety Committee meetings which they have with officers and employees. If the Chairman demonstrates real interest in the subject by regular attendance at the meetings the members generally are very apt to become imbued with the importance and possibilities of the work. Upon the Chairman depends very largely the success of the meeting, and we would do well to devote a large amount of time and energy to strengthening this feature of our organization.

A fact which will not admit of debate, and which is of prime importance in the relation of Safety to railroad operation, is that when experienced men are taken out of the service because of casualties the employment of new or inexperienced men in their stead not infrequently causes additional casualties to occur, because of the lack of familiarity with the work in hand; and always such a situation decreases efficiency and output, and otherwise costs money and causes hardships. This fact emphasizes too the real necessity for constructive thought and action in relation to the Safety education and training of the new man in the service, and of the employee who is promoted or changed from his customary occupation to one with which he may not be familiar.

PUBLICITY A VALUABLE AID IN ACCIDENT PREVENTION

Another of the aims and purposes of the Safety Section is to secure liberal publicity. Not of individuals or of the Safety Section or of railroads, but of the work we are doing and the necessity for it; of the altogether too large number of railroad men who are killed and injured every year in the business of operating the railroads of this country; of the appalling number of people who are killed and injured each year while wrongfully trespassing on railroad premises, and of the alarmingly increasing number of people who meet death and injury while passing over highway crossings. Publicity is a wonderful thing. It furthered the sale of billions of dollars of securities for the Government during the war, it conserved food, clothing, and fuel for the people associated with us in the war, and performed many other services. It will be of wonderful help in accident prevention if it is judiciously used, not only with employees but with the entire community served by the railroads.

Concretely, this publicity in the case of employees should be in the form of bulletins, posters, pamphlets, casualty statements, and such other data and information as may be deemed advisable. We must never lose sight of the fact that Safety is fundamentally a work of the employees who do the physical tasks incident to railroad operation. They are almost entirely responsible for the accomplishments heretofore

made in this great movement and will be the strength and power for good which will come in the future.

The railroad men of America have responded nobly to the activities of the Safety Section of the United States Railroad Administration. But if we expect them to continue in their interest and enthusiasm it will not suffice simply to beseech them to stop deaths and injuries. It will be necessary to keep them constantly informed as to the number of casualties which occur, what causes them, and what may be done to prevent a repetition of similar casualties. The data, so far as is practicable, should be prepared in some competitive form so that rivalry will be created between the various units of the railroad.

In the case of trespassing and highway-crossing accidents, it has seemed to me for some time that we have not applied ourselves to this vital question with deserved attention. We are too prone to take for granted that nothing can be done to check these evils. Consistent publicity, posters, and the medium of public and parochial schools, automobile clubs, and commercial associations, village, city, county, and state officials represent available avenues of approach in this matter.

I should be ungrateful indeed if I did not on such an occasion make at least brief reference to the National Safety Council. That organization, under whose auspices this great Congress is being held, has coöperated in every conceivable manner with the Safety Section of the United States Railroad Administration. They are doing a splendid work, have accomplished commendable attainments, have contributed very appreciably to the cause of Safety as a national matter. As the officer charged with the responsibility of accident prevention by the United States Railroad Administration, I thank them for this coöperation, and assure the Council of an earnest desire for a continuance of our cordial relations. It is indeed a pleasure thus to express publicly the appreciation we have for the Council.

The Steam Railroad Section of the National Safety Council for the past year has been in the hands of our good friend, that great Safety pioneer, Ralph C. Richards. You know better than I can tell you what it has meant to your Section to have him in charge of its affairs. We all love and admire and respect him, because, in advance of the thought of that time, he conceived the plan of railroad safety. He saw a vision and he has realized an ambition to do service to his fellowmen, which doubtless means a very great deal to him, as it does to all of us.

HIRAM W. BELNAP

At your last Congress in St. Louis, this body heard an inspiring address delivered by Hiram W. Belnap, the then Manager of the Safety Section, who died in Washington a year ago this month. I do not need to tell you about this wonderful character,—for he was a friend to every one who knew him,—except to say that he, too, had a vision—a God given vision of the possibilities of organized Safety. He told you men about that vision at St. Louis; he told you of his hopes and ambitions and of

his determination to make railroading a safer occupation. He told you what he would do and how he would sustain you in your work.

Hiram Belnap was a man of his word, and because I believed in him and what he said and did, I took up this great task when he was called by the Great Father, and with God's help and the help of you men and of every man in railroad service in this country, I have realized a stupendously large portion of the vision which I, likewise, have had in this matter.

SAFETY ENDORSED BY CONVENTIONS OF RAILROAD BROTHERHOODS

It is but natural that certain developments during the past year should stand out preëminently as auguring well for the future of Safety. One of these developments is the truly remarkable interest which has been manifested in Safety by railroad men, as evidenced by the endorsements of the work of the Safety Section in the national conventions of the Brotherhood of Locomotive Firemen and Enginemen; Brotherhood of Railroad Trainmen; Switchmen's Union of North America; Order of Railway Conductors; Order of Railroad Telegraphers; Order of Railroad Station Agents; Brotherhood of Railway Clerks, Freight Handlers, and Station and Express Employees; Brotherhood of Maintenance of Way Employees; with a total membership of 1,182,000 railroad men and women. I think it would be altogether fitting and proper if these resolutions were inscribed on bronze tablets as a perpetual memorial to the work that one of the departments of the United States Railroad Administration has done for an immense body of the finest workmen of the world. The spirit and intent of these resolutions have been observed almost universally by the local lodges of these organizations the country over. I regard likewise as a good omen the fine, intelligent publicity which is being afforded this work by the periodicals of these organizations, the railway employees' magazines, trade journals, and the public press generally.

Another development of significance is the universal approval of the Safety Committee organization and the entire plan for conducting this work as promulgated by the Safety Section. It is encouraging thus to observe as we go along that we are on the right track, and because we are right we are bound to achieve the goal of all Safety men, whereby the lives and limbs of men, women, and children will be saved from railroad casualties, so far as it is humanly possible so to do.

NATIONAL RAILROAD ACCIDENT-PREVENTION DRIVE

I cannot refrain at this time from a brief mention of the National Railroad Accident-Prevention Drive, which takes place on all railroads under Federal control for the period of October 18-31. This is beyond question the most stupendous undertaking of its kind in the history of railroading in this or any other country. We are now afforded an opportunity to demonstrate better than it could be done in any other manner the capabilities of this work. Great things have been done in campaigns of this kind heretofore held in several of the regions, and every one from

the Director General of Railroads to the most humble railroad employee will be watching the record of the October Drive. Most of you have already formulated a program and are actively engaged in this matter now, so that I will not attempt a lengthy statement concerning it. My most cherished desire at the moment is that you men will go away from this Congress with a determination that you will not merely reduce accidents during this Drive, but that you will abolish them, and that when October 18 arrives every railroad man in this country will be steeled to the point of determination to win.

The President of the American Federation of Labor, who is remarkably qualified to voice sentiment of world importance, recently said: "Let us of America face these new labors, then, in the spirit of individualistic mutuality—in the spirit of real democracy." It strikes me that we people, especially those of us who are devoting our time and energy to Safety—and most of us would, if need be, give our very lives to the cause—can well afford to pause and reflect on the wisdom of these few words. The successful culmination of the unsettled state of affairs in this country as they exist today depends largely upon the application of such principles as these, and we Safety men will do well constantly to keep them in mind and to practice and preach them.

SERVICE, TODAY ALMOST A CREED

These, Gentlemen, are days of service, not service to oneself, but service to our families, to our fellow workers, to the community in which we live, and to the greatest of all nations. It has been said that a life without service is a life without hope or happiness. Service today is almost a creed. The war has made it so. And the new industrial era which has come as a fitting climax to the war has intensified that creed. The teaching that we have had in this direction is the greatest inspiration that I get from this wonderful work of Safety—that I am performing a real service to mankind. So it would be with you and with every officer and employee of the properties with which you are associated. More especially should it apply to the Safety Committee members. The idea of service must predominate our every thought and action to the end, which is wholly possible of attainment, that we will demonstrate to all the people that we are men among men, each man being safe himself and having proper regard for the safety of other men.

Thus we will truly make railroading the safest occupation in the world. It can be done. You are the men to do it, and I have an abiding faith in the fact that the railroad men of America are equal to the task.

CHAIRMAN RICHARDS: You have heard this very interesting and illuminating paper by Mr. Duffy. Is there any discussion which anybody would like to make in this connection?

Before we proceed, however, there are two things that the Chair forgot to mention when we were going through our formal arrangements. You will notice that one order of business to come before the meeting was the appointment of a Nominating Committee. It has been customary, I think, since the inception of this Section, to have a Nominating Committee

appointed by the Chair for the purpose of recommending to the Section the officers for the ensuing year.

At a meeting of the Executive Committee held yesterday, it was decided to recommend the abolishment of that practice, and to recommend that nominations for officers for the ensuing year should not be made by a Committee appointed by the Chair or anybody else but should be made on the floor and that everybody should have a chance to speak their minds and nominate their candidates.

With the consent of the Section, the Chair will dispense with the appointing of a Nominating Committee if he hears a motion to that effect.

MR. A. V. ROHWEDER (D. M. & N.): Mr. Chairman, I move that we dispense with the appointment of a Nominating Committee.

(The motion was duly seconded and carried.)

MR. ISAAH HALE (A. T. & S. F. R. R.): Harking back to Mr. Duffy's able paper, I recall the statement that to have real joy one must share it and that happiness is born a twin. It seems to me that we fellows here might, as individuals, see to it that Mr. Duffy's happy enthusiasm or his enthusiastic happiness might find its twin of enthusiastic happiness in all of us.

CHAIRMAN RICHARDS: As Mr. Duffy mentioned in his paper, since the last meeting of this Section we have lost a very enthusiastic and important member of the Section, Mr. Hiram W. Belnap. The Chair has taken the liberty of appointing a Committee, of which Mr. Meyers is Chairman, to present to the Section a resolution in relation to Mr. Belnap.

MR. FRED MEYERS (Wabash R. R.): Mr. Chairman and Fellow-members of the Railroad Section of the National Safety Council: We have prepared a set of resolutions, as our Chairman has stated, which we should like to have acted upon here.

In presenting the resolutions of respect to our departed friend, fellow citizen and co-worker, Mr. Hiram W. Belnap, as chairman of the committee appointed to draft same, I feel the time very opportune to make a few remarks outlining briefly some of our friend's deeds.

Brother Belnap was born in Nakomia, Ill., June 21, 1867. His father was an operator and agent for over thirty years on the Indianapolis and St. Louis Railroad, now the St. Louis Division of the Big Four. He learned telegraphy under his father and assisted in the telegraph and station work for about two years. Later he accepted a position as passenger brakeman and remained in that service about six months when he entered freight service as a freight brakeman. He served in that capacity for a little over two years, being promoted to a freight conductor in 1893. From 1893 to 1903 he was employed on the St. Louis Division of the Big Four in that capacity. Resigning his position there August 1, 1903, he entered the service of the Interstate Commerce Commission as an Inspector of Safety Appliance. On July 1, 1911, he was made Chief Inspector of Safety Appliance and later Chief of the Bureau of Safety, Interstate Commerce Commission. On February 19, 1918, he became Manager, Safety Section, Division of Operation, United States Railroad Administration, which position he held at the time of his death, October 12, 1918.

Brother Belnap was a very active member of the Order of Railroad Telegraphers and the Brotherhood of Railroad Trainmen. He assisted the organization and officers of the Order of Telegraphers in many ways while occupying an official position in Washington. As a member of the Brotherhood of Railroad Trainmen from July 10, 1892, he participated actively in all its affairs, having served on the Board of Trustees, also a Vice-Grand Master. —

It was while serving the Interstate Commerce Commission that he rendered railroad men untold service. His utterances on his specialty of safety work were inspiring and clear. He sounded the true note, not merely for ideal safety, but pointed out in practical lines the rules of conduct essential for the conservation of life, and the promotion of safety on railroads. —

Being a natural leader of men, his untimely death robbed us of a strong and able guide and after years of service in behalf of mankind. God called him home at the very moment his biggest life work was to bear fruit—the organization of safety work on all Government railroads.

The corner stone of Safety First has been laid and to him we owe some fitting memorial. We can in a small measure acknowledge this service by placing upon the records of this organization our resolutions of respect.

"He lived and everybody loved him;
He loved and was never alone.
His associates were loved by him,
And God loved him and took him home."

RESOLUTIONS

Adopted By

NATIONAL SAFETY COUNCIL

(Steam Railroad Section)

At Annual Congress Held at Cleveland, Ohio, October 1-4, 1919

WHEREAS, The Great Arbiter of the destinies of men, on the twelfth day of October, Nineteen Hundred and Eighteen, summoned to his last, long rest, our friend, fellow citizen, and co-worker in Safety,

MR. HIRAM W. BELNAP

Manager, Safety Section, United States Railroad Administration, and a man prominent in the great humanitarian movement among railroad men in particular, therefore, be it

RESOLVED, That, in his death, our country lost one of its most upright, progressive, and valued citizens, the railroad fraternities, and the Safety Organizations of the United States, one of their most successful, valued, and constructive associates; and be it further

RESOLVED, That the deep sympathy, respect, and friendship of the Officers and Members of the National Safety Council, Steam Railroad Section, through a copy of these resolutions, be transmitted to his family,

and a copy spread upon the minutes of this Council in session, as a tribute to our departed friend.

(Signed) R. C. Richards

Chairman, Steam Railroad Section

F. Whitemore

Secretary, Steam Railroad Section

L. G. Bently

M. A. Dow

Fred Meyers

Chairman, Resolution Committee

Arthur V. Rohweder

Peter Groome

John T. Broderick

Thomas H. Carrow

Fred M. Metcalfe

Committee

I move the adoption of these resolutions, Mr. Chairman.

MR. ROBERT SCOTT (Atlantic Coast Line Railroad): In seconding this motion, I would like to say that this Committee has not in the least been extravagant in the language that they have applied to our deceased friend, Mr. Belnap.

MR. H. A. ADAMS (Regional Supervisor of Safety): I would ask that in passing this action the audience arise and stand in silence for one minute.

(The motion to adopt the resolutions was carried by a rising vote.)

CHAIRMAN RICHARDS: These resolutions will be shown on our minutes and a copy will be sent to the family of our deceased friend.

The next paper on our program is by our friend Marcus Dow, on "Value and Necessity of Safety Agents".

THE VALUE AND NECESSITY OF SAFETY AGENTS

MARCUS A. DOW, GENERAL SAFETY AGENT, NEW YORK CENTRAL LINES

Safety work, ever since this life-saving and conserving idea was first conceived, has been in a continual process of development and improvement, and I think that we can safely say has now passed from the experimental stage into the stage of scientific development along the lines of proven effectiveness. Wherever safety work has been inaugurated on a railroad or in an industrial plant, the first important step has been to place the responsibility for the development of the work upon the shoulders of some one person. Often-times this responsibility has been placed upon the shoulders of men who were also charged with other duties of such importance as to require the major part of their time, thought, and energy. Sometimes the responsibility for safety work fell upon the shoulders of men who were competent to carry the double burden, but in any event the idea of requiring one officer to devote his entire time to safety work was not taken into consideration, because of the fact that in its first stages safety work had not developed into a work of sufficient volume

required to show the number of employees he has interviewed on the subject of unsafe practices in each department or class of employment, the number of meetings of employees he has addressed—such as safety committee meetings, noonday gatherings of shopmen and others, or meetings of any character. Much of the material he uses in such interviews or personal talks to the men is furnished him from the headquarters of the Safety Bureau or in the monthly staff meeting which he attends, and the information which he imparts direct to the men by word of mouth includes the number of men killed or injured by indulging in certain specified practices and a recitation of the principal causes of injury which he illustrates by the use of illustrated National Safety Council bulletins which he carries with him. Each safety agent in this manner talks to or cautions in a definite and specific way an average of 350 or 400 employees monthly. These safety interviews are held in cabooses, yards, switch shanties, tool houses, and similar places where one or more men can be reached and the time secured for the few moments necessary for the interview.

REQUIRED TO ATTEND COMMITTEES

In addition to the foregoing duties of both inspector and teacher, the safety agent is required to attend each division, shop, and sub-safety committee meeting held in his territory for the purpose of taking part in the meeting, injecting life into it, and encouraging the members to put forth their best efforts in making the safety work effective.

While these safety agents on the New York Central Lines report to the General Safety Agent and are members of the Safety Bureau, they work in close cooperation with the division superintendent—with whose approval they were originally appointed, conferring with that official frequently and either receiving or offering suggestions for a better promotion of the work.

SAFETY WORK LARGELY PSYCHOLOGICAL

I have briefly outlined the character of the work of the safety agents on a railroad system which has found the safety agent to be a valuable and necessary part of the safety organization, for the purpose of showing to you that a man of divided responsibility cannot undertake such detailed work. Safety work is largely psychological. Its function is so to interest each individual employee that he will give personal thought to the work while engaged in his regular occupation, and so thoroughly to impress him with the benefits to be derived by his cooperative effort, by his careful attention, and by his approval that a lessening of the chances of his getting injured or causing an accident will be the logical result. To produce this attitude or frame of mind in the average employee requires *personal* contact and individual mouth-to-mouth solicitation by some one who not only has the time to do it, but who also knows his subject, who thoroughly believes in it and who has the enthusiasm and forcefulness to make his work effective.

VALUE OF WORK DEPENDS ON SAFETY AGENT HIMSELF

If I may be permitted, I should like to have the privilege of briefly discussing, on my own account, a certain feature of this paper. I believe that the necessity of a safety agent and the value of a safety agent will be proven and will depend very largely upon the character of the work which the safety agent himself will perform.

First of all, the safety agent must realize how greatly important his work is and what a privilege it is for him to have the opportunity to serve his fellow-men and his country by helping to prevent accidents. If you should ever, at any time, my friends, have happened to stand on the bank of a river and you should have seen another human being struggling in the water and at once all of the instincts of bravery and of chivalry that lie in the human heart scourged you to action and before you knew it you had your coat off and you were in the water, and after a desperate struggle you succeeded in bringing an unconscious form to the shore, which you laid on the bank and saw revive and breathe and live again, you would have thanked God that you were there and had the enviable privilege of saving that life. You could not but have a wonderful feeling of justifiable pride that you had done something worth while, that you had answered the call of humanity and that when the real test came you had measured up to the full requirements of a real man.

A life saved is a life saved. It makes no difference whether a drowning man is pulled out of the water just in time to save his life or whether, in a less spectacular way, he is dragged from beneath the wheels of a locomotive just in time to save him. The result is the same, and, if I may be permitted to say so, it is because the safety men of the railroads of this country, during the past year, under government control, have responded to the call that so many lives have been saved. Every reduction that has been made in an accident record means that lives have been saved, just as truly as if they were snatched from a watery grave within a few minutes before life would have become extinct. All of you men who did respond to the call, who did respond to humanity's call, who did help to decrease accidents on the American railroads during the past year, had a share in the saving of the lives that were saved, and you are entitled to the same credit and the same feeling of justifiable pride as the man who plunges into the water to save a drowning comrade.

Don't you see, then, my friends, that service as a safety man means something more than merely following certain defined rules and regulations? Don't you see that it means something more than simply drawing your salary as a safety agent?

A SERVICE OF THE HEART

In other words, can't you see, my friends, that when you are given the privilege of serving this country and your railroad as a railroad safety agent that you are given the same great privilege as the man on the river bank who heard the cry for help? Can't you see that safety work is a service of the heart, a service which calls for that spontaneous, ever-

ready, never-let-go, determined effort that you irresistibly put into the saving of a life which you know would be lost without your best efforts?

What a wonderful privilege it is, and how proud we all ought to feel that we have been given the opportunity to share in the credit and in the glory of the achievements in the accident prevention campaign that is to be made because of our effort in this work.

As I have said, so much depends upon the kind of work that is performed by the safety agent as to whether he is necessary and valuable in this work. We must all strive to become leaders in the safety movement. It has been said, at least you often hear it said, that the great majority of accidents to railroad and industrial employees are of a character caused by the fault of the injured person or the carelessness of that person. That is not altogether true; at least accidents caused by carelessness are not necessarily the fault of the injured person. The fault may have been with the man who hired him because he did not point out to him the unsafe things that he must not do, and did not teach him how to do his work safely. It may have been the fault of the other men who worked around him and who are careless and whose habits he followed because he wasn't immune to his careless, chance-taking environment.

It seems to me that a better statement and a more truthful one is that the great majority of accidents to railroad and industrial employees are of a character which can only be prevented when all of the employees and all of the officials get together and cooperate in the task of creating an atmosphere of safety, an atmosphere of carefulness. Here is where the work of the safety agent is of the utmost importance. Ever since the time when history first records the deeds of men, human beings have been known to follow a leader, and good leadership has been the secret of the health and prosperity and success of communities the world over from time immemorial. Likewise has poor leadership left in its wake untold misery, hardship and suffering.

You safety men who give real, honest-to-God heart service in this safety work will be the right kind of leaders in safety work and you will do more than anything else that I know of to help to create this atmosphere of safety, this atmosphere of carefulness. This, then, I believe is the character of the work of the safety agent which makes him indispensable, that makes him necessary to the safety movement.

"THE COMMAND IS FORWARD!"

Safety work, my friends, is essentially a progressive work. It is a work which denies the possibility of failure or retreat. In the great battle of the Argonne Forest, in the recent World War, a young American captain was shot down by a machine-gun bullet and mortally wounded. Two of his enlisted men picked him up tenderly and carried him to the rear. They laid him on the ground, and his first lieutenant, stooping over him with a pencil and paper, took down his last words. Lifting his head painfully, he looked at the first lieutenant and, pointing a shaking finger

to the front, he said, "Lieutenant, the command is forward! Lieutenant, the command is forward!"

Men of America I say to you that the command today is forward. Railroad safety men, the command is forward, forward for country, forward for loyalty, forward for justice, for humanity, for safety. Let you and I who are privileged to act as leaders in the great railroad safety army of America take heed and remember that the command is forward.

CHAIRMAN RICHARDS: Gentlemen, after the inspiring address which we have just heard, Mr. Dow's paper is open for discussion.

DISCUSSION

MR. JOHN S. ROCKWELL (Buffalo, Rochester and Pittsburgh): I have listened with wonderful interest to this splendid paper of Mr. Dow's, and I agree with him perfectly so far as the large roads are concerned. On the New York Central, on the Pennsylvania, on the Santa Fe, and the other big roads, a safety man should be employed who devotes his entire time to the supervision of the work. Safety agents should be employed to devote their entire time to the work. But how about the little roads with 400 or 500 miles? We can't have a man devoting his entire time to the superintendence of the work unless we are satisfied to have a cheap man, and it is thought best by many of the little roads to let some other official, some man who has other duties, act as the superintendent of the safety work. So far as our assistants, our safety agents, are concerned, we think it is better to use men who have work to do in other capacities. On my own little road, I have four men who act in the capacity of safety agents a part of the time. They attend safety meetings; they go about the road talking with different people. Two of those men are district claim agents and they know every man on their entire division. Three of them, rather, are district claim agents. One of them is a traveling store keeper who goes about to every shop periodically, almost weekly, examining the materials in stock, and incidentally he is working every minute for safety. There isn't a man or an employee in all the shops on our system who hasn't been talked to by him on safety.

I think Mr. Duffy will bear me out that the little roads are accomplishing as great a reduction in the number of personal injuries and deaths as the larger ones.

It seems to me that Mr. Dow should have given us some instruction or opinion as to what should be done on the little roads.

MR. FRED M. METCALFE (Northern Pacific R. R.): A feature that struck me very forcibly in Mr. Dow's remarks was the statement that the employees injured are not always injured by their own carelessness. Primarily, yes; secondarily, no. That was emphasized very recently by an inspection trip I made. I found two very bad conditions. The engineering department men were doing some work. They had unloaded a lot of scrap from a flat car right in the pathway of a switch where men were working at night. I saw this pile of barrel hoops and twisted wire and stuff of that sort, and I asked the assistant car foreman who had charge

of those tracks how long that stuff had been there. He said, "I don't know, maybe a couple of days." I said, "Have you seen it before?" He replied, "Yes." I said, "Was it too heavy for you to lift?" He said, "No, but I didn't put it there."

Then I got the yard master. I said, "Have you been around lately?"

"Yes."

"Have you seen this stuff here?"

He said that it hadn't been there the night before. I said, "Do you know that for a fact?" He said, "No."

Then I got the foreman of the bridge and building crew and I said, "Do you know anything about that stuff there?" He said, "Yes, some section men had this flat car out and filled this place up. When we got the car in we had to get rid of it so we dumped it off there." I said, "You are the foreman of this crew of twenty-five men and you let those men drop this stuff there and walk away?" He replied, "Yes." I said, "Don't you see anything wrong about that?"

"Oh, of course, it shouldn't be there."

"Why don't you have it moved?"

When I asked that he called two fellows and said, "Mike, Bill, come over here and take that stuff and throw it away." I said, "Wait a minute. Don't you want to tell those men something?"

"What is there to tell them?"

"Aren't you going to tell them why you asked them to remove that?"

"Why is that necessary? They do as I tell them."

Mike and Bill came over, and I said, "Wait a minute, boys, before you move that. Do you know why Mr. Bell, your foreman, has asked you to move that?"

"No not particularly."

"Why are you going to move it?"

"Because Mr. Bell told us to."

Then I talked to those fellows and showed them why it was that that stuff should be moved.

"I went down to another place where they were loading some 8 x 12 timbers and there they had placed a couple of long skids leading from the end of the ties up to the pile of lumber. They had left those two skids there. I got in touch with the man in charge of the work and I talked to him and the foreman in the same way. He did not explain to those fellows, when he asked them to move those skids, why they should be moved. I am just stating that to illustrate the lack of education on the part of our own foremen in safety work.

How can foremen be good safety men when they don't know enough to tell their laborers why they request them to remove obstructions from the path of work? I thought Mr. Dow's remarks in that connection were very good in illustrating that particular thing.

Easily 50 per cent of the accidents that we charge to carelessness are due to nothing more nor less than lack of supervision on the part of our supervising officers and foremen. Our field men that we put on beginning September 15 were put on solely and wholly to educate the supervising

ing officers and foremen and also to get in personal touch with the men and let them know what is being done.

Mr. C. R. STAPLES (Southern Railway): I would like to ask Mr. Dow what percentage of his monthly personal injuries is caused by bad conditions. Just approximately, what percentage is caused by faulty methods?

PERCENTAGE OF ACCIDENTS CAUSED BY FAULTY METHODS

Mr. Dow: I can answer that in this way: One year's record on our railroad indicates that 9.65 per cent of the injuries to employees were due to defective conditions. We will have to assume that the balance was due to other things.

Mr. STAPLES: I made my confession of faith in the safety movement in 1910 and was received by Brother Richards, and in my line I have been talking safety from that day to this. I have spent a world of time in the elimination of bad conditions. The perusal of the personal injury reports from 1910 up to the present time show me that 90 per cent of my personal injuries have been caused by bad practices, faulty methods, or thoughtlessness. I give that to the new members because I hope it will save them an untold amount of trouble.

Mr. T. P. BRENNAN (Long Island R. R.): One of the gentlemen, a moment ago, spoke of the small roads adopting the use of the store keeper, the freight claim agent and men in various other activities in safety work. You could achieve some things along that line, Mr. Chairman, but a man who has a divided responsibility or an accumulation of duties that pertain three-fourths to something else and one-fourth to safety, is just going to accomplish about one-fourth of what he has to do. In the first place, the man who gives his time to two or three other things is not going to be capable of being a safety agent. I speak as the representative of a small road of some 500 odd miles, conducting the densest passenger service in the United States on any steam road.

There are not enough hours in twenty-four for me to do that safety work. I may not be able to do the work that some of you younger fellows can, but I contend that it cannot be done and done efficiently. It isn't consistent with our organization. We are organized as a safety institution and not as a claim agent or store keeper organization. I contend that it is up to every small road to insist, and it is up to this organization as a safety section to insist, that the small roads assign one man who is solely and exclusively there for one purpose, to learn safety and to carry it on and not have it confined to courtesy and efficiency and a half dozen other different things, and coming in at the tail end. I think it is a thing of which all our small lines should think. The great, big fellows swallow the little ones up once in a while, but while we are small lines, let us stand by our guns.

In Long Island we are trying to make that sort of fight. I believe in one man giving his time to the work and not to a half dozen different occupations.

Mr. FRED W. MITCHELL (New York, New Haven & Hartford). I would

like to ask Mr. Brennan if he hasn't any inspectors or any other employees who give their whole time to safety work.

MR. BRENNAN: I regret to say that we have not.

MR. T. H. CARROW (Pennsylvania R. R.): I think you ought to mention how many employees you have, Mr. Brennan.

MR. BRENNAN: We have only about 8,000 employees.

MR. J. H. STADELMAN (Southern Division, Pennsylvania R. R.): I am connected with the safety work on the Southern Division, and we have committees on each one of our four divisions aggregating a total of about 100 men, and we are trying to impress particularly upon those committees that each one of the men wants to get after all the men on his division as far as he can to get them interested in the safety work. We have a total of 20,000 men on the Southern Division, and we want to get the majority of the 20,000 in the work.

EFFECT OF SAFETY AGENT ON SAFETY COMMITTEE

MR. A. V. ROHWEDER (D. M. & N.): We have two lines with about 1,300 miles of track, and I have thought a while about this safety agent proposition in that connection. We handle a tremendous ore business, and I have often wondered whether it was advisable to put on safety agents. I have always been afraid of the fact that if we put on safety agents, especially on the smaller lines where it is possible for the men in charge of the safety work to get around at frequent intervals, that we are going to destroy the safety committee idea. For example, if you put on a safety inspector at your principal points on the line and you put the job up to him to make corrections and inspections and correct practices and conditions, the safety committee men are going to feel, it seems to me, that part of their job has been taken away. On the smaller lines, I think it would be a good idea for the men in charge of safety to try to drill into the men on your safety committees that responsibility of carrying out, as members of the Committee, the duties that they are to perform. For example, on the New York Central, I have found that that has worked out very successfully. In 1916, the D. M. & N., for example, ran about seventeen accidents per one hundred men employed, and in the first eight months of this year it ran 3.32 per cent, so I believe that our program speaks fairly well for itself.

MR. DOW: As to Mr. Rohweder's suggestion about destroying the work of the safety committee, I will say this: After the division safety agents were appointed on the New York Central Lines, the efficiency of our safety committees increased to an almost unbelievable extent. On some of the committees, the number of unsafe conditions and practices reported monthly are practically doubled because of the inspiration that was given to those committee members through the attendance and the personal contact of the safety agent.

I do not agree with any suggestion that a safety agent will have any effect other than to increase the efficiency of the safety committee organization.

As to the contention that they are not needed on small roads, of course,

I can't speak for the small roads inasmuch as we have about 150,000 employees, but I will say that our safety organization of safety agents furnishes one safety agent for approximately each 6,000 men. I think that takes care of the suggestion that they are not needed in small units.

MR. E. S. CHAPIN, JR. (Pennsylvania R. R.): I have had some experience along the same lines as indicated by Mr. Dow in addressing safety committee meetings where recommendations were made in perfectly good faith by the members of the committee, which were, to a certain extent, impractical, or they might have originated at some other time and place and been met by certain measures which were found successful. In that way, knowing those points, I was able to advise the members of the safety committee so that they could intelligently draft their recommendations, possibly remove the impractical ones from the report, and point the way in which the other ones should be corrected, without their taking the time to worry about how to do it.

I feel that is a field where the safety agent, in whatever guise he may appear, can help and strengthen the hands of the safety committee members.

MR. BRENNAN: I will add to my previous remarks in regard to the appointment of a safety agent that I took the figures of our little road and I found that prior to the appointment of a safety agent, we had five suggestions on conditions, on practices and signs that we reduced three to one by going among our committees and bringing before them the importance of those things.

I might say, for the further elucidation of the question that Mr. Mitchell asked, that while we have no men exclusively as inspectors, we assign members of the several committees to those duties, and they feel it is an honor to be so assigned to assist in making inspections.

MR. JOHN T. BRODERICK (Baltimore & Ohio): I might say, for the benefit of the members of the Council present, that on the Baltimore & Ohio system, for a number of years, we conducted our safety work without the assistance of safety agents. We got along, it is true, and made good progress. About fourteen months ago, to intensify our work and to try to accomplish more than we had in previous years, we adopted the idea of the appointment of safety agents, and today we have six and we have had them for fourteen months. I am glad to say that those men have more than proven their worth. We feel that it has stimulated the work of our safety committee men. It has proven very valuable in many ways. Those men are all practical railroad men of experience, and the great good that we are getting from their services I can hardly measure in dollars and cents, and I think the same idea applies equally as well to the small roads as to the larger roads. Were I the representative of a small road, I certainly would press the idea of having at least one safety agent.

MR. H. M. ADAMS (Regional Supervisor of Safety): I have listened with a great deal of interest to the paper by Mr. Dow, and the discussion thereupon relative to the proper installation of committee organization has been very interesting. I know of no point that is of greater interest in getting the results that we are setting out to attain than the proper or-

ganization as to the sufficient number of safety agents, let the road be large or small.

I have in mind one large trunk line in the Central Western region that for several years, with 14,000 miles of track and some 50,000 employees, was handled by one man. Today, that gentleman has five efficient men from the ranks with him, and he is getting wonderful results. That is true with all of the large trunk lines with the exception of one in the Central Western region. That particular line has, I believe, four or five field agents, but the sphere in which those field agents work and the duties that have been outlined to them, carrying out other duties that are not in accord with the safety movement duties, I might say, to be specific, requires them to act as secretaries of the various committees, take care of all the clerical work and thereby relieve the various committees of their duties, taking away their initiative. That is the kind of field work, in my opinion, that will work as having a negative effect on the safety work.

The field agent in the name and meaning in which he is appointed to supervise, to attend and direct, is one of the most valuable assets that this safety section can create.

Mr. E. G. STEINER (Indiana Harbor Belt R. R.): I think we are classed as one of the smallest railroads, but I feel that it is one of the biggest little railroads that I ever saw. I think that the average small railroad makes a mistake if it does not appoint enough help to look after its men, just the same as they do on the trunk lines. We have only about 100 miles of road, and while I only have about 2,600 or 2,700 employees on that line, I have been able to make but three full inspections of the property since last February, and it is utterly impossible to think of handling more than 2,500 men or employees and do it properly where you have all the departments to look after.

Of course, we have a good many steel plants there, and they create a good deal of trouble for us. There are lots of other industries there, too, but where I get the most good from contact with the men on the outside is when I can be out on the road, riding with the crews. Those of you who have been in train or engine service will know that those men won't put their names to conditions. They want to tell it to you, and you have got to be out there to get it. That is where I get it, and so when possible we get to them with the personal touch and work on the conditions as they present themselves, taking that which is seemingly most important. I might have a line of work laid out for one day; something might come up at the extreme end of the line; I would drop the whole work and go there and have it corrected.

I think that the small railroad should have one or more men just the same as the larger ones, because it only requires one good, fair-sized accident to pay his salary for a year and he can't attend to other duties and pay proper attention to safety work. I do the examining of the train rules on our line, and it gives me an opportunity to talk safety in every examination, and that is why I welcome it.

It is only this intensive action and contact, day and night, being out with these men in all sorts of weather, that brings the results that we

want. If I don't get out with them late at night, I can see them early in the morning, and it is at times like that I find out what is going on on the railroad.

Mr. Dow: As a further evidence of what the management of the New York Central Lines thinks of the safety agent, let me say that in connection with the forthcoming national railroad accident prevention drive, I have had assigned me special men for the purpose of interviewing every employee on the railroad and soliciting his cooperation in this drive. There are to be five and six and ten on every division, and we will have 400 safety agents during the month of October.

Mr. E. M. SWITZER (Chicago, Burlington & Quincy R. R.): Mr. Chairman, this matter of safety agents is a very important subject. We have always had safety agents ever since we started safety work, and I don't see how we could get on without them on such a big railroad. We have about 10,000 miles of track. I can't be every place at once, and those men are my eyes to see with, my voice to speak with, but I think that some one ought to point out the danger from an overdevelopment of the safety agent idea. Most railroads are divisionally operated. The unit of operation is the division, and the man at the head of the division is the division superintendent, and we hold him responsible for what goes on in this division. The other divisional officers take their orders from him. If we put a man on his division who doesn't report to him but reports to us, who makes an attempt to do some of the work that ought to be done by that division superintendent, we will find that the division superintendent is very willing to surrender that part of his work to this man because he has a great deal of other work that is very pressing.

I don't believe that we ought to require the safety agent to attend every committee meeting. I don't think that we ought to require him to do any of the secretary's work, or that we ought to require him to be responsible for the success of that committee work at all. That is the responsibility of the chairman of that committee, who is the division superintendent or the master mechanic or the superintendent of terminals, as the case may be.

I repeat that I think there is danger in the overdevelopment of this idea that we may detract from the responsibilities of those men and lessen the efficiency of the safety work.

Mr. HARRY J. BELL (Regional Supervisor of Safety): I don't know exactly the trend of discussion this morning, but Mr. Switzer has so thoroughly expressed my own ideas that I want to subscribe to what he has said and to say, in addition, that we have been talking for years about the superintendents and the master mechanics being responsible for accident prevention, but we have had the accidents just the same. We have to have the safety agents, it seems to me, to follow up the work, to drive home to the superintendent and the other operating and mechanical department officers the fact that they have a real problem in front of them in this work.

The safety agent ought to make it his job to impress the officers with his added responsibility.

It is up to the safety agent to make it clear that his responsibility instead of being lessened by the employment of these men is made greater.

I have attended a good many safety committee meetings where the committeemen, to say nothing of the rank and file employees who had not had an opportunity to serve on a committee, were absolutely ignorant as to what the safety committee plan involved, what they were supposed to do as committeemen and how to do it, what their authority and what their responsibility consisted of.

It seems to me that any railroad, no matter how small, would improve its results materially by the employment of safety engineers or agents, or at least by the arrangement being made in such manner as to give the safety work on a railroad the proper supervision. It seems to me that in a smaller way it is just as necessary to have safety agents as to have train masters. We have train masters to see to it that the train operations are what they should be, that cars are moved, that engines are dispatched properly and promptly, and for the same reason I believe we need safety agents and plenty of them, but, at the same time, bearing in mind Mr. Switzer's warning not to over organize. I think there is little danger, however, of over-organization.

It seems to me that when you gentlemen present this information for consideration before your officers that one of the things that will confront you is the expense involved in such an arrangement and that we ought to be fortified with statistics to prove the possibilities of an increased saving from a financial standpoint by the employment of these men.

I have in mind a railroad in a Western country that had a material increase in its accidents in July, and it was figured that from the standpoint of the train department expense involved in that increase, basing the statement on the fact that the average cost of disposing of a case during 1918 was \$260, the railroad lost over \$21,000 during that one month because the safety work didn't properly function. Whether it was due to the lack of employment of safety agents or not, nobody can very well say. When a large railroad, in six months' time, can save in its train department expense almost \$150,000 on that one line (we all know what it costs to employ a safety agent and get a good one), it seems to me there can be no question about the increased efficiency and results that will be obtained by the employment of safety agents from the great and foremost humanitarian standpoint, to say nothing about the hard, brass-tack proposition that an operating officer might present in connection with the saving in dollars.

MR. JOHN S. ROCKWELL (Buffalo, Rochester & Pittsburgh): I realize that I have been pretty fairly shot to pieces, but I still believe that in my own case I am doing better work than I would if I had hired or should hire a safety agent. We operate 580 miles of road. We have about 7,000 employees. According to the talk here, 7,000 employees would be just about enough for the employment of one safety agent. Three of these young men who act for me as inspectors and safety agents were educated and trained in a school for safety supervisors which is run by our very pro-

gressive Chamber of Commerce in Rochester. They went through that course and got their diplomas, so they are regularly certified safety supervisors, and they go over the road and attend the meetings of the safety committees almost all the time. I attend a good many of them myself. It is my belief, notwithstanding all that has been said here, that I am getting better results from the use of these men who give a portion of their time to the work than I would if I had a single safety agent.

Our safety committees are very active and enthusiastic. We have eighteen committees on our little road, and they are very active and are turning in great numbers of safety reports, great numbers of conditions, though now they are unable to find any more unsafe conditions to speak of and they are turning in unsafe practices.

I realize, as I said before, that you have shot me all to pieces, but I still think that I am doing my work right. We have had a reduction every month. This year we have had a reduction of practically 50 per cent over 1918. I think that is going some.

MR. BRENNAN: I admire a man who stands by his guns even if he knows he is wrong.

MR. H. M. MAYO (Southern Pacific Lines): It is my opinion that the value of the safety agent, as well as the value of the superintendent of safety, depends entirely upon his influence with the employees. The selection of a man as safety agent or safety superintendent who cannot secure the cooperation and sympathy of the employees is a waste of time, energy and money.

Another thing which I call to mind: Recently, on a thirty-day drive in the Southwestern region, one railroad, a small one with four or five hundred miles of track and possibly 1,000 employees, on which safety work had never been done, saw its men pick up the spirit of the occasion and come through without an accident reportable to the Interstate Commerce Commission in those thirty days.

I can call to mind another railroad of some 4,500 miles of track which had no safety agents whatever, yet they made a reduction of nearly 56 per cent in the May drive. On the other hand, a railroad in the Southwestern region that has been well organized, well maintained and has its safety agents, made a reduction of over 70 per cent in the thirty days of the drive. I think, therefore, that you will find by viewing the situation from all of its angles conditions vary, but I still believe, as attested by Mr. Staples and Mr. Dow, that as 90 per cent of the injuries are directly attributable to the fault of the sins of omission and commission on the part of the employees, the conditions will nearly always take care of themselves.

I find, in my limited experience of about eighteen months, that the men are quick to report hazardous conditions, but they very seldom report on their cards or orally at the meetings a condition that approximates an error of practice. However, we have other means of getting at that, and through the men themselves, who, instead of recording as the result of their activities during the month the upturning of evils represented by hazardous conditions are reporting from 95 to 99 per cent errors of prac-

tice on the part of their associates. In that way, we are securing the benefit of the constructive development that is reaching out into every corner of the entire structure, building up a spirit of caution and a spirit of coöperation that we could not get in any other way.

You must have the men with you, and the appointment of any safety agent who cannot secure the coöperation of the men is going to be detrimental rather than helpful, but I believe with Mr. Dow and some of these other gentlemen that a proper supervision is only possible through the employment of outside safety agents or inspectors, and that there is no disposition on the part of the safety committees to delegate any of their authority or activity to the safety agent who really pursues a policy of suggestion to the men themselves.

In the Southwestern region, we have made it a most successful thing and have made a most excellent record; yet that record is divided among roads that have safety agents and roads that have none.

MR. P. GROOME (Union Pacific R. R.): I want to ask the gentleman from the B. R. & P. what other line of duties he follows besides being a safety agent.

CHAIRMAN RICHARDS: He has the same duties that I have.

MR. ROCKWELL: Two of my men are district claim agents, and it is only necessary to point to this gentleman standing here, our Chairman, for everybody to realize and acknowledge that no better safety man ever happened than he, who is a claim agent as well.

MR. GROOME: We will all agree on that as far as our Chairman is concerned, but in our Central Western region, I have in mind two railroads that have heads of safety departments with divided responsibilities. Their responsibilities are so great that neither one of those railroads is represented at this meeting so far as I know, and I have had a chance to observe the work on those lines and know that is true. I have travelled over their lines and attended some of their safety meetings, and I am frank to say that if I were at the head of that road I would want to have a man in supervision of the safety work who would have nothing to do but attend to that.

MR. ISAIAH HALE (A. T. & S. F. R. R.): Harking back to my friend's statement that he has an acting safety agent who is also a claim agent; this thought comes to me: When we launched our work on the Santa Fe in the safety line, that work was an adjunct of the general claim department. My experience was such that I would regard it most unfortunate for any condition to identify the safety movement too closely with the general claim department.

I grant you there is a notable exception in the case of the North Western and Mr. Richards. He has carried the work on the North Western to success simply because he is Ralph Richards, and you would find it very difficult to convince me that Mr. Richards' successor will find it easy to carry on the safety work with that same degree of success and smoothness in working conditions. I am very much opposed to that as a general arrangement.

Mr. Duffy spoke a moment ago of the absence of any comparison be-

tween the importance of safety work and the various conservations that are going on on our railroads. He mentioned fuel supervision. The road is a small one that has not now a fuel supervisor. If the conservation of fuel is important enough to demand the attention of one man's time, or more, then I ask you why is not that greater question of safety also entitled to that same attention?

CHAIRMAN RICHARDS: The Chair has felt great diffidence in saying anything on this question, because, as I stated in the opening of this meeting, I am here to be seen and not heard, but there has been so much said in favor of the division safety agents and the absolute necessity of having safety agents that I am almost obliged to say a little something on the other side.

My friend, Mr. Hale, just said that if it is necessary to have fuel inspectors it is necessary to have safety inspectors. It seems to me that the difference is so clear and plain that everybody can recognize it. We have no fuel committees to look out for dangerous conditions and dangerous practices and things that need remedying. We have safety committees on all railroads for that very purpose. It has always been my idea, although I am not so fixed in it that I cannot be changed, as Mr. Rohweder has well expressed, that there is the danger of lessening the interest of the members of the safety committees and the duties which they are supposed to perform by appointing field inspectors to look after the work.

The North Western Railroad, as you know, has about 8,500 miles of track and about 55,000 or 60,000 employees. We have only two safety inspectors, and our results so far have been at least satisfactory in the ratio of reduction of accidents.

I feel very deeply all that has been said here today in favor of safety inspectors, and I may go home with a different notion, but I think it is only fair to men representing railroads here today that have no inspectors and those where one man is in charge of the safety work who has other duties to perform, to say that I have always had plenty of time to perform the duties of the head of the safety department, as has Mr. Rockwell, because we have always taken time, and we always will take time. We think it is the most important part of our duty—the saving of lives of men who are doing the work on the railroads. Our friend Bell mentions the fact that some great railroad in the West that has a flock of safety inspectors has reduced its personal injury accounts \$125,000 or \$130,000 during the last six months. We have not a flock of safety inspectors, but we have a larger reduction than that in the personal injury account during that same period.

I don't know which is the right way to do the work, and it might be well for this Section to put itself on record as to what it thinks should be done in the way of safety supervision and the management of the safety department, or it might be well for this Section to refer that matter to a committee in order that they might give it careful thought and investigation and report at our next session. It seems to me that this very interesting discussion ought to result in something more than talk. Of course, I don't think that we ought to ever try to measure the success

of the safety organization by the reduction in the personal injury accounts, because the personal injury accounts for the first six months of this year probably cover many cases of last year, and you may have some one accident that, deplorable as it is, might wipe out any great saving that you would make in your personal injury account, which would be absolutely unavoidable. Perhaps there is nothing that any safety committee or any safety supervisor or any safety inspector could do to prevent such an accident that might cost you a half million dollars and increase your personal injury account that much instead of showing a decrease, so I don't think it is fair to measure the success of any safety work on any railroad or in any industry by the personal injury account. We want to measure it in lives and limbs saved and in the saving of lost time and not in the saving of dollars and cents, because that is the last thing that we want to think about.

I was impelled, gentlemen, to make these few suggestions because the discussion had been, seemingly, so one-sided, and my side was only heard from once or twice. If it is the sense of this meeting that we ought to take some real action in this matter, the Chair would be glad to entertain any motion that you desire to make.

MR. HALE: I recall the remark that the most becoming thing to a fool is a shut mouth. It is a bold man who takes exceptions publicly to a statement made by Mr. Richards, but I can't help but fail to subscribe to his statement that while we have safety committees we have no fuel committees. I don't believe that is true, because in view of the propaganda which has been spread during the last year along that particular line in the way of literature and school lectures and moving pictures and one thousand and one different activities, it would seem to me that every engine man today on every railroad is a member of the committee on fuel conservation just as much as the member of the safety committee has enlisted his services under the banner of greater safety, and, therefore, the appointment of a safety agent comes as naturally as the appointment of a fuel supervisor.

MR. J. H. STADELMAN (Pennsylvania R. R.): As a rule, the committees consist of members from the Maintenance of Way Department, such as track foremen, some of the train men in various departments, assistant trainmasters, division engineers, superintendents, master mechanics, assistant master mechanics, and they represent virtually the best talent on the division, and their ramifications are much broader than the number who comprise the committees.

MR. SWITZER: Mr. Chairman, you have expressed the opinion that this Section ought to take some action and make some motion on this important question. I don't think it is going to result in nothing but talk, as you seem to think, because we are all going home with more ideas on this question than we had before, but I don't think that we ought to make any motion with a view to recommending what ought to be done because railroads are not all organized alike.

I spoke before about the divisional organization under which most of us are operating. All railroads are not perfectly organized on the divisional plan. Some have an administrative organization, if I may call it

that, which means that the general officers attend to a great many details which, under the divisional plan of organization, are attended to by the local office, and I can't see how we can make any hard and fast rule about what we ought to do with this question of safety inspectors. What is good for one railroad is not necessarily good for another railroad with relation to this question.

MR. RUFUS S. JARNAGIN (Regional Supervisor of Safety): It is with some timidity that I attempt to add anything to this enlightening discussion. In fairness to John Rockwell on the B. R. & P., I do feel it my duty to tell you just a few things. I have been over the B. R. & P. and have met hundreds of their employees. Of the 7,000 men he has, I think it is safe to say that 6,000 of them know him personally. I think that same thing is true, or proportionately true, on the North Western Railroad in Mr. Richards' case. It is my humble opinion that the safety movement on the North Western and on the B. R. & P. is a monument to the personality of Ralph Richards, and John Rockwell.

No man who knows me can help but know how close to my heart is this question of safety agents. For three years, I rode over some 5,000 miles of track on four or five different railroads on the New York Central Lines west of Buffalo, attending safety committee meetings. In those days, I am frank to say that while we were making small reduction in accidents I would attend committee meetings of twenty-five, thirty, and thirty-five men, and half of them would attend a committee meeting with nothing to report. It was an example of the fact that we were spread out too thin, that we didn't have an opportunity to educate the members of safety committees through our Safety Bureau as to their duties. That necessitated attention on such properties as we have in the East, and resulted in the appointment of local safety agents. These men are known personally to the employees and they reach, within the course of two or three or four months, every employee on the division.

I shall not attempt to burden you with my own opinion further in regard to this condition but merely to recite to you a few facts which I am sure the officers on the individual lines will bear me out in stating.

In the New York Central Lines, safety agents were appointed at different times. In each instance, in the beginning at least, their duties were restricted to the territory covered by one division superintendent. In some cases, it was later extended to two and three divisions, one main line and perhaps one or two of the branch line divisions.

Mr. Dow will bear out this statement that after the appointment of a division safety agent on any single division of that road over a period of some three years, during which time they were being appointed, there was actually a decrease in accidents on that division of at least 25 per cent, and in every case where no safety agent has been appointed there was an increase.

It has been my good fortune, during the past year or year and a half, to talk to every Federal general manager of any railroad north of the Ohio and Potomac rivers, and in talking with them, I have asked them, during the course of our conversation, almost without exception, "What do you

think would happen, Mr. Federal manager, if you could be relieved of all your duties for a single month, even a single week, and go over the road and talk the principles of accident prevention and safety first to as many employees as it would be possible for you to reach?" Almost without exception, although I am frank to say that all these men—big men they are whom I have met—have been extremely modest, they said, "I know the results would be startling."

My next query was, "If you can't do that, and we all know you can't, couldn't we come nearer to accomplishing those results by having your representatives appeal directly to the men?" I think the results in the Eastern region through the appointment of safety agents amply justified that statement. I might go a little further and speak of something else. Mr. Broderick has told you what resulted when he put six men on the H. & O. I am frank to say that I have never met a bigger railroad man than R. E. McCarthy, General Manager of the Pennsylvania Lines. There was absolutely nothing that the safety section of the Railroad Administration wanted that we didn't receive at my first interview with Mr. McCarthy, which resulted in the appointment of an extremely high-class man, Hugh Reynolds, Superintendent of the Safety Bureau, and eight safety agents. Mr. Reynolds will bear out this statement. I believe, that almost the day those men were appointed—all high-grade men, train masters, divisional engineers, assistant train masters—their accidents began to decrease from 35 to 50 and 60 per cent. I believe that statement holds true today, and no man in this room will contend that even before we had safety agents there was a better operated, a more safely operated, railroad than the Pennsylvania Lines West.

The thought I want to bring to you today is that perhaps of all the railroads in the United States there are two single exceptions where we do not need or require, if you please, safety agents, and those are the North Western and the B. R. & P., and that is because only one thing is responsible—the personality of Mr. Richards and Mr. Rockwell.

MR. FRED W. MITCHELL (New York, New Haven & Hartford): You mentioned that the nomination of officers would come from the floor. Tomorrow's program mentions that order of business but it does not specify any time. In order that there will be no misunderstanding, I move you that a specific time be appointed for the nominations and elections. I suggest twelve o'clock, if that is agreeable with the Chair.

(The motion to make a special order of business at twelve o'clock of the nominations and elections of officers for the ensuing year was duly seconded and carried.)

MR. L. F. SHEDD (C. R. I. & P. R. R.): I believe I am right in saying that I voice the sentiments of every soul in this meeting when I say that the paper which Mr. Duffy read to us this morning on this great and important subject is a Duffy masterpiece. In that paper, we heard reiterated by Mr. Duffy those high aims and noble purposes that we heard his predecessor, the late Hiram W. Belnap, state. We heard Mr. Duffy reiterate them at the St. Louis convention, where we realized something of Mr. Duffy's great ability.

In connection with that paper, I believe it is fitting that we in some

way acknowledge better than we have the great inspiration that has come to us and the splendid principles inculcated therein, those principles that will lead to the culmination and the formation, if you please, to the climax, of those plans so well laid by his predecessor and so earnestly desired to be carried out by him. I have particular reference to his conclusion, Gentlemen, where he expressed the great work for us to do. But there is even something greater—his vast personal confidence in us to do it.

I suggest that we now stand in proper recognition of our appreciation of the paper, its sentiments, and the interest of its author?

(The Section gave Mr. Duffy a rising vote of appreciation.)

MR. DUFFY: Mr. Chairman and Gentlemen: You have been magnanimous in your kindness towards me. You have demonstrated by your applause and by your generous thanks that you gave me and by the feast that you gave me last night your appreciation, and I want to say to you that I accept it in no personal spirit other than that we have met here in the safety cause in which we are so intensely interested.

CHAIRMAN RICHARDS: We will now have the last paper on the program. Mr. Doolittle, Supervisor of Safety, Colorado Southern Railroad, was to have presented a paper on "Coöperation of Officers and Employees in Safety Work on Railroads." At the last minute, we got word that he couldn't be here and that he had not prepared his paper. We picked out the man we thought was the best in the Section to fill his place. He is our good friend Fred Meyers. Like a good soldier he agreed to do it.

COÖPERATION OF OFFICERS AND EMPLOYEES IN SAFETY WORK ON RAILROADS

FRED MEYERS, SUPERINTENDENT OF SAFETY, WARASH RAILROAD

It is needless for me to emphasize the necessity for harmonious co-operation between officers and employees of a railroad. We each appreciate and recognize that the principle is the foundation of our safety efforts and achievements. Man alone amounts to very little, it is only when he acts in coöperation with his fellowman that his efforts count for the most.

Experience has demonstrated beyond question of doubt, that the greatest measure of success is brought about where employer or his representative (the officers) and employees meet on common grounds of fellowship, each doing his utmost to further the cause for the benefit of all; each one a part in unity, purpose, responsibility, and service.

The sentiments of Labor (the employee) are today demanding a larger share of recognition and a voice in the administration of business affairs and a share in the profits. I am satisfied the great United States Government wants to see the true interest of employees advanced with justice and equity. The trend toward friendly coöperation between employer and employee has been most marked, particularly since the war

B

threw all classes into intimate association for a common cause, community of interest developed by conflict—A real democracy.

The farsighted wisdom and sagacity of our lamented and beloved manager and Chief of Safety Section, United States Railroad Administration, Mr. Belnap and his democratic, able, and experienced associates and advisors recognized these principles. In U. S. R. R. A. Circular No. 3, uniform methods of organizing and conducting safety work, the employees representing 65 per cent of the personnel, thereby giving them a larger voice in administering the affairs of safety work as well as the larger share in its profits and success.

His excellent address before this Congress at St. Louis last year on "What the United States Railroad Administration Expects of the Officers and Employees" was a clearly defined and intelligent exposition of the duties and responsibilities of every employee from the highest officer to the humblest employee, of the methods and the purposes of this organization which says in effect "get together." I wish he were alive today that he might share in the praise and gratitude of thousands of railroad employees for the blessings and happiness brought about by the education and cooperation of both officer and employee in the prevention of accidents.

The best part of it all was the "punch" he put in it and which his successor has developed so effectively since, when he said to all officers in executive positions that they shall give safety work their active cooperation; that they shall regard it as of the same importance as other branches of railroad work; and that they shall take an intensive interest in it and do everything they consistently can to make it successful. Again when he said that officers and employees shall cooperate to the maximum, and that proper effort shall be made to get all to realize that in safety committee meetings officers and employees meet on a common level, all being members of the committee, and each having an important duty to perform in the prevention of avoidable accidents.

That cooperation has accomplished much is proven by the following figures taken from the Wabash Railroad which I represent. For the first eight months of 1919 84 per cent of all recommendations and suggestions relative to unsafe conditions and unsafe practices have been corrected. Twelve per cent are under investigation or work not completed, or being held up awaiting material and only 4 per cent of the 4,487 suggestions deemed impractical. The result is a reduction of 24 less employees killed and 212 less injured. For all cases 37 less killed and 271 less injured.

These and many other convincing figures could be quoted indicating the remarkable results achieved under our plan and methods of organization of intensified, educational, cooperative efforts.

In passing I am not unmindful of the persistent stimulating effect and guidance of our worthy chief and leader, Mr. A. F. Duffy, and his capable family of efficient, energetic, experienced supervisors who have never found the trail too long, nor the train too late to cooperate with officers and employees in giving the best they had in enthusiasm, loyalty, interest and service. The record of the United States Railroad Administration

will ever stand as a tribute to their guidance and leadership to a cause that is worthy the desires of all mankind. I am, as I well know you are, proud of their acquaintance, association, and friendship.

CHAIRMAN RICHARDS: The opening discussion of this paper will be by Mr. Anderson. As I understand it, Mr. Anderson is the originator of the No Accident Week plan.

DISCUSSION

MR. C. M. ANDERSON (Regional Supervisor of Safety): It seems like Mr. Richards picked me just as soon as I got here. I have just completed a month's trip through the Southern region in the interest of the coming drive, and have made from eight to ten speeches a day, and in that thirty-day period of talking to something like 35,000 men. I thought I had had my share and that I would get to the Council and have a little recreation, in other words, that I could sit back in the rear of the room and have no fear of being called upon.

I want to digress just a moment and give you my experience when I first started on an individual line some four or five years ago. My enthusiasm covered me up. Fundamentally, I went at the work in the wrong way. I am very glad to confess it. I started with the employee. I attended one of the meetings of the National Safety Council five years ago in Detroit, I believe, and I left that meeting with the thought that all I had to do was to go up and down the line, preach safety, possibly have a few parades, wear a few buttons, and the work would be absolutely 100 per cent perfect. Do you know, it took me six months to find out that I was wrong. I started out on my railroad with the employees. I overlooked the superintendents, the master mechanics, the train masters, and many other local supervising officers, and while I was overlooking them, they were looking over me.

I would meet a train master and he would say, "How is the safety movement today?" He would shake hands with me and ask how things were going. In reply, I would say, using an expression we use in the South, "Everything's pretty." He would say, "Safety is a fine thing. It's coming." Then he would wink at the roundhouse foreman when I happened to turn my back. It took me six months to find out that I was wrong and that where I should have started was among the supervising officers before I even attempted to get out on the line and endeavor to get the firing line men with me.

If you can get 100 per cent cooperation between the heads of departments and those whom they supervise, you have an easy job in the way of making a success, which means you will prevent accidents to a great degree.

I want to read to you a very short paragraph from the minutes of a meeting that was held in my office on August 25 at which there were some thirty representatives of the Southern region lines and at which we had the pleasure of having with us our manager, Mr. Duffy. We also had at that meeting a gentleman who gave me a great deal of assistance on the railroad from which I came, Mr. John Kimbro, general chairman

of the B. R. T. We called upon Mr. Kimbro for a little talk, and he made a splendid one. I was very much reminded of his remarks when I first got up here. He said that he was very short on oratory but he was long on facts.

The following is the paragraph that I want to read to you which seems to strike home strong.

"Safety is one of the most important things in the railroad service, and it is different from any other branch of the service. I will tell you why this is: You can put a man in the operating department, and he gets the backing of the management, or you can put him on the road and he gets the backing of the employees, but the man in the safety department does not, at first, get the backing of either the employees or the management until he has made his own record. He has to show that he is saving lives, limbs, and property before he can either interest the management or the employees, but I want to say to you that there is not a man in the railroad service who is higher in my regard than the man in the safety department who is in the work heart and soul, and there is no man who looks smaller to me than the man who is doing safety work just to get by."

The only impression that I want to leave with you and particularly with those who are young in the safety work, is, do not make the mistake and think that the whole proposition rests with those on the firing line. Start right and get the supervising officers educated up to the point where they feel and know that safety work is above all other things, taking into consideration, of course, general operation. After you have done that, you will find that it is a very easy matter to get the man on the firing line to follow.

You remember the old saying, "So is the head, such is the body," and I think it applies very forcibly in safety work.

CHAIRMAN RICHARDS: If there is no further discussion of this subject the session will stand adjourned.

Adjournment.

FRIDAY MORNING SESSION

THE meeting was called to order at 9:40 A. M., Mr. R. C. Richards, Chairman, presiding.

CHAIRMAN RICHARDS: Gentlemen of the Steam Railroad Section, will you please come to order so we can proceed with our program.

MR. H. E. WATKINS (Superintendent of Safety, Terminal Railroad Association of St. Louis): I would like to move that this Section request Mr. Hines to have enough copies of Mr. Duffy's address, delivered yesterday, printed to put one in the hands of each employee on all railroads under Federal control.

(The motion was seconded and carried.)

CHAIRMAN RICHARDS: The first matter that we have on the program

this morning, gentlemen, is the paper on "Organized Labor's Interest in Safety Work," by Mr. W. G. Lee.

ORGANIZED LABOR'S INTEREST IN SAFETY WORK

W. G. LEE, PRESIDENT, BROTHERHOOD OF RAILWAY TRAINMEN,
CLEVELAND, OHIO

Those who know me must have been surprised at the program stating that I was to read a paper. I haven't been in the habit of doing that. In fact, I don't think I could read it so that it would be intelligently understood, and I have been in the habit for a good many years of just talking. That is one of the principal ways I have of earning my salary.

What I may say to you as representative of the various railroads under Government control, and I hope of those roads not under Government control as well, will be said to you from the heart and sincerely, and in the hope that it may be the means of aiding some one to save the life or limb of some associate employee.

I have always known something of the value of safety first. No class of employees, in my opinion, should recognize the value of safety first more than transportation employees. In fact, employees of the transportation companies of this country, whether it be the most humble employee or whether it be the general manager or the president, should recognize its necessity because the terrible slaughter of life and limb that is bound to occur is certainly worthy of the closest scrutiny and the greatest care all of us can give to it.

The organization I represent has a membership of something in excess of 190,000 men at this time. The death and disability list occurring annually is perhaps surprising to the most of you. While I am as much interested in the furtherance of any plan or any legislation that will stop, as far as possible, this slaughter of life and limb as any man in the service, it requires the personal effort of every man engaged in the occupation in order to make it a success. The officers of railroads nor the officers of your safety-first departments cannot make it a success without the cooperation of those they claim to represent, and I have endeavored in every honorable way to encourage those for whom I speak to assist in the safety-first movement at all times.

SAFETY ORDERS NOT TAKEN SERIOUSLY

For a great many years safety first was spoken of. You would see an occasional article in some magazine. You would find an occasional article from general managers or the president of a railroad in substance to the effect that he did not expect brakemen or switchmen to go in between the cars. They must not do it; they must know the equipment is safe before they undertake to make a coupling; they must know that the hand holds on the ladder are in good order before they attempt to climb onto a car. Those were the orders issued by the principal operating officers of some of these big trunk lines, but the subordinate officials under them.

principally yard masters or train masters, men who came in close touch with that class of employees, did not take those orders seriously. They seemingly did not believe that the president or general manager of that railroad really meant what was accredited to him, and so Mr. Brakeman or Mr. Switchman was constantly speeded up and he only knew one thing and that was that regardless of the weather, regardless of day or night service, regardless of the condition of that equipment, when a cut came down over the hump and he didn't get it, he knew he would be hit with the time check. He had no time to inspect the equipment. He had no time to see that everything was as the president of that railroad said it should be before he attempted to handle that car.

AUTOMATIC-COUPLER AND AIR-BRAKE LAWS SECURED

Operating officers generally wanted the safety-first movement if it didn't cost any money, but they hesitated to have certain things that looked to safety put into effect if it cost money. So with all respect to your Chairman, who, I think was first in that movement on the railroad from the operating standpoint, the Brotherhood of Railroad Trainmen claims the credit for the real first safety-first movement in this country and that is not egotism when I say it because the records will prove that thirty odd years ago this organization spent its money and kept the men at Washington to secure the automatic-coupler law and the air-brake law that are in effect in this country now. We were opposed to the finish by interests supposedly being supported by railroad companies. For ten long years we fought that battle and finally succeeded in getting those laws enacted and some of you baldheads and gray heads who have been in the service with me for forty years will remember something of the work required in order to have those safety-first laws enacted. One representative of a big trunk line in this country publicly declared, as the record will show, that he would not equip a freight car or a freight engine on his railroad (if it was possible, by law, to defeat it) with the automatic coupler and air brake. That road is equipped today, and I am confident that those in charge of that property could not be persuaded, under any circumstances, to go back to the old condition. There are many reasons for it and you will excuse the seeming egotism in my saying that the Brotherhood of Railroad Brakemen and Brotherhood of Railroad Trainmen were the first, to my knowledge, and I want to see records produced to the contrary, who spent their money and attempted to do what we think was a safety-first movement.

My experience as an officer of the Brotherhood, now in the twenty-fifth year, is that we were compelled to enact State and Federal legislation in order to secure some of the now recognized safety appliances, safety conditions that are on all of these railroads.

It took a great deal of time and money to do it because it was cheaper in the old days to pay for life and limb than it was to equip the property with the best recognized safety appliances of that time. I am proud of the fact that that day has passed.

Somewhere in your program I noticed a question something like this that is to be considered at your round-table talk as I understand it: Is it advisable that the safety committees' recommendations should be carried out or that the committees should have authority to cause their recommendations to be enforced?

Now, to me, that seems to be the only legitimate solution of the safety-first question. If you are going to have safety committees of good men, of select men, on these railroads, who express and make recommendations as to what should be done to save life and limb, then it is absurd to me because it is not safety first if money is to be considered.

I have always believed and shall continue to believe that any business should furnish the revenue properly to operate that business and it is not a question of money, but it is a question of how can we save a life, how can we save the limbs of these employees and of the travelling public, and when it is determined that if a certain thing is done, even though it costs a few thousand dollars to do it, your committee should have the absolute authority at least to have that put into effect or to know who is responsible for continuing the slaughter.

I was scheduled to talk to you from 9:30 to 10:30, according to my understanding of the program; but a safety-first movement came along in the form of Sheppard, President of the Order of Railway Conductors. He dropped into my office accidentally, not knowing of this meeting, but on other business. I said to him, "You are it. You will go along with me and I will cut my time in two with you and you can impose on those people half of the time I am supposed to abuse them." So my good friends, I want merely to say to you that the Brotherhood of Railroad Trainmen is for safety first all the time. In this gathering I find a number of members of my organization from various parts of the country. They know that they have been told through the official publication, through the official circular, and verbally by myself and other officers to encourage and assist in the safety-first movement wherever possible, and in that way try to stop, as far as they can, this slaughter of life and limb in the service.

We know that as long as these railroads operate, we know that as long as these trains run twenty-four hours in every day and night, boring holes through the darkness as they do, regardless of the weather, regardless of who is in charge of that switch or that tower, we know accidents are bound to happen, we know men will be killed and crippled. At the same time we must recognize that the careless fellow who gets out and lets them hit, has no more scruples than that careless fellow, who, as a brakeman told me, when he didn't go in and give the slogan to slow down, let them hit and broke a couple of cars, and said, "To hell with them; I don't own them." That is the spirit that makes a safety-first organization and committee necessary.

There are men in the service, in all classes of employment, with railroads, who should not be permitted to have a job with the railroad. If they work, they should not be permitted to hold a position as responsible as the brakeman's position even, or any other of the more humble classes of employees, because every one of those units have direct connection with

the main wheel of the machine and the slightest bobble or mistake may cause many deaths or much injury.

My good friends, I am proud of the opportunity to come before you a few minutes and, in the name of the organization I represent, assure you that I will continue, as long as I am with the organization officially, to do all in my power to encourage our membership to help the safety-first movement for their own sake, if not that of others.

Before closing I want to extend an invitation to all of you who may have the desire to come up to the twelfth floor of the American Trust Building if you have a few moments. You will find the International offices of the Brotherhood on the entire floor.

We are fortunate today in having Brother Stone as he expected to sneak in at the door and hear what I had to say and then roast me afterwards.

I am going to surrender the floor so that Mr. Sheppard or Mr. Stone can say a word to you.

CHAIRMAN RICHARDS: I am sure, Mr. Lee, that the members of this Section appreciate very much your taking the time to come over here and make your very interesting address. We appreciate your drafting Mr. Sheppard to come in to occupy part of your time. I take great pleasure in introducing Mr. Sheppard, President of the Order of Railway Conductors.

MR. N. E. SHEPPARD: First of all, I desire to express my appreciation of the honor and pleasure of being permitted to be here on this occasion and to say a few words to the safety section and to those who are so much interested in what to me is very essential for the welfare of men and the proper operation of railroads. I did not expect to have this pleasure because when I was first notified of the meeting, my other engagements were of such a character that I thought it would be impossible to be here. I am very much interested in the work that is now being done on the railroads by men interested in this safety movement, for various reasons. First, it is humanitarian, doing a world of good for man, the most important factor in all creation. Next, it is materially assisting the railroads in their ability to handle the vast amount of traffic that is committed to their care. Third, it enables the railroad brotherhoods to maintain insurance or mutual benefit departments at a much less cost than they could otherwise be operated.

If there were the same number of accidents and as many casualties in this day as there were twenty-five years ago, the rates of these various brotherhoods would be very much higher. They are so little at the present time that they are the wonder of the insurance world. Men in old line life insurance will not believe at first and cannot understand why these brotherhoods are able to have the rates they do. It is the work of men like yourselves in cooperation with others who are interested in their own welfare who have brought about a much better condition on the roads. Therefore, as a representative of the Order of Railway Conductors, I take pleasure on this occasion of expressing to you the best wishes of that body of men for your continued efforts and additional successes in this worthy work in which you are engaged.

Were it not for the constant admonition and constant supervision that men like yourselves give to these problems, many men would unconsciously get into more dangers than they do. Our sense of caution as energetic railroad men lies dormant. Usually we are more concerned in getting results than we are of considering the consequences, and when this safety idea was first promulgated, it was somewhat of a joke, as I think you will all agree with me. Men in the brotherhood looked upon it askance and they were fearful that it was done for advertising purposes only, and there was a time when the dollar was greater than the idea, but I think the time has come when it can safely be said that the principle involved now is being maintained regardless of cost. The railroads, I think, without exception, are doing their very best to make it possible that you can get the utmost results through your safety section and they are not counting the cost as they formerly did, so much so that I know on some of the railroads men will be disciplined if they disobey some of these safety rules. I remember when some men were disciplined how they complained to the organization but they received no support or encouragement from the organization. They were told, "It is for your good and you get in line and support the idea."

It is said of railroad men that weaklings die and cowards resign. I think that is largely true. I didn't resign: I got another job (laughter), but were it not for that very faculty, these railroads could not be operated today. Were it not for the willingness to sacrifice life and limb or take the chance, these railroads could not handle the traffic that is given them today to handle.

I remember when I applied for a position as a brakeman the train-master said to me, "Are you not afraid of getting killed?" I said, "Yes, but I didn't come here to get killed."

That is the spirit of the average railroad man. More than that, it is the inherent quality of Americans in any occupation as exemplified in the recent war. When the Americans got started over in France they never waited for the safety section; they kept going, just as they do in railroads. Therefore, I hope that you will not relax your efforts; that you will get encouragement from all sides and support in every direction.

Without taking any more of your time, I wish to say in conclusion that I thank you for the efforts you are making in behalf of the conductors whom I have the honor of representing. As an officer of that organization I will do my utmost to assist in every possible manner and may this humanitarian work continue as long as railroads are needed and may men grow up to call you blessed.

CHAIRMAN RICHARDS: I am sure we all appreciate very much what Mr. Sheppard has said about endorsing the safety first movement and doing all he can to push it along and make it even more successful than it has been in the past. Assistance coming from such quarters as those we are hearing from this morning is very gratifying to all of us and I know will do us much good.

I think, Gentlemen, we are peculiarly fortunate in having with us this morning a man whom everybody knows, whom everybody recognizes as one of the labor leaders of the country, and I have taken the liberty of

drafting him to say just a few words to you and I hope he will bring a message that will be convincing to us all. I take great pleasure in introducing Mr. Stone. ==

MR. STONE: I only came to hear my friend, Mr. Lee, talk. As usual, he quit when he got half-way through and left the time for the rest of us. Some one has said that if you listen to any great orchestra and listen to one particular instrument, you will always hear a discord. Composers of music say that is necessary in order to blend into a harmonious whole. ==

I am interested in the safety-first movement as any other man should be who is interested in conserving the lives and limbs of the railroad men of this country. We want to do everything we possibly can to uphold the hands of the men who are doing that work, and yet you know, and I know, when we call things by their right names, that a whole lot of this safety-first movement has been a joke from start to finish and it has been the catch phrase for advertising purposes instead of a real safety first movement to save the lives of men. There is no way to get around it.

Safety first doesn't mean anything to me if you have it printed on every box car and caboose and every roundhouse and every street crossing if, at the same time, you are sending power out in rotten conditions to help cripple our men.

On one particular road (I am not going to name it although it has been very prominent in the safety-first campaign) I am sure if you would wake up one of those officials in the middle of the night the first thing he would say is, "safety first." Yet on that particular road, I recall that one of our crack engineers, a man who stood without a peer in his profession, a man who was handling one of the limited trains of this country, and yet, who gave his life because a hand-hold on the side of his cab gave way when he leaned out to look at the hot tender truck and dumped him in the middle of a track in front of a fast passenger train, and yet that hand-hold had been reported time and time again by men who ran the engine. We paid \$4,500 insurance and that man sacrificed his life for the sake of a two-inch screw to hold that rail on the cab. The work on that was done like lots of it—with a pencil. They O. K.'d it and the work wasn't done. You are never going to get the results with your safety-first committee until you have power to force your recommendation and then, and not until then, will you get the results we hope for and anticipate. ==

PUT THE MAN FIRST AND NOT THE DOLLAR FIRST

Gentlemen, the time has got to come some time in this railroad world when the man counts for more than the dollar and you have to put the man first and not the dollar first. I take the position that no money, no outlay that you can make, is too much if you can save the life or limb of just one employee. There is not a single law on the statute books, State or Federal, safeguarding the men, or laws for the improvement of the service that haven't been put there by the combined force of these railroad organizations and against the combined power of capital to de-

feat them, and unfortunately assisted by a few of our friends, who are members of our own organization.

I recall when the air-brake law was put into effect. I don't go back as far as Brother Lee. I was plowing corn when he was doing these things, but I remember when it went on the books, and I know the effort of our own members to defeat it. It has been one long struggle to put these safety laws on the statute books and we all know just as well as we know we are living that under the so-called Federal operation (it wasn't Federal operation you know; the Federal Government simply paid the bill) the safety laws have been lost sight of in many cases. We have a number of operating officers throughout the country who are honestly and conscientiously trying to carry out and enforce the safety laws. Unfortunately we have another group of officers who don't intend to carry them out and the only way to make them be good is to have them come into court and say good morning. When you do that, that is the only thing they pay any attention to and as long as they don't have to do it, they don't intend to comply with safety laws. Our violations of safety laws are increasing right along at the present time. Our violations of the hours of service law are increasing on some particular roads. Why? Because they are not being enforced as they were under private control.

There is one group of men you can try moral suasion on and get results. There is another group of men you have to use a club on if you get anywhere, and you men can make all the recommendations you please with your safety committees on some of these roads, but you cannot get results because you do not have the power to enforce your recommendations. There is no use to print "Safety First" on a locomotive and then send her out leaking steam so badly that the man can't see where he is going. There is no use to do this or that or the other and talk safety first and have your committees and know that you are sending out men with power every day on that particular road that isn't fit for service and isn't fit for men to work with and isn't safe. I believe some one asked Mr. Duffy, "What would they do in a case of that kind?" I think Mr. Duffy replied that if the road foreman O. K.'d it that relieved him.

It may relieve the road foreman but it doesn't relieve the poor fellow who took her and probably never got back with his life.

We are with you first, last, and all the time in enforcing these laws and making safety first a real safety first as it was intended to be in the beginning.

In conclusion I want to extend to you an invitation, the same as Brother Lee. The Brotherhood of Locomotive Engineers has a building over here that we are proud of. Come over and see how a labor organization is really handled in the Headquarters.

CHAIRMAN RICHARDS: Gentlemen, all of the time that was assigned to Mr. Lee wasn't used. I think he has a few statistics that, I believe, would interest this audience and I am going to ask him to occupy the rest of the time and give us the benefit of that information.

MR. LEE: I think each of us who are connected with the transportation

organizations should use our every effort in cooperating with your organization after the roads are returned to private control. In my opinion, it will be more necessary to have a perfect organization then than it really is now, because now Mr. Tyler, Mr. Hines, and those gentlemen who really have the final O. K. to place on these things (I know how they feel in reference to safety first) have encouraged and permitted and ordered the expenditure of a great deal of money while the roads were under Government control, and I doubt whether the same degree of success could be looked for on some of the lines if under private control. Therefore, I think we should use our every effort to try to build up a machine known as your safety-first movement that will be continued successfully when the roads are returned, as they certainly will be before very long.

It may be of interest to those here to know that the men I speak for generally are the younger employees in the transportation department operating the trains and we may consistently look for a majority of the casualties to come to that younger class of employees because of their inexperience, yet the records of my organization do not bear that out. It is not, generally speaking, the young fellow who has only been in the service a few months or a few years, but it is the old timer, as we call him, who steps in the way of a train or goes in between them without looking, or accidentally gets killed or injured in some way in the performance of his duties. I hope you will impress upon those men, particularly, the fact that as they grow older they should become more careful.

ACCIDENT COSTS TO BROTHERHOOD OF RAILROAD TRAINMEN

In the Brotherhood of Railroad Trainmen it may be interesting to you to know that during the year 1917 we paid for 627 accidental deaths in service a total of \$954,400. During the same year we paid for 408 total and permanent disabilities from accidental causes an amount of \$627,200.

During the year 1918, we paid for accidental deaths in service of 691 men a total of \$1,051,600. In the same year we paid for 368 total and permanent disability accidents an amount of \$556,000.

In 1919, up to September 18, we paid for 487 accidental deaths in service amounting to \$875,600, accidental and total permanent disabilities during the same period of 255, amounting to \$425,800.

That is not showing very much of a decrease, but when you take into consideration the war conditions, the traffic congestion, and the many things in transportation that the men had to contend with during that time, I think that this year, 1919, is going to show a percentage reduction over either 1917 or 1918.

It may be interesting to you to know that the one organization, and the other three insurance departments along the same lines, (and perhaps their deaths and disability expenditures have been as great proportionately) which I represent paid for 1,295 deaths; in 1918, 1,458; that for the three years mentioned, 1917, 1918 and until September 18 of this year, 91 of those deaths were caused by collision, 146 coupling cars, 250 falling from train, 150 knocked off cars, 23 getting on or off train, 451 run over

switching, 211 wrecked, a total of 1,322 deaths during those three years traceable to those causes just mentioned.

In the disability payment of claims during the same time: Collision, 10; coupling and uncoupling, 97; falling from train, 104; knocked off train, 82; getting on and off train, 52; run over switching, 394; wrecks, 27. In other words, 766 men have been paid for who were totally and forever disabled from performing the duties of a trainman.

Of the accidental deaths and disabilities only, mentioned here, you will notice that 451 deaths were caused by running over while switching, and 304 disabilities while switching; so that indicates that more chances are taken by these men switching cars than in almost any other occupation pertaining to the movement of trains. I know how those things are done. You old fellows who have been in the service know that we used to pride ourselves on seeing how fast they were going and still be permitted to go in between them and pull the pin. It is a wonder that many of us, who put in the years that we have, are here today.

You may be interested in knowing that during two months, January and February of this year, the organization that I represent paid in excess of one and one-half millions of dollars for members of its organization dying from the result of the Spanish influenza.

I am proud of the fact that our fellows who drew from two dollars a day and up saw far enough in advance to permit the accumulation of a little fund out of which these death and disability claims could be paid, out of which an emergency such as that could be taken care of without an extra assessment on the organization. It is a fact that every one should be proud of and it proves again, to my entire satisfaction, that organized labor should be more interested in the safety first movement than unorganized men could possibly be, because they must put up the money to take care of these death and disability claims to which I have referred.

During the terrible influenza epidemic that swept this country, the record of my office shows that thirty-four years was the maximum age of the hundreds of men who were swept out of existence on account of the "flu." It seemed to have taken the younger element, and so the Brotherhood of Railroad Trainmen and the Brotherhood of Firemen and Enginemen were hit the hardest, of course.

In addition to that came the war, or it was going on at the same time, and let me say this in closing: No class of working men in this country is entitled to more credit for loyalty than the employees of these railroads in this country who gave their services to the war. You hear all about loyalty to the flag and to the colors, and I have seen in years gone by, published statements coming from supposedly eminent gentlemen who said that organized labor, in their opinion, would not be true to the colors, would not be true to their country if this country got into trouble, and were opposed practically to the Government. I am proud that never again can the statement be made with any accuracy to that effect, because on November 1, of last year, eleven days before the armistice was signed, the organization I have the honor to represent had 15,166

members in the army and navy of this and other countries. A majority of the railroad men who went into the service volunteered to go.

On the twenty-fifth and twenty-sixth of September last year, Messrs. Sheppard, Stone, Shay, and myself, were called to Washington and met with the representatives of the War Department because we were asked to assist in getting together another unit of 65,000 experienced railroad men of all classes for use in France by June 1, 1919. We read, or heard read, General Pershing's requisition from France, asking for 65,000 more experienced railroad men because it required a unit of that number of experienced railroad men for each fighting unit of 1,000,000 men in the service. We had in France at that time a unit of 65,000 experienced railroad men, and they wanted another unit because on the first of June they expected to have two units of a million men each fighting, to say nothing of the thousands and hundreds of thousands of men necessary behind them to take care of the issue. I mention that merely to convince you, as it did me, that even General Pershing and the War Department did not know, on September 25 and 26, 1918, nor did they have any idea, in my opinion, that the whole thing was going to be exploded and the war be over on the eleventh day of November. That shows what good guessers they were, and on the ground, too.

In closing I want to thank every man who gave service to his country, whether he worships under the Union Jack in Canada or under the Stars and Stripes in this country. He gave his all. We, who stayed at home, contributed our mite to the fund to pay the dues and assessments and insurance of every one of those men until they were honorably discharged from service.

On the first day of September there were something over 3,000 members of our organization still in army service and we are paying the premium on their insurance until they are honorably discharged.

We, who stayed at home and are gray-haired and couldn't go for various reasons, contributed our mite to take care of the insurance of those men, and it is creditable, I think, and I did not hear a complaint from our membership. I did receive numerous communications saying, "If it costs us who stay at home \$5,000 a month apiece to take care of the insurance of those men who went away and are giving their all, we will willingly pay it."

That is the spirit of loyalty and, still, some gentlemen in the past have said, "Labor organizations will not be true to the colors." You can form your own opinion, and I am not saying that with the slightest discredit to those who do not belong. I have no criticism to make.

These four transportation organizations are not closed shop organizations. They have never asked for closed shops. They have always tried to make their organizations so good that the majority, at least, of the men of their class would see the necessity of affiliating themselves with it rather than a compulsory feature connected with it. These four Brotherhoods have been often criticized by other so-called labor organizations because of our methods. Now, Gentlemen, we make mistakes: we have men who have imaginary grievances; we have our little fights with subor-

dinate officials and sometimes with the National Conference Committee representing all the roads, but it hasn't been very bitter.

CHAIRMAN RICHARDS: I am sure we have all been very much interested and very glad to hear from Mr. Lee, Mr. Sheppard, and Mr. Stone, and I want to say to these gentlemen that we thank them very much for coming here. We want them to bear in mind, however, that the safety movement didn't just happen; it isn't something that just befell. It is something that takes time to make perfect. It took them many years to get these laws that they have talked about, which we all know, now, are good laws, on the statutes. It took them many years to educate people to the necessity of having such laws and that education must come before we can get laws.

I do not believe that there has been any movement started in the annals of our history that has spread so fast as the safety movement in this country. If we will all only have a little patience, the accomplishments that will stand to the credit of the safety movement during the next ten years will be surprising to all of us. I am sure that with their assistance and the enthusiastic cooperation of the men who are in this room and the men who are to follow you during the succeeding years of our organization, we are going to surprise the world in the reduction of preventable accidents.

The next matter on the program is a question that I know we all will be very much interested in.—"Safety Suggestions—How They Should Be Treated and Disposed Of", by Mr. Carrow. We will be glad to hear from Mr. Carrow now.

SAFETY COMMITTEE SUGGESTIONS AND RECOMMENDATIONS: HOW THEY SHOULD BE TREATED AND DISPOSED OF

THOMAS H. CARROW, SUPERVISOR OF SAFETY, PENNSYLVANIA RAILROAD,
EASTERN LINES

The membership of the Steam Railroad Section of the National Safety Council is composed of representatives of nearly all railroads in the United States and since the subject under discussion will be treated in a general way and from the standpoint of all roads, a reading of the following statistics, which indicate the size of the railroads of the entire country, the volume of business handled, the number of train accidents, fatalities and injuries and not only the possibilities of safety work, but the necessity for making safety work efficient, will be helpful:

Property value of the railroads.....	\$ 21,000,000,000
Number of miles of track	400,000
Gross revenue (1918)	4,913,319,604
Number of freight tons carried 1 mile (1917).....	294,040,446,000
Number of passengers carried 1 mile (1917).....	39,739,682,000

Number of railroad employees	2,000,000
Number of different occupations	300
Number of derailments, collisions, and other train accidents (1917)	19,435
Cost of derailments, collisions, and other train accidents (1917)	\$ 15,181,810
Number of passengers, employees, trespassers and others killed on the railroad (1917)	19,087
Number injured (1917)	194,805
Payments on account of injuries to persons including employees, yearly (estimated)	\$ 30,000,000

In the very nature of things railroad work is hazardous and since the beginning of train operation safety has been of necessity a fundamental consideration, the formulation and application of safety rules and regulations and the introduction of mechanical safety devices having been an important feature in the progress and development of the business. It was not until recent years, however, that safety committees, composed of officers and employees from all classes of service, were instituted as a means of enlisting the coöperation of all persons engaged in railroad service in a concerted effort to prevent accidents, and on account of the scope of the safety committee work and the short time the committees have been operating, the field for developing a better understanding of the subject abounds with possibilities.

The May report of the Safety Section Railroad Administration shows a total of 2,051 Safety Committees on the roads under Federal control, consisting of 10,471 "Officer Members" and 21,592 "Employee Members", or a total membership of 32,063. This provides one committeeman for every 62 employees engaged in the railroad business.

Upwards of 300,000 suggestions and recommendations covering dangerous conditions and dangerous practices are being made and recorded yearly by these Safety Committees and fully 80 per cent of all recommendations thus made are being complied with. But an examination of reports shows a marked difference in results accomplished with respect to the number of recommendations made, the character of the recommendations, the manner in which they are stated and the time elapsing between date initiated and the date complied with.

A single illustration will make this observation clear. A Division Committee report for January showed a total of 55 recommendations, all but two having been complied with. The report of another committee contained 23 recommendations, only two of which had been complied with. The inefficiency of the committee last referred to is typical of many others and is primarily due to ignorance of safety work or indifference, which can be eliminated only by the adoption of suitable methods for teaching the details of the subject. For this purpose the following tentative outline of the physical characteristics of the railroad, the items covered by recommendations, the corrective measures necessary to comply with recommendations, the purpose of recommendations, the departments respon-

sible or involved and a separation of recommendations, as between conditions and practices, is made in the order mentioned.

CLASSIFICATION OF THE PHYSICAL CHARACTERISTICS OF THE RAILROADS AND RULES AND REGULATIONS

The first step necessary to develop a definite understanding of safety work is to get clear in the mind the various divisions of railroad property and the rules and regulations governing operations, which are shown as follows:

1. Tracks and appurtenances.
2. Buildings, bridges, tunnels, poles, etc.
3. Machines, tools, implements, and equipment
4. Engines, cars, and trains
5. Fire apparatus
6. Signs
7. Illumination
8. Rules, regulations, laws, methods, and practices (various depts.)
9. Miscellaneous

The next step in the process is to develop a general knowledge of the specific parts of the railroad that may be related to safety under the above divisions. The following classification, which is based on an analysis of eighteen hundred and thirty-six (1836) recommendations, is presented for this purpose.

Tracks and Appurtenances

Code No.	Detail of Recommendations	Number of Recommendations Made	Code No.	Detail of Recommendations	Number of Recommendations Made
1001	Air line and appurtenances in yards.....	4	1252	Fence—N. O. S.....	1

CORRECTIVE MEASURES NECESSARY TO COMPLY WITH RECOMMENDATIONS

After observations of dangerous conditions or practices have been made, the next step in the procedure is to apply corrective measures, 15 classifications being made under this general heading, and the original total of 1,836 recommendations being used as the basis for calculating the percentages, as follows:

	Number of Recommendations
Installation of Guards	140 (8 per cent)
Under this heading are included all recommendations covering apparatus on the track, in buildings or around machines, used primarily for personal protection. As the safety work has progressed, such recommendations have gradually diminished. But there are yet many places on the railroads where guards are necessary, but have not been installed.	
Application of Minor Parts	43 (2 per cent)
Under this heading are included all recommendations that involve the application of small parts which are comparatively inexpensive, such as nuts, bolts, lights, counterweights, etc.	
Other Extensions, Additions, New Construction, Etc.	373 (20 per cent)
Under this heading appear all recommendations covering new work and particularly recommendations that cost considerable money, such, for example, as the installation of derails, stop-blocks, foot bridges, buildings, stairways, etc.	
Change of Design or Kind	71 (4 per cent)
Under this heading are included all recommendations covering change in the design of equipment or parts of equipment or the substitution of one kind for another. Some of the items involved are derails, lids for man-holes or openings, stop-blocks, doors, machines, tools, etc.	
Change in Arrangement	69 (4 per cent)
Under this heading are included recommendations such as change in layout of track, or switches, lights, signals, doors, etc.	
Increased Clearance	147 (8 per cent)
Under this heading are included all recommendations for increasing the distance between tracks and structures alongside the track.	

Steam Railroad Section

1259

Change in Location (Except to Increase Clearance)

Number of Recommendations
57 (3 per cent)

Under this heading are included all recommendations covering change in location of tracks or appurtenances, buildings, machines, etc.

Removal

166 (9 per cent)

Under this heading are included all recommendations for the removal of obstructions on the track, objects that obstruct the vision or anything else that interferes with operation or renders the work unsafe.

Repairs, Adjustments, Replacements, Etc.

442 (24 per cent)

Under this heading are included all recommendations that cover the general deterioration, wear and tear of railroad property.

Providing Tools, Implements and Equipment

49 (3 per cent)

Under this heading are included all recommendations for any sort of tools and equipment that may be necessary in making the operation more safe or efficient.

Rules, Regulations, Laws, Methods, and Practices— Observance of

221 (12 per cent)

Recommendations under this heading include all reference to the enforcement of rules, regulations, laws, methods and practices now in effect.

Rules, Regulations, Laws, Methods, and Practices— Introduction of

42 (2 per cent)

Under this heading are included all recommendations for new rules, regulations, laws, methods and practices.

Providing Additional Help

7 (1 per cent)

Under this heading are included recommendations for Crossing Watchmen, Police Officers or any other assistance.

Dissemination of Information

3 (0 per cent)

Under this heading are included all recommendations for disseminating information, such as letters to employees on safety or correspondence with Superintendents of Schools, local authorities, etc.

MiscellaneousNumber of Recommendations
6 (0 per cent)

Under this heading are included all recommendations not shown above.

Total1,836 (100 per cent)

PURPOSE OF SAFETY COMMITTEE RECOMMENDATIONS

In order to pass intelligently on Safety Committee recommendations it is necessary to define the purpose to be served by complying with them. This is an important feature of safety work and while the duties of a Safety Committee relate primarily to safety there is no restriction placed on helpful suggestions whether for safety or not, although a line must at times be drawn as to what should be considered as within the scope of committee work. The following classification is made in this connection, the original total of 1,836 recommendations being used as the basis for calculating the percentages:

Safety OnlyNumber of Recommendations
1,068 (58 per cent)

A very large percentage of all recommendations are made primarily and exclusively for safety, such, for example, as the erection of a foot bridge, the installation of a derail, the adoption of a safety rule, etc. In other words, if it were not for Safety, action in connection with such recommendations would not be necessary.

Safety, But Regular Operating Requirement

634 (35 per cent)

Under this heading are classified all items that relate to safety but which should ordinarily be attended to in the same manner as any other feature of the railroad business, that is, by the departments involved. For example the cleaning of a yard, the repair to a platform, the installation of a mechanical guard, etc., are duties that rest upon department heads and should be attended to, as a rule, before the Safety Committees have an opportunity to observe such conditions.

Other Than Safety

21 (1 per cent)

Recommendations that appear under this heading are those that in no way relate to safety, such, for example, as measures for the protection of property, the damage to which creates no hazard but merely entails expense or measure for convenience or general efficiency.

Fire Protection

Number of Recommendations
63 (3 per cent)

Under this heading appear recommendations relating to the protection of property from fire.

Sanitation, Health, and Welfare

50 (3 per cent)

Under this classification appear all recommendations for the removal of conditions inimical to health and for the adoption of methods calculated to improve the welfare of employees, such, for example, as rest rooms, drinking fountains, removal of filth, etc.

Total1,836 (100 per cent)

DEPARTMENTS RESPONSIBLE OR INVOLVED

The following classification is made with a view of directing attention to the department and finally to the individual in each department that may be responsible, if any responsibility exists, for the presence of dangerous conditions or practices, the original total of 1,836 recommendations being used as the base for calculating the percentages:

General Management—Transportation Department

Number of Recommendations
..... (0 per cent)

Under this heading are included all recommendations relating to the movement of trains and train rules, that require action of the General Management.

General Management—Maintenance of Way Department

..... (0 per cent)

Under this heading are included all recommendations relating to the track, signal system, bridges, tunnels, etc., that require action of the General Management, such as change in standards or the adoption of general rules and requirements.

General Management—Motive Power Department

12 (1 per cent)

Under this heading are included all recommendations relating to engines, cars or machinery and require action of the General Management, such as change in standards, upkeep of equipment and the formulation of general rules and requirements.

Division Engineer

823 (45 per cent)

Under this heading are included recommendations relating to the Maintenance of Way Department on the Division and, for the most part, relate to new construction and repairs.

Train Master	Number of Recommendations 113 (6 per cent)
Under this heading are included recommendations relating to the conduct of conductors and brakemen and to the introduction and enforcement of rules and safety regulations.	
Master Mechanic	600 (33 per cent)
Under this heading are included recommendations relating to the construction and maintenance of engines, cars and machinery, and the enforcement of rules and regulations relating thereto.	
Road Foreman of Engines	21 (1 per cent)
Under this heading are included all recommendations involving the performance of enginemen and firemen, particularly the enforcement of rules and regulations relating to the handling of locomotives.	
Division Operator	27 (1 per cent)
Under this heading are included all recommendations involving telegraph and telephone employees and the condition of the telegraph and telephone lines.	
Supervising Agent	130 (7 per cent)
Under this heading are included all recommendations relating to safety at stations, such, for example, as the condition of platforms, manner of handling and stowing freight, etc.	
Police Department	43 (2 per cent)
Under this heading are included all recommendations involving the enforcement of laws, the protection of property, breaking up trespassing, etc.	
Floating Equipment	8 (1 per cent)
Under this heading are included all recommendations involving boats of all kinds.	
Joint or Indeterminate	59 (3 per cent)
There are some recommendations that cannot be classified by departments. These should be placed in the general classification, Joint or Indeterminate.	
Total	1,836 (100 per cent)

CONDITIONS AND PRACTICES

Seventy-five per cent of all recommendations cover dangerous conditions and 25 per cent cover dangerous practices, while less than 10 per cent of all fatalities and injuries are attributable to dangerous or defective conditions, indicating that great progress has been made in providing physical safeguards and surrounding railroad operation with measures to protect life, limb, and property. And while there should be no diminution in effort to improve physical conditions, the exercise of greater precaution on the part of individuals is the source from which most results may be expected.

SUMMARY

In the foregoing there has been presented a general outline of the salient features of Safety Committee work. Attention has been directed to the general parts into which the railroad may be divided: the items covered by Safety Committee recommendations, under each part: the measures necessary to comply with them; the Departments responsible for the presence of dangerous conditions and practices and lastly a separation has been made between conditions and practices.

Within these general classifications there must be developed the details necessary to place safety work in the realm of a specific science and as we progress along this line, we shall better understand how to treat and dispose of Safety Committee suggestions and recommendations, a feature of railroad business that is sure to increase in importance as the years roll by.

CHAIRMAN RICHARDS: We shall be very glad to hear from Mr. Hale. I think he is on the program to discuss this paper.

DISCUSSION

Mr. ISAIAH HALE (Safety Superintendent A. T. & S. F. R. R., Topeka): I suppose I might get up and say that the first thing that should be done with a recommendation made to a committee is to determine the merit in it and if found meritorious to put in motion the machinery that would correct it. One trouble with those recommendations is that they are allowed to hang fire too long and another is that when a local committee, for instance, passes that recommendation to a division or a higher committee, although the action may be taken with reasonable promptness, the advice that the action has been taken is very often not conveyed at all or, if it is conveyed, it is relayed in getting back to the committee and the man from whom the recommendation came.

Mr. Carrow tells you that 75 per cent of their recommendations have had to do with conditions. I want to congratulate him. I am nothing, if not honest, when I tell you that I do not believe that our recommendations on the Santa Fe will run in just that proportion, but I think a large number of them have to do with conditions.

I do not mince matters nor use ambiguous phraseology in telling our committees that so long as we come into those meetings and confine our-

selves to talking only about defective conditions, we are not entitled to walk out and kid ourselves into thinking that we have really accomplished very much because what we have accomplished is of a negative or, at least, a questionable value.

The management of the Santa Fe has been most liberal. We did not have as much preparatory work to do when we started our safety work nearly eight years ago as was the case on some railroads, but I really know of no meritorious recommendation that has been made that, if it was possible, has not been favorably acted upon. The management is still willing, as Mr. Carrow's management is, to do everything humanly possible to safeguard conditions, but on the other hand, we must change the ratio between the recommendations that have to do with practices and those that have to do with conditions. We all agree that at least 90 per cent of our personal injuries to employees come from some irregular practice.

We are not entitled to come into our committees, even on Mr. Carrow's basis, and spend 5 per cent of our time talking about the other 10 per cent of our causes.

I believe, along that particular line, that if we don't get the men to appreciate that ratio between the avoidable and the unavoidable injuries that are due to practices, and to talk about them, not only in committees but out among ourselves, we shall fail in the accomplishment of our chief objective.

I am very frank in saying that, so far as the Santa Fe is concerned, we are constantly striving toward that end. Just what the result will be, we cannot prophesy, but the future looks mighty bright because just at the present time we are making a very enviable showing, and it has simply been due to the fact that the men are waking up to that pungent fact to which I have just referred, that if we are to make real headway in our safety movement, we must get the individual man, of course keeping the physical condition of the property as nearly perfect as money and time will permit it to be kept.

CHAIRMAN RICHARDS: Is there any one else here who has the temerity to discuss this paper?

STANDARD SET OF RULES

MR. FRANK A. WIGHTMAN (Regional Supervisor, St. Louis, Mo.): I notice that Mr. Carrow touches on rules. We have found with some eighty corporations in one region, consolidated into nine groups of railroads working under the standard book of rules, so-called, that no two books quote the same language for the most important safety rules under which the men operate.

Rule 22, our flagging rule, Rule 210, our thirty-one train order rule, Rule 26, having to do with the repairs of cars and rip tracks. There is a misunderstanding in our groups where different roads are operating under the same management and I am advised, after receiving a large number of transportation and maintenance books of rules from other regions, that the same conditions exist there, and I do not think that the Railroad Administration could be of more assistance, in any one thing, to

the safety section than if they would get out a standard book of rules for the maintenance and operation of steam railroads under Federal control, and I move you that this Railroad Section recommend to the Railroad Administration such action as would meet with their approval.

(The motion was seconded.)

CHAIRMAN RICHARDS: It has been moved and seconded that this section recommend to the United States Railroad Administration the publication and distribution of a standard set of rules. Is there any discussion?

Question.

All in favor signify by saying aye, contrary no.

The noes have it. Motion lost.

ELECTION OF OFFICERS

CHAIRMAN RICHARDS: We are to have a special order of business at 12:00 o'clock. It is now 11:55. We won't have time to hear any further papers, but before we enter on that special order of business there ought to be some general understanding about the question of nomination of officers of this Section for the ensuing year and the rights of the men present to vote.

The Constitution and By-laws of the Section I will read to you because it practically leaves it to us as to how we shall take the vote in electing our officers.

"Section No. 5. Nominations of officers shall be made by a Nominating Committee—"

We decided yesterday that we wouldn't have a Nominating Committee, that we would have the officers nominated from the floor.

"—of three appointed by the Chairman of the Section, which Committee shall report at the Annual Meeting its recommendation of officers, which report shall be followed at the meeting by the election of officers for the ensuing year.

"Other nominations for officers may also be made by any members at this meeting."

You will notice that in this Section of the By-laws there is nothing said as to how we shall vote for the officers, whether we shall vote by roads, each road being entitled to the number of votes that it has memberships in the Council, or whether we shall vote as individual representatives of the Section.

It has always, I think, been customary heretofore, for every man who was attendant upon the convention, whose road belongs to the National Safety Council, to have a right to vote for the officers for the ensuing year; so unless there is some objection on the part of the members of the Section to the following of that custom which has always been in vogue, the Chair will rule that everybody here who is connected with a railroad, which is a member of the National Safety Council, will have a right to one vote for officers and that no one who is not present will have a right to vote by proxy or otherwise. If that isn't satisfactory, the Chair will be glad to entertain any motion that you desire to make

as to the manner in which this election shall proceed. Each man shall have one vote.

I want to announce that I am not a candidate for re-election and couldn't accept the office if it was tendered me.

Is there any objection to the plan as outlined by the Chairman of taking the vote?

MR. C. R. STAPLES (Safety Supervisor, Southern Railway): I move that plan be adopted.

(The motion was seconded and carried.)

CHAIRMAN RICHARDS: We will proceed to the election of officers for the ensuing year, and we shall be glad to hear from any gentleman who desires to place in nomination any man for Chairman of the Section for the ensuing year.

MR. JOHN S. ROCKWELL (Buffalo, Rochester & Pittsburgh Railroad): Mr. Chairman, I have the great pleasure of presenting to the consideration of this convention for the Chairman for next year a man whom you all know, a man who has been one of the closest students of safety in the United States. That man has shown us today his ability in the wonderful address he has given, and without further remarks I place in nomination Mr. Thomas H. Carrow, of the Pennsylvania.

MR. BRENNAN: In rising to second the nomination of Mr. Carrow, I think he has demonstrated, I might say, that we have passed beyond the initial stage of safety and have entered the field in the scientific line. In doing that thing he has conferred upon not simply the men who are engaged in transportation service but upon the whole human race a lasting obligation.

He has invented a compass and a chart for us and I think if we follow that chart, ultimately developed into a scientific practice, we shall have the privilege of knowing that we have working at the head of the organization one of the noblest men in practical and real knowledge of railroad practices and conditions in the whole world.

MR. J. C. CLARK: Mr. Chairman, during the past year I have had the very great pleasure of a rather close association with a superintendent of safety on a certain line in the Central Western Region. I have come to admire greatly this man's ability, his personality, his energy. It seems to me that during the coming year we are going to face a rather vital situation with regard to the Railroad Section of the National Safety Council.

I think we should have a man at the head of our Section who is able and willing to work and work hard for the Section, a man who has the personality to put himself across, a man who has the energy to work all the time, a man who has the initiative to work for the best interests at all times. I believe the man I am about to nominate has these qualities and I am convinced that he will not hesitate to do anything that is within his power to put across the work of the Steam Railroad Section of the National Safety Council. I wish to place in nomination, Mr. Fred Meyers of the Wabash Railroad.

MR. WEBB: I rise to second that nomination.

MR. E. R. SCOVILLE (Baltimore & Ohio): So that there may be some rivalry in the selection of the Chairman, I rise to nominate a gentleman who has had several years' experience on one of the trunk lines of the East as a superintendent of safety and welfare, and who is now the Vice-Chairman of the Steam Railroad Section of the National Safety Council, Mr. John T. Broderick.

MR. CARROW: I rise to second the nomination.

CHAIRMAN RICHARDS: Are there any more? If there are no further nominations, the Chairman will declare that the nominations are closed.

We have before us now the names of Mr. Carrow, Mr. Meyers, and Mr. Broderick. Shall we vote by ballot, or how?

MR. CARROW: Mr. Chairman, I must interrupt for a moment to say a word.

Mr. Clark, my dear friend from Salt Lake, not eloquently but sincerely has undertaken to delineate the character, the sterling worth, of a gentleman connected with a big railroad. My aspirations for the Chairmanship of the Steam Railroad Section are always subordinated to the interests of the Council, and for that reason, and knowing my lovable, energetic friend, Fred Meyers, as I do, knowing that he has sat with us in the dark days when interest was lagging, knowing that he has put forth every intelligent effort that a good, virile American citizen could put forth to forward the cause of this great movement, I take pleasure in withdrawing from the nominations and in leaving the field open to Fred Meyers.

CHAIRMAN RICHARDS: After the very magnanimous talk of Mr. Carrow, which makes us feel prouder than ever of him, the question still remains as to how we shall take this vote.

(It was voted, upon motion duly made and seconded, to take a rising vote.)

CHAIRMAN RICHARDS: It has been decided to make it a rising vote. All those in favor of Mr. Broderick will please rise.

(There were eighteen votes for Mr. Broderick. The balance were cast for Mr. Meyers, who was elected Chairman of the Steam Railroad Section of the National Safety Council.)

MR. FRED MEYERS: Mr. Chairman and Gentlemen: I am deeply grateful for this honor. I appreciate very heartily the election to the Chairmanship for the ensuing year. We have been favored, in the past year, by having in the Chair one of the pioneers, one of the finest and one of the best men in safety that I know. He was signally honored, last night, by being elected President of the National Safety Council. That is a tribute worthy of this great institution. We all know Ralph Richards, and we love him. I can only say that in my service as Chairman for the following year, I will endeavor to do my very best. If I can secure the same help and cooperation that was given the Chair the past year, I will assure you that we will do as well as, if not better than, we have heretofore.

CHAIRMAN RICHARDS: I take great pleasure, now, gentlemen, in turning over this Section to the new Chairman.

(Mr. Meyers took the Chair.)

MR. SHEDD: This convention of the National Safety Council, and particularly this Steam Railroad Section, to my mind, seems to have been fraught with good things, things beyond the anticipation of most of us, and yet we were looking for something high, noble, and splendid. I believe that when they elected that grand old man, that Christian character, who lives for others first, President of the National Safety Council, that splendid organization simply showed again that it was composed of men of the highest character, men of the keenest perception.

I am going to suggest that we all rise and give Ralph Richards, that grand old man whom we all love, three cheers. God bless him and further his every effort.

(Prolonged applause and three cheers for Ralph Richards.)

MR. RICHARDS: That is all very kind of you, Gentlemen, and I thank you.

CHAIRMAN MEYER: Gentlemen, we will proceed to the election of a Vice-Chairman. Nominations are open for Vice-Chairman.

MR. STAPLES: I desire to place in nomination the name of a man who is not as big as Mr. Meyers physically, but who is just as big in his energy and his efforts, a man who has devoted years of his life to this work, and for the last ten years he has worked twenty-four hours a day for the safety movement. I place in nomination Mr. Robert Scott.

(The motion was seconded by Mr. Shedd.)

MR. CLARK: I move that the Secretary be instructed to cast the unanimous ballot of the Section for Mr. Scott as Vice-Chairman.

(The motion was duly seconded and carried, and the Secretary cast the unanimous ballot of the Section for Mr. Scott as Vice-Chairman.)

MR. ROBERT SCOTT: Gentlemen, this is an honor that I very much appreciate. I don't know that my shoulders are broad enough to wear the epaulets. If I had a hale constitution and a physique like my friend from the Santa Fe, if I were endowed with oratory like my good friend from the New York Central, if I had the power to shed tears like my good friend from the Rock Island, if I were rich enough in Irish wit like my good young friend Richards, I would make the welkin ring. But, Gentlemen, this is the age of service. That has been the keynote to everything that has been said here during this convention, and if service means anything to the Steam Railroad Section of the National Safety Council, I am here to render it to Mr. Meyers.

MR. WISE (Dallas, Texas): Mr. Chairman, because of the natural modesty of your Regional Supervisors, we do not like to talk about ourselves, but there is a time when I think either bashfulness or undue regard for others has to be put in the background.

I say this because I want you to understand that in bringing to you the man I am about to name, it isn't because we are trying to get some one

from this particular region; it is because we are in a great and wonderful work. I want you to elect him as your Secretary. He is a man who has served those around him, who has won their honor and confidence, a man of literature, an editor, a newspaper writer, a thinker, a man whose heart is in the safety work, who has occupied responsible positions, who can serve us better, perhaps, than any man in the United States, Mr. Henry M. Mayo, Superintendent of Safety of the Southern Pacific Lines, of Houston, Texas.

(The motion was seconded by Mr. Shedd.)

(Upon motion made by Mr. E. Richards, of the Cotton Belt, duly seconded and carried, Mr. Mayo was elected Secretary by unanimous ballot cast by the Secretary.)

MR. H. M. MAYO: Mr. Chairman and Gentlemen: I think you might have spared my modesty, at least, because you must realize that we people down in the Southwestern region are modest if nothing else. While I feel that I am under intense obligations to my friend, Mr. Webb, for the most delicate manner in which he called attention to my qualifications for this high office, at the same time, I was blushing all the while he was doing it. It is my natural innate modesty to blush when somebody accuses me of something I don't possess.

I very heartily appreciate your electing me Secretary of this Section. I promise you that to the best of my ability I will do my duty and more, if possible, but I also want to call up your sense of duty in this particular. I know that my friend Whittemore went up against this same thing. Your Secretary represents you. You boys have to come across if you want to make your Secretary a success and hence your Section.

MR. CARROW: I make a motion that we rise and express our appreciation collectively for Mr. Richards and for Mr. Broderick, who have acted on the Committees in a quiet but in a very enthusiastic way, and for Mr. Whittemore, the efficient Secretary, who had to do most of the work, and any others who have contributed to the success of the Eighth Annual Congress of the Steam Railroad Section of the National Safety Council.

(A rising vote of thanks was given to the retiring officers.)

(Because of the lateness of the hour, it was voted to adjourn, and to hear, immediately after convening at the afternoon session, the paper on "Methods of Selecting Committees and Maintaining Interest in Safety" by Mr. Robert Scott, which was to have been delivered at the morning session.)

FRIDAY AFTERNOON SESSION

THE meeting was called to order at 2:00 p. m. by Mr. Fred Meyers, Superintendent of Safety, Wabash Railroad, the newly elected Chairman of the Steam Railroad Section.

CHAIRMAN MEYERS: Our program indicates a round-table discussion for this afternoon but in view of the fact that a special order of business cut off a completion of the morning session we will, if it is your pleasure, pro-

ceed to complete the morning session, there remaining one subject by Mr. Scott.

METHODS OF SELECTING COMMITTEES AND MAINTAINING INTEREST IN SAFETY

ROBERT SCOTT, SUPERINTENDENT OF INSURANCE AND SAFETY, ATLANTIC COAST LINE RAILROAD, WILMINGTON, N. CAR.

Before touching upon the methods of selecting committees it seems proper that some consideration should be given as to what is expected of them. SAFEGUARDING and EDUCATION represent the essential elements of any safety organization, which naturally requires efficient planning, direction, and supervision.

While safety committees of foremen or men from the ranks have demonstrated their value as a medium for detecting misplaced guards, poor housekeeping and minor structural defects, their value as an educational factor is also worthy of utmost consideration.

The writer has, during his brief experience in accident prevention, observed a tendency on the part of safety committeemen to confine their attention to the obvious mechanical and structural conditions, which should have been remedied by the foremen or supervisors, instead of studying the broader and more productive field of dangerous practices. Even when directed to consider only the latter, it has been the experience that their reports were still almost entirely given over to recommendations regarding supposedly unsafe conditions. In other words, there is always a tendency to superficial inspection which is difficult to overcome.

Mention is made of this with a view of laying emphasis on the importance of exercising care in selecting committees. It should ever be kept in mind that men selected for this work of safeguarding and educating must themselves be capable of becoming "Safety men" and also be able to impart to others the knowledge they have gained by experience.

After selecting as head of the organization a man who has an abiding faith in the necessity for the work, it is apparent that next in importance is to place upon the committees only such men as are believed would prove loyal to the cause and can grasp the real meaning of Safety, i. e., that it deals with human nature and human relations more than with structural or mechanical conditions.

In the formation of committees one aim should be to have them well balanced. While such qualifications as loyalty, level-headedness, and enthusiasm should be common to all members, attention should be given to the peculiar fitness of committeemen with respect to temperamental characteristics as well as special training along some particular line of work.

It is believed that if safety committeemen, or safety workers, as they might properly be designated, are of the type mentioned in the foregoing paragraph, they will create an atmosphere of intolerance of careless and reckless habits in the territory in which they work. Not only will they be active aids to the Safety Department, but they will serve in various ways

as the connecting link between the management and the rank and file men—between staff and labor. These are the men who will come to the assistance of the management in time of stress; who will come forward with information beyond the officials' vision, and who, in countless ways, will promote the unity of the entire organization.

While it is possible to lay down some general principles to be followed in the selection of committees, the real work of picking out individual men must necessarily be left to the local chairman, who in most instances is the supervising officer and usually has an intimate acquaintance with his men.

GENERAL SAFETY COMMITTEE

This committee should be composed of general and division officers, chosen in such a manner that the different departments of service shall be represented on that committee. The Chief Operating Officer usually acts as Chairman. It is desirable that this committee shall have general supervision of the Safety Organization.

One thing that it might be well to point out is that the General Safety Committee, as well as other safety committees, possess no executive power but are purely advisory.

It may not be found practicable to have representation of all branches of service on the General Safety Committee, but it is especially desirable that the heads of such departments as Transportation, Maintenance of Way, Mechanical, and General Claims shall have places thereon, since these are the men who are held responsible for the results obtained, while the General Claims Department is in fine position to keep in close touch with personal injuries to employees and others.

The selection of this, as well as all other safety committees, should be in the hands of some one who has intimate knowledge of safety work, its aims and objects.

DIVISION SAFETY COMMITTEE

A Division Safety Committee, composed of division officers, with the Superintendent as Chairman, and one or more representatives of each of the different classes of service, should be formed. The same good judgment should be exercised in selecting members to place on this committee as in the appointment of general committeemen. The Division Safety Committee can be of much assistance to the General Committee, provided it has the proper conception of its functions, and will with intelligence and zeal seek to perform these functions.

SHOP SAFETY COMMITTEE

At all shops employing more than several hundred men a Safety Committee, composed of the principal officers of the shop, with the ranking officer as Chairman, and one or more representatives of each of the different classes of service, should be formed. If the shop is under the jurisdiction of the Division Superintendent, the Committee should report to the Division Safety Committee, otherwise to the General Safety Committee.

Eighth Safety Congress

Too much care cannot be exercised in the selection of men to serve upon shop committees: this is not so much on account of the problems encountered in safeguarding the machines, but rather because of the necessity for having intelligent and enthusiastic committeemen who will take it upon themselves to instruct and advise new employees or older ones who are not inclined to follow safe methods in the performance of their work.

TERMINAL SAFETY COMMITTEE

At each large terminal a Safety Committee should be formed, composed of the officers in charge, with the Superintendent or ranking officer as Chairman and one or more representatives of each of the different classes of service. If the terminal is under the jurisdiction of the Division Superintendent, the Committee should report to the Division Safety Committee, otherwise to the General Safety Committee.

This Committee, like most of the others, should be made up of men well qualified to act as leaders and who, by their exemplary habits, encourage safe practices on the part of others.

ADDITIONAL SAFETY COMMITTEES

Where conditions require, local committees may be organized in yards, roundhouses, smaller shops, large freight houses, etc. In all cases the same general principles as outlined above should be followed in selecting committeemen.

MAINTAINING INTEREST

Upon taking up the work for the first time some few months ago I sought interviews with the foremost members of this Council so that I might learn something about Safety from those who had made accident prevention a specialty instead of a side issue. Without exception these men told me that the very nature of the work was such that it could not be carried on successfully unless accompanied by intense active interest on the part of all concerned, and I am now able to testify to the correctness of this after almost a year of experience.

Much has been said and written on this phase of the work in recent years, and many of you are already familiar with the various methods employed by progressive safety organizations in propagating the germ of Safety so that it will eventually overcome the Accident germ. About all that is left for me to do just now in the treatment of this subject is to reiterate some of the things that have already been told you, and to place thereon the stamp of approval of one who has found them effective.

INTERESTING THE OFFICERS

Needless to say, no accident prevention work can be successfully carried on without the hearty support of executive and supervising officers. As a rule, however, difficulties are not encountered through failure to gain such support, but rather through failure to make this support clearly manifest. Officers on roads, especially those on which much safety work has been done, naturally feel that their men know that they do not want

accidents. They may be mistaken, however, in the depth and permanency of this impression and in any branch of the service there may be newer or less perceptive staff men to whom a direct expression of purpose would bring enlightenment, as well as others who would derive from it encouragement to renewed efforts. It is satisfying to feel that our executives are backing us in our daily work, but when we are made to know rather than feel—when we realize that they look to us for results—the work goes forward.

The first and essential step, then, in inaugurating a safety educational movement, or in "waking up" the men, should be a clear, unequivocal statement by the management as to where it stands. Now, as to how this can be brought about is the question for us to consider. It is well known that these men are intensely occupied with problems requiring immediate attention, in other words, the things that to them seem most pressing. Therefore, properly to maintain interest in Safety among the officers it is necessary that the man in charge of the work of accident prevention must be possessed of a compelling personality and that he will with diplomacy, tact, and perseverance keep the subject of Safety ever before these officers, and present to them such interesting facts as will not only command attention but will actually cause them to become and remain deeply interested in it.

There is no more successful way of doing this than by the use of statistics, either in statement form or by graphic chart, showing the common causes of accidents and the class of employees suffering injury therefrom. Data of this character soon begins to reveal that if accidents are occurring in any given locality with greater frequency than at other places where the same work is performed, investigation and study of the conditions surrounding the method and manner of doing this work is in order and may make it clear that some special treatment is necessary.

Again, if the staff or supervising officers are allowed to leave the whole matter of accident prevention to the Safety Department, there will be very distinct limits to what can be accomplished. The more efficient a Safety Department becomes, the more likely is such a situation to arise. The change takes place imperceptibly, but the educational work is in the end devitalized, accidents do not decrease, and the Safety Department is directly blamed for not accomplishing what was never within its power to accomplish. Freedom from accidents cannot be brought about by a repetition of direct attacks conducted by the Safety Department; it is attained only through work by the entire organization, inspired by the enthusiasm and efforts of the Safety Department. Let this be clearly made known to all officers of the road to the end that their interest may be gained and held to a reasonable degree.

It goes without saying that any operating officer of a railroad will become interested in the promotion of safety work just so soon as some one has convincingly pointed out to him that the prevention of accidents means not only the prevention of untold mental and physical suffering, but also a great economic saving. He should be informed that accident prevention has passed the experimental stage, since it has been demon-

strated beyond doubt that personal injuries, just like disease, result from some cause and that just so far as these causes are determined and eliminated, in the same degree will accidents disappear.

Sometimes it is necessary to put before these officers the more serious side of the question, i. e., their moral responsibility for the safety of men working under their direction. This refers both to remedying unsafe conditions and to seeing that workmen are properly instructed as to the safe way of doing their work, and pointing out any special hazards connected with the plant or its operation.

Officers should be constantly and forcibly reminded that accidents destroy that which has been created, and that accident prevention preserves not only property but human life as well.

INTERESTING THE EMPLOYEES

The most convincing argument that comes to my mind just now in connection with awakening interest among rank and file men in the cause of Safety is the one that has been used a great deal of late. Ask any man in train, shop, or roadway service, "Who suffers most as a result of personal injuries brought about by unsafe conditions or dangerous practices?" There is but one answer, and when this is brought home to them they invariably begin to think, and this is the first step in the right direction.

Another important thing is to impress upon all employees the fact that the safety organization embraces every man connected with the road, and that all of them are expected to do their part in carrying on the work of accident elimination.

Next comes the task of educating the men as to how all this can be done without undue interruption of their work. It can be accomplished by personal appeals to the men by head of the Safety Department or some well equipped representative. It can also be done by the distribution of literature on the subject, but this method is not so effective as the former one.

Now, after having aroused the interest of employees, a more difficult problem arises as to how this interest can be held. I am convinced this cannot be done by following any one scheme, but can only be successfully accomplished by the employment of a combination of methods such as the following:

- (a) Well prepared bulletins posted on Safety Bulletin Boards.
- (b) Safety Rallies, with a good program, effectively advertised and supported by hearty cooperation of officials.
- (c) Introduction of special papers on live topics at regular meetings by employee members.
- (d) Acknowledging receipt of all suggestions by letter, and advising those making them of disposition in each case.
- (e) By having SAFETY discussed at Brotherhood Meetings of Labor Organizations.
- (f) By judicious distribution of SAFETY propaganda through the means of Employee's Magazines or Circular Letters.

- (g) Through the employment of a Motion Picture Car, accompanied by a capable lecturer.
- (h) By personal work among the men: this to be done only by those peculiarly fitted for converting influential unbelievers in the doctrine of SAFETY.
- (i) By the rotation of committees, thus bringing new life into the organization.
- (j) By issuing Membership Cards and SAFETY emblems to all members of safety committees.
- (k) By awarding medals or trophies to either individuals or committees, divisions or shops, for special accomplishments in connection with the Safety Movement.

Among the things that have been used with the greatest success is the Motion Picture Car, accompanied by a lecturer, on account of the benefit that accrues from placing the importance of SAFETY before employees and their families, also in enlisting their interest and support in accident prevention. It is almost universally agreed that education in safety work is more vital than anything else, and that the majority of accidents on railroads can only be prevented when employees have had instilled into their minds the important principles of safety. When the human element can be made as nearly one hundred per cent safe as our mechanical devices and as our physical conditions have, accidents will be reduced to a minimum. There is no better way of making an indelible impression upon a person's mind than by exhibiting a picture of conditions. In many ways in everyday life motion pictures have proven to be of great educational value, so it is in accident prevention work, and even more so for when a railroad man sees a picture of an accident it seems to write the conditions and circumstances more deeply in his memory than anything else could possibly do.

SAFETY SUPERVISORS

It will be noted that nothing has been said about the travelling agent or supervisor, and here I would like to touch upon the value of the service that is capable of being rendered by these men. We are all aware of what personal work means in any line of endeavor where the human element is to be dealt with. These representatives of the Safety Department are in position to do a great deal of good in maintaining interest in the work of the department both among employees and officials, and it speaks well for any safety organization that has seen to it that only men of clean character, high principles, clear intellect, and a keen knowledge of human nature, coupled with practical railroad experience are selected to handle the field work. These men can either do or undo, and they should have a clear conception of their responsibilities, for it rests upon them to do a large part of the moulding of sentiment in favor of Safety. It is their task to seek out the unbeliever and convince him of his error, likewise to look up the lukewarm and do the needful, as well as to locate and make use of the enthusiastic leader who can be used on a committee to good advantage in maintaining interest among the rank and file.

These field men are close to the pulse and can in many ways aid the head of the organization in diagnosing special cases of lack of interest and are often able to suggest the remedy. While, as for getting valuable cooperation at the hands of supervising officials, there is no one better able to do this, since on account of frequency of contact which brings about a close relationship, they can convince foremen that service and supervision that permits men to get hurt is a mockery not to be tolerated. They can encourage foremen to give their workmen the things that money cannot buy and thereby satisfy their craving for human recognition, since they are bound to pay back in kind.

In conclusion let me say that I consider it a distinguished honor to be called upon to take part in the proceedings of this Council, and I want to acknowledge it here and now with grateful thanks. The high calling of our task is indeed an inspiration to me and should be to all of us. Every obstacle we meet ought to spur us on with renewed and stronger vigor. The daring of our enterprise to create safety where peril has so long thrived should bring us to a clearer realization of the value of our service. Let us be firm in the conviction that the principles underlying our work are correct, for we know beyond doubt that our cause is a just and noble one. Therefore, let us apply the acid test by endeavoring more than ever, if possible, to make this idealism a realism. It can only be done by the application of such common-sense methods as are capable of being applied to our present physical conditions and to human relations as they exist today.

Our common enemy is CARELESSNESS, and Carelessness has slain, crippled, and blinded more men, has made more widows and orphans, has left on the face of this earth more hands outstretched for charity than all the great wars or other calamities that have befallen mankind. Let us fight it with all the intelligence we are capable of developing and with the full strength of our manhood to the end that the world will be a better place for our having lived in it.

CHAIRMAN MEYERS: We will have a discussion on the paper, led by Mr. Peter Groome, of the Union Pacific Railroad.

MR. PETER GROOME: In view of the fact that this subject has been entirely covered in a very able manner by Mr. Scott, I am going to leave off the discussion of this paper.

CHAIRMAN MEYERS: I will now turn the meeting over to Mr. J. T. Broderick, Supervisor of Safety, Baltimore & Ohio Railroad, who will act as Chairman of the round-table discussion.

ROUND-TABLE DISCUSSION

CHAIRMAN BRODERICK: It is my privilege to have the task of acting as Chairman of the round-table discussion and I am very glad to enter upon that work.

The first subject on the list is, "Prevention of Accidents at Highway Crossings." Mr. Reynolds, of the Pennsylvania Lines West, has very kindly consented to open the discussion on that subject.

PREVENTION OF ACCIDENTS AT HIGHWAY CROSSINGS

H. B. REYNOLDS, SUPERINTENDENT, SAFETY BUREAU, PENNSYLVANIA LINES,
WEST

Up to the present, and for a considerable period in the future, highway crossings have been, and will be, a necessity in the operation of railroads. This is true because of the item of expense involved in their elimination.

When the present roads were first constructed, the financial aspect bore the same relation to their elimination as it does in this day and age. In fact, the financial burden would have been so great as to have precluded their building had an attempt been made to do away with them when they were first constructed.

My source of information reveals the fact that there is approximately one highway crossing for each mile of railroad in operation. I am also informed that the average cost of eliminating these crossings is in excess of \$50,000 each, which, when considered in connection with the thousands of crossings, indicates very clearly why the financial burden is too great to permit of an immediate correction of the condition. However, all railroads are constantly engaged, as far as their finances will permit, in effacing these crossings at points where the need is most urgent, and we may expect, at some time in the future, a practicable solution of the proposition through the doing away with of all grade crossings. This may occur solely through the efforts of the railroads or through the initial assistance of the Federal or State governments, backed by an awakened public, demanding that the needless slaughter of human beings be stopped.

The railroads are privileged to share highway crossings with the public through the medium of legislative enactment, and each has its responsibility to bear in the prevention of accidents occurring thereon. The time for mutuality of action has arrived, and to my personal knowledge, the railroads stand ready and willing to meet the public far beyond the halfway mark. The trouble today lies almost wholly with the indifferent manner in which the public in general views the situation.

We are all aware that accidents at grade crossings are increasing at an alarming rate. Rarely do we peruse our daily paper but what our eyes are greeted by a news item, generally local, conveying the information that one or more lives have been snuffed out in a grade-crossing accident. A majority of us are wont to consider practically all of these happenings as being due to some fault of the parties involved and more often this is the truth. However, a careful consideration of all the factors having a bearing thereon indicates that quite frequently the fault lies either with the railroad or its employees.

The railroad company is often primarily responsible on account of faulty construction, poor maintenance, or because of some condition it has permitted to exist, such as shrubbery alongside the right of way that obstructs the vision, or because of large advertising signs so common to all railroads, that afford the same condition. I might add at

this point, that we have corrected the latter condition on the Lines of the Company I represent by having a careful survey made, and requesting the owners of all signs that interfered in any manner with vision to remove them. They have furnished us excellent cooperation in this respect, and, as a result, there has been a rearrangement of these signs at all points on the system.

Carelessness on the part of the railroad employee is also an important factor. Quite frequently we learn upon investigating an accident, that the engineman failed to sound the whistle or ring the bell. Oftentimes, in towns or cities, he was travelling at an excessive rate of speed. We also learn that other members of the train crew are often responsible, due to their failure to protect properly a crossing in backup movements, switching operations, etc. We are also confronted with the fact that in numerous instances employees whose duty it is to protect crossings are inefficient or fail to have a thorough understanding of the requirements of their positions. Such shortcomings on the part of the railroads and their employees can readily be detected and corrected by the application of the means which lie within the authority of railroad officials. Unfortunately this is seldom brought to notice until an accident has occurred.

MOST GRADE-CROSSING ACCIDENTS ARE PREVENTABLE

We are all acquainted with the fact that most accidents at grade crossings are entirely preventable, some being due to conditions or practices for which either the railroad or its employees are responsible. However, you will agree with me when I state that the vast majority of such occurrences are due to practices indulged in by the public, especially the travelling public. Naturally the public has a right to use grade crossings jointly with the railroads, but from the reports which reach us, we are forced to the conclusion that at least a considerable part of it is unwilling to concede the railroads any rights whatever, when they themselves are desirous of using the highway. This quite frequently leads to disastrous results as far as they are concerned. We are all familiar with the fact that it appears to be an inherent trait of human nature to endeavor to beat a train over a railroad crossing, disregarding the first principle of self preservation. No doubt you have witnessed, the same as myself, some one hurrying over a crossing, either on foot or in a vehicle and stopping on the opposite side to watch the train pass by. This same spirit seems to be rampant in most of our fellowmen when in the vicinity of railroads, and no doubt accounts for the actions of the individual, who, when crossing gates are lowered, will pass under them, in the full belief that he is quite able to take care of himself.

Another trait of human nature that is responsible for thousands of deaths yearly, both in industry and in everyday life, is the failure to "Stop, Look and Listen," in the presence of impending danger. This one trait alone is probably responsible for more accidents and casualties at highway crossings than any other. This failure on the part of the individual is usually traceable to the fact that the party involved has his

mind occupied by some one subject to the exclusion of all others, which momentarily permits him to disregard his immediate surroundings. Perhaps he is involved in an interesting conversation with some one, or if alone, perhaps he is revolving some proposition over in his mind, and endeavoring to reach a conclusion. Another important factor, from the public standpoint, is the permitting of children, by careless and indifferent parents, to play about or on railroad premises, thereby inviting disaster.

NINETY-FIVE PER CENT INVOLVE AUTOMOBILES

The largest proposition of all, in considering highway-crossing accidents, is the automobile. Since the advent of the latter vehicle accidents have increased yearly by leaps and bounds, and will continue to increase until some remedy, not yet applied, is placed in operation. Statistics indicate that more than six million automobiles are in service today, and that the rate of production will add to this number more than one million cars per year for an indefinite period. With the addition of each car to the everswelling ranks, the potential source of highway crossing accidents is increased in the same proportion. I can state from a knowledge of the accidents occurring on the Lines I represent, that fully 95 per cent of all the crossing accidents involve automobiles. This percentage will increase rapidly under present conditions, as the automobile industry is fast crowding other means of conveyance off our streets and highways.

Before prohibition became a reality, we frequently heard that a majority of crossing accidents to automobiles were due to the driver being intoxicated. No doubt this was oftentimes true, but the fact remains that such accidents are still occurring and their diminution is scarcely noticeable. The one factor, in all such accidents, which stands out above all others, is the carelessness of the driver. It has been my experience that no matter how careful a man may be in the ordinary affairs of life, no matter how strongly he may denounce someone else for the careless and reckless manner in which he may drive an automobile, he himself will be noticed to be as careless or as reckless within a short time after coming into possession of such a vehicle. This, of course, is not true of every individual who owns an automobile, but my observations have led me to the belief that it is applicable in most cases. The ability to drive a car seems to breed a speed mania with its attendant disregard of those principles which make for personal safety.

It is my belief that such a condition exists only through the apathetic attitude of the general public. Let the public be aroused to its responsibility in connection with these accidents, and I feel sure that within a remarkably short period of time such calamities will be decreased below our fondest hopes. No man can hope successfully to compete against an aroused public opinion with its attendant features, laws, etc. But how is the public to be awakened? No matter how great the slaughter it seems to be an impossibility to prod its slumbering form into action.

No law that can be devised is stronger than public opinion. No law that will ever be enacted will cure this evil unless it is backed by public

opinion and strict enforcement. While laws have been placed on the statute books of various states to regulate traffic at highway crossings, some meritorious, some worthless, yet they have failed of their purpose, due to a lack of enforcement. We are aware that one reason for this is the apathetic attitude of the public, but did you ever stop and consider that the various railroad companies are in a way responsible for present conditions, and that they too are almost as indifferent as the public? Naturally we cannot expect to enlist public support unless we make an effort to secure it.

THE ILLINOIS LAW

Recently the legislature in the state of Illinois placed on the statute books of that Commonwealth an excellent law designed to prevent the many highway-crossing accidents occurring within the confines of the state. This law provided a heavy penalty for anyone operating a vehicle who failed to stop before crossing railroad tracks, and assure themselves that they would be safe in proceeding. There has been no decrease in grade-crossing accidents within that state, so I am informed, because the law is neither obeyed nor enforced. Recently while attending a meeting of the safety supervisors in the city of Chicago, the application of this law was brought up for discussion, and a canvass of those present indicated that not a single railroad represented at the meeting, was making an effort to enforce its provisions.

Inasmuch as the railroad companies of this country are as vitally interested, if not more so, than anyone else in the elimination of grade-crossing accidents, it seems to be a queer condition, indeed, when they fail to even furnish their moral support in the enforcement of such an excellent law. It is quite understandable why the public fails to interest itself when the railroad companies make no attempt on their part to see that laws in which they are vitally interested are enforced. Laws such as the above would prove of wonderful value if enforced, but under present conditions, they are valueless, as far as their immediate value is concerned, although they are an excellent thing to have on our statute books when the time comes that action will be demanded by an outraged public.

We have been installing at some particularly bad crossings wigwag signals, a signal with which no doubt you are all familiar. The peculiar maneuvers of this signal rarely fails to attract the attention of the driver of any vehicle approaching it, and has proved of considerable value in preventing injuries at crossings where they are located, especially among that class of people who are absent minded, or are oblivious to their immediate surroundings on account of something else occupying their attention. However, these signals have but very little effect, if any, on that class known as chance-takers, who regardless of any warnings, are always willing to risk their own judgment and trust to the mechanical perfectness of their vehicle to carry them to safety.

We have also in a few instances, at particularly bad crossings where the view is obstructed on account of natural conditions, erected warning signs a few hundred feet from the railroad right-of-way. However, as

this is a condition that properly should be looked after by the state authorities, I do not feel that the railroad companies can properly attempt to construct and maintain such signs, to say nothing of the necessary expense entailed.

CROSSING GATES ON LONG ISLAND RAILROAD

I have been told that the Long Island has practically solved the proposition of crossing accidents on that particular road. My information is to the effect that a crossing gate has been devised, the principal feature of which is a telegraph pole, used as a barrier, which is lowered on the approach of all trains. I am informed that this arrangement has proven to be very effective in keeping vehicles off the track until the train has passed, for the reason that the barrier is of sufficient strength to wreck the machine or vehicle, and prevent its passage. This method, no doubt, would prove effective in thickly-populated districts, where of a necessity crossing watchmen or towermen are stationed at all crossings, but of course would have no effect at other points. A similar arrangement could be used to advantage in our cities as it is a daily occurrence for drivers of automobiles to drive through the present gate maintained by the Company I am representing. Such drivers seem to have no respect either for gates or flagman, as twice recently flagmen who were endeavoring to perform their duties and attempting to save the driver of an oncoming machine from his own folly have been deliberately run over and seriously injured.

There is a factor in the automobile world that is actually assisting to better present conditions. I refer to the various automobile clubs and organizations. Most of these bodies are fully aware of the seriousness of the situation, and are endeavoring in every possible way to impress upon their membership the necessity of using care. These bodies have also erected at their own expense thousands of warning signs and have distributed tons of literature. No doubt their influence has had a wonderful bearing, nevertheless they have not as yet solved the problem. However, they are worthy of our most serious cooperation, and we should assist them with every means at our command.

EDUCATE THE PUBLIC

Another feature that has been overlooked is the publicity end. We take up our morning paper and read that some unfortunate individual has been killed at a grade crossing and the subject immediately escapes us, and is forgotten. We consider it as an incident in the country's affairs and let it go at that. If we could furnish the daily papers with well written articles at different times, to be published as a news item, setting forth the needlessness of such accidents, their great number, and the methods to be pursued in their prevention, I feel satisfied that such a procedure could not fail to make an impression upon the public and assist in crystallizing sentiment.

Some one has well said that "The public school is the hope of the future." Such a statement is true, to a large extent, in the elimination

of carelessness of our future citizens if proper methods are employed to influence the young and plastic mind. I know of no better opportunity to advance the interests of Safety than in our schoolrooms. I feel sure that when the day comes that Safety will be made a part of the curriculum we will notice a great falling off in the number of personal injuries suffered unnecessarily. This is true with respect to the highway-crossing proposition, the same as in industry. Form careful habits in youth, and they will remain with you throughout life. In this connection we have been advancing Safety in the public schools, served by the lines I represent, at every point and upon all occasions possible. In fact, we have been so successful that we were able to persuade the great commonwealth of Indiana to incorporate a course of study, devised by us, in their teachers' manual, to be made a part of the curriculum. We are also meeting with considerable encouragement at all other points and our safety agents quite frequently address large bodies of teachers or school children.

To my mind education is the great feature in the prevention of crossing accidents. Laws have proven inadequate. All other means have either been total failures or only partially successful. Our hope lies in the education of the public, backed by proper laws that are vigorously enforced, both by railroad companies and public officials. We will never be entirely free from such accidents until the grade crossings are entirely eliminated, which will be at some distant date in the future. However, it is my belief that by a proper consideration of the principles I have enunciated in this paper, and a serious attempt to apply them, we will be able to make a wonderful reduction in this distressing class of accidents. We should keep the subject before the public and continue to prod its sleeping form until the great body is fully awakened to its responsibility and duty, after which, I am sure, that adequate action will be taken successfully to meet the situation.

CHAIRMAN BRODERICK: Gentlemen, you have heard the interesting paper prepared by Mr. Reynolds. We are quite anxious that some of the other members here give us the benefit of their experience in this line. Will some member please start this discussion?

MR. BRENNAN: Mr. Reynolds spoke of the crossing gates that had been devised by the Long Island Railroad. Now the safety organization has recommended that we adopt those gates for general use where it is possible to use them because we have only five hundred miles of railroad.

We have to take care of nearly 500,000 automobiles registered in the state of New York besides the visitors coming in to see us. Of 371 cases of grade-crossing accidents for the year ending September last, we had 283 that ran through the gates. A number were run down while crossing man stood there. The only way to do is to put something there to stop the machine.

The majority of people who drive cars don't drink to excess. They didn't do it even before the 2.75 limit was put on.

During the war, men from Camp Mills and Camp Humphries and some of the aviation camps driving these big army trucks would drive right

on when they were in a hurry. Several trucks have been smashed and a few men killed. Some of the accidents can be excused because they happened at night and they didn't know there was a grade crossing there.

MR. H. E. MCGINNESS (Pennsylvania Lines West): I can't help but feel that one of the greatest, if not the greatest, weapons we have before us today to fight this enemy of carelessness is through our schools.

Since I have been identified with the Safety Department of the Pennsylvania Lines West, I have done considerable work in the schools. As Mr. Reynolds mentioned in his paper, we have been able to get the schools of Indiana to print in their annual for the instruction of teachers, a course of study in accident prevention from the first to the eighth grade.

I didn't know just how to get it to the parochial schools, so by inquiring of a friend, I found that all of the parochial schools in a certain Sisterhood were taken care of by the Sisters of St. Mary of the Woods, Terre Haute, Indiana, and by calling at that school and explaining to them what we were trying to do. I was asked by the Sister in charge to come to that school and give the Sisters, who would be there at the summer normal course, a talk on safety and she assured me that they would put the safety course of study in their schools. I had the pleasure, one evening, of addressing eight hundred teachers of that Order and those Sisters are teaching safety to 25,000 school children in their schools between Chicago and Boston. This Sisterhood teaches in a district which covers the area between Chicago and Boston. In addition to that, I was asked to come this Fall and talk safety to the pupils of St. Mary's School. St. Mary's School is a school for girls, and the Sister told me she thought a safety talk would help them considerably.

MR. E. M. SWITZER (Chicago, Burlington & Quincy Railroad): We must get more publicity. It is a serious matter and the most immediate publicity we can get is through the local newspapers. I don't mean the big city newspapers, I mean the country newspapers. We all have hundreds of them along our line. There is a man on my staff, a safety agent, or safety inspector, as we call him, who has a knack at writing and who has been around to the local newspapers on our lines and he is able to get an editorial in any of those papers any time he makes a visit. We had editorials, I think, in all of our papers. Now I don't know how much publicity that gets but it certainly must get a great deal.

You might think that the publicity that is given every time one of these horrible accidents happens ought to serve the purpose but it doesn't because the newspaper reporters, in reporting an accident, do not print the true cause, and the impression is very often left that the accident wouldn't have happened had the railroads elevated their tracks or put their tracks in subways or done something else that they didn't do. The underlying fact that the automobilist was careless and did not stop, look, and listen, is passed over.

I would like to suggest that all the railroads take this matter in hand and go at it something in the way we have gone at it. The amount of publicity that you would get would be tremendous. You would have

no difficulty at all in getting local newspaper editors to publish an article either as a news item or as an editorial. You will find that those men are very glad to get an article of that sort and they will be glad to cooperate in so important a movement.

I would like to propose that we get busy and get some more publicity on automobile highway crossings.

MR. E. S. CHAPIN (Pennsylvania Railroad): One thing which has impressed me in studying grade-crossing accidents, is the fact that when grade-crossing signs are erected they are put right on the right-of-way along side the crossing. Now we know when we put block signals on our railroads, we place those signals so that a man seeing one would have time to stop before he got to the danger point, and I believe the signs should be such that they could be seen at night.

MR. J. G. FITZGERALD (G. C. & S. Fe): I would like to state that we have on a campaign in the state of Texas for the prevention of automobile accidents. We have had sent out 335,000 letters to individual automobile owners. This letter is sent by the Texas Automobile Dealers' Association. It states the number of accidents and solicits support for the prevention of these accidents. This same letter is being sent to the various states in the Southwestern region. There has also been appropriated \$10,000 for the Southwestern region for newspaper publicity—full page in the form of advertising. We feel that a great deal of good will be accomplished by this.

MR. WERNER: I want to agree with Mr. Switzer in what he said a while ago. We tried that editorial proposition and we only had one incident where we had any difficulty at all. My experience has been in all the country papers that if the editorial is made live reading, they are glad to get it. We did that from one end of our lines to the other and right now we are in the middle of a campaign which I believe has wonderful possibilities in it.

About a week ago we put out a letter personally addressed and personally signed. I first got the names of all the clergymen on the lines that I have the honor to be associated with and then I signed these letters myself and sent them to the clergymen. The answers that I have received are absolutely wonderful.

One great preacher in New Orleans, who has the largest Sunday school in that territory, told us he was not only going to preach a sermon on that subject but he was going to lay it before his Bible class and follow it up in every way he could; that he was with us heart and soul.

The response of the ministers to that appeal has been marvelous. We have learned that the personally addressed and signed circular going to the men as a letter will bring results.

MR. ANDERSON: In the Southern region we inaugurated a very unique scheme by getting the interest of the ministers in this grade-crossing proposition. Possibly some of you have heard of the success of some of the lines in the Southern region. When I have finished I would like you to call on some of the gentlemen here who represent lines in the Southern region and let them tell you of their experience in this cam-

paign. We also have a grade-crossing committee, of which Mr. Beatty of the Southern Railroad is Chairman. If he happens to be in the room I would like him to say something as to the activities of that committee and just what they have in view and what they are going to do in the way of handling publicity towards the grade-crossing proposition in the Southern region.

I would like you, Mr. Chairman, to call on Mr. Robert Scott of the Atlantic Coast Line, one of the roads that conducted the minister campaign, and I believe he will tell you that it was very successful.

CHAIRMAN BRODERICK: Mr. Scott, will you enlighten us on that?

MR. SCOTT: I addressed a personal communication to between 4,500 and 5,000 ministers along our line of road, and it was a startling revelation to me to find how these men, engaged in a pursuit so entirely different from ours, so readily responded to this cause.

In addition to calling upon the ministers, we gave all of our activities along that line as much publicity as we could through the newspapers. Mr. Switzer referred to the country newspapers. We found these publications very anxious to get our copy. They wanted something to put in their papers that would be of interest to their readers and we had no difficulty at all in getting them to publish everything we sent them.

MR. WEBB: I would just like to read for the benefit of the gentlemen present this particular letter from a minister:

"My dear Sir:

"Your letter of the twentieth is very much out of the ordinary. It is at once official, brotherly, and instructive.

"Like every other pastor, during the last two years, I have received an immense volume of mail from various official sources requesting me to do my part in putting over drives. To all of those I have tried to respond as best I could, not to neglect the essentials of a divine calling.

"You are the first man to get right down by my side and discuss things in the real phase of life.

"Very unfortunately I have but little success with that class of people with whom you are most concerned. As a rule, the very same automobile which carries people to death and destruction on your tracks, carries those people out joyriding at the preaching hour on Sunday morning.

"Only a few days ago I was sitting by my window where I had a full view of the crossing. The fast train at noon was running in from the West. There was not even a freight car on the road; there was not anything to obstruct an open view of two hundred yards down the line, yet two men in an automobile rushed onto the track right in front of the engine and were knocked off.

"I will be glad at any time to receive your letters and help you all I can."

That is typical of the letters we have received. The original has only been out some four days.

MR. ANDERSON: Any one who would like to get a copy of the letters that we have issued to the ministers, can secure these by writing to me or to Mr. Scott.

MR. WEBB: We would like to add that for the Southwestern region and we recommend that some of the things we have down there would do some good.

MR. W. J. ORR (Toronto, Hamilton & Buffalo Railroad): I want to endorse what the gentleman said here in regard to signs being always near the crossing. I wish to say that some years ago our traffic manager, Mr. Martin, suggested that they should be placed a distance from the track. We find that has been done in some cases. Now he wants me to suggest having a board or a mark of some kind put across the roadway so an automobile coming down a side street might see it. Recently we had a young boy killed coming from the side street and crossing over our tracks. He should not have crossed there, of course, but he came down there and ran in front of a passenger train and was killed. The Ontario Safety League sent a moving-picture man down there to make a picture of how the accident occurred. A boy took the place of the boy who was killed and ran as far as he could that the engine wouldn't hit him and then they put a dummy up there and the engine came along and ran over the dummy. Those pictures are going to be shown in our schools around in Hamilton and other places, and, of course, in Hamilton the boys all know this particular place and we believe it will be a source of profitable education.

MR. BELL: I just want to say a word in regard to the matter of locomotives giving proper signals. I have in mind the engineer sounding the whistle nine seconds from the time he starts to sound it at the whistling post until he gets through, on the theory that any one near the crossing will be bound to hear it.

MR. J. A. PEABODY, signal engineer for the Chicago and Northwestern Railroad, has come to our meeting to gather what information of value he could, and like all Northwestern men, it is rather difficult to get him on his feet but I believe he would be very happy to tell you some of the things he has learned in listening to this very interesting discussion.

MR. J. A. PEABODY (Chicago & North Western Railroad): Perhaps, first, from a signal standpoint you would be interested in my viewpoint, or lack of viewpoint at the present time because I haven't got my views in proper shape yet as to what should be done in the protection of a crossing. Some one here has already spoken about an approaching signal or advance signals to a crossing. That has been called to my attention several times and I rather opposed it, and when so stating I want you to understand that a crossing bell or a wigwag at a distance from the crossing, it seems to me, is a very good thing. You can place that at the crossing and still give the indication at a distance of two hundred feet, which is ample as a general proposition. I believe the wigwag has come nearer giving such information at crossings where they are very busy or in the vicinity of towns. The bell is not a good protection because with our larger and inclosed automobile it is almost impossible to hear it until you are very close to it and even then, bundled up in the winter time and in the closed cars, it is doubtful very often if it is heard at all. In order to be economical in our expenditures, I feel that we very

often install but one signal wigwag or bell at a crossing instead of two. That is particularly true where a crossing is at an angle to the railroad. We could well afford to put the extra money in for two.

This point of education by publicity or through the schools has attracted my attention a great deal. I have heard, and I think it must be true, that prohibition was brought about largely through education in the schools and Sunday schools. I don't think that fact has been brought out very clearly as a general proposition, but I do believe it is a general fact and it has taken nearly two generations to accomplish it.

Now on the Long Island Railroad they installed these poles. I went down there some four or five years ago to look at the first crossing that was so installed and they had a barber pole effect which has since been adopted all over the country and everybody in that region knew that those poles were there and they stopped for them. The crossing man told me that from the time they were installed to the time I was there, which was only a short time ago, there had been no crossing accidents, whereas before they had been unable to stop the automobile or the joy-riders. Now that was fear that caused that: fear of an accident to themselves.

A short time ago I went out to look at a crossing where it is felt that more protection should be installed. We had crossing bells and had had them there for some years. An automobile drove up with ten people in it, three women and seven children. The crossing bell began to ring and the women immediately started across the crossing to beat the train. Now that is madness and nothing else and we have got to cure the people of that madness.

If through publicity we can create a public feeling which will cause our legislators to pass laws which will require not that the railroads but that the public prosecutors shall prosecute these who disobey our flagman, our gates, or our signals, and attach something to it like a good heavy fine, we possibly will get obedience to these things but until then it looks as though we would not.

Mr. D. K. RAWLINGS (Oregon Short Line): There was an experiment conducted on a road in Los Angeles of placing the bell from the track 250 feet. Out of ten passengers that came by with their cars, there were nine, when the bells started to ring, immediately stepped on the gas in order to beat the train over. In the month of May, there were 447 gates broken off on the Southern Pacific. The people come down to the gates and immediately drive through them. In Corona we had a motorcycle that tried doing that; this man was a motor policeman. He rode through the gates and was killed, breaking off one of the gates. I think the solution is a good heavy pole or an iron roller gate. They have been trying to invent a roller gate to roll the same as a door.

Mr. SHEPP (Rock Island): The Rock Island has not been lax in its efforts to do something to prevent such accidents. We have placed signs, we have distributed literature and we have done many things to overcome them along educational lines. We seem to have made appeals in vain. One of the real satisfactory results, or rather arrangements that we have is at Cedar Rapids in Iowa, Moline in Illinois, and just re-

cently in Sallisaw, Oklahoma. We have men on the crossings with police authority and we are having very little trouble at Cedar Rapids in particular, and Moline where this arrangement has been in effect for some time. The crossing men at Cedar Rapids and Moline are uniformed men and given police authority while in the performance of their duty on the crossing with power to arrest, and they use it.

The Common Council of Sallisaw, Oklahoma, have recently enacted an emergency ordinance limiting the speed of automobiles approaching crossings in that city to eight miles an hour, giving the crossingmen police authority and even going further, giving our switchmen police authority while in the performance of their duty, switching and doing other work on the crossings. I believe therein lies the real solution of a great deal of trouble. I further believe that we should look to our property and put our crossings in good shape. The automobile driver soon learns where the good or bad crossings are. I believe there are times if he knew he could go he would go. If it is rough, he finds it out and naturally halts a little. The old horse and mule would do the same thing when he came upon the hump.

The American Railway Association made certain recommendations regarding the placing of additional signs. I know I am not alone in the thought that we, as railroad men should not absolutely advocate that we go beyond our property and place signs, and, as the gentleman said, or at least as I got his meaning, that that should be done by somebody in authority of the right-of-way of the railroad. I am mighty proud to see that Illinois has followed practically the recommendation by the special committee on grade-crossing accidents of the American Railway Association, and I know the other railroads in Illinois have been ordered by the Utilities Commission to place a sign at what they term extra-hazardous crossings. This sign is located at a point on the public highway designated by the Utilities Commission representatives and a representative of the railroad. It is just a half disc containing the word "Stop." The law places a penalty on the driver who fails to stop, and then farther back on the public highway they place a warning sign; that is a disc with four sections with "railroad" up in either the right or left hand corner. The great trouble is that the law is not enforced. While we are willing to do everything in our power, it does look a little bit like straining a point when we have to see that the state of Illinois or any other state enforces its railroad laws. While we may have to do that, I am not against it, but Mr. Switzer has a splendid idea; he didn't tell it but I am going to.

We are going to have a lot of copies of that law printed (of course this applies only to the state of Illinois) and circulate those copies generally, putting them in the hands of our agents at various cities and towns along our big railroad, asking them to get them in the hands of automobile drivers and automobile associations and in the newspapers. I believe when we do that we have performed a real service.

When you begin to talk about talking to school children, or any other children for that matter, you get way down into the depths of the souls of those fellows on the Rock Island lines who are handling the safety

work—myself and my four capable supervisors. There is one of them in this room now who has personally talked to upward of a thousand teachers assembled by themselves at county conventions and other places, and between 75,000 and 100,000 school children, and never lost a minute from his work. His talks were cordially received and later commended.

In some of the schools he had to really break in. In one school, in a large town on our railroad, the principal said he didn't believe he needed him, but he would let him talk to the small children and hear what he said and if he liked it he would take him up to the bigger children.

Now I do not say this pessimistically, but I believe that we need something more than literature, more than preaching, more than personal appeal to reach the fellow who, like myself, is controlled by his bad habits. He is a speeder and he is going to remain a speeder until he goes across one of those telegraph poles unless we do something through barriers or legislation to stop it.

My thought is this: Let's put our crossing in the best possible shape and then we will have done a great service. Our engineers have been instructed that in addition to using the regular crossing whistle—2 long and 2 short blasts—when they see an automobile approaching the crossing they sound the stock alarm to give the automobile driver the benefit of the doubt at least and not wait, supposing that he is going to stop, because many of our good engineers think that the man will stop when he will not stop. Our idea is to give him the benefit—what you lawyers call (if there are any lawyers here) "The doctrine of the last clear chance." You will pardon me if I made a mistake, but unless some of you are lawyers you won't know the difference. In other words, we are going to carry the burden as far as we can and we have asked our men to do it. They will do it all right. We are going to help as far as we can to carry the burden of the other fellow.

CHAIRMAN BRODERICK: Mr. Fred Custis, of the Chicago Northwestern has requested that this question be presented before the body: "What is the best method of protecting road crossings at grades and rural districts where gates, bells, and other devices are not practical?" Does any one wish to say anything on that point? If not, we will move on to the next subject.

Gentlemen, as you all know about the National railroad accident prevention drive that begins on October 18 and is to continue until October 31, inasmuch as that is a paramount subject at this particular time, we thought it proper to bring it up before this body, and we are going to ask Mr. Duffy to say a few words on the subject and then invite a general discussion from the members present.

MR. DUFFY: I was so gratified with the no-accident prevention drive, first in the Southern country, and later in the Southwestern country, followed later by the Central and Northwestern countries, owing to the good efforts of you gentlemen in your respective countries, and the great number of lives and limbs through your efforts, that you saved, that I conceived the idea of putting on a national railroad accident prevention drive, and the Washington office laid their plans before the Director General of

Railroads which he approved and sent a letter out to the Regional Directors.

Now, then, Gentlemen, it is up to you. We have started what has never been undertaken in this, or any other country—one of the largest safety drives. The whole nation will be stirred by your personal efforts, and I have abiding faith in every one of you good fellows whom I have met at the various meetings I have had the pleasure to attend. I feel that I have made no mistake; that even though you may not be first, you may not be second, you may not be third, you may be seventh in the race, but when you are all through with your best efforts, I am satisfied that not one of you is going to renege but will give every coöperation that lies in your bodies.

I might say that we have written to the forty-eight governors of the states and we have a reply from each and every one of them that they are going to give us their earnest coöperation. Some of them have sent men to Washington, and other governors have men on the way, to confer with us in what way they may be of assistance to us, so you can rest assured, as far as the Washington office is concerned we have done our duty. Now, boys, I know you are going to do yours.

CHAIRMAN BRODERICK: I am sure you have all listened with a good deal of interest to what Mr. Duffy said about the national drive. We would like to hear from some of the members as to how they think the most gratifying results could be obtained in conducting this drive. I think it would be useful and helpful to all of us.

MR. SWITZER: Before we do that, Mr. Duffy has asked for our coöperation, our enthusiastic coöperation. May I not express the opinion of this whole section to Mr. Duffy that he will have that coöperation?

CHAIRMAN BRODERICK: We will give a rising vote of evidence to that. (The audience arose.)

CHAIRMAN BRODERICK: I want some of the members present to give us their views now as to how they are going to conduct this campaign in their particular territories.

MR. S. M. GALATY (Chicago & Northwestern): There is one matter I wanted to bring up here in connection with this drive and that is it seems to me if we are all going to do our best that we need all the assistance we can get; all the publicity that we can get.

The thought occurred to me while Mr. Duffy was speaking of the governors, if it wouldn't be possible to get the President of the United States to issue a proclamation, calling the attention of the country to what we are going to do and asking the people for assistance. The governors might do the same in their respective states.

CHAIRMAN BRODERICK: You have all heard the suggestion made by Mr. Galaty. Does any one want to second that and put it in the form of a motion?

(The motion was seconded by Mr. Herrington.)

CHAIRMAN BRODERICK: You have heard the suggestion and it has been seconded that the President of the United States issue a proclamation asking for the assistance of the whole country in putting forth this great

undertaking of the national railroad accident drive in order to make it an unqualified success.

MR. H. M. MAYO (Southern Pacific Lines): Mr. Chairman, the question arises whether the resolution should go from here to the President or whether we should not take it for granted that the representative of the President, the Director General, who has already taken action in the matter, would be sufficient.

MR. GALATY: I might say that my idea for that would be to have it transmitted in the form of a motion to the Director General and the President and have a proclamation issued in a formal way.

MR. CARROW: That is perfectly proper, Mr. Duffy has heard the request, and he will take the proper and immediate action to get a proclamation from the Director General.

CHAIRMAN BRODERICK: Any further discussion on that subject?

Will some of the members present give us their views about how they are going to conduct this campaign?

MR. MAYO: It is possible that I may voice the views of a great many of the people here in suggesting that they do not like to divulge the methods that they are going to put into effect because each line is practically going to make an effort to get the high point in this contest and they may not want to give away their thunder. That might be a rather selfish way of looking at the situation. So far as our region is concerned, our cards are on the table. We would be glad to tell you everything we have done and everything we propose to do, but I am merely suggesting that it may be embarrassing to have figured out a splendid scheme for getting the first place in this campaign, and then to be called upon to cough it up.

MR. J. B. ROBINSON (Southern Railroad): It may be that some of our brother workers have thunder up their sleeves but I don't think it is the right spirit for any safety worker to have anything under cover. If I have an idea you are all welcome to it. I wish I had a whole lot of them.

MR. SWITZER: Mr. Chairman, I don't think any of us are trying to conceal anything, while we all want to be first, we are willing to let anybody use anything that we can use, and if you are interested, I am perfectly willing to say what we are going to do and what we have already done on the C. B. & Q. Railroad.

We have a letter from the regional directors announcing the no-accident drive, and we have a letter from our Federal Manager announcing it. I have a letter from our General Manager announcing it; so it has plenty of authority back of it. I have drafted a letter, which our General Manager signed, addressed to officers and employees, making the announcement and asking for the cooperation of all. That has gone out and has also been posted everywhere we have safety bulletin boards in every section tool house, round house, freight house, etc. That will be followed by another letter which has been drafted and which the General Manager has signed, addressed to the man in charge, asking, and even directing, that they shall give their cooperation in making this a success and pointing out how important every individual man in charge is to the success of this movement. That letter will go to all officers, fore-

men, conductors, locomotive engineers, section foremen, and to every man who has charge of other men, and attached to that is a receipt which the man in charge will sign and return so that we will know that no man in charge of other men has been overlooked. That is the method we used last time. It was very effective. Now that puts it up to the officers and foremen.

The whole scheme is to put this thing up to the man in charge of the work. That was successful before and I believe it will be again.

MR. J. C. CLARK: Coming from a region that has made the best record so far in no-accident drives and representing the road that secured record No. 1 in that region, I want to say just a word. You can put out all the bulletins and circulars and everything else of that nature that you want to and they will do good, I believe, in advertising, but in order to make a success of a drive or to make a success of safety work in any way, you have to get right down and work. You have to get out among the men, get the cooperation of every officer, every employee on the road. You can't do that by written words. You have to get out and do it by personal contact with the men and I believe firmly that the organization that can get right down to the men, secure their interest and their cooperation, is the one that is going to win first place in the coming accident-prevention drive.

MR. ROWE (Lackawanna): We, in addition to the things which Mr. Switzer has spoken about—having letters written by the Federal Manager to heads of employees, etc., have required that from the Federal Manager down, every supervising officer, etc., must call in at a special meeting all employees under his jurisdiction and give them a personal talk upon the safety drive. We believe that the personal contact is absolutely necessary.

We are going to have over 700 preachers along the Lackawanna Railroad preach at least one sermon, many of whom have promised to do so; we are publishing editorials in our newspapers along our line, we are calling noonday meetings of all our employees wherever twenty-five or more men can be gathered together, we are advertising a special train to run over the entire system, ours being only a thousand mile system, that train being composed of a suitable number of cars properly decorated with advertising, we are going to have a brass band upon the train, we are going to have some good speakers who can talk for two minutes (I don't know whether I am in that class or not, I will be told very soon), and we are going to do everything possible to bring out the interest of the people in our community.

MR. FRED MEYERS: I might tell you a few things the Wabash intends to do in reference to carrying on this drive. As Mr. Switzer stated, we have out letters from our General Manager, the superintendent of motive power, the superintendent of maintenance of way, asking the men for their cooperation. In addition to that, we have issued a number of press notices to be published in all the papers along our line every three days, beginning about October 5. We have already secured the active cooperation of the preachers and we have set aside Sunday, October 19, for a sermon on safety in all the churches. In addition to that, we have pro-

vided the celluloid buttons for all the employees. We are not going to hold any rallies but we are going to hold noonday shop meetings in all our principal shops and local division points. We have already circularized the membership of the various organizations and those gentlemen have responded most heartily, saying they would give their active support and the question of safety would be discussed thoroughly, and particularly this drive, at all lodge meetings that are to be held up until that time and during that period.

We have also arranged to put out a train order daily to all transportation employees. a different order will be issued at twelve o'clock every night and the enginemen and trainmen have been requested, after they have read this order, to throw it off to section men. We hope, gentlemen, to make 100 per cent.

MR. MITCHELL: Our policy is going to be to reach every individual employee to make him realize his obligation to assume his responsibility for that period. We have started very much on the lines outlined by Mr. Switzer. The Federal Manager has put out a circular letter that has been sent to every officer, employee and assistant. We are going to see that it reaches every one of them and then we are going to follow it up through the heads of each department clear down through and see that those policies are in force.

MR. RICHARDS (North Western): Now you have heard about the many things that are going to be done. Our new Chairman has told us what they are going to do on the Wabash. We are going to do all those things, including the furnishing of celluloid buttons to every employee on the system, but it seems to me the place to start the drive, the way we are going to start it, is to hold meetings in the various states in which we run, have every superintendent, master mechanic, division engineer, foreman, trainmaster, and men that have supervision over men get their employees together and tell them what we want to do so that everybody will have a good start and understand the theory upon which this drive is going to be carried and then to get them to go home and carry the message and see if they cannot bring out the results that are wanted.

One of the things we are going to furnish them at that drive is the statement of the accidents that occurred in their territory during the same period in 1918, and also a statement showing the accidents by division and occupation during the no-accident week drive so that they will know exactly what they are up against, how many accidents they had before and what they have to do to improve their record. We are also going to send to every supervising officer on the railroad, a letter from the Central Safety Committee calling attention to the matter, and also letters to every member of every safety committee on the road.

MR. SHEDD (Rock Island): I think most of us, at least, are going to do the same thing. The first thing we are going to do is to follow out the wishes and the outline of the organization. I take it from Mr. Duffy's circular that he wants us to put our own initiative into the drive as far as possible and not expect some one to outline it and hand it to us. We

are going to carry it out the same as we did before. We were not first, nor seventh, but we did a good job.

We are going to get the greatest publicity possible. Our General Manager has already issued a circular, a personal letter I should say, instructing the men who are in charge of men to go out without delay and explain the movement, the idea and the desire to them. We want 100 per cent and we are going to try for it. We are going to reach the preachers, the school children and everybody else. We are going to lay a special emphasis on getting Bill either by the hand or by the nose and get something into his head from our head by coming in personal contact just as far as possible. We expect to have a good record.

MR. STONE (Erie Railroad): I am proud to say that our organization at the present time is very enthusiastic about the drive. We are going to conduct our safety drive along the same principles that we have conducted them in the last six months and we have had a record second to none of any road in our Eastern region. Our method of conducting drives is to select men for our committeemen who are practical and who are men that have a bearing with their fellowmen.

MR. STAPLES (Southern Railway): Did I understand Mr. Meyers to say he is going to issue a safety bulletin in the form of a nineteen order?

MR. MEYERS: Yes.

MR. STONE: Don't you think there is an element of danger there?

MR. MEYERS: Absolutely not. Do you think the same of a slow order?

MR. PETER GROOME (Union Pacific): The Union Pacific Line, I believe, was second in the Central Western region in the last drive and we are going to hold all our safety committee meetings, forty-eight in all, before this drive comes off. We will hold meetings in all our shops and in all our terminals where the master mechanic, general supervisor, and supervisor of motive power will address the men. We are going to try to get in touch with every man. The trackmen are an element nobody seems to think much about but we are sending our general road master over the line to talk to every section foreman and every lineman in the track gang and also the bridge gang. We are reaching everybody and I am going to serve notice on these men from other regions that when the vote is counted you will hear from the Central Western region as in the first rank.

MR. RAWLINGS: During the last drive we went over the entire system with motor cars of the Salt Lake, Los Angeles, and Oregon Short Line and we got in touch with every man on the road, the station agents and all the section men and in this drive we have the cooperation of the superintendent, the trainmaster, and the master mechanic and we are going to take the inspection car and go over the entire line and stop and talk with every man we come to on the right-of-way. We also have a number of stickers that we are placing on every letter that leaves the office, and we have bulletins besides the National Safety Council bulletins which will be posted during that week.

MR. J. A. McNALLY (Wabash Railroad): I see a chance to slip over two extra minutes. The boss just sat down and they cut him pretty short. I

want to say that the Wabash Railroad is going to do something this time that we did before, that is we blow the whistle for a period of one minute at the shops and it causes the people to wonder what it is and when they ask questions they soon find out what it is for. It is a daily reminder to the employees.

We have the superintendent of motive power issue instructions to the master mechanic and shop superintendents to hold a daily inspection of tools in the shop, not only previous to the no-accident drive but all the time, and we have men going over the road on motor cars making talks to the section men along the line and we have also taken it up with the automobile drivers of the country by having posters made and placing them in the garages and other places, and there is one other thing we are going to do. We are depending on the women to help us out in this no-accident drive. We are going into their lodges and auxiliaries, telling them the object of this drive. In view of the fact that the Interstate Commerce Commission are showing that 27 per cent of the accidents are caused by quarrels in the family before the man leaves, we are trying to get these women to follow the old proverb, "Always leave them laughing when you say, 'Goodbye.'" That is what we are getting into the safety movement on the Wabash; we are going after the women. God bless them and help them always.

MR. ISAAH HALE (A. T. & S. F. R. R.): With the possible exception of the special train and the brass band, I do not know of anything that has been spoken of here as being under way or going to be undertaken that the Santa Fe is not going to undertake. We expect to make some noise working on this drive on the theory that "the wheel that does the squeaking is the wheel that gets the grease."

MR. ANDERSON: I want heartily to endorse what Mr. Richards, of the North Western Railroad has said about having meetings of heads of departments and their subordinates. Start it right. That is one of the fundamental and most important things to do. Now the point I want to bring out that has not been touched upon is this: If you all recall the man who served at our Section last year, whoever he was, got up and made a talk to you all and he appealed for a clean-up week. I want to say to you if you want to get real results in this campaign, have your clean-up week just prior to your national railroad accident-prevention drive and then when you begin talking and preaching safety to the men in the yards and on the line of roads, you have something to show them in the way of clean yards, clean rights-of-way, and clean shops.

MR. ARTHUR KIRKENDALL (Regional Supervisor of Safety, Allegheny Region): We have had many examples of publicity during the last year or two, more than we have ever had in the history of the world, through these campaigns that were conducted. During the war all the literature put out by the Red Cross, Liberty Loans, etc., wouldn't have gotten them very far in accomplishing what they intended to if they hadn't gotten right down on the ground to the man. They got hold of them individually and talked to them. Some men said, "I can't buy a bond," but through a little persuasion and explaining the matter to them they

bought bonds and they got away with it. We can do the same thing in this safety campaign; tell the men right on the ground what we want them to do and enlist their coöperation and we can get that coöperation in any degree and I am sure the results will surprise us.

MR. BRENNAN: I am impressed with the remarks of track conditions. I might say that on the Long Island we have been having mid-day discussions, with moving pictures (as a great number of our track men are Italians and not familiar with the English language) on track conditions.

We are circularizing all the churches and schools, and the General Manager is sending out to every employee in the service a letter enclosing the celluloid button and we are going to go on driving with every possible effort. We have a small road and we hope to get good results.

MR. T. F. BARRY (Chicago Junction R. R.): In connection with our activities in the no-accident campaign we have shown our employees that they are in the right place by starting a clean-up campaign. In two weeks we loaded up 300 carloads of dirt from our right-of-way and it was still going on when I left.

MR. H. H. HAWES (Union Pacific): I speak as an employee. The way to put this drive over is to show these men you are going to do something, none of this camouflage. I have heard agents get up in here and say their roads are perfect and representatives have told me that the conditions are rotten. Clean up your own back yard and then look at your neighbors.

MR. F. C. HUNTER (Union Pacific): I believe it is the duty of every safety man and every safety committeeman to see that his house, as far as safety is concerned, is clean at all times. I fear that our committees are not doing what they should for themselves. Let us watch that condition and impress upon our committees that they must have a clean house.

I know my friend, Hawes, is not talking about the Union Pacific at Council Bluffs. We have called attention to transfer lines not receiving the attention that they should and if any of the directors of safety on those roads have received those suggestions I hope that they will get busy in order that we may maintain our organization in its full capacity on our line.

CHAIRMAN BRODERICK: The time is getting very short and we have several more subjects to discuss. The discussion of, "How to induce members of Safety Committees to report unsafe practices among employees" is next. Won't someone start the ball rolling?

HOW TO INDUCE MEMBERS OF SAFETY COMMITTEES TO REPORT UNSAFE PRACTICES AMONG EMPLOYEES

MR. FRANK E. OLDS (Union Pacific): Now you are getting into a question that deserves a lot of attention from the most conservative members of this organization. "How to get employees to report unsafe practices among employees?" That sounds like you are going to jeopardize some man's position in train service. Those things have taken a great deal of my attention. I haven't reported many a man but have personally consulted and talked and pleaded with him and tried to teach and show him

the necessity of not practicing what he was doing, such as sitting on the brake staff and doing other things which we all know are very dangerous and hazardous. I have done that to no avail and I have felt at times in my own heart that such a man is a detriment, not only to my organization, but to the railroad that is advocating safety first and to competent employees. What can you do with those men? You know they are unsafe and not competent and you can plead with them until the dawn of day, finally you will see them with a foot off or a hand off, or they have fallen and broken their back or their leg.

It seems to me that the operating officials of the different roads should, in some way, take those men, after their examination is over and they are entitled to receive their switchkey and their book of rules, and give them a lesson upon those unsafe practices which they are bound to go out and commit immediately in order to class themselves as old-timers or as old-heads.

I would like to hear from somebody on this who has had more railroad experience than I.

MR. WENDELL H. STILLWELL (Chicago, Rock Island & Pacific Railroad): We have no trouble whatever to get employees to report unsafe practices on the part of other employees. The committeemen come to the meeting and do not hesitate to say, "I saw John Brown yesterday riding on the pilot step of a locomotive, contrary to the instructions, and I talked to him about it and I saw him do it again this morning: now I think you should talk to him."

We work along those lines and we don't have any trouble because they know it is all done for safety first. They are not going to be disciplined but they are going to be talked to.

MR. ORR: Every fireman and every brakeman employed come to me for instructions in safety first. We have first aid boxes on all our trains and they are instructed in the use of those boxes.

CHAIRMAN BRODERICK: Has any other member anything to say on that subject?

MR. MAYO: We have found a great deal of difficulty on our lines to secure reporting practices by members of safety committees. However we are getting by that to a very large extent by providing each member of the safety committee with two forms which he uses each month. This form is a record of what the individual committeeman accomplishes during the month. They give a record of the unsafe practices of employees during the month. They do not furnish the name, we do not care about that. They report something like this: "Saw a brakeman kicking draw-bar over with foot. Cautioned him. Promised he would not do it again." That is merely an illustration of the manner in which these forms are used and they are bringing to us practices that we never would have gotten any other way.

MR. V. M. PACKWOOD (Wabash): Now my experience along that line in getting men to turn one another in has been a pretty hard proposition.

We carry no discipline whatever. Whenever I catch a man doing an unsafe thing I turn in a safety card and the superintendent will write

that man a letter. In that way we are advertising to those men that there is no discipline and it is not held against them.

CHAIRMAN BRODERICK: If there is no further discussion on this subject we will pass to the next. "Best method of conducting 'No-Accident' Campaigns. Should train accidents be included?" Will some one start the discussion?

BEST METHOD OF CONDUCTING "NO ACCIDENT" CAMPAIGNS

I might say that the B. & O. has conducted, what we term, no-accident campaigns. One is going on right now. It started on July 15 and will terminate on October 15. We are including in that campaign, accidents of all characters with the exception of injuries to what is designated as other person's injuries. As you all know, railroads don't have full control over accidents happening to other persons. We are not including accidents of that class in the totals but we are including what are commonly known as train accidents and a train accident is charged when the wreck train is called out to help put things right. If the wreck train is not called out, then it is not classed as a train accident. With those train accidents we are also including the casualties to employees.

The Eastern lines conducted a similar campaign which ran for three months and terminated on August 31. In both cases the results have been very gratifying.

The last report of the Western lines that I received before leaving Baltimore, as of September 20, the last record made up, showed that of all those accidents, train accidents as well as accidents to employees, they had a reduction of fifty-nine and seven-tenths per cent compared with the same period of last year. That is conducted on the basis of gross ton mileage for the period of this year compared with last year, and the division making the best improvement will get the pennant flag that will be offered as a prize in addition to a dinner that will be given to one hundred employees from the division winning that particular prize. Those one hundred employees will be arrived at by selecting thirty-three employees from the maintenance of way department, the maintenance of equipment and the transportation department, and the division officers and the general officers will be invited to be present. It has caused a great deal of rivalry. The divisions are on their tip-toes and endeavoring to win the prize and make the best showing.

That is what we have done and if any other roads have had similar experience we will be glad to hear from them.

If there is no discussion on the subject, of course, we will pass it along and go to the next one.

MR. ANDERSON: Regarding the question, "Should train accidents be included?" I believe the Railroad Administration means personal injuries and casualties and train accidents.

CHAIRMAN BRODERICK: Of course, if it is a personal injury as a result of a train accident, that would be included, but of course there are a lot of train accidents where there are no personal injuries involved.

MR. H. A. ADAMS: Do I understand that you mean by accidents: One wreck, two wrecks, three wrecks, etc.

CHAIRMAN BRODERICK: I mean where the wreck train is called out to clear it up.

MR. H. A. ADAMS: The question was whether or not that should be included in computing this no-accident campaign.

CHAIRMAN BRODERICK: Not in this particular campaign. It wasn't intended to apply that way.

MR. WEBB: I personally do not think the train-wreck accidents would come within the original scope of this thing.

CHAIRMAN BRODERICK: Does any one else wish to express his views on this subject?

The next is, "Should Safety Agents be clothed with authority to require correction of unsafe practices?"

Mr. Mitchell of the New Haven road has kindly consented to start the discussion on this subject.

SHOULD SAFETY AGENTS BE CLOTHED WITH AUTHORITY TO REQUIRE CORRECTION OF DANGEROUS PRACTICES?

FRED W. MITCHELL, SUPERVISOR OF SAFETY, NEW YORK, NEW HAVEN, AND HARTFORD RAILROAD, NEW HAVEN, CONN.

No person will question the necessity for effectively correcting unsafe practices or conditions with the least possible delay.

The New Haven Road's safety work is conducted on the basis that supervising forces understand that safety is the first consideration and that their responsibility in this particular is as exact as in any other and can be subordinated to no others.

Safe practices are inseparably yoked to safe conditions.

The safety agent must be interested in both.

Forbidding the use of defective tools without providing suitable ones, has no place in a Safety program. Neither has the criticism of wrong practices without pointing out the right ones.

His work is humanitarian and is based on the second commandment "Love thy neighbor as thyself." Therefore the safety agent's work includes the giving of advice or words of caution to the uninformed or the reckless.

He should have permission to talk to employees on duty with a view of promoting confidence in the work, but he should not abuse the privilege or become annoying.

He needs no authority to command correction of unsafe practices or conditions except through the proper supervising officers. His knowledge that they prevail, reported to those in authority takes the burden from him and places it with responsible officials working under definite instructions. But the fact that he (the safety agent) is no longer responsible does not relieve him from following the matter to a conclusion.

He should suggest and recommend, not direct and compel.

Coöperation is what we want not coöpposition.

No man can serve two masters—the foreman is responsible to the general foreman, the general foreman to the master mechanic and to no other. Any attempt to compel recognition of direct orders from a safety agent except through the supervising officer, tends to demoralize effective supervision and delays the correction of wrong practices and conditions through a possible feeling of antagonism to usurpation of authority.

When our safety inspectors visit a shop, roundhouse, terminal or yard, they note all things unsafe and suggestions or recommendations made by employees toward safer working conditions, and before they leave the plant they submit a copy of these notes to the official in charge who is expected and required to handle the suggestion promptly.

A copy of the notes is also sent to my office and each item is followed up until final disposition is made.

The safety inspector is informed of the action reported and on his next visit sees that proper handling has been given.

We are getting the right kind of coöperation by following these methods. Working harmoniously with all departments has done so much in advancing our work that I feel any changes would be detrimental, and I therefore am opposed to clothing our safety agents with authority to correct unsafe practices except through the proper supervising officers.

In fact, I think we can answer that in just about two words: They should be clothed with authority to correct the unsafe practices. The question is, how should they correct it? I don't know what the training of most you representatives has been and what department you came up through, but I came up through the operating department and I believe our theories are correct. There is one thing you will have to bear in mind if you are going to get the coöperation of the operating officer: I was talking to the general superintendent on our lines the other day and he was discussing certain positions. He referred to a trainmaster and he said, "That trainmaster is the fellow who can roll the most wheels."

That is what the operating officer has in mind first: Move your track. The first thing the trainmaster has to do is to "roll the wheel" and that is the first thing to which he is going to give his attention. I believe we have got to recognize the practical side of the safety efforts as applied to the operating department.

CHAIRMAN BRODERICK: Does any one want to discuss this subject?

Mr. BRENNAN: I think it is self-evident to every railroad man that when you make a suggestion it is made for a particular reason and that the element of courtesy should enter into the solution of the matter. I think, as Mr. Mitchell said, you should coöperate to a certain extent with the foreman; otherwise, you will antagonize him and your best efforts will be in vain.

CHAIRMAN BRODERICK: If there is nothing else on the subject we will pass to the next one.

Mr. J. C. Clark is to start the discussion on that subject.

TO WHAT EXTENT SHOULD SUPERVISING FORCES BE
HELD RESPONSIBLE FOR THE SAFETY OF MEN
UNDER THEIR DIRECT SUPERVISION?

J. C. CLARK, ASSISTANT TO GENERAL MANAGER, OREGON SHORT LINE AND LOS
ANGELES AND SALT LAKE RAILROADS

The supervisor's forces work under different conditions in different departments on a railroad. Take the mechanical department in the shops and the men of the various gangs work under the direct supervision of a foreman. The foreman is in a position to see what each man does almost every minute of his working time. That same thing applies in the case of section crews and in bridge and building department crews. In cases of this kind where the individual workman is under the constant and watchful eye of the foreman, I think that he should be held responsible for the safety of those men for the reason that he is able to determine, by personal contact, the men who are safe and the men who are unsafe. If he has a man whom he considers unsafe for the work he is doing, he should get rid of that man, transfer him to some other department where he is not hazardous or else relieve him from the service entirely.

On the other hand, we have trainmasters, for example, who have supervision over men scattered over the entire division. It is not possible for a trainmaster to watch constantly the performance of all the conductors, brakemen, engineers, firemen, and other employees in that line while they are out on the road. He soon becomes familiar with very foreman; he knows in a general way what men are safe and what men are unsafe. Of course, it is his duty to correct the unsafe methods of the men when they come to his attention, but it is not possible for him to know continually what these men are doing. Therefore, in the case of a trainmaster or other supervising officer who has men scattered over a large territory, I don't believe it is possible to hold a supervising officer responsible to any great extent for the safety of the men under his supervision.

The question of securing safety men is one that is of vital importance to all the railroads and in all the departments. It seems to me that we should go at the selection of employees in a more scientific and definite manner. As a rule, the employing officer takes the man whom he thinks can do the work. That opinion is based very often on previous records which he secures from other companies with which this man was working, but there is no test given, so far as I know, by any railroad in the United States to determine the capabilities of a man. It is possible to apply intelligence tests to test new men who come into the service, but, of course, that wouldn't determine whether he has good judgment, it wouldn't determine whether he is capable of leadership but it would determine the general intelligence of the man.

It is not so difficult to train a man of good sound intelligence in a safe and efficient method of doing work. If we have a man who is not up

to the average of intelligence. it makes the task of educating that man immensely more difficult.

In the recent draft of men into the United States army, such an intelligence test was inaugurated and put through. More than 1,000,000 men were given this intelligence test. After these men had been assigned to the various regiments and sections of the army and navy, the Secretary of the War Department, who had charge of this test, asked the officers of various companies, and the various units in all the departments, for a rating of these men. This was in order to check up the results of the intelligence test and they found that in about 90 per cent of the cases their intelligence test showed the same results as the report of the officer in charge of the man.

It seems to me that the whole question of organizing an efficient railroad organization depends upon getting the right man to begin with; next, it depends upon the proper education and training of that man. The education and training is largely up to the supervising force, although there should be an educational department in every railroad to follow up, particularly, the education of the employee. In any event, the supervising officer is the man who has the best opportunity to train the man. If the employing officer has the good sense and the good judgment to select intelligent men, energetic men, who have a common school education at least and who are capable of development, the supervising officer will, in 90 per cent of the cases, do good work; where he is given good support, he will secure good results.

When it comes to the direct question, though, as to what extent the supervising officer should be held responsible for the safety of the men under his direct supervision, it is hard to give an answer. Very often the supervising officer has nothing whatever to say about the employment of the man. He asks for a man to fill up his gang and they send him some one. He didn't hire him; he doesn't know anything about where he came from, but he has to take him in a great majority of the cases. Where that condition exists, I don't believe it is fair to put too much on the supervising officer.

CHAIRMAN BRODERICK: You have all heard Mr. Clark's talk on this subject which was very enlightening. Has any one else anything to say? We will be very glad, indeed, to hear from any one present.

Mr. Baltzell, I understand, has a proposition to bring before this body on the subject, "Reaching the children in schools in educational work."

Mr. C. H. BALTZELL (St. L. & S. F. Ry.): I am a division superintendent on the Frisco Railroad down at Fort Smith, Arkansas.

This is the fourth year that I have had an opportunity to attend these wonderful safety meetings. I was, just wondering how many other division superintendents had visited this Congress this time. It does seem to me that every division superintendent throughout the country should make a special effort to attend these meetings because the division superintendent is certainly the mainspring of the whole proposition when it comes to safety on his division. If he is a real honest-to-goodness safety man, it is going to be a safe division; that goes without saying.

The division that I had up to the last three years was between Springfield and Memphis. When they began the safety work on the Frisco Railroad, my division won the safety-first prize three years in succession. That in itself was a mighty good showing.

Since I have gone over to Fort Smith on the Central Division, we have continued to make a splendid showing in the reduction of personal injuries, and in the May drive throughout the Southwestern district, my division made the best showing of any division in the territory.

I am strong for organization in all the departments, and especially in the safety department. I believe that your safety committee should be selected with the utmost care and if you find that you have made a mistake after careful consideration and a fair try-out of the man, don't keep him on the team. Get the right kind of men, but you must be tolerant and patient as it takes a number of years to bring about satisfactory results in safety work. We see it now in a way that we didn't recognize it in the first year by any means and it is growing stronger and stronger. Not only the railroad companies, but the industries throughout the land are recognizing this wonderful work in safety.

REACHING THE SCHOOL CHILDREN IN SAFETY WORK

I want to tell you briefly the plan that I put into effect at Fort Smith some time ago. Our division meets once each month; I have a good strong committee of about thirty men (you can't have too many if they are the right kind): we move from one point to another on the division, and towns along the line are making bids for these meetings, we have applications five and six months ahead to hold these division meetings at the various towns. We hold our regular business meeting in the morning, and at one o'clock I make arrangements with the superintendent of the schools to have my entire committee there with the boys and girls in the assembly room, or if it takes two rooms we use two rooms, but we reach all of the school children in that town.

I introduce my committeemen and tell them, "This is Bill Jones who runs 5 and 6. He is an engineer and Tom White here is a conductor," and so on all the way down. It is interesting to them and then we point out to them, in a way that they thoroughly understand, the dangers that surround them when they are on the right-of-way, the danger of hopping trains, passing under the cars, in and around and about them, etc.

I have a printed slip that I place on their desks and I say to them, "I have a printed slip on every one of your desks and I want you to fill in your name, your age, and this date, and I ask you to pledge yourselves in the interest of safety, and to use your influence with other boys and girls to do the same." We gather those slips up and I make those children a part of my auxiliary committee.

Right now I have 1,050 high school boys and girls who are on my personal committee. You can't beat it. They go home and tell about the superintendent and his committee who came to the school house, what they talked about and the folks at home say, "If the railroad men are taking an interest in my boy and my girl like that I am for them."

In the evening we have a meeting, as most committees do. If there is a band in town we have it out and we make it a kind of a community picnic.

Make your meeting attractive to your committeemen and not have that old thing thrown up to you. "Well, here is another date for a safety meeting." Make it so attractive that when these dates are set the men will look forward with pleasure to that particular meeting, and those men must be trained by the superintendent and others to never let go of the job to be a safety man day and night, always on the job.

I want a rigid investigation conducted, perhaps, by myself. I want the foreman of the job to tell me all he knows about this case, what he did to prevent such an accident to one of his men. If a section man gets hurt, I want the section foreman to tell me what he did to prevent the accident of that man.

When you get your section foreman, your bridge foreman, your train-master, and every man in charge of men to really and truly work for safety, not only once in a while, but every day and every night, they are going to get results.

Another thing, I put it up to my committeemen like this: When you see a man taking chances, doing things in full violation of the safety rules and principles, caution him against those things. If that man gets hurt or killed, I want you to feel that you are responsible. You helped contribute to that man's injury or death. Now make that strong to the fellows in their meetings, in a general way you understand. Make that thought predominant constantly, that they are their brother's keeper and that they must get to the man, in the right sort of way, the man who is violating the rules, before it is too late. We make it a very friendly game but we certainly get results.

I must not take up any more of your time, but it is a real pleasure to me to see so many new faces and some of the old-timers whom I met in Philadelphia, New York, and St. Louis.

MR. J. J. HENRY (Pa. R. R. Lines): I make a motion that the association give a resolution of thanks to the superintendent for coming down here and addressing us.

(The motion was seconded and carried.)

MR. BALTZELL: Gentlemen, I thank you very heartily and kindly and I wish you could see my safety committee when I tell them about this resolution.

CHAIRMAN BRODERICK: Gentlemen, is there any business any of you would like to bring up before this session closes?

MR. CHAPIN: Gentlemen, I know we are all tired but I want to take a minute to place before you for your consideration and for your action, a topic which, I believe, deserves our future consideration and that is whether there is a need in the Railroad Section for a man or for a committee, if you please, to give expert advice on general questions which may bother us. To illustrate my point, I might say that on one of our divisions we had an accident which resulted fatally: A workman was adjusting the cross-head of a locomotive, which was under steam.

equipped with a valve gear. In so doing he had the bar and the cross-head and he pulled against the lap and lead lever. That moved the valve. The cross-head came back and he was killed. That was a very peculiar accident. We had four of those accidents and we found we were up against a real proposition.

It was put up in the form of instructions to the motive power department that in case a workman was repairing a valve gear on a locomotive so equipped, that he should disconnect the valve. The fact that we knew about those accidents enabled us to forestall other accidents potentially on other divisions.

Isn't it possible that some of us in this Railroad Section have had problems which have baffled us? We do not know that these problems are going to arise but if we can get some information from some central source which will point the way where danger lies we can perhaps head off potential accidents. My thought was that there certainly is material in this Section for such information. The proper method of getting that material or information would be to publish it so that it will be of use to all of us. It seems to me it would be worthy of consideration.

CHAIRMAN BRODERICK: Gentlemen, do you wish to discuss that subject? If not, and if there is no further business, there is a gentleman here by the name of Mr. J. D. James. He has some sort of a patent belt for preventing accidents that he wants to demonstrate before this body of men in this room.

(Mr. James gave a demonstration of a safety belt.)

Adjournment.

SATURDAY MORNING SESSION

THE meeting was called to order at 9:45 A. M. by Mr. Fred Meyers, the Chairman of the Section.

CHAIRMAN MEYERS: The first thing on our schedule this morning is an address by Mr. G. L. La Fountaine.

IMPORTANCE OF PROPER INSPECTION OF TOOLS USED IN SHOPS AND BY MAINTENANCE OF WAY GANGS

G. L. LA FOUNTAINE, GENERAL SAFETY SUPERVISOR, GREAT NORTHERN RAILROAD, ST. PAUL, MINN.

When I first learned that I had been designated to present to this meeting my ideas upon the importance of the proper inspection of hand tools used in shops and by maintenance of way gangs as a means of accident prevention, I was considerably disturbed, to say the least. Because the question had been so thoroughly and frequently discussed from every possible angle, I was rather inclined to minimize its importance and to feel that there was no possible further suggestion in the matter worthy of presentation to a body of expert Safety Men, but as I delved into the subject, I began to realize that, par-

adoxically speaking, its importance lay in its apparent insignificance—that merely because the question has been so widely discussed we are apt to “lay it on the table” and quite lose sight of it in the press of the more formidable phases of our work.

The Interstate Commerce Commission records for the year 1917 inform us that fifteen railway employees were killed and fifteen thousand two hundred and ninety-six were injured during that year while using hand tools, and certainly a very considerable portion of those accidents were due directly to defective and worn tools which would have been discovered and the unfortunate results of their use prevented had a proper inspection been made.

Of the entire number of persons injured, the shopmen were the heaviest sufferers, with five killed and eleven thousand four hundred fifty-one injured; maintenance of way employees were second, with a total of three killed and three thousand two hundred twenty-three injured.

In view of the above facts, I have come to believe that the subject is worthy of careful thought and, in my opinion, the only means of eliminating or at least reducing to the lowest possible minimum this ever-present source of accidents is by a well defined and carefully planned method of inspection.

METHOD OF INSPECTION

For the purpose of formulating a definite plan of inspection, all hand tools used in shops and engine houses may be roughly divided into two classes—those which are circulated in general use and those which are regularly assigned to individual workmen.

In connection with the first class, I would suggest that every shop or engine house employing any considerable number of workmen maintain a tool room in which all hand tools of general use be assembled at the close of the day's work. A competent man should be placed in charge of this room with the care and inspection of those tools as his sole duty; he should maintain his stock in a good, serviceable condition at all times, and any tools worn to any appreciable degree, such as a chisel with a burred or mushroomed head or a wrench with rounded jaws, the further use of which invites one or those minor accidents, should be repaired or replaced at once. It should be impressed upon this man that the primary purpose of his being employed is in the interest of accident prevention, and that the responsibility for any accident resulting from the use of a worn or defective tool which left the tool room in that condition must lie directly with him. We all know from experience that the average workman becomes calloused to repeated warnings and cannot be relied upon to inspect his own tools, but by thus making one individual responsible for their proper inspection, I believe we shall have done much toward reducing our minor accidents.

In respect to those tools regularly assigned to shop employees, we encounter, I believe, our greatest difficulties. These tools are kept in private lockers, and in a great many cases are subject to no other inspection but that of the employee himself. You will find as a rule, although he is known to be a conscientious and thoroughly dependable workman, that

his tools have been gathered during a long period of selection and he regards them with not a little pride—they have served him long and well and he resents the inspection which may question their further serviceability. He is perfectly aware of their little imperfections, but is loath to replace the old with new, feeling that the tool that he may get in exchange will not be to his personal liking. While it is true that he may continue using the old tools to the end of his working days with never a mishap, the chances are strong that sooner or later one of those imperfections of the tool will result in an injury to the user.

It is this ever-present possibility of accidents that demands our attention, and to meet that possibility we must have frequent and thorough inspections. Since the majority of workmen cannot be relied upon to inspect their own tools, that duty must devolve upon the shop foreman. Here again, of course, safety depends upon the attitude of the individual. The foreman can accept that duty in its higher light, as an opportunity to render real service to those in his charge by removing potential danger in the form of imperfect or worn tools, or he can accept that duty as an unpleasant task to be performed with the least possible inconvenience to himself.

To my mind, the foreman can make the most effective inspection of tools while they are in actual use because of the opportunity this affords him tactfully to demonstrate and explain the elements of danger in the imperfection, thereby teaching the employee by example, as well as precept, which would leave a lasting and favorable impression with him. This is much more desirable and productive of good, in my opinion, than the inspection of the tools in each individual locker, as the latter method does not care for the educational feature, which is of paramount value. Also such an inspection may be regarded by the workman as an intrusion upon his private property, even though such an assumption is entirely unwarranted.

The inspection by the foreman might well be supplemented by a competent Safety Committee, such as now exists in practically all well-organized shops. Inbued with the proper spirit, the members of the committee can make frequent inspections of their fellow-worker's tools with their own daily experiences as a guide.

TOOLS USED BY MAINTENANCE OF WAY GANGS

The importance of keeping the tools used by the maintenance of way gangs in good, serviceable condition is just as essential as that of every other department upon the railroad, and what I have said in connection with the method of inspecting tools assigned to individual workmen in the shops, will serve equally well with the maintenance of way gangs. The foreman of the gang should inspect the tools daily and know that they are in first class condition before permitting the employees to use them, and should be held strictly responsible for all accidents resulting directly from the use of worn or defective tools.

This inspection by the foreman should be especially severe during those seasons of the year when "green" men are added to his gang. Many of these men are absolutely inexperienced in the use of tools of any kind.

and defective tools in their hands are a cause of far greater concern than such tools would be if their use were confined to experienced men.

Not only are such inspections an absolute necessity in the interest of safety, but they all should contribute much toward economy and efficiency. A well conducted method of tool inspection serves a double purpose: Safety and Efficiency, the two great factors of modern industry, which go hand in hand. If a tool is to do the work it was originally designed to do, it must be kept in its original entirety. The more it lapses from that state, the less efficient and more dangerous it becomes.

In conclusion, I can only reiterate that which we already know so well, that in this class of accidents, as in all others, the human equation is the greatest problem—a problem that can only be solved by educating each man to supervise not only his own safety, but that of his fellow-workman as well, by convincing him that the principles of safety are designed only for his benefit and that his failure to observe them may work as great an injury to his family as to himself—by instilling those principles so deeply in his mind that their practice becomes automatic and instinctive. When men have been educated in safety to that degree, then and then only will safety supervisors take their place in the sun, along with the other great contributors to the welfare of mankind. Only when that millennium of safety and efficiency arrives may the safety man relax his ceaseless efforts and contemplate with pardonable pride the perfection of his work.

CHAIRMAN MEYERS: We will now have discussion of this very able and constructive paper by Mr. Broderick.

DISCUSSION

MR. JOHN T. BRODERICK (Supervisor of Special Bureaus, Baltimore & Ohio R. R., Baltimore): Mr. La Fountaine has covered this subject very thoroughly. We all appreciate the great importance of having tools of all characters, in the railroad shop, in the proper condition. We all know that by their proper maintenance and care they do contribute to the reduction of a great many accidents. Different roads, of course, have different methods of taking care of tools.

I suggest, Mr. Chairman, that you call upon Mr. Clark, of the D. M. & N., who, I understand, is a practical mechanical man and can tell us something on this subject that will be beneficial to us.

MR. W. A. CLARK (General Car Foreman, D. M. & N. Railway): I want to compliment Mr. La Fountaine on touching upon and covering a very vital and important subject that is not generally recognized as being as important as it is.

Speaking as a foreman in charge of shopmen, I can say that I have found the statements that he has made to be correct. I find that the key-note of safety lies with the foreman in our department. Our supervisor of safety adopted a system of calling the shop foremen together and holding weekly meetings. Over some of these meetings I had the honor of presiding.

We made a special point of emphasizing the necessity of the foremen

checking the condition of the tools and equipment that the men are using, also calling to their attention the fact that they are responsible not only for the output of the work in the shop but for the safety of the men in their charge.

It took us some time to get them to realize that that was a condition that we wanted them to observe at all times and under all conditions of service.

I might tell you that we have found that certain materials that were being used in the manufacture of certain tools were not suitable. That was taken up through our Safety Department, and through the Purchasing Department a better grade of steel was furnished for the manufacture of chisels and wrenches, thereby materially reducing the accidents from battering of mushroom faces and chips flying from chisels, chisel bars, and punches. We also found that it was very necessary to make a daily and a close inspection of hammers, particularly sledge-hammers.

We found that the grade of material which was used in the hammers was not that which was suitable. From a lot of them, little slivers and small pieces of steel flew off and men became injured. Through our Safety Department, that matter was called to the attention of the Purchasing Department and the conditions were improved. The same is true of the grade of materials—the wood or lumber—furnished in the handles of hammers. A lot of hammer heads flew from the handles. We were successful in obtaining a better grade of lumber and more care in fitting the sledges in the handles. We reduced our accidents along that line.

In addition to our foremen having realized that they were responsible and expected to make a careful check, we put on one of our men—a tool room man—who was thoroughly familiar with conditions of all our tools and the shop requirements. He is required to and does make a daily inspection of all tools. He not only goes through the lockers but he goes through the shops and examines the different tools that the men are using. In that way, we discovered that we could check up a number of defective tools that the foreman did not always find otherwise and which the men did not report.

I wish to emphasize Mr. La Fontaine's statement that the men do not think of their tools or examine them or pay any attention to their condition. We found that it was not until a man was injured or one of his fellow workmen was injured that he made any comment or report as to the condition of the tools he was using. Then, invariably, his comment would be that the tools were defective, showing that he knew it beforehand. In some cases, workmen have said that the foreman told them to use those tools and do it in that way.

I don't wish to take too much of your time, but to any and all of you who have charge of men and to the safety supervisors, in particular, I want to say that there is no more important part, in my opinion and in my experience which has carried me through various departments of railroad work, that will pay larger dividends or do more to reduce accidents in the shop than the careful and close inspection of tools.

MR. WENDELL H. STILLWELL (Chicago, Rock Island & Pacific R. R.): This matter of tool inspection is of vital importance to safety supervisors and superintendents. It may assist some of the men to get information as to how the different supervisors are handling this matter. As Mr. La Fontaine has recommended, a committeeman or some one designated by the foreman, who is a member of the Committee, inspects these tools in our plant. At one of our shop safety meetings last Monday, where between 550 and 600 men are employed, the Safety Committeeman who had been instructed by the general foreman to inspect the tools reported that a year ago he found thirty-three defective tools in the hands of workmen who were working with them. He immediately took steps to have them taken away. The month previous to this meeting, the Committee inspector found, in one of our shops, where a workman had taken a flat file and made a chisel out of it and was pounding it with a hammer. Another had taken a round file and was using it for a punch, pounding it with a hammer. Those things have been eliminated. Through a campaign of education on the part of the safety committees in that shop, and with the assistance of the general foreman, that kind of work has been stopped.

As regards tools in the hands of the maintenance of way men: Our maintenance of way department supplied the hand car tool houses with a Keystone grinder. I think the first intention was to sharpen their tools with this Keystone grinder, but our safety supervisor immediately got busy, when he found they had them, and insisted that they should also trim down the heads of their track chisels that were battered. It is being done with good results.

I merely mention these as some of the experiences that we have had. Possibly lots of others have had the same experience, and I think we ought to give such information to the supervisors.

MR. E. S. CHAPIN (Pennsylvania R. R.): I have found from inspections in sixty or seventy different shops, that the blacksmith's tools are the ones that need dressing, and he is the one who is busy dressing the tools that belong to the rest of the fellows.

Another point of attack that I have found in this question is the subject of the tool room with the engine house. The engine house tools are used by all gangs in all sorts of weather, indoors, outdoors, and frequently they do not receive the attention that they should. As an aid in that connection, the orderly tool room is greatly to be commended. You can tell when you walk into a tool room if that man has his tools in good shape. If he has them arranged so that he can see them readily and can pick them out without any hesitation, he is in a position to know whether or not they are in good shape. If they are piled in the corner or on racks, racked up one behind the other, he can't see them and they do not receive the inspection they should in his odd moments of comparative leisure when the tool room window is not busy. If we are to give proper attention to this subject generally, we must give the tool room our careful inspection. I never make an inspection without going over that point.

MR. J. A. McNALLY (Wabash R. R.): Mr. La Fontaine hit the nail

square on the head when he said that a good bit of responsibility should rest on the foreman in regard to the tools. In view of the fact that there had been some accidents in the shop on account of defective tools, we found it necessary to put this proposition directly up to the superintendent of motive power on the Wabash Railroad, and it was through the safety section that we had the superintendent issue an order to the master mechanics and shop superintendents over the road to cause a daily inspection of tools to be made, as well as a monthly inspection of all tools that the men had in their lockers.

We are holding the tool room foreman, where we have one, responsible for the condition of these tools. In small places, where we have a helper handing the tools out and taking them in, we hold the foreman responsible.

At the opening session of the Steam Railroad Section, Mr. Richards requested that if any of us have any accidents, he would be glad to have us relate them as they might be of benefit to the rest of the people. I have in mind one or two. There was one occasion when we had a man from the laboring ranks (he was not a skilled mechanic) who was placed on a job of wrapping steam pipes, that is, all the steam pipes on locomotives and throughout the shop. We had one main steam pipe running from the boiler in the blacksmith shop over to the machine shop. It was a six-inch pipe. It crossed two tracks. It would not clear a man on top of a car. The Safety Committee turned in a card to the effect that this wouldn't clear, so they had that pipe raised and they used an expansion joint. It was in the summer and there was no hurry to wrap the pipe. The foreman waited until such time as he could have a few spare moments for a certain man to do this work—the man I mentioned who was not a skilled laborer, and he put that man on the job. He got up there on a twenty-foot scaffold and was wrapping the pipe. When he got up close to the joint, unfortunately the joint blew out; the man fell off the scaffold and broke his thigh bone. He was a man of about forty-two years of age and had five children.

The question came up yesterday in regard to carelessness and a statement was made that 87 per cent of the accidents were caused by carelessness. Was that accident due to the carelessness of that man or was it due to lack of efficient supervision on the part of the foreman who would let a man work on a steam pipe under pressure? The only information he was given when he went up there was to wrap the pipe. The steam should have been shut off before he was permitted to work on it. No man should be permitted to work up on a high scaffold on a steam pipe with the pressure on.

I have in mind another accident—the only one of its kind that I know of on our railroad. A man was turning down a brass bushing on a lift shaft box. It was sweated together, and it was made long enough so that he could make two out of the one piece. You know what a piece of brass sweated together will do when it gets a little warm. He took a clamp and used a three-eighths stud, putting one on each end. He put the nut flush with the stud and ran the nuts down on the other end of the stud, leav-

ing about an inch and three-eighths of that stud sticking out in the center of this bushing. Then he started to file right-handed. He had on a new jacket. It buttoned at the wrist and turned back, leaving a little gap in the sleeve. This stud, revolving around, caught in the jacket; the jacket was new and it didn't give; it wrapped his arm around and broke his arm at the elbow, tore the muscles in each arm, injured him across the back over the shoulders, and the tool he was working with flew up and made a hole in his neck so that when he was given water to drink it would come out through this injury in his neck.

It so happened that within two or three weeks after the injury he was back in the shop working around, although at first it was thought he wouldn't recover. That is another case where both the man and the foreman, I believe, were careless. The man should never have put a clamp of that kind on with a stud of an inch and three-eighths, and he should not have filed it right-handed. The foreman should never have permitted a man to allow that condition to exist if he had an opportunity to see it.

Besides the daily inspection, there is one member of the Shop Committee in the department where the inspection is made. They have the machinist on the Shop Committee go through the shop with the tool room foreman and through the tool room and make this inspection. The boiler maker in the boiler shop goes with the tool room foreman and makes the inspection on the tools of the boiler makers.

We have been able since April 1, (that was the day this order was issued by the superintendent of motive power) to hold this daily inspection and reduce the number of accidents by defective tools 63 per cent.

I went over the road on a motor car and made a personal inspection of maintenance of way tools, and it was indeed surprising to find the conditions of the tools in that department. In five weeks, I caused to be turned in to the supply department 485 defective chisels, spike mauls and wrenches and crow-bars. That was over 260 more than had been turned in to the supply department in the previous eighteen months.

Another thing you meet in regard to the tool inspection is to find the man occasionally who knows it all. I recall one instance of a man who was doing a small piece of work with a saw, a hand saw. He was wearing gloves that came out over the end of his fingers and dangled. The wind from the saw was moving the ends of the gloves. I waited until he got through because I was afraid if I spoke to him he would hurt himself. When he finished, I said, "Brother, don't you think it would be better for you and for your fingers, the only ones you have, if you would remove your gloves when you are sawing? I wouldn't take that chance in a hundred years." He said, "Let me tell you something, kid! I bought this saw nineteen years ago, and I have run it for nineteen years. They didn't furnish me with one when I came here so I bought my own and put it up myself. I pretty nearly know what I am doing. And let me tell you, if they cut my fingers off, they are going to pay me." I tried to talk to him later, but he wouldn't listen to me. The next time I went back there, I talked to him again. The third time I went back the

fellow in charge down there gave me a card from this man with five items on it and they were all good ones. Today, he has his saw guarded, and he told me that that glove stuff was off.

MR. WILLIAM D. LENDERKING (Baltimore & Ohio): In connection with the paper just read, we have instructed all our tool room men to make a careful inspection each day. In fact, the tools, as they are passed back after having been used by the man in the shop, are examined before being placed in the racks. If they are found defective in any way, they are laid aside to be sent to the proper department for such corrections as may be necessary. The matter of chisel bars, cutters, punches, tools of that kind which formerly gave considerable trouble and which we all know caused many minor injuries and sometimes very serious injuries, is being taken care of now to such an extent that it is scarcely necessary for the safety agent, in passing through the shops, to call attention to defective tools. There was, however, a time, and that very recently, when maul handles and sledge-hammer handles were giving us considerable trouble.

My understanding was that because of the conditions which the war brought about, proper materials were hard to obtain; I mean materials which otherwise would have had ample time to season were placed in ovens and dried, and in that way the life of the wood was sapped out. After having had a number of maul handles break, the engineer of tests told me that such things, under war conditions, were not to be overcome then, and we have found since then that the materials received for this kind of work are very much improved.

The matter of mauls was also giving us considerable trouble. I recall two cases where an entirely new eight-pound maul was taken out and two licks struck with it and the maul fell into four pieces. That was due to imperfection in the manufacture. We immediately traced up the entire purchase, and we found many of them that wouldn't stand the test. We found some had been shipped out on the road to the various shops, and upon inquiry in the various tool rooms where they had been used, I found they were giving trouble. In one place, seven of them had completely crumbled just as though they were made of clay. Most of this has been eliminated.

We find that our tools from one end of the system to the other are in much better shape today than they have been for a long while, and it is simply due to the fact that the men who heretofore were willing and satisfied to use a tool in any condition are now realizing the importance of having all such tools dressed and placed in perfect order before using. I have seen men who, in fact, when somebody would try to slip a tool through with a burred head, would flatly refuse to take it out and work with it. That is true because the spirit of safety has gotten into the men themselves. They begin to realize more clearly that the safety movement is one for their particular benefit and they appreciate it.

MR. E. RICHARDS (Cotton Belt Route): I want to ask if the use of emery wheels or Keystone grinders for dressing up burred chisels is con-

sidered satisfactory. My experience is that when you grind a burred head on an emery wheel or any kind of a grinder, it camouflages the burred head and the crystallized particles are still present. Little flakes will fly when you strike it. That manner of dressing burred heads, I find, is not satisfactory. It has to go to the shop to be heated and annealed before the tool is safe.

MR. W. H. STILLWELL (Chicago, Rock Island & Pacific R. R.): Two of our roadmasters requested that goggles be furnished track men and section gangs to use while doing this work. The matter is now before the general committee.

MR. LENDERKING: The matter of dressing tools is one that possibly too many men think lightly of. No tool that has been used long enough to be battered at the head and have burs should be put on an emery wheel and dressed up. It should go into a forge and be properly annealed before being sent out for use again. Otherwise, the crystallized heads will do the very thing we want to get rid of, and the only way to treat them is by putting them into a furnace and properly annealing them.

MR. CHAMIN: When I was Chairman of the Safety Committee of one of our shops before I was in this game thoroughly, the question came up as to how far down they should permit a head to be hammered before the punch or cutter was discarded. It was found that if a man had a favorite cutter or a favorite sized punch for a certain job, he would take that back and ask that it be dressed, and he would do this so many times that he would be working with a half inch of metal if you would let him. A limit was made in the neighborhood of an inch and a quarter or an inch and a half, depending upon the size of the tool, below which a tool could not be redressed.

Another question which has been discussed here is the matter of tool inspection. This was brought up in our shops and the practices are not exactly uniform, but in general, regular inspections are made either by some man appointed by the foreman or the master mechanic, as the case might be, or by some member of the Safety Committee. The responsibility of the condition of the tools is kept upon the foreman no matter who makes the inspection.

MR. C. W. MOYTS (Union Pacific): I am not a blacksmith, but I have watched the tool game pretty closely. This thing of grinding burs off of chisels is not dangerous at all. If the proper material is used to start with, the chisel will stand burring over as far down as you can bur it and hang on to it. However, if the tool has been burned in the blacksmith's fire, the metal becomes hard and the sparks begin to fly right away, which is a dangerous thing.

Where the men are using files and one thing and another around through the car department, there is only one thing to do and that is to have the safety supervisor keep track of them. If you leave it up to the foreman, he will let good enough alone. He will be in a hurry today and will pass them up thinking that he will take care of them tomorrow. Tomorrow never comes. Have the supervisor of forces hold the man who

is using the tools responsible, and if he won't use good tools, get rid of him.

As a general thing we inspect our tools every day. Of course, there are regular monthly inspections made, but every day is the time to keep these tools in proper shape. Tools that are continuously being used are bound to get defective, and there is only one thing to do and that is to keep them lined up.

Mr. F. C. HUNTER (Union Pacific): With reference to the maintenance of way department tools, we have a pretty good scheme on our road. We run a supply car over six divisions once a month. That supply train is accompanied by the storekeeper, the roadmaster, the supervisor of signals, the trainmaster, the superintendent, one of the members of the Safety Committee or Department. We find that by giving a thorough inspection of everything the conditions have improved. One of my first trips on a supply train developed the fact that there were a number of defective tools in the maintenance of way department. I immediately interested the general roadmaster on that division in the matter of safe tools. I had the pleasure of going over that division a month ago with the supply train, and it was impossible, by the closest inspection, to find a defective tool on his division. I feel that that man has done a great thing to protect his men in the matter of unsafe tools. I think that we can do that on every division. There has been an improvement in the matter of repair tracks. One of my first inspections of the repair track developed the fact that there is something about all railroad men that makes them want to collect and accumulate something from somebody else. Repair track men, in a great many cases, will pick up chisels and things of that kind that we are unacquainted with in that department and will use them. On my first inspection, I found a number of defective tools. I got next to the Safety Committee, the foreman, the sub-foreman, and demanded an inspection be made at the end of each day after the work was over of all the tools. Not only that, but whenever a member of the Safety Committee was going through that part of the terminal or wherever the track foreman was moving about on the track, he would pick out a set or a few sets of boxes and go through the tools thoroughly. I find that that has made a great improvement in the condition of tools.

Recently, I looked through twenty-five boxes of tools with the result of finding three burred chisels, probably the effect of work during the day, but the men had put them back in the boxes and expected to dress them up that afternoon, while eight months ago, there were more than that. I believe that is a scheme that can be used universally. If a man is up against a surprise test at any time, not knowing when he will be called upon to account for the condition of his tools, you are going to have a better condition than you will have under a stated inspection period.

Mr. D. K. RAWLINGS (Oregon Short Line): In regard to the repair track, I would like to say that on my first visit to Pocatello I got in touch with the general car foreman and his assistant. We went over

the repair track to make an inspection of the boxes. About the third or fourth box that I got to was enough for the men to know all about it, and it spread over the track like wildfire that we were making an inspection of the tools. Wherever we found a tool short, we supplied it, and wherever we found a hammer in a handle that didn't fit, we had a man put a new handle in. We improved their tools, I would say, 90 per cent. On the next inspection, every man on the track was asking, "Are you going to inspect our tools today?" We said, "Yes." They said, "Our boxes are open." We went through every box on the track and supplied them with new, good tools and equipped them to such an extent that they were mighty glad that we went over their boxes. In doing that, we got in closer touch with every man on the repair track. I took the name of every man on the repair track and talked to him personally. There isn't a time now when I go over the track that these men don't come to me and say, "Come look at my tools. Tell me if I can make any improvement." They are keeping their boxes clean; they are keeping out the oily waste and the things that are hazardous and cause fire, such as an accumulation of dirt, grease, and the like in the boxes.

I have the cooperation of every one of those men along the repair track. I have been in close touch with them, and today I think I could go over the track and make an inspection of something like 240 boxes on the track and I don't think that out of the 240 I would find 200 bad tools other than those burred in the day's work.

At Milford, on the Los Angeles and Salt Lake, after holding a second or third meeting in the Milford shop, one of the men of the pipe shop came to me and said, "You gentlemen are preaching safety first and you are telling us about what to do. I wish you would come to the pipe shop and look at the tools we are working with." After the meeting was over, I went to the pipe shop. I am sorry to say that I did find a bad condition there. I talked to the man in charge of the shop, and we went to the store department and found enough material there that had been in the store department for nine months to repair every one of their tools and put them in first-class shape. It showed them that we were actively engaged in the things that were necessary to make it safe for them to work.

MR. CARROW: How long ago was that?

MR. RAWLINGS: In January of this year.

MR. F. S. BARCOCK (Pittsburgh & Lake Erie): I would like to ask the previous speaker whether his inspection of tools includes inspection of jacks. I would also like to ask what method of inspection he pursues in going over these jacks and determining whether they are in proper shape for lifting a load.

MR. RAWLINGS: All of our jacks on the repair track are inspected monthly. The jacks have all been painted red. They start in at the bottom, and they put a ring around the jack for each month that it has been inspected. When we come to a jack in the seventh month that has only six stripes on it, we take it out and send it to the shop, and we have a man at the shop who does nothing but work on jacks. We use

nearly all Norton screw high-speed jacks. They are taken down and the threads are examined and all the levers and latches and ratchets are gone over to see that they are perfectly square on the ends and not rounded. The jack is then oiled; we put a special grease in the head of the jack that keeps it moving all right.

MR. BARCOCK: With reference to the ratchet jack, I want to say that on several engines, shortly after the jacks have been inspected, we have had men hurt by a slip of the ratchet, the handle flying up and striking the man's jaw or some part of his body. We try to make the best inspection possible, but sometimes there is a defect in the ratchet which is not detected in the inspection. It is pretty hard to determine a defective jack until you really give it an actual test under load. Do you do that?

MR. RAWLINGS: Ordinarily, if a jack should kick or anything else happen to it, it would be taken out of service. The men would report it themselves. We make this monthly inspection, oiling and testing, but we don't test under load other than in service. If there is anything defective, it is reported. We have a card that goes on the jack immediately if it is defective, but whether it is defective or not, it goes under inspection. The jack is taken down and oiled, the cases are taken off the side and the ratchet is taken off to see that it is square on the end and not rounded. Sometimes they become round on the end. That very often causes a slip.

MR. DAVID MORE (Union Pacific): I want to tell you how far we have gone into this tool inspection. Our general manager gets a tool report from every shop on the U. P. every morning. The greatest trouble we have is among the men. There are two men in this country that we have to fight, and we have to fight them hard. One is the ignorant foreigner who doesn't know anything, and the other is the self-satisfied, conceited American.

We sent a man over the road to put safeguards on every machine that he could possibly get his hands on so the operator couldn't possibly hurt himself. He went up to one old man's machine and put a safeguard on it. The old man looked at the machine and said, "I don't want that on there. I have run that machine for thirty years and I don't require it. I know how to run that machine." When the safety man was gone, he took the guard off and threw it away. He was the self-satisfied, conceited American. The consequence of that is this: The guard was put back on that machine again and he took it off again. Two weeks from that day, our self-satisfied, contented, conceited American came up minus two fingers. He forgot what he was doing. Now we can't tolerate that. A man of that kind shouldn't be retained. We don't want such men.

The other fellow is the ignorant man. We have one man in our car shop who was injured with tools twenty-seven times in ninety days. That was a fact. He was an ignorant man and you couldn't talk to him. That was some years ago, when I had charge of the safety work in the U. P. shops in Omaha. I just know that to be a fact because I checked

up on it. I got the doctor's records and I got the records of the accident clerk and they couldn't fool me. I have the record of every employee on the U. P., whether he is a safe or unsafe man, and I can tell how many times he reaches the doctor. One morning, when I was in the doctor's office, he told me that he had had this same fellow back again. I asked to have him dismissed. He said, "What is the matter with me? Don't you think I'm a good man?" I said, "Yes, you're all right, but suppose all the employees on the U. P. were to be injured twenty-seven times in ninety days. We could not get enough doctors to attend to 32,000 employees." We don't want that kind of men.

I will tell you another thing that we have, and I will ask you to consider it. At one of our terminals, we have a novel method of checking up accidents. This is the way it goes: we post as follows: "For the last so many days, we have had no accidents in this plant." I look at that every time I go to that terminal. I go and see what is on that board. It is up there where everybody can see it. There were sixteen days in that plant, one time, when they had no accidents. One day they had an accident, and they all wanted to find the guy that broke the record.

At the bottom of that board is written "Safety Committee". Nobody's name in particular is put on it. It just reads "Safety Committee". That bulletin creates enthusiasm in the boys and they help us.

CHAIRMAN MEYERS: We have with us this morning Mr. Hawley, General Secretary and Treasurer of the Brotherhood of Locomotive Firemen and Engineers. Mr. Adams tells me that he succeeded in getting him to take part, this morning, in our program in place of Mr. Shay, who is the President of this organization, and whose presence is required elsewhere. We would be very glad to hear a few words from Mr. Hawley.

MR. A. L. HAWLEY: As I look among the members present, I see some of those whom I met years ago when I was engaged in the Interstate Commerce Commission work in the inspection of safety plans. I was the fourth inspector appointed. I stayed with the Commission eight years until I accepted my present position. I believe that I had a very good opportunity of seeing the advancement in the work of trying to protect the railroad employees. I know some railroads were in very bad condition, and I believe it only needed a little stirring up on the part of the government to have those railroads begin to look after their equipment. At the time I left the Commission, the improvement in the condition of cars and engines on the railroads over which I traveled was so noticeable that the average employee was speaking about the advances that had been made in looking after the interests of the employees in so far as the safety feature of it was concerned.

We closed our convention in the middle of July, in the city of Denver. There were about 540 delegates present. They unqualifiedly went on record unanimously in favor of the Safety Section in connection with the railroad employees, so that if the work is continued, as we hope it will be, you will have the hearty cooperation, in so far as the officers can prevail upon the members, of the Brotherhood. I hardly feel that it will

be necessary for them to put forth much of an effort. I do feel that you will have the cooperation of all those who are members of the organization which I happen to represent this morning.

I talked with a good many of our delegates at the convention in connection with the safety movement and the safety feature of it, and those who had taken a prominent part seemed to be enthused over the manner in which the safety features were being handled. They seemed to feel that all that was necessary was a continuance of what had already been done and what had already been put into effect, and that there would be less injuries and less deaths on account of neglect or something of that kind in connection with the employment.

It has been over ten years since I left the service of the Commission. I am going to take this opportunity of saying that my experience during the years that I was with the Commission showed that there was a lack of the railway companies furnishing the proper repairs in order to maintain equipment as it should be maintained.

Inspectors, as they pass through this city, whether they be new or old, generally drop into the office to shake hands with me, and I naturally ask them how things are going. They tell me that many bad things have been eliminated. If that is true, no one can say that the work is not redounding to the benefit of all the railway employees. That was one bad feature that we found during my time with the Commission. If the railroad companies will furnish the necessary supplies in order to make repairs when they are needed, I feel satisfied that the accidents will be reduced very materially.

All that is necessary, I believe, in order to make the Safety Section a pronounced success is a hearty cooperation of officials and employees.

I listened with interest to the remarks of the gentleman from the Union Pacific with reference to the cooperation of everybody, and especially that feature of his remarks where he said the bulletin was up there where everybody could see that they had gone for such a long time without an accident, and how everybody got around the board when they found one accident put up there. That shows that there is an interest being taken by nearly all of the employees, and if that work is continued that interest will grow, and I feel satisfied it will redound to the benefit of all railroad employers in so far as accidents are concerned.

I am glad that I have had this opportunity to say a few words to you, even though it came unexpectedly. I sincerely trust that the work in which you have been engaged this past week will result in much benefit to every one, that you will go to your homes carrying with you the thought that there is renewed vigor on the part of everybody to try and reduce the number of railroad accidents, no matter how large or small they may be, and if you carry to everybody the thoughts that have been expressed to you by the many who have addressed you and the thoughts that have emanated from your own body, I feel satisfied that as time goes on, you will find the accidents reduced almost to a minimum, and the railroad employees will feel that there is an interest being taken in them by the officials. They will come back with the same interest and

will try to avoid every accident, and soon you will have good reports of a month or more passing without any accidents.

CHAIRMAN MEYERS:—I know we all appreciate the very interesting remarks made by Mr. Hawley. We are very glad to have had him with us this morning, and we hope that he will be with us again.

The next number on the program is a paper by Mr. J. L. Walsh.

HAND AND MOTOR CAR ACCIDENTS

J. L. WALSH, SUPERINTENDENT OF SAFETY, MISSOURI, KANSAS AND TEXAS
RAILROAD OF TEXAS, DALLAS, TEXAS

When railroads were put in operation it was soon found necessary to provide some means for getting maintenance material, tools, and men to and from the work, and the means at first provided was a small car somewhat similar to the push car of today. This car was awkward, slow, and required considerable effort to operate. From this beginning hand cars were developed on the principle of a windlass transmitting the power to the wheels through a belt. Improvements were gradually made, developing the present-day hand car with a walking beam, transmitting the power to the wheels through gear. These improvements increased the speed at which the cars were operated, saved time and labor, but also increased the number of accidents and injuries.

About twenty years ago when the gas engine was brought out, experiments were begun in fitting these engines to push cars, and improvements made until we have today quite a selection of more or less efficient motor cars which provide the modern means of transporting maintenance men and material. Motor car manufacturers are spending considerable time and money in perfecting their cars and are of course anxious to put out the safest practical car possible. As this is very much to our advantage. I would suggest that railroads will materially benefit by coöperating with these manufacturers to develop a safe car, and that this can probably best be done by periodically giving the manufacturers a synopsis of the number and causes of motor car accidents, probably through the Safety departments.

With the increasing cost of labor and the pressing need for increased efficiency in all departments of railroad work which is to be brought about by increased supervision, the field of the motor car, already a wide one, is being extended very rapidly. They are not only now being used to advantage by track department employees, but by telegraph department linemen and repairmen, tie inspectors, stock claim adjusters, maintenance and valuation engineers, car inspectors and repairmen, painters, fire patrol men, signal maintainers, as well as by superintendents, roadmasters, supervisors, train masters, and others for whom it is necessary to get over the line, making frequent and irregular stops. The gasoline motor car is to the hand car what the automobile is to the horse-drawn vehicle, and I believe it will be but a comparatively short time until all railroads will adopt the motor car as standard over the hand car, for the reason that the motor car has demonstrated its value as

a time saver, as well as a labor saver. A section or a bridge gang pumping an old style hand car eight or ten miles to work have but little energy left for their regular duties, and in addition, the prospect of the return trip when the day's work is finished.

Injuries incident to the operation of hand and motor cars on the lines I represent for the year 1918 were about 5 per cent of the total. I find in classifying 275 of these fatal and non-fatal injuries that the principal causes were as follows:

Collisions

Train and Motor Cars.....	27
Train and Hand Cars.....	16
Motor Cars	11
Hand Cars	4

58

Derailments

Motor Cars	35
Hand Cars	9

44

Total Motor Car Accidents.....170

Total Hand Car Accidents.....105

The greater number of serious injuries are sustained in motor and hand car collisions and derailments, and it will be noted there were 102 such accidents, injuring 37 per cent of the total. The great majority of all motor car accidents are caused by main failure, that is the failure to comply with the operating department's rules, lack of ordinary care and

good judgment in operating the car, or in operating a car that is in defective condition, which could have been noted by a proper inspection, and corrected. This is the human element which has been mentioned so often and which can only be corrected by education.

When efforts are made to reduce the number of hand and motor car accidents, the first consideration is usually given to the rate of speed at which cars are operated. When accidents occur, such as collisions and derailments, the rate of speed at which car is being operated certainly has a great deal to do with the severity or extent of the injury sustained, but the speed of the car is not usually the primary cause of the accident. While division inspection cars might be operated safely at twenty or twenty-five miles per hour between stations on straight track, I think the general rule for section and B & B cars should provide a maximum speed of fifteen miles per hour between stations, and a maximum of ten miles per hour over road crossings, through yards, over frogs and switches, in cuts, on curves, and during foggy weather.

ORGANIZE MOTOR CAR DEPARTMENT

Railroads adopting the motor car as standard for the maintenance of way department, and others having occasion to use them, should organize a motor car department, in charge of experts to keep the cars in repair, to make frequent inspections, and adjustments from time to time, and to educate the employees using the car in its proper maintenance and safe operation. The expense of such a department should be offset by less delays and greater efficiency in cars in use.

On some railroads it has been the practice in the past to allow foremen to purchase their own motor car or gasoline engine with their personal funds, and in the latter case, a foreman usually fits the engine to a dismantled hand or push car, and creates a home-made motor car. This practice I think should be prohibited, as it is wrong in principle to require the employees to purchase their cars, and it leads to bad practices on the part of the foremen in many cases. Instances have developed where a section foreman made a monthly charge on his men for taking them to and from their work on motor car, in order to reimburse himself for the cost of the car. Other bad practices have also developed in this connection that have probably cost the Railroad Company more money than the purchase of a car would amount to besides encouraging dishonest methods among employees. In addition to this, hand and push cars are not constructed sufficiently strong to stand up well in service under the strain and pounding to which they are subjected when equipped with gasoline engines. These home-made motor cars in many cases are not properly equipped with the necessary safety devices, such as seats, guard or hand rails on the front of the car, toe-boards, and proper hand breaks.

The service for which a motor car is intended should of course be taken into consideration when car is ordered. Thus, the car intended for use of the superintendent, supervisor, or trainmaster in making inspection trips on the district, might well be fitted with an automobile type body, free running engine, electric starter, electric lights, signal

horn, etc. These facilities however greatly increase the cost and weight of the car, and make its operation and maintenance the work of expert mechanical ability, which we cannot expect among the rank and file of our maintenance of way employees.

For general use the motor car should be as simple as possible, fool proof, easy to operate and maintain. These cars I think should be of the direct connected type, two-cylinder engine with its few parts to get out of order and adjustment. If possible to attach a speed governor restricting the speed to a maximum of fifteen miles per hour to these cars, one that cannot be easily disconnected or tampered with, one that is simple and will not cause engine trouble, would suggest that all cars for general use be so equipped. There should be a curved hand rail or guard extending to the floor in front of car, and also a toe-board, to prevent tools and material from bouncing off and derailing it. The wheels should not be more than sixteen inches in height, and the floor of the car should be extended flush with the outer edge of the wheels to prevent men getting their feet under the wheels in attempting to board the car from the side. Last but not least, each car should be fitted with a positive acting, effective hand brake.

The surest method of keeping hand and motor car accidents to a minimum after adopting a practical, properly-equipped car as standard, best suited for the purpose intended, is I think, to promulgate a practical set of rules covering their inspection, maintenance, and operation, and see that they are strictly complied with.

I will not attempt to outline a complete set of rules or instructions in this matter, as they would necessarily vary under different conditions, but the following are some of the points that should be covered:

SUGGESTIONS FOR INSPECTION, MAINTENANCE, AND OPERATION

Some member of the gang using the motor car, other than the foreman, should be assigned and trained to operate the car, thus leaving the foreman free in going over the line to make necessary inspection of the track, bridges, right of way fences, etc., and also allow him to act in the capacity of conductor. The foreman, of course, should be equipped with the current time table and standard watch.

Each member of the gang should be assigned a certain regular place on the car, overcrowding avoided, and expected to keep a sharp lookout for trains in each direction. Certain members of the gang should be charged with the duty of flagging in either direction if necessary, and equipped with the necessary flagging equipment.

The men charged with the responsibility of putting the car on the track and taking it off should be assigned to a regular position with reference to the car, instructed and frequently drilled in the most practical and safest manner of handling the car, somewhat similar and for the same reason that boat drills were held on our trans-Atlantic steamers during the submarine warfare. This will result in less confusion, and increase the cooperation in cases of emergency.

Certain members of the gang should be assigned the duty of starting

the car from the rear, the other members of the gang taking their seats on the car before it is started.

Instructions should be issued and the men trained in the safe manner of loading tools and material on the car in such a way as to avoid chance of it falling off and causing derailment.

Motor cars should not be operated at night except in cases of emergency, and then only when protected by a red light that can be seen from both directions.

Employees should be prohibited from standing on the car or attempting to mount or dismount from same while in motion.

If truck or push car is attached to the motor car, it should be coupled close, and the men pushing the car to start, must push from the rear of the truck or push car. The truck or push car should never be placed ahead of the motor car.

Motor car should not be set off on public highway as serious injuries have occurred to drivers because of teams being frightened.

When necessary to apply brakes in emergency cases, warning should be given to all occupants of the car to prevent chances of their being thrown off by a sudden slackening of the speed of the car.

Motor cars should not follow a moving train closer than one thousand feet, nor follow another motor or hand car closer than five hundred feet.

The use of motor car should be confined strictly to Company business and should not be taken off the section on which it is assigned, except on instruction from superior officers, or in case of storm or emergency making it necessary to file report at nearest telegraph office and secure instructions.

Motor and hand cars should be thoroughly inspected by operator daily before starting to work, and necessary repairs and adjustments made.

The gasoline motor car has come to stay, and I believe all the railroads using them have issued rules and regulations governing their operation, but there is a general neglect in enforcing them, and little attention is paid to maintenance forces until a serious accident occurs, when for a short time the matter has more or less attention, followed by a gradual relaxation, until another accident occurs. We must bring about a realization that an injury or death among our maintenance forces is just as serious as in any other department of railroad service, and make a consistent effort to prevent them through safety education.

DISCUSSION

MR. D. C. SULLIVAN (M. & N. Railway): I notice that Mr. Walsh has said nothing about cars carrying torpedoes, which I think every car ought to carry.

MR. J. C. CLARK (Oregon Short Line): If I recall Mr. Walsh's statements correctly, they were to the effect that the car should carry full flagging equipment which would include torpedoes.

CHAIRMAN MEYERS: I would like to have this discussed by Mr. Johnson.

MR. O. F. JOHNSON (M. & St. L.): This paper gives in a very clear and concise manner the way motor car accidents occur and how they should

be avoided. I will make a few remarks as to how that is handled on our railroad. I might state, for your information, that we have approximately 265 hand and motor cars on 1,600 miles of railroad. One hundred and sixty-three of those cars, or 69 per cent, are equipped with motors. The balance, or 31 per cent, are common, ordinary hand cars. On only about one dozen of these cars that I mention are the motors owned by the railroad company.

It has been the practice for years to have the section men, the foremen, and possibly some of the men, purchase their own motors and install them on the handcars by removing the handles and part of the frame. This worked out fairly well. However, in a good many cases, we find motors are attached to hand cars that are not in very good condition. As a result we have accidents. The motors we have on our railroad at the present time comprise probably twelve or fourteen makes. I think you will find that quite a number of accidents are caused on the railroads in the United States through the fact that the car body is not of sufficient strength to handle the motor. Like a good many other lines, we make car bodies in the shops, and sometimes we have found that the section man used a battered up car and before we knew it some accident happened.

The paper that has just been read has a classification of 275 fatal and non-fatal injuries. The principal causes shown under the following classification are:

1. Collisions. I might call your attention to a few accidents that have happened on our railroad. In one case, the car was running about twenty miles per hour in a fog. Two cars collided. We found, upon investigation, that one of the cars had no light on the front end, which, of course, is against the rules of our company.

2. Derailments. In one case, a car struck two dogs on the right-of-way. That is something that could have been avoided by proper care on the part of the men. In another case, a car jumped the track due to the fact that the man operating the car was an unfamiliar person with the route and the track was also more or less rough. In another case, they ran into an open switch, throwing the men off. This could have been avoided by care. We had one accident where a car was derailed on account of a loose wheel and because the gage of the track was a little too wide on a curve, in other words, wider than standard gage.

Here is one case where a car jumped the track due to the fact that the engine was placed on an old hand car body. The body was badly worn and should not have been used. The foreman used his own judgment about using an old hand car body, and instructions were gotten out to discontinue that practice. We had one more case due to mechanism out of order on a motor, and as a result it was necessary to operate the car full speed in order to move over the railroad. The section men took a chance and as a result they had a derailment.

3. Falling from car. We have had several accidents from that. While riding on a hand car in front of a gas car, a man tried to stop the hand car by holding on to the gas car and was pulled off on to the center of

the track and run over by the gas car. That is rather an unusual stunt.

4. Lifting. The section man and laborer were putting a car on the track. While turning the car around on the track, the man assisting the foreman, dropped his end and as the result the foreman fell over.

5. Persons struck by. We had one case where a car was struck on a public crossing. There was a cornfield on the west side of the track and an automobile was coming along. The section man bombarded over the crossing and struck the automobile.

6. Other causes. We had several cases where the men got on the motor car from the front end instead of the rear, which resulted in three reportable accidents.

In this room, there are representatives from almost every railroad in the United States. Every railroad has a different set of conditions with which to contend. Some roads have tracks that are ballasted with rocks, others with slag, others with cinders, some with dirt, some with mud. Whenever you find those conditions existing on railroads, those roads are in line for accidents that would not apply to the hard-grade railroads. A good many railroads have a heavier rail than others. They have straight tracks, very few sags and hills. In the Spring the roads get rough and a man has to exercise a great amount of care to keep his motor car on the track.

For some reason or other, we have had quite a number of motor car accidents within the past six months, and I believe a lot of other lines have had the same trouble. I am unable to tell what is the cause of it. Except what few rules are in the operating rule books, our railroad has gotten out no special rules in the way of a booklet, except that we have issued one or two bulletins.

I will call off a few of the instructions to our men: Inspect cars before leaving tool house. See that tools are properly loaded before starting. See that men are seated on the car, both motor and trailer, so their feet will not get caught in frogs or switches. Have pushers get on from behind and not from sides. Do not overload the car. Run car yourself. Do not permit others to operate it unless they are capable. Obey flagging rules. Watch the speed. Fast speed spells danger. Approach highway crossings at slow speed. The more obscure the view the more need for caution.

Unsafe practices: Trying to beat an automobile or team to a crossing. Trying to get to a crossing either ahead of or against an approaching train in order to get an easy place to get off. Racing cars one behind another and running them too close together. Pushing a carload of either men or materials ahead of the motor car; the load should be pulled behind always. Leaving a car on the track any considerable length of time while doing work in the vicinity. Taking parties out for joy-rides or carrying passengers. Parking cars on a public crossing, and many other practices.

I don't know what information I can add to what has already been said. The subject is a big one, and I know that there are others who would like to discuss the matter.

One other thing, first: There are no hard and fast rules that can come

out of the book of rules that is issued, and any of the special rules that are gotten out in regard to handling motor cars, except that all men should use extreme good judgment the same as they do in other work, should be well applied to see that everything is done along safe lines.

MR. STILLWELL: I would like to ask a question. I assume from Mr. Walsh's paper and from this gentleman's statement that they are using a motor car that is direct connected, that the men have to push and then jump on after they get the exhaust started. There are cars with belt transmission where they crank the car and they don't start until every body is on, and they can go at any rate of speed they want to and there is no danger of anybody getting caught in attempting to jump on. What I would like to ascertain is this: Do the gentlemen present find that there are a greater number of accidents in the use of either one of these styles of cars?

There has been nothing said about an audible signal, approaching highway crossings. We have had a great many recommendations to equip our motors or motor cars with the Klaxon horn. I have opposed it, claiming that with a Klaxon horn on a motor car, at crossings in the city, if a horse-drawn vehicle or automobile were to approach and hear a Klaxon horn, they would assume it was another automobile on the highway and wouldn't look up and down the railroad track. It has been contended that we should equip them with a bell. I claim that we ought to have a gong. I think we ought to have something different than those used on automobiles and loud enough to be heard quite a distance away.

MR. JOHNSON: I might say that we have no audible signals on our motors except those on two Ford cars that we use for our superintendents. Those two particular cars are equipped with a whistle signal like the automobile signals.

Practically all of our motors are direct connected. In fact, all of them are, and it is a case of getting out and pushing.

MR. WEBB: Following up what Mr. Stillwell said, we are tremendously interested in this thing. We have had a regular epidemic of accidents the last three or four months, due not to the speed of the cars but to tools falling off. At the last meeting of our general committee, the general superintendent was instructed, together with the chief engineer, to design a standard for our motor car equipment, looking to the proper safeguarding of that feature. After digging into the matter, I find that there are two or three different kinds. I would like to know from some of these men who have the cars already if they find satisfactory that type that has an arch over the front with a bar running through the center to the back, high enough for the men to hold to, and then an arch at the rear, closed in, or a standard at the rear.

The point was raised that the man getting on after pushing the car, unless we left it open at the rear, would find it difficult to get on and in case of an accident it would be difficult for the men to unload.

I want to know what has been the experience of these men. Do they have the safeguard at all? Perhaps you who are running and using a perfectly guarded car can tell whether the type of motor car in use is

successful in keeping the tools on the car as they have it guarded, whether those cars have provision made in the shape of a receptacle or some other way for the tools, or are the tools placed on the car depending upon the guards in front and rear to keep them from falling off, and whether the installation of such guards, particularly in the rear, would interfere with the men getting on and off the cars.

We are designing a standard to be used on our line. If there is a successful standard, I would appreciate knowing it tremendously, because we are paying for the fact that we have no real guards on our cars at the present time.

MR. CLARK (Oregon Short Line): I would like to answer that question partially at least. A few years ago, we equipped our motor cars with the hand railing. We used it complete in front. In the rear we had just an arch to the box that houses the motor; that left the platform at the back free.

Just a word of warning: After we had equipped a large number of our cars with this hand railing, which was designed by one of our own men, we found the device was patented and had been for sale by a railway supply firm. You might get into trouble if you don't observe that point.

With regard to the free-running engines, we have a large number of Buddha engines or cars which have a friction drive and are free-running engines. We have a large number of Sheffield cars that are direct connected. I haven't analyzed our injury reports to determine if one car causes more accidents than the other, but looking at it from a practical standpoint, I think there is no doubt that the free running engine is preferable from the safety standpoint.

There is another point that Mr. Walsh brought up in his paper that I think is of very great importance. A year ago this month, we had a section man killed. It happened in this way: They were starting out to work in the morning, and the foreman was running the car. While he was doing that, he was watching the track. They came to a road crossing, and some of the men saw a team approaching on the highway, but they supposed that the foreman would see the team also. The driver of the team saw the motor coming, but he got up so close that the end of the tongue, or probably the neck-yoke, was so close that it struck one of the men on the car. It knocked him off and he was killed. It broke his back. There is a case where, if the foreman had had some one else running the car or some man assigned to look out for what might be on the track and approaching on the highway, and give instructions, the accident might have been averted.

That is just an illustration of the point Mr. Walsh brought up, and I think it is very important.

Another thing that I wish to mention is the speed at which motor cars are operated. Mr. Walsh showed that out of the total, there were 58 per cent, I believe, due to derailments and collisions. It is very probable that some of the collisions could have been averted if the speed had not been excessive, and no doubt a large proportion of the derailments were due to excessive speed. On the line that I represent, I am

convinced that the speed—the high speed—at which the motor cars are often operated is the cause of a great many injuries. I have found that it is practically impossible to get the men to hold down their speed. They are in a hurry to get home, and in a great many cases, we have them call the dispatcher to find out what trains are on the road. It frequently happens that the dispatcher will tell them that a certain train will leave a side-track maybe eight or ten miles away at a certain time, and they will run at excessive speed to make that distance first, because if they don't get there, they will have to take their car off and cause a lot of delay.

There is a governor appliance that will, if applied, give the necessary power to climb hills and also get a maximum speed, holding the speed down. I have seen one of them. In order to go on record, and possibly get some action on this important question, I wish to offer a resolution.

RESOLUTION

"WHEREAS, The largely increasing number of accidents and personal injuries result from the operation of track motor cars, and

"WHEREAS, A large number of such accidents are the result of excessive speed in the use of these cars, therefore, be it

"RESOLVED, That the Steam Railroad Section of the National Safety Council, assembled at Cleveland, October 1-4, recommend and urge that motor cars be so constructed and built that they will not exceed a speed of fifteen miles per hour, and be it further

"RESOLVED, That a copy of these resolutions be placed in the hands of all the principal manufacturers of track motor cars."

I move the adoption of this resolution.

(The motion was seconded by Mr. Robert Scott.)

Mr. Geo. L. Wmerr (Chicago, St. Paul, Minneapolis & Omaha): I would like to ask Mr. Clark if there is not an engine manufactured now that makes it impossible for the section foreman to exceed fifteen miles per hour. We have such an engine on our line, and it is impossible for them to exceed that speed. It is the Fairmont, manufactured at Fairmont, Minnesota.

Mr. WALSH: Mr. Chairman, we have those same engines, but we find that they are easily tampered with. If the section foreman wants to go thirty miles an hour, he can do it. We must get away from the use of a governor that they can regulate. We must get something automatic that cannot be monkeyed with.

Mr. CLARK (Salt Lake City): All this is a gas engine proposition. Every tractor that is manufactured has a governor on it. I happen to own one and operate it myself and I know that the governor is effective and cannot be tampered with easily. You have to take the whole case of the engine off in order to get at the governor. I have looked at the governor on a good many gas engines, and I know that there are several kinds that are effective. They are inside the case of the engine, so that you can't get to them without taking the engine down. They are

not sensitive; that is, they are not easily out of adjustment. If you get them set once, they will run as long as the engine will, practically, without being adjusted or tampered with at all, and it would be impossible for the ordinary man to get into that governor and make any changes.

MR. CARROW: Mr. Chairman, I have followed that resolution very carefully, but I am afraid that I didn't digest it.

(The Chairman reread the resolution.)

MR. CARROW: I have had something to do with this subject. I was in touch with it several years ago. I don't know anything about it from a technical standpoint, but I do know there are many divisions on our railroads where we operate the motor cars by train orders, and fifteen miles an hour would be simply out of the question under such circumstances.

It seems to me that the resolution has some features to it that might involve some delicate points. I doubt the propriety of subordinating efficiency to that extent. I can't see where a motor car, if it is going between points on a straight line on a good track, could be benefited by that. I don't think the efficiency of the railroad operation should be curtailed unnecessarily by curtailing the speed of the motor.

As I said, I am not speaking with any definite technical knowledge, but that is just the way the matter appears to me from a general impression of it.

MR. ROBERT SCOTT (Atlantic Coast Line R. R.): I was partly responsible for this resolution. I would like to clear up just one or two little points. We don't want to sacrifice efficiency, but we do want to introduce safety in the operation of motor cars.

On our line, we have had some very bitter experiences during the past six months, whereas up to that time we had enjoyed almost absolute freedom from motor car accidents. Those who followed the reading of this resolution very closely must have observed that we are not making this thing mandatory on any manufacturer or on any railroad. We are simply attempting to have this resolution passed for the moral effect which it will have in the reduction of these motor car accidents.

MR. DAVID MORE: On our railroads it hasn't been a question of speed that has caused the accidents, but it has been two other things that were brought up. One is a question of man failure, and the other a question of a car not being built mechanically right. We have proved that. There is a car that is centrally driven, with an engine in the center of the car, delivering the power to the two wheels or two sides, and there is the side-driven car. Our accidents on the Union Pacific Railroad have been altogether caused by the side-driven car, which is a mechanically imperfect car. I can prove that to you. It is a question of the engine driving the car on one side and having a tendency to push the car off the track: to overcome that in that style of car, they have a concave wheel which has a tendency to hold the car on the track. The outrigger wheel is set at an angle of $\frac{3}{8}$ inch to curve that car over to the side on which it is driven so that the car is kept up against the wheel.

We had an accident at Lindenwood, about seven miles east of Lawrence, Kansas, where a car was derailed and a man fell off. We made an investi-

gation and found that the concave wheel got in between the point and the stock rail, and the three men sitting on there were of sufficient weight with what was already on the car—950 pounds, we figured—to hold the concave of that wheel between the point and the stock rail and throw the outrigger wheel off. One man fell off and his leg was broken.

It is a mechanical proposition with me. I took that car out with the supervisor. I told his man to just push it straight along and let us see what effect that had. There was a little recess between the point and the stock rail, and that car followed the same process that it did when the man fell off. These cars right themselves at eighteen feet, six inches. We took that car, made a mark, measured off eighteen feet, six inches and put the car to the outrigger wheel, and at eighteen feet it was righted. That car was properly lined for business then and there was no defect.

We had another case in Kansas where a man took one of those cars of that type out to test it. He had another man with him. The two of them sat on the seat, and one of the men, unfortunately, turned around to face the back suddenly; his weight lifted the outrigger wheel off the track and it shoved the car off; he fell off and was killed.

I am here to say to you men who are discussing this question that a side-driven car is not a mechanically perfect car, and until you get a centrally-driven car, you are going to continue to have these accidents.

Take the other side—the man failure. Up here on the Kansas Division, to show both sides of the question, we had some foreigners. Unfortunately, we have to have those men for that kind of work. Coming through there, the Rock Island runs on our track. These foreigners were out on a motor car. They had a time table and they knew that the Rock Island train was on time, but they got off of the car, like fools, and stood there arguing as to whether they should take it off the track there or at a point about two feet further away. The engine struck the car. That was an accident due to ignorance or bull-headedness.

We have analyzed these statistics. Mr. Groome, who has all the statistics of motor-car accidents on the U. P., will no doubt find some of them listed under too-high speed. That isn't the trouble on our railroad; neither is the trouble due to tools falling off. It is a case of mechanical imperfection in the cars used.

In the case of a joint that is $\frac{1}{8}$ -inch higher than the rail: I have tried this out at twenty miles an hour, and when you strike that high joint, the outrigger wheel will jump out from $\frac{1}{2}$ to $\frac{3}{4}$ -inch. The faster you go, the higher it jumps and the greater danger there is.

I took it up with the Fairbanks and Rand agent. We will have to change that imperfection in the construction of the car before we reduce our accidents on that line.

MR. FRANK E. OLDS (Union Pacific): I just heard the remark that motor cars on a line were operated under train orders. I would like to ask Mr. Carrow if the men have passed the standard rules and regulations examination.

MR. CARROW: Yes. Mr. Murphy can tell you about that.

MR. MURPHY: They are operated under train orders and the persons stand the examinations.

MR. CARROW: It has been some years since I handled that question; I presume that everywhere between New York and Pittsburgh and on many of the larger branch lines the motor cars are always operated under train orders.

MR. GROOME: It is a fact that we are having too many motor-car accidents on our road, and almost all of them, if we trace them down, reveal the fact that they are being operated at too-high speed for the load they are carrying. Men start out and when they see a train coming, they open up to beat it. We have tried, without much success, to get a car that will reduce to a speed of fifteen miles an hour, but we seem to have more cars that will run forty-five or fifty than fifteen, especially going down the mountain grades. The men like to run and get home.

We have a number of minor accidents, men falling off the cars and getting their feet or their hands run over. The thing we have to do is to get a car, as Mr. Clark indicates in his resolution, that will not exceed fifteen miles per hour.

I know there is some discussion about operating a motor car by train orders. I don't think that a track motor car ever is operated by train orders. We have an automobile car that runs on the track—an inspection car—and that we handle with train orders. In such cases, there is always a man with the car who has passed examinations on train orders. I think that on Mr. Carrow's road that is the kind of car they are referring to. It would be utterly impossible for a man to handle a motor car on train orders.

MR. MURPHY: We do handle all our motor cars on single track with train orders, and other motor cars, too.

MR. MERCALFE: There isn't a question that we discuss more frequently at these gatherings than this motor car question. To my knowledge we have discussed this same question in about much the same way for four years, and we are in exactly the same place we were four years ago as far as any real action is concerned.

Personally, I don't believe that resolution submitted by Mr. Clark is going to be good. It is a question that each individual railroad has to handle for itself. On the Northern Pacific, there are more employees injured on motor cars than by train accidents; that was the case last year. Every motor car involving injury is made a special report to our general manager, who, last April, appointed a Motor Car Committee, composed of the mechanical superintendent, mechanical engineer, signal engineer, the engineer of maintenance of way and, I think, the general foreman of the telegraph department, so they had all the departments represented operating motor cars.

The purpose of that Committee was evident. It was formed upon my suggestion. There are mechanical defects that caused those accidents, and we all know what they are pretty well. A great many of the accidents are due to the improper construction of the car or of the engine. There are, of course, a great many accidents due to carelessness on the part of the foreman and the operator of the car, but I think what this section ought to do is to draft some sort of a resolution, if you want to

get it through collectively, that could be presented by the safety representative of each railroad to his general manager, giving the general managers an opportunity to see what united action ought to be taken.

We are furthering our activities with that Motor Car Committee by temporarily putting on inspectors of motor cars. We have one to every two divisions. Each man devotes his entire time to going up and down the road on those two divisions and keeping things in proper shape.

MR. WEBB: I understand the purpose of Mr. Clark's resolution to be that we go on record as endorsing the installation or use of motors which will make the maximum speed of the car fifteen miles per hour. The fact that there is a road that works under train orders and has different operating conditions seems to me ought not to cut the little fellows out who haven't those conditions.

If this Section of the Council goes on record recognizing a hazard due to undue speed and suggests a remedy in the shape of the installation of a motor, if there be such, geared to a maximum speed of fifteen miles per hour, I believe that will give me, personally, moral support to go to my general manager and say that the safety section discussed this thing generally and went on record as in favor of installing that kind of a motor. There are probably a good many of us who do not work under train orders, some of whose accidents are due to speed and which could be helped by the passage of such a resolution. I think that the resolution as presented is a most excellent one. It will not interfere in any way with the Pennsylvania standard. It doesn't undertake to establish and make mandatory any standard at all anywhere, but it suggests, recommends, endorses this action. I, for one, should like to see the resolution passed.

MR. ADAMS (Reginal Supervisor of Safety): It seems to be the consensus of opinion that a great many motor-car accidents are due to excessive speed. That fact is conceded by all. That being the case, why wouldn't the moral support of this resolution work and redound to the great benefit and not take away, as Mr. Webb has stated, any of the rights of the Pennsylvania system. I can't conceive why the Pennsylvania system, even though they do operate their motor cars under train orders, would want to run at such a speed that would carry with it hazard. If the train order does give them a certain right of track but at the same time permits them to go at a rate of speed that would carry with it hazard, it seems to me it is not practicing safety.

It occurs to me that this resolution is a valuable one with regard to this motor-car accident proposition.

MR. CARROW: As Mr. Adams' remarks were not made with any effort to discredit what I said or reflect on the Pennsylvania system, I might say that we have 40,000 maintenance of way employees, and our record of accidents wouldn't correspond in any particular with the figures that I have heard read here from some of the smaller roads.

I presume, if you have looked into the matter, that you realize that our supervision of operating these cars is such as to guarantee a maximum of safety, even though we have reasonable speed.

So far as I am concerned, I don't see any special objection to speci-

fyng or suggesting that there might be a speed limit to the engines on roads where it is necessary. I don't think that would bind any road where it wasn't necessary or desirable to adopt such an engine.

MR. ANDERSON: As Mr. Metcalfe has said, you have been discussing this problem for the last four years. I move that the resolution be adopted and made retroactive.

(The motion was seconded.)

MR. METCALFE: Wouldn't it be better for a Committee to be appointed to frame up the entire objection to the motor-car operation as it is now instead of passing that resolution to reduce speed? There are enough other features besides speed that are hazardous to justify general attention to them all.

MR. CARROW: That is an imperfect resolution, with all due deference to my friend.

(The question was called for and the vote resulted in a tie. The Chairman was requested to cast the deciding vote.)

CHAIRMAN MEYERS: I dislike to do this. I have no doubt that the Pennsylvania Lines are well equipped in every way to handle these cars satisfactorily according to the conditions and physical characteristics of the road, whereas a railroad such as I represent, with long divisions and heavy tonnage, where we have an unusual amount of work for our train dispatchers, would find it necessary, in many instances, to divide the territory if it were to attempt to operate the motor cars by train orders, especially on our heavy single track territory. Therefore, under the conditions, I would be compelled to vote for the resolution.

I am of the opinion, as Mr. Webb has stated, that the only benefit it would be to us would be found in the moral support of having the advantage of recommending to our general safety committee that other roads of the same mileage are having as many motor car accidents as we are having. I am frank to admit that we are having quite a number. They are distressingly large.

If it is left to me, I will have to vote for the resolution.

We have with us this morning Mr. Baltzell, Superintendent of the Central Division of the Frisco Lines, who is very much interested in this work. He gave us a little address at our round-table meeting yesterday afternoon. It was at a time when the majority of our membership had left the room, and I have asked him if he will not talk to us a little this morning regarding his experiences and his viewpoint in this work as a superintendent of one of the big trunk lines in the United States.

MR. C. H. BALTZELL (Frisco Lines): I feel highly honored in having a second opportunity. As I told you boys yesterday afternoon, this is my fourth year in the National Safety Congress. I was at Philadelphia, New York, St. Louis, and Cleveland. Yesterday afternoon, I asked how many Division Superintendents were present. There were none at that time. I am still wondering if there is a Division Superintendent in the room.

(There were two Division Superintendents present.)

MR. BALTZELL: The reason I asked that question is because I can't see how a Division Superintendent anywhere in the United States can over-

look the importance and the advantage in attending these meetings. I came a long distance—from Fort Smith, Arkansas, to Cleveland, Ohio, to meet with you and hear what you have to say in regard to this wonderful work.

The first three years that I was taking part in the safety work on the Frisco Lines, I won the safety prize each year in succession. The first year's work I remember very distinctly. Of course, it was all new to all of us, but I made a reduction of 63 per cent as compared with the previous year. That was very satisfactory indeed, and the Saturday Evening Post had two stories throughout the year 1914 in regard to some of the unique methods employed to secure results.

That is what we are after—results. I never diminished my efforts in the safety work. Really, that is where I get the fun out of the job. I have a big, heavy operating division—765 miles in four different states with about 2,000 employees on the pay-roll.

During the month of May, when the drive was made in the Southwest region, as most of you know, the Frisco Lines made the best showing in that group, making a reduction of 71 per cent, and my division had the honor of making the best showing of any division on the Frisco Railroad. So you see we are still keeping up the work.

I believe in organization in safety work just the same as in any other work. We haven't the time to go into a lot of details in connection with that work at the present time, but I have observed that men whom you get interested in the safety work immediately begin to show better results in their particular line of work. If you succeed in interesting a brakeman in the safety work, he is more careful, more cautious and does a better job. A conductor interested in the safety work is more careful and cautious and does a better job as a conductor. In every line it is the same. I believe in getting in personal touch with everybody; know every man by his first name. Get acquainted with the men, and every time you are with them, let them understand distinctly that you are for safety first of all. It doesn't cost you a cent. Whenever you find a man doing unsafe work, using unsafe practices, caution him in the right kind of a way.

If you can get all your section foremen, your bridge foremen, every man who is in charge of other men, to be a real, honest-to-goodness safety man not only once in a while but every day and every night, you are going to show fine results.

Above everything else, be careful about selecting your Safety Committee on your Divisions. Get men who will secure results. That doesn't always mean to put on your Committee men who are known to be safety workers. Pick out men who have influence with their associates and educate and drill them in safety work and make them safety men. In that way, you will certainly get fine results.

There is one thing that I think we should never overlook. We should impress upon the staff officers on the Division and the Committeemen on the Division the responsibility that they carry when they observe infractions of the rules; we urge them not to turn their backs on viola-

tions of the rules but to get behind the man who is at fault and caution him in the right kind of a way. If they fail to do their part and later on a man gets hurt because of that, I want them to feel that they have contributed to that man's injury or his death. I put that up pretty strong to the fellows and the Division men. When an accident does happen, I want to know all about it, and I want to know from the foreman or the general foreman or the trainmaster or the master mechanic what effort he made to cause that man to be more careful. If somebody has neglected to watch that man and help him, we are all disgraced and we have all contributed in a certain measure to his accident. In that way, I get a very intense interest in the work constantly.

The transportation book of rules is really the foundation of safety, and when we discuss, as we do at our meetings on every occasion, the cardinal rules of the work, we serve to keep that alive. Every week, I get out some circular pertinent to the work—Rule 99, Rule 210, and other rules of that kind. Every time that we read in the *Railway Age* or the newspapers about some big railroad accident, we take that and discuss it thoroughly.

We have to do something to overcome the automobile accidents that are piling up on us and on you. They must be cut down. One of the best methods I have found so far is by the "Stop, look, and listen" to the public, urging them to be more careful and to anticipate the danger which surrounds them when they are crossing the tracks.

At the same time, every engineer on my division is constantly alert, anticipating a man paralleling him or crossing ahead. We urge upon them to slow down, if necessary, but in any event to try to avoid the accident.

There is one other rule that I want to mention about which I have not heard a single word at this meeting. That is in connection with Rule 88, trains of the same class have absolutely no variation at all; the inferior train by direction simply clears the leaving time of the superior train. That, to me, has always been a very serious proposition. I remember distinctly that investigation on a neighboring division developed the fact that one fellow's watch was thirty seconds slow and another fellow's watch was thirty seconds fast. There was a sharp curve right at the switches, and that slight variation of watches, which you know and which I know frequently is to be found among the men, caused a head end collision because one edged out a little ahead on account of his watch being wrong, and the other fellow was using the last second to get in, and they hit.

Every one of my watch inspectors on my Division has Rule 88 printed in typewritten sheets and pasted under the showcase. I talk to the men about their watches and tell them to be careful with them and be absolutely sure and certain that they have a good watch and are keeping up with their comparison cards, comparing time frequently. I tell the men, "Don't take it for granted that because you have had your watch a long time that it is infallible. Be absolutely certain, safe and sure."

CHAIRMAN MEYERS: Gentleman it is indeed refreshing and inspiring

to hear such words of wisdom from a man who has served so wholeheartedly and shared the reward of safety with the public as well as his men. A man with that spirit and determination never fails to get results. Mr. Baltzell, we thank you and feel honored for the address and your presence.

MR. WEBB: I want to ask Mr. Baltzell a question. He touched on the point of being careful in the selection of the committeemen. Recently, on one of the lines under my jurisdiction, one of the committees asked that their men be allowed to select, or that their order be allowed to select, their own committeemen in the future when we were replacing those who resigned or left for various reasons. I wonder if you have found that that has been done elsewhere.

MR. BALTZELL: That has been entirely in my hands.

MR. WEBB: That has been the case with us heretofore. I wonder if any of the other lines are allowing the brotherhoods or crafts to select their own men.

MR. WRIGHT: It is our practice, Mr. Webb, to allow the men to vote for their representatives, the trainmen for the trainmen, the conductors for the conductors, and so forth. We find that we get better results by allowing them to handle it in that way. I think the North Western also handles it in that manner.

MR. ANDERSON: I think we should very much appreciate Mr. Baltzell's coming so far to attend this meeting and to give us such a splendid talk on the viewpoint of the superintendent.

I would like to ask you, Mr. Baltzell, whether or not, from the standpoint of a superintendent, you feel that operation has been slowed up on account of this new safety work or intensified safety work and also whether or not it has added any additional burden on you to handle.

MR. BALTZELL: I am glad you asked that question. A good many of the superintendents on our road, from time to time, have remarked to me, "Baltzell, how do you get so much time to attend to safety work?" My answer has been invariably the same. "I don't miss the time that I devote to safety. It is amply made up in other directions, because I know from experience that the work has been speeded up because of our safety work." As I mentioned a while ago, if you get a man in every department interested in safety rules and principles, his regular line of work immediately comes up. Higher efficiency—an absolute fact.

MR. ANDERSON: I was convinced of that fact myself, Mr. Baltzell, and I just wanted to verify it. I am glad to have a man from your side of the house confirm my feeling and opinion and belief in the matter.

CHAIRMAN MEYERS: I notice that we have with us Mr. Webb C. Ball, General Time Inspector on the Eastern Railroads, and we will be glad to hear from him.

MR. WEBB C. BALL (Cleveland): I am certainly glad to see you here in Cleveland. We have a beautiful city and it is a great inspiration to see so many young men interested in this safety work visiting our city. I have attended all of your sessions and I have accumulated a lot of valuable information. I have also got my storage batteries recharged fully with

enthusiasm and inspiration which factors are very important in the work of safety.

My work for the last twenty-eight years has been among railroad men, officers and the rank and file, and my particular activities have been directed towards improving and standardizing the safety appliances known as watches carried by the employees entrusted with the responsibility of moving trains. I feel that I am justified in saying that the quality of watches has been improved at least 50 per cent, and the prices have been reduced at least 50 per cent, all of which is progress in the right direction.

I have had the support of the railroad officers and the railroad men. I am fortunately located here in Cleveland where the headquarters of three big brotherhoods have their offices—the Engineers, the Trainmen, and the Firemen. My efforts have been directed towards educating the men of these organizations who are the men who really carry the watches.

STANDARD WATCHES

We want the engineer, the fireman, the conductor, and the rear flagman to have standard watches. We aim to have those watches regulated to such a degree that they will be brought into what is considered a pretty safe standard of varying not more than thirty seconds per week. I am pleased to say that on some of the railroads where the service has been established a good many years, the New York Central, for instance, we have 11,000 men with standard watches. I believe I am justified in saying that I can find 5,000 men among them whose watches will not exceed ten seconds variation, some of them less than that, in a month. That is correct time.

The dial is one of the most important things in connection with the railroad man's standard watch. It should be plain and distinct and not confused with a lot of red figures and other irregularities that make it difficult for him to note the time. When an engineer is out, looking after signals, going seventy miles an hour, perhaps, he has no time to stop and go over the multiplication table and count the various red figures on the dial.

There is one thing on every dial that represents two things. That is the five-minute division point. That not only represents that, but it represents the hour point. If the railroad man is able to see the five-minute point, and there is nothing else confusing it, he becomes so accustomed to his dial that he can note the five-minute point or the hour point quickly and get the time correctly.

There are three dials made by the different watch factories. One has a very large square emphasized dot over the five-minute point. Another has a diamond and the other has a round mark. Either one of those characters represents the five-minute point and the hour point. If they are emphasized as they should be, with the five-minute dashes in between, a man can read the time easily and quickly. That is one of the safest features in connection with standard watches.

When I first got into this work twenty-eight years ago, the best watches we had on the market were fifteen jewels, flat hair-springs, single roll escapements, garnet jewels, and not adjustable except with a punch and

a hammer. I soon learned that those watches would not keep time. There would be committees up at Mr. Stone's and Mr. Lee's offices frequently, and they would send for me and tell me the various difficulties they had with the watches. I immediately went to work to encourage the watch manufacturers as much as I could to improve these faults, or eradicate them.

Standards have been adopted of ten seconds limit in five positions. That brings a watch in such condition that a railroad engineer or conductor or any one else will get the correct time. Recently, since the first of the year, we have reduced and simplified the standards. Up to the first of this year, the Elgin people had twelve standard recognized watches; the Waltham had twelve, the Hamilton twelve and the Springfield twelve. That was very confusing to a railroad man or any one else who wanted to get a standard watch. On the first of the year, we simplified and revised or standardized them and brought it down to three of each kind or three of each company. The Elgin best grade is a twenty-three jewel; the Waltham best grade is a twenty-three jewel. There used to be, until we revised this, three grades—nineteen, twenty-one and twenty-three. That made it very confusing for a man with pride who wanted to get the best watch he could. He would go to a jeweler and would say, "I want the best Waltham watch." The jeweler would pull out whatever he had in stock, perhaps a nineteen jewel if he was out of the others, and he would tell the fellow that was the best. The party might not be satisfied and might go to another jeweler and find a twenty-one jewel. Finally, he might land on the twenty-three jewel. That is eliminated now. The watch companies have discontinued making them in any other way.

My efforts have been to educate the watch inspectors to educate the men, and I have nothing to do with the sale of watches. That doesn't interest me. All that interests me is the safety features in the watches used by the men who are responsible for the movement of trains.

When we get the support of the superintendents and trainmasters, we will be in a fair way to make greater success. I would like to make the suggestion that you gentlemen who are at the head of these Safety Committees, when you are in a town where there is a watch inspector located, invite him to become a member of this Safety Committee or Section. He is in touch with your men more than any other individual on your system. He has an opportunity to see them every day.

We aim to select the best watch inspectors on the railroads who are the best citizens and the most useful citizens. If you can get them into your organization, it will help them and it will help the efficiency of the service.

I have been very much interested in this convention. I have received a lot of valuable information and a lot of enthusiasm, and I wish I could have had my watch inspectors here.

Mr. BRENNAN: Mr. Chairman, we have been the guests of the Statler Hotel people, and the word "Statler" in hotel parlance means the standard of perfection almost. We have no perfect railroads, and I suppose we have no absolutely perfect hotels, but there are so many perfect things about the hotel that we might say it is perfect.

Yesterday afternoon, the Regional Supervisor of the Allegheny Region asked the members of that region represented here to go up to his room for a few minutes. In doing so, after returning from the room, we took the elevator. Some of us were getting into the elevator to come down, and the elevator operator shot down with the gates open. It occurred to me that is one defect, and it is possible to kill a man in the elevator with the doors wide open. I think it would be a courtesy on the part of this organization to the Statler people to call their attention to that. In most hotels, it is impossible to do that, because the doors are closed and locked. We are here for safety. I am new in the safety organization, but I am old in railroad work. I have practiced safety nearly all my life. I think this is a courteous suggestion to the Statler people, if we make it. I recommend that you submit that in a polite way to the Statler Hotel.

CHAIRMAN MEYERS: Gentlemen: We have completed today's program, the last of our three-day session and are now ready to say good-bye with never-to-be-forgotten memories. We can all feel a just and lasting pride in our membership; in its efforts and accomplishments in helping to make the world a better and safer place in which to work and live. This session has been the largest in attendance, interest, enthusiasm and results. We cannot measure at this time the influence and benefits that will follow in the years to come, but it is coming strong—a reward for service to our fellowman.

As your Chairman (I take the liberty of including the vice-chairman and secretary, Messrs. Scott and Mayo) we wish to express our sincere appreciation to those who have honored us with their presence and addresses—a lasting inspiration to the great cause. What my predecessor said at the opening of first day's session are my sentiments. "This is your section. It depends upon you for Success." Let's make it the very best. We can do it. We need real thinkers offering their suggestions and advice; we need real workers giving their active and loyal cooperation. With each and every member thoroughly alive to his obligation, duty and responsibility we can make the Steam Railroad Section of the National Safety Council paramount.

I wish also to express our sincere gratitude to the beautiful City of Cleveland, its officials, and its splendid citizenship for its generous hospitality and our best wishes for its future growth and prosperity.

There being no further business we stand adjourned until the next session of the Council. Good-bye—good luck.

Textile Section

October 2, 1919

DAVID S. BEYER, Chairman

Vice-President and Chief Engineer, Liberty Mutual Insurance Company,
Boston, Mass.

William S. IDE, Vice-Chairman

S. Slater and Sons, Inc., Webster, Mass.

JOHN RENNIE, Secretary

Safety Engineer, Joseph Bancroft and Sons Company,
Wilmington, Del.

THE meeting was called to order at 9:45 A. M. by the Chairman, Mr. David S. Beyer.

CHAIRMAN BEYER: The past year has shown some interesting developments in safety work among the textile plants, although the textile industry, as a whole, has been rather conservative in taking hold of accident prevention work. One of the lines of activity of the Textile Section this year has been to collect data in an effort to establish a standard accident frequency rate among textile workers, and thus determine whether the accident rate for a given plant is high or low as compared with the average for the industry. We have some rather interesting data along that line, accumulated and compiled from the reports of accidents in a number of textile plants during the last two years.

In the past, there have been, on the average, about six "tabulatable" accidents (that is, accidents involving loss of time in the day or turn following that in which the accident occurred) per one hundred workers per year. We now have a number of plants that have improved on that rate very materially and there are a few charts here that I will run over hurriedly; just to give you an idea of the progress that has been made along these lines.

Here is a cotton mill with about 600 employees that has an accident rate of 4 per cent for the year 1918, and 1919 finds it decreased to 3.8, which is about half the ordinary accident rate for the industry. Here is another one covering the years 1917 and 1918 with an initial accident rate of about 5.5, which has been reduced to 3 per cent, a reduction of almost

one-half. Here is another plant with 1,200 employees; in the year 1916 they had an accident rate of 4.5, but now show a rate of 2.7, a reduction of 41 per cent. I have another chart here of a cotton mill having about 3,500 employees. Since 1917 their accident reduction has been 4.6 per cent, from 5.5 to 3.0. Another cotton spinning and weaving plant having 4,000 employees, whose accident rate for 1918 was 2.8 per cent, has reduced it for this last year to 1.6 per cent, getting under the 2 per cent limit.

So, we have records here of plants that have already reduced their accidents 40 to 75 per cent below the average for the industry.

Another interesting feature is the reduction in the cost of compensation for these plants, several of which are now receiving a reduction of approximately one-half in their insurance rates as a result of their accident prevention work.

Perhaps some of those present have brought records with them of the work along these lines done in their own organizations; if so we would very much like to get their records, for comparative purposes.

The officers of the Textile Section have had two meetings during the year, in addition to considerable general correspondence. The Secretary, Mr. Rennie, will submit a memorandum of the detailed activities taken up at those meetings.

(Secretary Rennie gave a brief account of the meetings held in Boston during the year. On motion the report was adopted.)

(A nominating committee was appointed, consisting of Mr. Scully, Mr. Coffey, and Miss Wilson to submit names of officers for the Section for the coming year.)

CHAIRMAN BEYER: The first of the formal papers that we have on the program for this section is, "Plant and Machinery Layout as Affecting the Accident Hazard in Textile Mills."

PLANT AND MACHINERY LAYOUT AS AFFECTING THE ACCIDENT HAZARD IN TEXTILE MILLS

KENNETH MOLLER

LOCKWOOD, GREENE, AND COMPANY, BOSTON, MASS.

It is obvious that the best insurance against accidents in a cotton mill or any other manufacturing establishment, for that matter, is to educate the help properly so that they will use ordinary precaution in pursuing their duties. It is also obvious that human nature solely is too frail to rely on for the prevention of accidents. Mill owners and others in authority must do all possible to make the surroundings in which the help work as near accident proof as possible even if people are careless and forget the danger which always exists even in the best protected mill or factory.

There are two elements to be considered besides the campaign of education which must be carried on unceasingly and the general welfare work such as hospitals, physical examinations, etc., which we are to take for granted.

The first of these is the proper guarding of certain moving parts of machinery and machine drives. The second is the plant layout and upkeep, which is a tremendous factor in the accident hazard of any factory. The question of the detail guarding of textile machinery is being treated in a separate paper and it is my intention here to call your attention to a few features of plant layout and upkeep which tend to reduce accidents and safeguard the workers.

One point which I wish to call to your attention is the fact that practically all of the features brought out are cardinal rules for increasing production. It is a fact that in plant layout and upkeep almost all accident-prevention work is production increasing work. If you don't want to put these ideas into practice for the first reason do it for the second reason and kill two birds with one stone.

As it seems simplest to discuss one type of plant in this paper I am going to confine these remarks to cotton mills although they would apply in general to any other type of textile mill. I want to describe first the elements which make for safety in a cotton mill, discuss each one briefly and then illustrate as many of these ideas as possible by showing the layouts of a new cotton mill in which these points were given careful consideration.

The principle elements which go for safety in a cotton mill layout are as follows:

1. Proper lighting both natural and artificial
2. Proper alleys which are obviously definite lines of travel
3. Proper prevention of short cuts
4. Proper spare floor for trucks and material in process
5. Proper heating and ventilating
6. Proper dressing, toilet, and rest facilities for the help
7. Proper care and use of all of these facilities after they are installed

LIGHTING

Let us consider the lighting first. One of the most prolific causes of accidents in cotton mills is poor light. Natural light is always the cheapest and best to work under. How are we to make the most of it? First have ample glass area, just as much as you can crowd into the walls. Second, have a sufficient story height to use the light admitted by the windows. Third have the working alleys run across the mill with windows at each end. Fourth eliminate as far as possible overhead drives and fifth spend money in keeping the mill painted. You get accidents in old dingy mills and you get poor production, a coat of paint once every two years will always pay for itself in increased production and saving in artificial light. Where possible use general lighting, it is best and cheapest. Where this will not work out use individual lights in the alleys but up too high for the help to touch them. Keep the windows clean, it is a very cheap way to get light and light always means increased production and decreased accidents. Keep the mill clean. Dirty floors strewn with waste and bobbins cause accidents; scrub the floors but

be careful when scrubbing that people do not slip. This is difficult and must be handled through your educational campaign. Scrub the walls, it is almost as good as a coat of paint.

ADEQUATE SPARE FLOOR AND ALLEY ROOM

Now as to alleys. Most accidents occur when help are away from their machines. A card hand loses a finger in a speeder frame, a weaver gets burned by a slasher. Most mills do not have definitely-defined lines of travel and help will take short cuts. You must have perfectly clear broad alleys along which people and material must go and it must be impossible for them to go by any other routes. The routes which they are to take must be made safe.

Congested floor space is probably the cause of more accidents than any one other thing. Of course, we all want to get the maximum production off a given floor area and there is a very prevalent idea that in order to do this it is necessary to cover every square foot with machinery.

This is absolutely not so. In your crowded spinning room you would probably get pounds more production if you took out some of your machinery and rearranged the rest. You certainly would reduce accidents. You must have adequate spare floor and alley-room. You must have space to handle the product in process, as much as space for the manufacturing itself. This space is just as much an adjunct of manufacturing as the area covered by machinery and don't skimp it. Have perfectly definite space for full and empty trucks and see that they are kept there and not in the alleys. A good plan is to have stalls marked out on the floor and insist that trucks be left in the stalls until wanted. A better way still is to install a conveyor system wherever possible even if it does not reduce the number of men necessary to handle the product. It does keep the work in perfectly definite channels and gets it away from the machines as soon as it is finished. The proper place for work in process is behind the next machine it is going on, not in front of the last one it came off. It is no good there.

HEATING AND VENTILATING

Proper heating and ventilating have a big effect on the condition of the help and doubtless tend to reduce accidents on this account. By far the best arrangement is one which heats and humidifies the air at a central point and circulates it through the mill. Give the help proper atmospheric conditions and they will not get so tired. Tired people are careless people and careless people cause accidents.

It is important that facilities be provided for the help so that they will not have to change their clothes in the mill or near the machinery. They must if some special arrangements are not made. We must provide adequate locker rooms and wash rooms and see that they are used. How often we go through a mill and see women doing their hair near a belt or moving machinery. Don't permit help to dress near moving machinery, but they will, unless you provide other space.

SYSTEMATIC INSPECTION MUST BE MAINTAINED

All the precautions listed above will fail of their purpose unless you see that they are kept up and used to their full extent after they are installed. Spare floor is no good if trucks are left in the alleys. Locker rooms are no good if the help leave their shoes on the spinning creels and hang their coats on the radiators. A systematic inspection must be maintained to see that the mill is clean, is in good repair, and all the precautions taken to prevent accidents even after the ideal layout is installed.

In order to analyze the layout of a cotton mill to minimize accidents, let us start at the beginning of the cotton manufacturing process and go through the various rooms studying the layout of each room with the idea that when we get through, we will have done everything possible which will have any effect in reducing the number of accidents.

I am going to take as an illustration the new Jackson Mills of the Nashua Manufacturing Co. at Nashua, N. H. This mill is being designed, erected and equipped by us, Lockwood, Greene & Co., engineers, having taken a contract to turn over a complete cotton mill ready to run and assumed all responsibility in the matter. The mill is to produce the famous Indian Head sheeting and is to contain 50,000 spindles and 1,200 looms. (See pages 1346 and 1347.)

On account of the peculiarities of the site it was impossible to incorporate all of our ideas in this mill. For example we could not run the spinning frames across the mill on account of the restricted width. Also a good many changes have been made since the drawings have been made. It seems as if every time we studied the layout we were able to improve it some way. I think you will be interested in the exterior of this plant, feeling that the exterior of cotton mills had been given very little consideration (They are probably the worst looking buildings in existence next to shoe factories). Lockwood, Greene & Co., engineers, have a large architectural department working only on exteriors of manufacturing plants and industrial housing of which we are doing a great deal.

The cotton arrives in cars at the storehouse siding where there should be a wide covered shipping platform. For best arrangement, the storehouse should be of concrete with concrete floors and no wood top floors. The cotton will probably be carried on hand trucks although in a great many cases it works out best to handle it on electric trucks which can be run right on to the elevators and when the bales arrive at the proper location, they should be stored on the floor one high. The proper stud for a cotton storehouse is about eight feet and it should be built of flat slab construction without beams. Never pile cotton. Many accidents and costly handling will always result. The opener room should be on the ground floor of the storehouse. Cotton ready to be opened is put on each side of the opener apron; the bales cut with snippers and the cotton thrown on the opener apron. The delivery from the openers is automatic either to bins or to the pickers direct. The drive for all openers is usually by one motor driving a group. In this paper, we are talking

PLATE I. COTTON MILL LAYOUT

The upper cut shows seventh floor plan at left, fifth floor plan at right; lower cut shows first floor plan.

PLATE II. COTTON MILL LAYOUT

Above, cross-sections; below, longitudinal section. See first floor plan on opposite page.

about ideal conditions only and the best which can be had so we will start out at once by considering only electric drive and individual motors wherever practical as I do not believe there is any one who will dispute the fact that this form of drive is at once the safest and gives greatest production and is the one which should always be used where these two considerations will outweigh the added cost.

The most interesting feature of this plant is brought out by the fact that we have turned the conventional cotton mill upside down and with the first process on the roof and the finished product coming out on the ground floor. This allows us to blow the raw cotton to the top floor and let it fall by gravity from process to process making extremely cheap handling and reducing accidents by keeping the material moving in perfectly definite channels. As soon as it is off one machine it is on its way to the next. As we have said the proper place for the product of each process is in front of the next process where it is to be used, and not in the room where it has been manufactured. It is no good there.

The cotton is blown to the picker room and by far the safest and most economical way to handle it is by some form of automatic distributor which places it directly in the hopper of the picker. There is no reason in a great many cases why the cotton should be touched at all in this process. Each picker should be driven by an individual motor directly mounted on the machine and the machines should be arranged either so that it is impossible to walk between them or so that the clearance is so great that there is no danger from moving parts. If there is a passage between the machines, it should be at least five feet wide. Adequate space should be left in front of all machines so that the laps from one machine will not block up the passage ways before they are put on the next machine. The best system is to have racks between the breaker pickers and finisher pickers where the breaker laps may be stored.

After a lap is taken off a finisher picker, it should be put on a truck or a conveyor at once. A lot of accidents are caused by stock in process and full or empty trucks blocking spare floor, operating floor or the space between machines. Incidentally, if the work is kept in motion and there is a steady flow between machines, the inventory is kept down to the lowest point.

THE CARD ROOM

The card room should be laid out if possible with all working alleys running across the mill so that we will get the maximum light and the cards should be placed so close together that there is no chance of anybody trying to walk between them, leaving just sufficient clearance for the working parts. Every eight cards, there should be an alley at least four feet wide which will be an obvious and safe passageway. There is practically no hazard in the back or front alleys. The working alley should be four feet between coilers and the back alley five feet wide to allow full lap trucks to be handled without injuring the laps. Around the drawing frames, there must be sufficient space to take the cans of card sliver and the full cans of drawn sliver. It is very important that adequate space be left around this machinery as it is too common a fault

in cotton mills that the congestion due to a desire to crowd in machinery causes alleys to be blocked by material in process. Leave at least six feet clear behind the breaker drawing; six feet between the breaker and finisher drawing and six feet in front of the finishers. This should give adequate space to prevent congestion. The same is true of slubbers. There must be sufficient space allowed to take care of the material in process. Leave four feet between slubbers in the working alleys and six feet of spare floor behind the machine.

As the card room will probably be driven by group drive, care must be taken to see that the shafting is properly located so as not to bring the belts low in a working alley. If necessary, run two lines of shafting rather than have one line run in two directions and so bring belts at a low angle in a working alley or where people work. Have perfectly definite spare floor for slubber roving next to the speeders and have full slubber trucks delivered to this floor as soon as they are doffed.

Cut out trucking where you can. You will notice in the layouts shown, there is a spiral chute in the center of the room near the speeders. As soon as a frame is doffed, the boxes are carried immediately to this chute and sent on their way to the spinning room. There is no reason why there should ever be boxes of roving cluttering up the floor of that card room. The floor should be clean all the time. Roving frame drives are usually so well guarded that there is little danger from that cause and it is usually an advantage to have an alley at each end of the frames. It will be seen that the full roving boxes when they leave the spiral chute run on a gravity conveyor along the wall in the spinning room. There is constantly a supply of roving the whole length of the spinning room. A conveyor under this shelf of gravity carries the empties back to the card room.

THE SPINNING ROOM

There are apt to be a good many accidents in spinning rooms. Put the drive end of the frames together and make it impossible to walk between them. Have large alleys on the other end or between every two frames, at least five feet wide. Use individual motor drives if possible, otherwise four frame drives. The frames should run across the mill so that the light will shine down the alleys and provision should be made to take the full bobbins away from the machines at once so that the floors will not be congested. The proper place for full spinning bobbins is either in the weave room or the spooling room. It might be interesting to note that in the plans attached hereto there are chutes in the floor located at convenient places and as soon as a frame is doffed the yarn is on its way to the next department. These chutes lead directly to the weaving for the filling and directly to the spooling for the warp. Return conveyors carry the empty boxes back to the spinning room.

THE WEAVE ROOM

The looms should have individual motor drive if possible and be arranged with the alleys running across the mill if possible if the weaving

is carried on in the lower stories of a mill. Of course if the weave room has a saw tooth roof, this is not essential. Have perfectly definite lines of travel: alleys which are obviously meant to walk in and have all other spaces too small to get through. Front on working alleys should be about 2½ feet wide so as to make it easy for a weaver to run looms on both sides. Back alleys should be at least two feet six inches clear and cross alleys should be three feet. At convenient points, broad cross alleys and broad back alleys at least five feet wide should be located which are obviously the main arteries of travel.

There is no reason why the alleys should not be kept clear all the time except for trucks carrying filling from the conveyors to the looms and the beams from the slashers. A conveyor carries the cloth from the weave room to the cloth room.

People have been in the habit of thinking of a cotton mill as machinery placed in a building: As a matter of fact it is a building placed around machinery. The layout is the most important thing. We spend sometimes months on the layout of a mill. I think until the Jackson Mills plant was designed that there has not been a radical change in cotton mill design for years. The Jackson is only a start. Nobody knows what can be done in reducing accidents and costs by proper machinery layout but we mean to find out.

CHAIRMAN BEYER: I am sure that Mr. Moller has covered the subject so well that few here will be able to improve on his clear exposition of the matter. However, the subject is up for discussion and any questions as to plant and machinery layout are in order. Mr. Moller, I know, will be glad to make any further explanations desired.

DISCUSSION

MR. HENRY A. OWEN (Whitin Machine Works, Whitinsville, Mass.): Mr. Moller, what kind of floors do you put in?

MR. MOLLER: Concrete floors, covered with wood.

MR. OWEN: How is a wooden floor put on the concrete?

MR. MOLLER: Two inch hemlock was used fastened to screeds set in cinder concrete. A layer of tar paper is placed on the hemlock and maple flooring nailed on the top. We consider it is the safest flooring in a plant of this kind. Of course it is very expensive, the flooring alone in this case costing a hundred thousand dollars.

MR. OWEN: What do you think of cement floors?

MR. MOLLER: These will always crack. Help much prefer a wood top floor. We believe it is worth the extra money.

CHAIRMAN BEYER: There are no fire walls in that building?

MR. MOLLER: There is a fire wall here (pointing to picture with pointer).

MR. J. J. COFFEY (Inspector, Department Labor and Industry, Philadelphia, Pennsylvania): It seems to me that an expensive up-to-date building like that should be equipped with fire towers.

MR. MOLLER: You couldn't put in any more towers there without

taking up too much space. Of course, these plants are protected by automatic sprinklers.

MR. COFFEY: I should think where there is no question as to the cost of the plant, there ought to be sufficient fire towers in addition to using the fire escapes.

MR. MOLLER: These two doors (pointing to picture) give sufficient means of exit. This door would open into a horizontal escape and is easily gotten through, and, with the other facilities, is about all anybody would want. On the second floor there is a bridge which goes over to the other building.

Drinking water for the men and others working in these mills is also very important. I understand some mills spend as much as twenty thousand dollars installing cooled water systems.

I don't know whether you consider this information appropriate or not, but in the Alaska Mills we have built a nursery that cost fifteen or twenty thousand dollars, where the help can leave their children during the day time with good nurses in attendance. I don't know the actual cost for taking care of their children, but you can figure that three meals a day runs into money. (Laughter.)

CHAIRMAN BEYER: Most of you know the firm of Lockwood, Greene, and Company either by reputation or through actual business dealings, and I am sure you are not surprised at having one of their representatives give us such a valuable paper on this subject. I think there is a great deal of helpful information in the material he has presented.

The next paper will be by Mr. Owen, in which he treats of mechanical guards, and which he illustrates with mechanical slides.

STANDARD GUARDS FOR TEXTILE MACHINERY

HENRY A. OWEN, GENERAL ENGINEER, WHITIN MACHINE WORKS,
WHITINSVILLE, MASS.

Among the earliest recollections which I have as a boy during the late '70s around a textile plant with which my father was connected, is an accident whereby a man was terribly injured. He was working on a picker and the machine started up unexpectedly, catching him in the fast-running beater, which resulted in the loss of his arms. The safeguards now attached to this machine make such an accident impossible, but this has only been accomplished in the last few years, though the mechanical parts necessary to prevent such accidents are few in number and simple in design, showing it was not for the lack of inventive skill that this improvement was delayed, but rather for the idea to come that it was worth while to put such devices onto machinery.

To show the growth of the protective idea, consider the early type of gear-cover, which covered the law better than the gears. It covered only the gear faces and "bite" of the teeth, leaving opportunity for a pinch between the revolving gear and the stationary casing, to say nothing of the chances of being caught and drawn in by the catching of

cleaning waste and brushes, for at that time to stop a machine to clean it was waste time indeed.

A little later when gear-covers were somewhat improved, there were holes in them, thought too small to get one's fingers through, left so as to hold up the core to make molding in the foundry easier, and they were not closed up until the loss of fingers by some unfortunate stood as a monument to the fact that every conceivable avenue of approach must be closed before a gear-cover fulfilled its proper function.

A. 1880 WHITIN SPINNING FRAME

The cut "A" shows a case where a cover supporting slot proved a finger-nipper and many were put on the market before the weakness in design developed. These slots show over the word WHITIN on the front roll gear-cover on the 1880 Whitin spinning frame.

A comparison of this spinning frame made in 1880, with one of today, is worth studying, as it shows what the years of experience have brought out in the art of safeguarding. The idea of separate or bolted-on gear-covers has long ago disappeared and in its place we find the head-end or frame made deep enough and of the so-called "boxed type," entirely to cover all the gearing except the draught gears; these are slow running and wholly covered by a hinged casing, which in some frames cannot be opened while the frame is running. The gear studs are attached to the back or web of the frame, with oiling tubes sticking outside, safely accessible and it is impossible to get a brush or waste caught in either the arms or teeth of the gears; nor will one's clothing catch while passing through even a narrow alley.

The frame-covering panels are without dangerous holes and often provided with devices which prevent the belt being thrown on to the tight pulley when the panels are not in place; the panels cannot be taken out when the machine is running. This saves many fingers, and even hands,

as the fixer may be down behind the head out of sight, working on the gearing, when the operative or overseer concludes to throw on the belt without looking about to see why the frame is stopped.

On the pulley or driving end we find outriggers, to guard against bumping into the revolving pulleys, and guards to stop clothing being drawn into the belts or getting caught in the spokes. The loose pulley runs on a dead bushing, so is stopped while the speed is on. Belt shippers take the place of a stick or brush handle to start and stop the frame. The operating parts are designed so as not to be too high for small help; in fact, the whole machine is designed so as to protect the operative from danger, and to make his labors easy and comfortable.

The class of help in the textile plant today makes the need of protective devices more necessary. In the old day, even the most ignorant laborer understood English, and could be told where the danger spots were, but now, no one knows from what the operative says whether he understands or not. In the old days the ignorance of the laborer was one of the greatest causes of accidents and he was blameless in the matter, for he could do nothing to help, but the mill manager who well knew

11. SACO-LOWELL BEATER LOCK

his employees were working under dangerous conditions was surely to be blamed, because most of the improvements in this line were the results of demands made by the mills until the operative sought the aid of the law. This has been the politician's opportunity; he has pushed punitive legislation as far as the times would allow, and that is evidently but half of what he expects and probably can do, in the fast coming days of labor's domination, when the slightest opening will give politicians the chance to push through drastic and unreasonable laws at the expense as well as inconvenience of manufacturers.

Let us consider cotton machinery, with which I am personally best acquainted, starting with the picker and card rooms. Mr. Swallow of the Amoskeag Mills tells us that while these rooms only employ about 10 per cent of the mill employees, they furnish 25 per cent of the acci-

dents. Here we find the greatest danger lurks around the fast running pullers, particularly where the belts "take on"; the laws of some of the states make it obligatory to have these belts guarded six feet high from the floor, so in most cases it has been found more practical to have the guards made of bound expanded metals, or better still, of wire grill to which cotton lint does not stick and is so much easier to brush off. Means to take off the belts must be provided, but without lowering the protective qualities of the guards.

A tendency to the use of web pulleys and gears has begun to be evident, as this removes the possibility of getting caught in the spokes. All draft holes on pickers should be covered with wire grids wherever one can get a hand through into the beaters. Beater locks are now applied so that pickers cannot be started with the beater bonnet or glass doors open, nor can these be opened while the machine is running.

C. AMOSKEAG MILL BEATER LOCK

These devices are simple in construction, and meet the requirements of the liability insurance rules.

The Saco-Lowell beater lock "B" consists of a sliding dog having three legs and a slotted disk tight on the beater shaft. When two of the legs lock the beater bonnet and glass door, the third is out of connection with the beater slotted disk. Before either the bonnet or glass door can be opened the machine must be stopped and the dog slid sideways, with the beater disk in a position so the locking pin can

enter the disk slot, holding the beater against rotation. As the locking dog cannot be pushed out of the disk with the doors open, it can be readily seen that an accident is impossible under any condition.

The Amoskeag Mills on their old pickers employ a lock on a plan somewhat similar to that shown in cut "C." but the construction allows connecting bonnets located farther apart. As the cut shows, the lock consists of a long casting bolted to the machine frame, having a shaft with gears which throw racked bolts into notches in the bonnets, leaving the locking pin out of the beater disk. To withdraw the bonnet bolts, the pickers must be stopped so the beater locking pin can enter the holes in the beater disk, locking it against rotation. The sprocket chain drive between the feeder and opener should be better protected; a good design is made by the Amoskeag Mill.

Beaters are built so they can be turned end for end to save repairs and the unused keyway end should be covered with a tin sheath to save any one being caught and wound up. This is necessary as the shaft extends well towards the alley.

Cards. The revolving flat card as now manufactured is a much safer machine than many of the older type we find in the mills. It was never considered necessary to have belt shippers on a card but there were so

D. WHITIN CARD BELT SHIPPER

many accidents caused by the operatives getting their arms caught in the belts when starting up, that practically all the machine builders now have shippers which can be applied to their make of card.

This shipper is constructed with a shaft extended front and rear far enough so the card can be started from either alley. The crank and link motion locks the belt on or off and is very easy to operate. Cut "D" also shows a door lock, making it impossible to have the door open with the belt on the tight pulley, thus avoiding accidents to the hands by coming into contact with the fast revolving cylinder.

The Saco-Lowell Shops include a round shaped ball binder with their shipper motion, by which pressure can be applied to the belt after it is on the tight pulley to help the belt "take hold" in starting.

It has been suggested that the Burrow Pulley which drives the doffer and doffer gear motion be made with a web in place of spokes and that a cover be placed over the side shaft small bevel and feed roll gears: the location of these gears is such that if a man's overalls get caught, his privates are drawn into the gears causing a very bad injury as well as an expensive one to settle.

Combing machinery has only been manufactured in this country within the last few years, so the designers have had the safeguarding idea well in mind and have left few points for criticism, for the gears are all covered, and the points of danger well out of the way; webs are used on pulleys and large gears in place of spokes.

Drawing Frames. This was one of the first machines on which the

E. WHITIN DRAWING FRAME GEAR LOCK

scheme of locking the gear covers by use of the belt shifting mechanism was first put into general use, and was covered by patents issued to H. A. Owen and O. L. Owen.

As cut "E" shows, stops are placed on the shipper rod at a point which brings them into position so the covers cannot be moved while the belt is on the tight pulley; neither can the belt be moved onto the driving pulley when any of the covers are open, making one of the most completely guarded machines on the market today.

Many shops furnish lower shaft, pipe covers and a pulley and belt

guard for the drive from this shaft—the outside pulley is usually of web construction and is covered by a guard usually furnished by the mill.

Speeders. The old style speeder was a machine on which many of the gears were poorly guarded.

The Amoskeag Mills in their safety work use covers of No. 16 sheet steel joined at the corners by an autogenous welding torch; this is only one of the many useful purposes this scheme can be used for in textile plants.

The textile machine manufacturer of speeders has looked after the weak points in gear covering by putting casings from the floor to the table, to be sure to get everything protected. The head end has for years been of the "boxed type," but it recently has been reinforced by pulley guards and out-riggers to prevent bumping into the belts, with trucks, etc.

The flyer spindle gearing covers, which in years back were made of wood, are now almost wholly made of steel, which is stiffer and holds its shape much better. Some speeders have means for interlocking the belt shipper and casings so the latter cannot be opened when running.

Spinning and Twisting. Some of the things accomplished in guarding these machines I have previously stated.

Fales & Jencks Co., Pawtucket, R. I., safeguard their spinning head end and draft gear covers in a manner which is very effective as it takes care of all the gearing on the frame. While these gear cover locks of all makes are a simple proposition to put into the design of a new machine, it would be practically impossible to rig over an old machine with them without going to great expense.

Among the textile machines, the latest to be re-designed is the spooler, which now appears with a "boxed end" similar to the spinning frame, and has all of the good points of that design. Metal bobbin boxes, with their freedom from slivers, have been on the market many years. One manufacturer reports the use of hollow safety set screws on all moving parts of the frame, and head end doors which cannot be opened when the belt is on the tight pulley.

Warping and slashing machines have but few danger spots and these are well covered by guards on the machines put out today. The main driving belts must be covered up six feet from the floor in some states, but this calls for special expanded metal construction in every case. Safety blow-off valves must be applied to take care of excessive steam pressure.

Weaving. Many of the danger spots on the loom have been safeguarded—for instance, injuries from flying shuttles were very largely stopped by use of the Sullivan Shuttle Guard, shown in cut "F."

This guard is simply a stiff wire attached to the hand rail running parallel with the race, high enough to be out of the way of the properly travelling shuttle, but low enough to hold it from flying out of the shed. The patent on this guard has expired and we now see many modi-

fications of the first design; this, in fact, might be called a standard equipment for looms.

The Northrop and other automatic looms in 50 per cent of the mills, have made the threading of the shuttle by the operative unnecessary, but as the laws of some states make the use of plain-eyed shuttles unlawful, we find on the market many kinds of the self or hand threading type. With this shuttle, the operative simply draws the filling through and back under the thread holding beak and the threading is complete without danger or loss of time.

The doing away with of sucking filling through the eye of the shuttle has been one of the most far-reaching steps to safeguard the operative's health in what might be called one of the most unhealthful departments of the textile plant, for here we have noise, flying lint, hot, humid, stale air, besides the usual dangers of getting into running machinery.

The danger of the operative getting caught in the gearing of the loom is not as great as when he is working on some other types of machinery, for most of the danger spots are well back from the working alley out of reach, and besides, we find most of the gears covered. The fixer,

P. CROMPTON AND KNOWLES LOOM

however, who must get close to the moving parts, is often in danger from the weaver starting the loom without looking to see whether the fixer is out of the way.

The Amoskeag Mill furnishes each fixer with a red wooden plug, as shown in cut "G." This plug fits the loom shipper handle stand slot and is plugged in before a start is made to fix the loom; it makes it impossible for the loom to be started and also calls the weaver's attention to the fact that some one is in danger. for the weaver, in his ordinary round of duty, almost unconsciously goes from loom to loom, starting them without looking, his only thought being to keep them going.

Many of the very heavy duck looms, in fact some fairly light ones, are being driven by motors which do away with the dangers from belt drives. The mills often place wire or expanded metal fences between these heavy looms to take care of flying shuttles.

One danger on looms fitted with harness head motions, is the fast revolving shifting hand wheel with its crank; this could be corrected by some form of clutch motion so constructed that the wheel would be thrown into action by the pressure of the hand on the handle, so it would only be in motion when needed.

Finishing Machinery. These machines, particularly the heavy calenders with their massive gears and frame work, even in the machine of today are not designed with the usual type of cast iron cover so common to textile machinery, but the makers generally leave it to the many firms who make expanded metal covers to attend to the guarding proposition after the machines are set in their places in the mill. This is done from an expense point of view, but they might as well be designed safe as to be fixed up after installation.

G. LOOM SHIPPER PLUG

Motor drives have helped out by doing away with the large belt risks and most of these gears have been amply covered by suitable cases.

The Cloth Folder in cut "H" shows the influence the mill has on textile machine design; this comes from the fact that running a machine brings out its weak spots and many times we find the corrective features are made by the mill and later adopted by the builder. In this case some one got caught by the folder crank and the result was an apparatus to make it stop every time in the same place, also, its arc of swing was covered by a circular casing.

The experience told regarding the Cloth Folder holds good with the Cloth Winder. Here the accident was caused by both ends of the pulp board not being secured, so when the machine started the board flopped about and injured those near it. An attachment now prevents starting the machine until everything is secure; this is another application of the shipper interlocking idea.

Acid Carboy. The Amoskeag Manufacturing Company, to whom I am indebted for much I have brought to your attention, particularly on

what has been done on machinery already installed, has evidently solved the way to handle dangerous acids by use of their carboy pouring stand. The carboy box is firmly held by straps into the pouring fixture, and the back slap of the liquid is well attended to by the use of the glass shield which does not interfere with watching the flow of the acid.

Pneumatic lifts properly designed and placed can save many a strained back and muscles—accidents easy to claim and hard to disprove.

A few ideals to strive for in textile machinery guarding might be summed up as follows:

Gears should be completely covered.

Covers that have to be opened often should be protected by devices interlocking them with the shipper motion.

H. CLOTH FOLDER

Bolt on all covers which protect danger spots that should only be looked after by the fixer.

Use web pulleys and gears where not covered by casings.

Use safety set screws on all revolving parts.

Belts should be covered by screens, particularly where they "take on" to the pulley.

Be sure the belt guards are stronger than the force produced by the breaking belt: if not, the danger from flying pieces may cause more injury than if the belt were left uncovered.

Do not allow covers and protective parts to be taken off and not put back again.

Do not allow any exposed keys or keyways.

Be sure a cover is not a trap; some are.

Prevent accidents before they happen.

Keep ahead of the law.

CHAIRMAN BEYER: Mr. Owen has had a wide experience with machine design and construction for textile work, and I am sure we are very much indebted to him for the thorough way in which he has handled the subject. We will have an opportunity to discuss his paper later, and I think we had better proceed with the next item on the program. It is only comparatively recently, so far as I know, that safety education has been taken up to any considerable extent in the textile industry. It was long felt by the executives that the problems in this industry were different from those of the iron and steel and other industries where there had been safety organizations.

One of the concerns which, within the last couple of years, has organized safety committees to combat accidents in its mills is the concern of S. Slater and Sons, Inc., of Webster, Massachusetts, and Mr. Ide is going to tell us something of the splendid work they have done in that direction in the last year.

SAFETY EDUCATION IN THE TEXTILE INDUSTRY

WILLIAM S. IDE, S. SLATER & SONS, INC., WEBSTER AND FARNUMSVILLE, MASS.

HISTORY OF THE PLANT

The Slater Mills were founded at Webster, Mass., in 1812, by Samuel Slater, who had already established the first commercially successful cotton mill in the United States, at Pawtucket, R. I.

The first mill operated at Webster, Mass., was for the manufacture of cotton yarns. These yarns were woven into cloth on hand looms at the homes of the farmers in the neighborhood, for at that time the power loom had not come into use.

In the year 1815 Samuel Slater, associated with Edward Howard, started a mill for the manufacture of woollens, and soon established an enviable reputation for the manufacture of broadcloths and uniform cloths, a reputation which continues to the present time.

In the process of time these mills were enlarged, and as they stand today comprise the Woolen and Worsted Mill, employing some 1,350 workers; the cotton mill, employing about 600, and the Cotton Finishing Print Mill, employing about 400 workers. In connection with these three mills, a mechanical department is operated, employing about 150 men, and a farm branch, employing 50 men, all at Webster, Mass. The mill at Farnumsville, Mass., employs 450 people, and is engaged in making Cotton Worsted Narrow Goods. The employees of all these forces number 2,000 men and 1,000 women.

There is no doubt whatever, that the Slater Mills were the pioneer

mills in the textile industry. Neither is there any doubt that the Slater Mills were the pioneers in safety work. Originally, it is said, pails of turpentine were always kept convenient for cleansing scratches and cuts; while this protection measure today may seem crude, yet it indicated forethought and business acumen. Today safety work at Slaters is recognized as one of the vital links in the chain of manufacture.

RESULTS OF HIGH ACCIDENT RATE

When the Liberty Mutual Insurance Company rendered its analysis of our accidents for the year 1917, we were very much disturbed to find that our plants had more accidents per capita than the average Massachusetts textile plant.

We had our first-aid rooms, our nurses in attendance, etc., and had guarded our machinery as the State Police required from time to time. Our machinery was as modern as similar plants, our overseers were capable men of long experience, and we were at a loss to understand just why we should have more accidents than others had.

We realized, however, that this high accident percentage was costing us money in high insurance rates, that there was a considerable loss of production occasioned, and that our labor turnover was not being improved by having our mills known as dangerous places to work.

Right here let me state that Webster, Mass., is one of the finest mill towns in the country. The relations between the employer and the employee are of the best. A large percentage of our employees have lived here all their lives and have always worked for S. Slater & Sons, Inc., and know their interests and the company's interests are one and the same. All of the old families are personally known by the officials of the Slater Corporation and personal concern is taken for their happiness and general welfare; and so in taking up safety work, there has been that intimate personal interest of the officials in the matter, which has perhaps made it easier to make this work as successful as it has been.

We were advised by our Insurance Company and consulted with other experts as to what we should do to cut the high rate of accidents, and the consensus of opinion showed the desirability of starting a safety campaign.

This advice was accepted and on June 1, 1918, we began under the direction of the Safety Department of the Insurance Company and formed our Safety Organization as follows:

SAFETY ORGANIZATION

A safety inspector was appointed to conduct a propaganda campaign of education among the employees and their families to follow up all accidents and learn how they happened, why they happened, and if a similar accident could be averted.

Three committees were formed to meet once a month, with duties as follows:

A General Committee composed of the Treasurer, and Superintendent of each mill; the Overseers' Committee composed of one overseer from

each mill and the overseer of all outside work; the Workmen's Committee composed of one workman from each mill and the Chief Electrician.

The personnel of the General Committee was made permanent, while the Overseers' and Workmen's committees are constantly changed by the dropping of one member of each, every month, and replacing with new ones, so that eventually a large number of men will have served, and will have learned to feel that this work can be a one-hundred per cent success only by each and every one doing his share.

The Overseers' and Workmen's committees meet regularly on the company's time every month at the General Office with the Safety Inspector for the purpose of going over accidents which have happened since the last meeting and taking up any matters which the Inspector may wish them to consider. At these meetings our Treasurer drops in and makes a few remarks which become food for thought. Every effort is made to impress upon each member the importance of this work.

The Committee then proceeds for an inspection through one of our plants—there being four plants and two committees, each plant gets an inspection once in two months—and later submits to the Safety Inspector any recommendations it wishes to make. These suggestions, good or faulty, reasonable or otherwise, are gone over by the Inspector and Superintendent of the plant affected and finally come before the General Committee. Practically all of the suggestions are good, and any that the General Committee do not approve are sent back to the recommending committee with full reasons for not carrying them out.

EDUCATIONAL WORK

Bulletin Boards have been erected around the plants and an effort made to keep bulletins of interest posted. Most of our bulletins are received from the National Safety Council and the Liberty Mutual Insurance Company. Newspaper clippings of accidents are followed up and then posted where a similar accident might be liable to occur.

First-aid rooms are fitted up at each mill where the minor cases and daily dressings are attended by a nurse. Considerable safety work can be done by the nurse; for instance, an employee has a septic finger caused by a neglected scratch and reports for daily dressings, the attention of each one coming in for treatment is called to this and the patient is generally willing to tell just how it happened, etc., and the chances are that any one who sees a case of blood poisoning will see it in his own mind when he gets a cut or scratch.

However, we have had several lost-time accidents due to blood poisoning, occasioned by neglected cuts and scratches, even recently, and it is our experience that about the hardest thing to eliminate in safety work is the human tendency to take a chance. We are all natural gamblers, to a certain degree, and few consider carefully the odds against them, when tempted to take a risk in work or play. So this is one subject that must be continually agitated, and brought to mind in striking ways. A great deal of time, thought, and money have been put into the guarding of machinery, and while the guarding of machinery is, of course, neces-

sary and helpful, it does not compare in protective value to the educational work on safety.

GENERAL HOSPITAL

A general hospital is maintained, completely equipped, with two rooms and four cots, being centrally located for the mills at Webster, and used for the more serious accidents. The nearest Public Hospital is at Worcester, sixteen miles distant.

SAFE CLOTHING

Every effort is made to have the employees dress in safe clothing. About 40 per cent of our help are women and for these we provide womanalls and caps. The girls are advised to wear these, but it is not made compulsory; about half the girls take advantage of this clothing.

MOVING PICTURES AND SPEAKERS

Through the Liberty Mutual Insurance Company we secured the moving picture scenario written by David S. Beyer, and entitled "The Outlaw," and ran it afternoon and evening for two days at Webster, and one day at Farnumsville, for the benefit of our employees and their families. We believe that this picture gave our safety work a tremendous start and we are planning to arrange for other pictures of this nature at regular intervals. The week following this picture show there was not one lost-time accident at any of our mills, whereas the average had been six per week.

Our overseers get together for a smoke talk occasionally, at which time we have some one present from out of town who can give a short informal talk on Safety. At these meetings each one is asked to contribute his ideas and to ask questions.

These meetings are profitable, we believe, in that they tend to get the men better acquainted with each other and with the management. Furthermore each overseer is made to feel that safety work is just as much a part of his work as production.

COST OF ACCIDENTS

We tell our overseers that every lost-time accident costs the Corporation one hundred dollars (\$100.00) or more, seventy dollars (\$70.00) insurance charge (which I believe is the experience rating basis) and thirty dollars (\$30.00) for the loss of production, etc. Really, money talks and no overseer cares to see his department lose a hundred very often, particularly when he knows that records for each department are being carefully kept and from time to time will be read at the general meetings.

Our nurses and doctors are impressed with the cost of lost-time accidents, not only to the Corporation but to the injured, and are requested, when an employee is so injured as to incapacitate him from his regular duties, but not from some other useful work, to advise him to return to work, when his overseer will give him something he can do.

We believe this policy is best for the employee, for several reasons, because he loses no pay, by being occupied he suffers less from his injuries, and gets back on his regular work at the earliest possible moment.

The Corporation benefits by not having the accident charged against it and has gone some way toward making the employee feel that a personal interest is being taken in him. All of this accrues naturally to the advantage of employer and employee.

The safety organization must deal with accidents very much as the health authorities deal with contagious diseases; the origin must be discovered and some definite steps taken to prevent further cases.

There are some cases that seem absolutely hopeless. We have in mind one man in particular, a very good workman, steady and sober, but always getting hurt; we finally had to release him as too heavy a risk.

The foregoing material will give you an outline of the general way our Safety Campaign has been worked. Now as to results.

RESULTS OF SAFETY WORK

During the six months previous to starting safety work there were one hundred seven (107) lost-time accidents, an average of more than four per week; for the first six months after safety work started there were fifty-three (53) lost-time accidents, or an average of two per week, and the doctor who had most of our accident work began to revise his estimate of what his income tax would be.

During the six months ending June 30, 1919, or the second six months of safety work, the lost-time accidents totaled thirty-two (32) or not quite one and one-fourth per week.

Our lost-time accidents for 1919 to date, figured on a yearly basis are 2.24 per cent of the total employees, and we have every confidence that this figure will be cut in two, one year hence.

For the purpose of knowing just what progress is being made from every standpoint, accurate record must be kept of all accidents and their cost. This data should then be summarized and comparisons drawn, and the facts as developed, brought to the attention of the safety organizations.

Such reports as are posted through the mill should be simple statements of the number of accidents each week occurring in the different department or mills.

The principal factors in making safety work successful are the same as in making a success of any other work; you must believe in it, you must get every one else to believe in it, you must put a lot of enthusiasm in it, and you must keep everlastingly after it. Nowhere can the maxim, "eternal vigilance is the price of safety," be applied with greater force or effectiveness than in a large modern industrial establishment, such as S. Slater & Sons, Inc., where the exercise of continual caution with manual skill means a high degree of productive efficiency, and where, on the other hand, carelessness of employees, with lack of alertness on the part of supervisors or foremen in the matter of preventable accidents, may mean heavy loss to both employer and employee in money and morale.

CHAIRMAN BEYER: Mr. Scully of the nominating committee has to

leave shortly and we will postpone the discussion of Mr. Ide's paper until this can be disposed of. The nominating committee will please report.

REPORT OF NOMINATING COMMITTEE

MR. SCULLY: The nominating committee submits the following names: Mr. H. L. Robinson, Crimpton and Knowles Loom Works, Worcester, Massachusetts, Chairman; Miss Ida May Wilson, Service Department, Lockwood, Greene, and Company, Bay State Cotton Corporation, Newburyport, Massachusetts, Secretary; and, Mr. A. E. Conrath, Chief Inspector and General Foreman of the International Harvester Company, St. Paul, Minnesota, Vice-Chairman. By way of a little explanation, I want to say that Miss Wilson was put on this committee, and she objected quite strenuously to submitting her name, but Mr. Coffey and myself held a special meeting, and we unanimously decided she was the person whose name should be submitted, and we are very glad to be able to do that, Mr. Chairman.

CHAIRMAN BEYER: I see we made no mistake in selecting as the Chairman of the nominating committee, one who did not hesitate to use the steam roller to secure desirable candidates when necessary.

(These persons were unanimously elected.)

CHAIRMAN BEYER: We would like to hear a discussion, or any questions that any one would like to ask, on the last two papers which have been read, or on Mr. Moiler's paper, as the formal business of the meeting is now accomplished, and further discussion is in order.

DISCUSSION

MR. COFFEY: One of the hardest things to guard successfully is the carding machine. I should like to have a little detailed explanation given on this.

MR. OWEN: There are not many women working around those machines, and outside of keeping away from the belt and so forth, the risk is comparatively small. As a rule, we haven't done much on the carding machine, because, to be frank, I don't know how it could be guarded successfully.

MR. COFFEY: We don't find many accidents occurring around the carding machine.

CHAIRMAN BEYER: Don't you think the belt shifter itself serves as a sort of guard?

MR. OWEN: Yes, it takes care of it very largely.

MR. COFFEY: We haven't got a record of the belt accidents in the textile industry, but in that one industry, we have not had a belt accident in a couple of years. Are there any statistics available on the subject?

CHAIRMAN BEYER: We have some such statistics. I made a study of the matter a few years ago, and found that the mechanical accidents in the textile industry were more frequent, comparatively, than in most other industries. Yet, educational work has been just as efficient and important as in any of the other industries. Some data on accident statistics were given in the 1917 Annual Proceedings of the Council.

SECRETARY RENNIE: I think the best way to prevent accidents is along the lines of the last paper—safety education.

MR. O. M. CARTER (Daily News Record of New York, Cleveland, Ohio): Has it ever been tried to reduce accidents by offering a bonus to the fellow that didn't have an accident?

CHAIRMAN BEYER: Yes, I think I can answer that. I was just at a meeting of the Midvale Steel Industry, which is divided up into committees, and the committee that has the fewest accidents during any month receives a bonus. There is also a bonus for the committee that shows the greatest decrease in the number of accidents in that period.

MR. ROBINSON: I don't think it pays to use that kind of incentive.

MR. MOLLER: Almost anything that will afford the sought-for protection is worth the price.

MR. ROBINSON: I can't see how it would take care of the carelessness of another employee.

CHAIRMAN BEYER: Double the bonus if he didn't injure anyone! (Applause.) "The proof of the pudding is in the eating." I think that anything which helps to prevent accidents is worth while, and sometimes the novel and seemingly impractical does do good work through arousing interest among those concerned.

We have some representatives from "across the border,"—Mr. Payne of the Empire Cotton Mills, Welland, Ontario.

MR. J. D. PAYNE: This is my first attendance at the National Safety Council. As a matter of fact, in Canada we have been a little bit backward with the safety movement, and it is tried out up there more on the statements of our neighbors in the States. Recently, however, it has come into more popularity and I believe is proving very successful. That is the situation in the eastern part of Canada, where we have one line of action just opposite, almost, to the western part. The trouble is that we really have no standards upon which to go.

A MEMBER: Perhaps it is a case of two men going toward the same point, and both meeting head on.

MR. PAYNE: That is just the point, but during the last three or four years we haven't gotten far enough along the road, and the travelling seems rather rough and unsteady. Our accidents in the mills have been cut down to a place where a fair improvement is shown, but by next year we hope to be able to give some very good figures to the National Safety Council, and also give more details of the work, than we can do at the present time.

CHAIRMAN BEYER: I am sure the fact that you are here shows that your plants are taking a great deal of interest in safety work, and where there is such interest there is bound to be results in a very short time, Miss McLaughlin may be able to tell us something of interest about the work at the Imperial Cotton Company, at Hamilton, Ontario.

MISS MONA McLAUGHLIN (Imperial Cotton Company, Hamilton, Ontario): About six months ago we organized a safety committee and, like everybody else, we think it is going to be a wonderful agent in the reduction of accidents, and we are going to put the good work across. Our fore-

men are going to be the real boosters and I believe will cause the greatest gain in this work, because a foreman is in closest relation and contact with the help and if he is a real enthusiast in the work of reducing accidents—and we believe ours will be—it is going to impress the value of the work more upon them than anything else and they should be more responsive to the benefit to themselves. We hope to have some very interesting statistics for the convention next year.

CHAIRMAN BEYER: I wonder if Mr. Newton would not care to add something to the discussion, as I am sure that he could give us some valuable thoughts.

MR. H. A. NEWTON (Assistant Superintendent, Pacific Mills, Hampton Mills Department, Columbia, S. Car.): Mr. Chairman, I don't believe I will add anything to the discussion, but I will say that all that has been said by the speakers has been very interesting indeed, and is going to prove of considerable value. Most of our accidents have been caused by belts and I had hoped to hear a little more along that line.

One unpleasant thing that we have to contend with down in our district is the fact that the employees almost always try to take an unfair advantage of the employer, and they do not seem to want to coöperate, and are really not very much interested in welfare work, as they take the position that we are trying to impose upon them. For instance, if a man gets a scratch, or any little thing like that, he will lay off two or three days, when he could just as well work, and probably goes home and works around his own house. And often those minor injuries develop into something serious because they do not have them attended to in time.

We have no workmen's compensation law and when a case comes up for settlement, we have to try to please all parties the best we can. We are trying to give as much publicity as we can to safety work and are endeavoring to secure the confidence of employees so that we may be able to give them greater assistance, and not only effect a considerable saving to them, thereby effecting a saving to ourselves, but to help them in every way possible.

CHAIRMAN BEYER: You don't have a compensation act in either of the Carolinas, do you?

MR. NEWTON: No, sir.

CHAIRMAN BEYER: I think we ought to have a word from the coming Secretary of the Textile Section, Miss Wilson.

MISS WILSON: I am afraid I can't add anything to what has been said. We have a safety committee in our organization, the members being the heads of the different departments of the plant. We add new members every six months, but no one is ever taken off the safety committee. We have very few serious accidents. When an employee comes into our plant, she is carefully instructed in the proper methods, and the accidents liable to happen are explained. She is also carefully observed and our employees are now very careful, thus proving the success of this plan of education. We show them the right way and the wrong way, and

insist on the right way of doing things. Since the time of 1930 we have had twenty-two accidents, though none of them were serious.

Our people are very much interested in the work. Every member on the safety committee considers himself individually responsible for any accidents happening under his or her jurisdiction, or in their department.

As soon as an accident is reported, it is kept under close observation, and the worker is visited regularly and his condition known and watched at all times, which has prevented serious complications in many cases.

CHAIRMAN BEYER: That is a very interesting and helpful summary of the work that is being done in your plant, Miss Wilson.

There are just one or two points that I would like to mention before the close of the meeting of the section. I remember that at the meeting last year there was some discussion as to the desirability of adopting standards for safety work in the textile industry, standards that could be followed by any mill, with the certainty that it was using the best safe practices now available. You have heard this morning much definite and detailed information that could be used in such standards. There was one paper dealing with plant and machinery layout, another took up the matter of guarding machinery, and the third covered the educational work, so that the field has been pretty well outlined, and in a tangible and definite form.

I believe that with the skeleton material given in these papers it should be possible to go ahead with the development of more definite standards, and that gives the succeeding officers of the Textile Section some suggestions to consider in carrying along the work during the next year.

TEXTILE BULLETINS

Another point that I should like to bring to your attention is the importance of the bulletins that are issued by the home office of the Council during the year. These bulletins are based on the experience of the different mills and members of the National Safety Council, and contain valuable data which can be used by all of us. The Council can work to much better advantage if you will make contributions during the year of bulletin information based on practices that you find in your own plants. This will further the work of the National Safety Council in the most effective manner.

Mr. R. H. GERRANT (Safety Engineer, National Safety Council, Chicago, Ill.): I would like to impress on you the importance of sending in to the Council headquarters the data that you collect in experimenting with various guards and any other interesting work in reducing your accident hazards; also in your educational work in safety. My time is limited, as I have about five other meetings that I am trying to get around to before twelve o'clock. There were however three or four remarks that I have heard in your discussions which are extremely interesting, such as the guard for shuttles, for eliminating shuttle accidents; this will surely be suitable for a bulletin. All members should realize that this is simply a

coöperative body, and the more you contribute the more all will be benefited.

CHAIRMAN BEYER: I will say in closing that I am sure I express the sentiment of the entire section when I thank the Vice-Chairman, Mr. Ide, and the Secretary, Mr. Rennie, for their time and effort in behalf of the textile section, as well as the speakers for preparing the interesting program that was presented in the furtherance of safety work this morning. They insist on giving me the credit for some of it, but I cannot accept it because I merely got the others to do the work.

I know you want to hear from Mr. Robinson, the next chairman of the section, before the meeting adjourns.

MR. ROBINSON: If the meeting next year is as great a success as this one has been this morning, I will be inclined to take quite a little credit for it. The program this morning has been a splendid one, and I feel sure it is due to the direct efforts of Mr. Beyer. He disclaims the credit for it, by saying that he got the others to do the work; but he used very good judgment in selecting the workers. I make the motion that Mr. Beyer, Mr. Rennie, and Mr. Ide be given a vote of thanks for their splendid efforts.

(The motion was seconded and carried.)

The Section adjourned at 12:35 P. M.

Women in Industry Section

October 2 and 3, 1919

MISS TRACY COPP, Chairman

Director, Women's Department, Industrial Commission of Wisconsin,
Milwaukee, Wis.

THURSDAY MORNING SESSION

CHAIRMAN COPP: We have the honor this morning of an address of welcome by Mrs. Bishop. Mrs. Bishop is the President of the Cleveland Federation of Women's Clubs and has been appointed by the Mayor of Cleveland as Chairman of the Women's Committee of the Northwestern Ohio District of the National Safety Council. I am honored in presenting Mrs. Bishop.

Mrs. Bishop: I am always proud to receive any invitation to represent the Cleveland Federation of Women's Clubs and additionally proud when I am asked to come before any gathering to represent Cleveland women.

I consider it a distinct pleasure to come and talk to you for a few moments this morning for two reasons. The first reason is that I am tremendously interested in the entire work of the National Safety League—it always appeals to me very strongly when any group of men and women undertake such an important piece of work or campaign, if you will, for the pure sake of the public good. Another reason is that the women have been given two morning sessions of one precious week's stay in Cleveland!

Because I know we all feel the necessity of this great movement, I am going to take the liberty of offering to this National Safety Council League the earnest, loyal cooperation of the women not only of Cleveland and of this Northeastern District of Ohio, but of the whole United States. In conclusion I wish to say that we Cleveland women wish to feel as hostess and wish you to feel that we are your hostess during your trip and sojourn in our city.

CHAIRMAN COPP: I have the pleasure of introducing to you Miss Wright of the State Department of Health, New Jersey. Miss Wright is eminently qualified to talk to you about the "Responsibilities and Oppor-

tunities of the Industrial Nurse"—as she has had years of experience in that work.

THE RESPONSIBILITIES AND OPPORTUNITIES OF THE INDUSTRIAL NURSE

MISS FLORENCE SWIFT WRIGHT, R. N., NEW JERSEY STATE DEPARTMENT OF HEALTH, TRENTON, N. J.

Three years ago it was my privilege to prepare a paper for this organization. Industrial nursing was still in the pioneer stage and the industrial nurse was often on trial. The great war has brought changes, not the least being a much more general appreciation among employers of the value to them of the trained nurse as well as recognition in circles of organized labor of her services to the workers. Today I shall not, as was the case three years ago, try to convince you that you *need* the industrial nurse; instead, I hope to show what may attract a nurse to work in industry as a means of self-expression which allows her to use for humanity all of her training and experience.

PREPARATION FOR SERVICE

To meet her responsibilities and take advantage of her opportunities she must prepare herself as a *public health* nurse by acquiring some familiarity with the principles of psychology and applied economics and an open-minded insight into present day social conditions. She must learn to understand all kinds of people and she can only do so by making herself familiar with their past condition, their ambitions, limitations, opportunities, and needs. She cannot understand the various types of Poles unless she knows of the partition of Poland and of the various factors which have consequently influenced the thought and habits of the Polish people. A knowledge of their history is also essential with the Russians, the Hungarians, the Italians. The people she deals with she must study daily. The American may be able to explain himself, but the immigrant can hardly become a good American citizen unless we understand his needs, if not his tongue, and make him know that we understand him.

FIRST DUTIES OF THE INDUSTRIAL NURSE

As an *industrial* nurse, the trained public health nurse on taking a position in a new industry, should acquaint herself as rapidly as possible with the processes of that industry. She should make herself familiar with its less obvious health and accident hazards and with the indirect effects of work and methods on the vitality and future health of the workers, especially young people and women, as well as with the hazards that force themselves upon the attention by their ever-recurring *visible* results.

A nurse who is allowed the privilege of studying the industry will, *providing* her records are well kept and efficiently used, become increasingly valuable in all her contacts.

Her further responsibilities are:

First: To herself, that she develop her powers.

Second: To her employers, that she perform faithfully what they have seen for her to do, while demonstrating the economic value of broader activity.

Third: To the workers, that she serve them acceptably and with the authority that will win their heed to her teaching.

Fourth: To the industrial physician, that she carry out his medical orders exactly and that she cooperate with him in all matters.

Fifth: To the community, that she act in the best and broadest meaning of the term as a good and progressive civic as well as industrial servant.

But I believe that the great responsibility of the industrial nurse who has a vision of the broader aspects of her work is a duty to our country for the best use of her opportunities in the making of good American citizens. Her privilege of rendering personal service gives her rare opportunity to understand the worker and puts this duty squarely on her shoulders. I consider her opportunities to be her responsibilities.

THE NURSE A PART OF AMERICANIZATION PROGRAM

How and why the public health nurse must be a part of the Americanization program has been told so concisely by Mrs. Haasis¹, of the National Organization of Public Health Nursing, that I quote her words.

"First: The Public Health Nurse enters the home of the foreign born at a time when there is trouble. Service is needed, and needed badly, too. Her uniform proclaims her as a worker, and to the men and women who have toiled and sweated in workshop or field, there is no passport to confidence like a pair of working hands. The uniform also proclaims a knowledge above their own, a familiarity with scenes of life and death, a kinship to the "professor," to which they are willing to trust their dear ones for care. Some, coming from countries where ministry to the sick is the field of the church, recognize in the uniform the added sanction and beneficence of religious service. . . . There is trouble, sore trouble, and she has service to give and her service assures her welcome.

"Second: Nine times out of ten her visits bring immediate and tangible benefit. Even if not in the recovery of a sick one, at least in increased comfort and in the confidence of the family that they are doing the right thing. A few simple admonitions and baby begins to gain weight. A burned hand dressed three or four times and the father is able to go back to work again. 'Hope deferred maketh the heart sick,' but immediate results are a wonderful help in gaining confidence and obedience to one's teaching.

"Third: Once the gratitude of the family and their confidence are gained there is no subject on which they will not ask or accept advice. And here lies the opportunity of the public health nurse to win the family over to such American standards and habits as are better than their own. The Italian mother can, after a time, be persuaded to take off the

¹"Public Health Nursing an Aid to Americanization," by Bessie A. Haasis, Educational Secretary, National Organization of Public Health Nursing.

"fasch" which binds her new born baby's little legs up into a tight mummy shape. The Polish mother, after patient teaching, can be induced not to give her three months' baby a taste of cabbage, stew, or whatever else is on the family menu. . . .

"There is no reason why the advice of the public health nurse should be limited only to matters of health. Public health nursing states as its aim: 'To remedy not only the case of illness, but *whatever is wrong* with the family.' And so the public health nurse may be the one to get the young wage earner into lighter work so that he can attend night school. If she has nursed his brother through a critical case of pneumonia he is likely to do what she advises. Or she may be the one to urge the father to take out his naturalization papers, knowing that in the hazardous industry in which he is employed he stands as good a chance as any other man of being killed and leaving his wife ineligible for a widow's pension. If she has cared for the wife when the last baby was born, he is likely to do that, too."

This is all true of the *industrial* public health nurse as well and her opportunities are even greater for two reasons.

First: Her services are free from any possible sting of charity as she is employed as a necessary provision for industrial safety and health; or if employed by the workers themselves, through mutual aid associations or labor unions, her presence shows the need of her service to have been so plainly seen by those she serves that they have already paid her for it.

Second: Her close relation to her patients, while at work as well as in the homes, during health as well as in sickness, makes it possible for her to become a friend before she becomes a nurse, with all the advantage of knowledge and understanding which the double relationship will bring.

GENERAL DUTIES OF INDUSTRIAL NURSES

Today the trained nurse is employed in most industries; in mining settlement and bank, laundry and hotel, tannery and department store, rolling mill and candy factory, packing house and silk mill. Her duties are equally varied. Most often we find her giving first aid and assisting the industrial physician; caring for the sick in the home and teaching there bedside nursing, home management, child care. However she is equally concerned with accident prevention, sanitation, health education, employment problems. Seeing cause of illness and misery, she is able to aid in finding the remedy.

In the plant she may have a large responsibility in searching out the more remote causes of injury, illness, and unhappiness, together with an obligation to enforce necessary precautionary measures. Her daily contact with the workers in plant and home, together with her neighborly, personal service to them, puts her, if she respects their racial traditions, in the best possible position to demonstrate the wisdom of change in habits which will make for healthy, rational life. If she is wise, she will not seek to do this by ruthlessly uprooting cherished custom, but rather by friendly interchange of ideas will strive to alter only that which is actually harmful while preserving the good to enrich our own national life. She will not fall into the error of the social worker in the old story who,

returning from a visit to an Italian family, reported that they were not yet Americanized as they were still eating Italian food. Rather, she will try to teach her American friends the value of the Italian salad, French soup, Swedish bread, Hungarian stew.

She will, by her understanding of the parents, almost unconsciously strengthen family ties by fostering in the minds of the young people respect for the opinions and customs of their elders, the loss of which is often a sad feature in the lives of the foreign born which gives dangerous freedom from restraint to their children and is the direct cause of much lawlessness among those of foreign parentage.

The industrial visiting nurse, already known to her patients, comes to them in their homes when they need her, and while her service to them is a friendly, neighborly one from a fellow-worker, her training and uniform give her words weight as suggested by Mrs. Haasis. Her co-workers and their families come to love and trust her and to depend on her to smooth out many rough places. She is a connecting link of understanding sympathy between employer and worker. Knowing both intimately, she is sometimes an unofficial mediator, explaining to the worker the aims of the employer and bringing to the employer what she has learned to be the needs, the handicaps, and the ambitions of the worker. Having the advantage of being on a common footing with them as a fellow employee and rendering, without any thought of charity, as special a service as a machine tender, the workers readily understand that her interests are theirs.

VALUE OF NURSE TO EMPLOYERS

In the plant the nurse may render many valuable services to her employers. Her records have shown ways of improving and strengthening their organizations. By seeing the benefits of a little attention to the care of health, employers are led to increase such service. First aid and health work, beginning with one nurse, have time and again grown in a few years to a large department providing full-time medical service with physical examination of employees and constructive work for the betterment of health conditions.

For the protection of the future of America, the welfare of girls and women in industry should be the special care of the industrial nurse. She should be able, ultimately, to show by her records the types of work which cause nervous exhaustion or undue physical strain; she can do much by proving the poor economy of the employment of mothers of young infants, and so help to keep for each young American his first birth-right, breast feeding by his own mother. Even in prosperous communities, the infant mortality rate is always high where many women are employed outside the home. Dr. Julius Levy, Chief of the Bureau of Child Hygiene of the New Jersey State Department of Health, shows that poverty is not the most important cause of infant mortality, but that any factor which separates the mother and her infant (whether employment in in-

¹"Education and Economic Adjustment for the Reduction of Infant Mortality," by Dr. Julius Levy (the National Conference of Social Work, 1919).

dustry or social life) by preventing the breast feeding of the baby, causes a high infant mortality rate.

The industrial nurse will see other than health needs. Efficiency is so dependent on health, health and happiness are so inseparable, that she will also take an active interest in the recreational and educational needs of the employees.

HER WORK IN THE HOME

Especially in the homes will her work yield results. More or less has always been done to educate foreigners in industry by means of settlements, societies, clubs, and night schools, but the foreign mother in her home had little general consideration. Hers has always been a heavy burden. Obligated to rear her family in a house unlike those of the homeland, with accustomed foods of prohibitive price or impossible to obtain, surrounded by opportunities she does not recognize and temptations she does not understand, it is no wonder that her children sometimes lack the health of their parents and often fall short of good American citizenship. The industrial visiting nurse reaches these mothers. Coming when she is needed, she is welcomed and her next visit is anticipated with pleasurable expectation. Having already seen the household at its worst, the nurse is treated with little reserve and is consulted freely on any subject, from how to manage schooling for the eldest child to the best way of keeping the children off the street or how to get good milk for the baby. The nurse who is alive to her opportunities for service will not be found wanting. If suitable means for recreation and education and a good milk supply are available, she will be able to advise. If they are lacking she can provide concrete instances for use in pointing out local needs.

HER WORK IN THE COMMUNITY

For their communities industrial nurses have been the indirect means of securing schools for foreigners, settlements, visiting nurse associations, child hygiene stations, open air schools, health leagues and medical inspection in schools, industrial clinics, better housing.

How shall the industrial nurse meet her responsibilities and seize her opportunities? By coöperation, first, with her employer, who, if she gives evidence of ability and if she is careful to show by means of facts, through her records and reports, the wisdom and economy of each step she takes, will allow her reasonable initiative and freedom to coöperate with other department heads in the plant and who will aid and abet all she does to become an efficient employee and a helpful friend to her fellow workers, a capable assistant to the industrial physician, and a good American citizen.

CHAIRMAN COPP: The members of the nursing profession have been very seriously developing the qualities in the nurse that are essential in industrial work: they are very eager that the employers in selecting industrial nurses should recognize those qualities and hire the nurses because they have them. I have asked one of our Wisconsin employers to give us a word or two of testimony regarding the qualities of their industrial nurse. I have the pleasure of having you hear Mr. Frank Shattuck of the Kimberly-Clark Company of Neenah, Wisconsin.

MR. SHATTUCK: It seems that the Chairman heard of a letter which went out from the Company last Friday to employees of one of our mills which employs 850 men, the purpose of which was to give them the results of the past year's work of the First-Aid Nursing Department. I will just read a portion of it:

REPORT OF KIMBERLY-CLARK COMPANY FIRST-AID NURSING DEPARTMENT

"Two years ago the Directors of this Company voted to place a nurse in the Kimberly-Clark mills. Miss Kirby was engaged, with Miss White as an assistant. Miss Kirby's figures have just come to me for the last twelve months and they are so important I want each to share with them.

"During the influenza epidemic Miss Kirby was on the job day and night. It was estimated that she took 5,000 temperatures during the days the disease was raging. Only three deaths out of the 840 people that were working in the Kimberly-Clark mills is the testimony of the good work which was done.

"During the past twelve months there have been 3,567 treatments given in the Kimberly-Clark First-aid Room by Miss Kirby. If this number of people had had to leave the mill in order to go to their homes or to the doctor's office, they would have lost about 11,000 hours of time. Before the First-aid Room was installed, there was an average of 20 per day out because of sickness or poor health; this is now cut down to an average of 8 per day. If we take the average lost wages before we had the nurse as compared with days lost on account of sickness, we find that the First-aid Department saved about \$13,000 last year in wages to the men and women in this mill. In many cases the nurses have saved the added expense of a doctor's bill.

"We have large numbers of employees thrown together in the mills and there is always the danger of the spread of contagious diseases—at one time it was the mumps, another time the measles, and I am quite confident that the spread of both of these diseases was cut off by the good work of these nurses. Miss Kirby also helped to prevent the spread of tuberculosis and to send the patients to a place where they could get the proper care, thus safeguarding the health of the fellow workers.

"If the First-aid Room should be abandoned and if the nurses in it should be abandoned, the expense and salary—and all expense and salaries is included—if put into the pay envelope would amount to a trifle less than one cent per day per employee."

CHAIRMAN COPP: Ladies and Gentlemen, the meeting is yours.

DISCUSSION

MR. S. W. ASHE (General Electric Company, Pittsfield, Massachusetts): I was very much interested in Miss Wright's paper.

The problem of an industrial nurse is difficult. We maintain an emer-

gency hospital and we have some very excellent nurses in charge. They handle about 100 cases a day of all sorts.

MR. A. H. CRAPSEY (A. T. Crapsey Company, Rochester, N. Y.): Industry owes a great deal to the married woman—a great deal more than she has heretofore been given, and I would like to hear some discussion on that point.

In regard to the health end of it, I think that industry ought to take care of a married woman at the time of maternity.

Then too, I would like to hear what the women have to say about the five-day week for women. We employ women in our plant and we have now worked for three years on the five-day week, giving the woman—the married woman, especially, a day in which to take care of her home and one day for recreation. This hasn't hurt our production in any way, but I would like to hear something about the five-day week.

MISS NESTA C. EDWARDS (Chicago, Ill.): I don't believe it's a function of industry to look after maternity. I am willing to see industry pay toward a community nurse and a visiting nurse, but I am not willing, as a worker in industry, to see the factory nurse do the functions of all the other organizations. It's the function of your factory nurse and your social service worker to bring your people in conjunction with the institutions that do the work.

DR. J. J. HARVEY (Akron, Ohio): I practiced industrial management for nearly a quarter of a century, both in industry and out. I think Miss Edwards is right. The industrial nurse has a function to perform and the industrial worker has a function to perform. There is no question but that there is a place in industry for the industrial nurse practicing her profession. The nursing profession until recently did not develop the industrial nursing profession—the nurses in industry were the pioneers in developing the industrial nurse. The profession has been taken up and they are developing splendid results in nurses.

CHAIRMAN CORP: I regret very much to have to announce to you that Miss Van Kleeck is unable to be with us this morning on account of illness in her family. Mr. Knoeppel has sent his paper, and printed copies are available.

HOW TO EMPLOY WOMEN SUCCESSFULLY IN INDUSTRIAL OCCUPATIONS

C. E. KNOEPPEL, INDUSTRIAL ENGINEER, NEW YORK CITY

Although the great war crystallized many conditions connected with Woman's industrial life, it remains for the post-war period to clarify them. The chemist generally clarifies his mixtures by filtering out the grosser particles or by absorbing them into a precipitate which can later be removed to leave the clear liquid. It is therefore fair to use somewhat similar analogy in respect to women industrial workers.

In justice to all concerned we ought to "filter out" as speedily and completely as possible, the individuals whose utter selfishness so often be-

gins with unrest and ends with unrestraint. To rid a business of these malcontents is much more difficult than to prevent their engagement in the first place. Some men acquire indifference to being discharged; but comparatively few women can consider discharge in any light but that of enmity. The other class of unsuitable employees which "absorption" removes, embraces those in whom personality and willingness are satisfactory but whose training has been insufficient, or whose physical condition is not adapted to their assigned duties.

Even above the purely industrial aspect of the subject of woman's work, there must always come the humanitarian aspect. Against strong opposition—sometimes on the part of the very class sought to be helped—laws were slowly formulated (and even more slowly extended from state to state) by which the labor of women and children was sought to be regulated as to hours and other conditions. It may be disastrous if we undo the good thus accomplished in an attempt to raise restrictions that were imposed for woman's own good, and our watchfulness in this connection ought to precede actual employment.

Here then is the first division of my subject "How to Employ" in the sense of *selection for employment*. A little later we will consider the second division that refers to *keeping them employed*.

It was my privilege about eighteen months ago to present some conclusions drawn from questionnaires answered by representative Americans. In that presentation I considered the subject under ten headings which I venture to repeat here, viz.:

- a. The work to be performed by women
- b. Finding the women
- c. Selection of women
- d. Training women
- e. Wages, hours, and fatigue
- f. Working conditions
- g. Living and social conditions
- h. State laws
- i. Coöperation of—
 1. Labor Unions
 2. Women's Organizations
 3. Government
- j. Post-bellum consideration.¹

Of course it is in the light of the last heading (Post-bellum consideration) that we are now viewing the preceding nine problems; but their relative importance has not been greatly altered in America's transition from war-time to peace-time activities. Yet enlightenment has come to us in the interval. Some of our hopes did not materialize and some of our fears were exaggerated; but in the main, things came to pass very largely as had been expected by those of us who had no personal "ax" to grind and who had sincere desires to serve America.

¹Women in Industry: An address delivered at Chicago in March, 1919, made under the joint auspices of the Society of Industrial Engineers and the Western Efficiency Society.

That American women rose so nobly to the demands of war is already history and if they were spared some of the harrowing overseas' experiences that claimed eyes and limbs and lives of the men-folk in those fateful years, we may yet conclude that even those sacrifices would have been made by our women in due course in the face of overwhelming Germanic domination.

Let us compare the present subdivisions of the subject with those of early 1918.

THE WORK TO BE PERFORMED BY WOMEN

Few manufacturers had any well-defined views as to the scope of work which women could perform in the plants. Therefore we could not say, "Here's the job! Where's the woman?" Instead, we had to analyze the operations that needed long-trained skill and those where short intensive teaching might take the place of longer normal experience.

Where such analysis was made intelligently by a Planning Department familiar with every (but not unduly favorable toward any one) department, the classification allowed more definite selection of women workers, and consequently with lower percentages of misfits and smaller labor turnover. Factory inspectors and women physicians were called upon in many instances to help decide what operations were or were not suitable for women's work.

Coincident with this effort was a wide awakening to opportunities for mechanical lifting and carrying of product-in-process. This not only relieved the emergency women workers from greater physical exertion, but it actually reduced production costs—and continues to reduce them even where women workers have retired in favor of the returning men. A number of other permanent improvements and advantages that arose during the stress of war, have remained to expedite and cheapen subsequent production. Jigs and fixtures were in this way further developed and both automatic and semi-automatic single-purpose machines were perfected and utilized. Incidentally certain laborious operations previously performed by male labor exclusively were analyzed to permit making labor-saving tools that could be handled by women.

In no small number of cases it was found desirable to vary intermittently the occupation of women where over specialization produced the nerve fatigue that follows continuous repetition of monotonous operations.

We may assume therefore, that a desirable division of work should be

1. Experienced men for difficult and complicated work;
2. Laborers for heavy manual work;
3. Women for light, simple or semi-complicated operations, wherein men set up the work.

Either the various trades, each for itself, or the government itself (for all leading trades) could compile and list the desirable or permissible operations suited to women's work. A field seemingly ideal for women would be that of tool-making, wherein her qualifications are manifest: accuracy, precision, neatness, dexterity, and quickness.

FINDING THE WOMEN

The questionnaire (already referred to) suggested a number of avenues of approach—chiefly the industries non-essential to war; the ranks of household servants, etc. Though the most obvious sources, the two named were somehow disappointing in the number of recruits obtained. This was partly due to assumption of war work by plants formerly engaged in non-war lines, and partly to a distaste among the better educated classes to enter gainful employment at such a time—"to accept pay from Uncle Sam while so much remains to be done which I feel I ought to do for nothing," as one bright woman expressed it. Largely from this class the Red Cross and similar ranks were recruited and the great majority of such workers have already returned to purely social or household duties.

The household servant class was a like disappointment. Near industrial centers the scarcity of such servants even before the war began was locally felt and the servants from non-industrial zones did not seem to possess or acquire readiness of hand and eye in industrial occupations.

But be it said to the honor of our women workers, that they entered war work more willingly than the parasite class of men servants who usually stuck to their sinecures until pryed loose by the famous "work-or-fight" order. Very likely this was due to the high percentage of aliens or partly naturalized individuals—those subjects from professedly neutral countries being the most loath to undertake war work, even at the tremendous wage attractions offered.

Women's societies, as a possible source of permanent additions to our industrial force will be well worth cultivation. Until now the Y. W. C. A. and similar organizations have drawn the bulk of their membership from office and store workers—and despite present high compensation, some such women still feel it a social "come down" to enter industrial plants.

SELECTION OF WOMEN WORKERS

No detailed qualifications for prospective women employees can be undertaken without considering the nature of the industry and its processes, but most of us feel that simple forms of both physical and mental examinations are desirable—together with some tests for deftness, skill, fatigue, and strain. Generally speaking, however, qualifications to be considered are: Age; adaptability; past experience; type; nationality; education; physique; health; intelligence; strength; moral character; looks; cleanliness; social standing; general aptitude.

The higher cost of training workers in these days of "paid learners" may lose much of its seriousness *when more careful selection raises the average quality* of such learners. It is fair, too, to credit the instruction-cost with full manufacturing value of salable product made by them. In this way each "taught worker" means lower net expense—or conversely allows engagement of higher grade instructors without raising the "cost per 'unit' taught."

To list the various "jobs" and let the incoming learners compare

them—and when practicable, to observe them during actual performance—helps to give clearer ideas of the employer's expectations, and lessens "choice by impulse" rather than after consideration. Unlike many men, women are not likely to select work chiefly because it "looks easy." It is altogether desirable that close supervision of learners should continue for from two to six weeks—and if the employment manager or welfare agent can get the foremen and superintendent to join in this observation, so much the better; especially if there is prospect of a job in another part of the business as an alternative.

Whether prospective industrial workers ought to be lured from the ranks of school teachers opens a field for serious discussion—especially in view of the proverbial underpayment of teachers and the proportionate attraction of industrial wages. But consensus of opinion is decidedly against such a draft upon so necessary an adjunct of modern life. Better by far raise the teachers' salaries and at the same time exact proper and higher qualifications that promise wider practicability of the teachings of instructors and their supervisors.

There is advantage oftentimes in seeking additional women workers from among the daughters of skilled workmen. Students of heredity claim that daughters favor father's traits and inclinations—and somewhat limited observation in this direction appears to bear out the view that daughters inherit latently, certain manual skill of their fathers. Other things being equal, such a daughter will become a better worker than one who undertakes operations in a different enterprise.

TRAINING THE WOMEN

Several phases of this aspect of industry have already been mentioned: and at least the nucleus of a corps of instructors should be organized before actively seeking women workers.

Preferably the instructors should be selected from the faster workers, in order to demonstrate dexterity; but the disposition of the teacher is also important. The "knack" of teaching is not confined to the "three R's" and one who has that knack will train a greater number and more competent workers than the teacher who has personal dexterity alone, without the gift of being able to impart the "how" of things.

Of scarcely less importance is, that the new woman worker ought to have a full trial; and if she does not show reasonably prompt aptitude in performing the operation in the "job" first assigned, she should be transferred to some other operation. In this respect women are even more than men amenable to the effect of immediate surroundings and activities.

The grouping of women workers is also important. A group of men of mixed nationalities may get along fairly well; but in case of women such arrangement is always risky and usually undesirable.

Keeping the instructors themselves under close observation and training allows each teacher's "special competencies" to be extended for use by other teachers, and the final net result is correspondingly improved.

It is nearly always fatal to best results if a newcomer is only par-

tially taught, and then left to continue as best she can. Striking examples of the seriousness of such a course may be found in the army of incompetent stenographers who boast of "making up their own" systems, because of their lack of study and training in one of the competent systems of authors whose text-books were merely skimmed (or largely misunderstood) by the student in haste to reach a "position."

If the worker is to be taught at all, let the instruction be continued long enough to prove competency—or the lack of it. It may seem superfluous to mention it, but qualifications of the instructor warrant consideration as well as in the case of prospective workers. Perhaps no other example of training workers offers more suggestive value than the telephone business, where the "quits" (due to marriage mainly, and to engagement for private exchanges) produce a very steady and considerable exodus month after month. There, as elsewhere, it is found that the teacher must possess, pleasing personality; tact; patience; sympathy; consideration for the rights of others; ability to perform the tasks, as taught.

It seems almost superfluous to urge the advantages of industrial training schools; but up to this time both Labor and Capital have looked askance at most proposals for their establishment. Labor apparently fears eventual encroachment upon its present strength by influx of too many apprentices; and Capital fears inability to retain a sufficient number of the newly-trained workers against attractive offers from competitive plants. Of course the "middle-of-the-road" viewpoint, as in other things, is the way out of the difficulty—for here again the honest co-operation of capital and labor will advance the interests of both.

WAGES, HOURS, AND FATIGUE

As I have stated upon former occasions, final success or failure of any specific case of women's employment must rest upon mutual satisfaction with results. The wage must be sufficient to attract and retain the right sort of workers; and the work done must be reasonably worth the wage paid. I am of the opinion that the balance between satisfaction and dissatisfaction is apt to be more finely drawn in case of women workers than with men. Yet the same prerequisites apply to both. The procedure must be—to determine standards and pay according to performance.

That the pay should be graded upon quality and quantity of performance and not made dependent upon whether the worker happens to be a man or a woman (to keep the question of sex out of compensation problems to the greatest possible extent) is generally agreed upon, and more and more frequently practiced every year. And this condition is being helped by the attitude of the more intelligent women workers themselves, who seek compensation based upon abilities, and not in any sense as an exploitation of their claims as women.

Trade customs, seasonal exigencies, sustained posture during work, and relative fatigue induced are fundamentals which demand attention in setting working hours.

Today, with the extension of the eight-hour day—and in intimations from some quarters that a six-hour day will be demanded just as soon as the trade unions acquire sufficient power—it would be ill advised management that sought to force women to work the old-time "long day," even if beneficent legislation had not forbidden it.

It is notable however that the desire for an 8-hour day is largely in the nature of demanding a 48-hour week, whereof the Saturday afternoon shall be a half holiday; and with reasonable precautions against unfairly heavy work, the consensus of Industrialists' opinion is that nine hours a day, for five consecutive days, is not harmful to women in good health if the day-and-a-half week-end intervenes. Therefore, present conclusions favor (for women):

1. No night work: —
2. No overtime (beyond 9 hours in any one day; or 48 hours in any one week); —
3. No Sunday work (in mechanical plants);
4. Half Saturdays off;
5. A 48-hour week; —
6. A rest period (varying from 5 to 20 minutes, depending upon the duties performed, during the morning and again during the afternoon; being in addition to the lunch period).

Plants employing large numbers of women will find it advantageous to employ resident nurses and to utilize their service also for preventing overstrain and nerve-tension, as well as for the first-aid help in emergencies. It is not necessary to have either the plant doctor or the nurse actually treat the patients (excepting in case of surgical emergency); but merely have them examine, diagnose, and advise the employees—so that actual treatment, where necessary, may be administered by their own family physicians—and this service by plant nurses should especially consider the eyes, teeth, and feet, yet the employer ought to know that the physician so called upon is reliable; and in case of prolonged illness, the employee may be visited by the plant doctor with advantage to both patients and employer.

WORKING CONDITIONS

Even the best pay will not suffice to retain the best workers unless working conditions are right. Just as good lighting, well spaced, helps the speed and accuracy of work during dull days, so does generous use of white paint on upper walls and ceilings accomplish wonders in avoiding cross shadows and dull spots. Until recent years it was often difficult to convince manufacturers that the slight additional cost of fuel, which would be required for quicker changing of the inside air is excellently invested in the results obtainable from the better-ventilated rooms. Force of example has spread the gospel of fresh air; and laggard management that pooh-poohed its advantages has seen employees lost to other plants where the good ventilation allowed operators to accomplish more—and thus earn more—because of avoided fatigue.

Sometimes working temperature must be partly dependent upon proc-

essing conditions. Any temperature between 55 and 90 degrees F. can be made satisfactory for sustained work if proper thought and judgment are given to clothing and ventilation, *and provided the temperature is kept reasonably constant.* It is the *variable* temperature that induces "colds."

Position at work affects health and endurance. In large departments grouping of employees according to height and build helps the worker's comfort, and therefore quality of output. It is not always practicable to alter the bench or table height, but both long and short chair-legs can be made available, and (unless absolutely impracticable through some peculiarity of the operation) the seats should be provided with backs. The low-back which reaches only to the sitter's waist-line can be adopted for many operations which require full freedom of arm and shoulder motion. There is evidence that for some kinds of work the high or medium-high stool is coming again into favor because it permits a half-sitting and half-standing position that is convenient during performance of some assembly operations.

The two excesses most earnestly to be avoided for women workers are excessive reaching (especially upward) and excessive lifting. When work-in-process is carried on racks or platform tote boxes, most or all of the lifting time is saved.

Standardization of work-clothes for women is helpful in lessening desire to outdress one another and also permits greater safety precautions to be taken against hanging loops and folds likely to catch in conveyors or other shop equipment.

LIVING AND SOCIAL CONDITIONS

Unless the community's industrial life is dominated by one or two very large enterprises, it is difficult to do very much affecting living conditions of worker without seeming to adopt a paternal attitude, and working women abhor that! The higher the percentage of workers whose homes are at a distance, the more need for the employer to provide entertainment that will relax nerves and muscles. Music for some, dancing for some, books for some—every plant has workers with these three preferences.

Some simple food, obtainable during the rest periods, *and only then*, pleases many women; especially the younger ones. Chocolate in cake form; a few well-chosen varieties of crackers; and good milk—these are universally appreciated. Any employer can buy them (excepting perhaps the milk) at wholesale and resell to the "consumers." Giving away food is scant advantage to the employers; and waste will be considerable. Keeping charge accounts with individuals is sure to end in arguments and recriminations. Let the women pay cash for what they eat, and keep the prices down to cost.

Cut out the accounting. Charge the "storekeeper" a gross total for original packages bought. Allow a small percentage for breakage and loss; and pay "storekeeper" a reasonable sum for the trouble of retailing the items. Two storekeepers are usually desirable, especially during risk of absence of one of them.

The average woman's contentment is said to be based on:

One-third *working conditions and wages*;

One-third living conditions; and

One-third amusement.

When the worker finds congenial, healthful amusement nearby, outside working hours, she seldom of her own accord seeks to leave the vicinity.

It is unwise and generally disastrous to combat class distinctions among women. Let the women fix their own social strata and run their own organizations. Advice in such directions is resented.

There is less need than in earlier days to encourage physical exercise among women employees; but help from the competent woman gymnasium teacher is appreciated by most women, *provided the classes are not made compulsory*.

It may often prove an excellent move to appoint a social secretary whose help the women may obtain about problems outside working hours, just as the matron is called to help on the problems during the work itself.

STATE LAWS

Present lack of uniformity among state laws, together with regional peculiarities of climate, and local racial conditions, make any universal recommendations of doubtful worth. Perhaps some of these days we shall have appropriate federal laws covering employment routine, but it is yet a long way off.

State legislatures can scarcely be expected to devise altogether wise provisions for women workers until women legislators sit in conference to supply more intimate knowledge of women's industrial needs.

With the present strength of organized labor, there is less danger than formerly of overworking women and children by too-long hours, or unhealthful and very fatiguing operations. And since the sharp barriers are being so rapidly broken down between "men's work" and "women's work," as our fathers and grandfathers distinguished them, we are learning to realize that almost any industrial occupation may be followed (by either men or women) without real danger to health, after proper safeguards and protective measures have been provided.

Industrial sanitation does not make blatant claims about its own progress, but every year sees improvement. In many instances, the shop committee and the welfare committee may be credited with the good results accomplished.

COÖPERATION OF LABOR UNIONS

Nearly twenty years' experience as laborer, moulder, draughtsman, office manager, cost accountant, and consulting industrial engineer convinces me that whenever Capital and Labor differ widely upon any subject, some misunderstanding has occurred by which each does not fully appreciate the exact position or aim of the other; and I can see no aspect of the whole question of women in industry that alters my conviction.

I do not believe that the leaders of organized labor will oppose the introduction of women in any suitable industry, provided:

1. The pay equals that for men on equal work
2. The shop day is no longer than that for men
3. The women are allowed to organize

Instead of becoming the object of investigations, there is increasing evidence that before long labor will become an investigator on its own account; and when that comes to pass, the whole subject of women's work will necessarily be inquired into because it is a factor of the labor problem as a whole.

I do not think we need to fear the outcome: for however strongly labor may seek to further its own interests, it will realize that the product of women's labor (as such) is no different from men's; and that the skill and experience which many women acquired during their war work can be made a real asset to organized labor if it is continued and developed under competent direction. This extension of women's work in industrial plants can be made such an asset provided Labor utilizes the opportunity to promote capable women whenever they can replace less competent men; whereby instead of diluting the "average labor competency" of a trade as a whole, farsighted Labor-management can markedly raise that average by admitting competent women workers to the unions.

Quite probably a good many of the less competent men may find it impossible to continue top-notch wages in such a competition, but that would only hasten by a few short years the time when Labor (in its own best interests) must classify its membership into two or more grades based upon relative value of service rendered. At no point in the development and advancement of women as industrial workers does it appear that their replacement of men has lowered the average wage of the average man worker; for as soon as women have entered some hitherto "man's domain" and demonstrated equal or greater ability in it, the men have found employment elsewhere at an equal or higher wage.

COÖPERATION OF WOMEN'S ASSOCIATIONS

To a great extent, unprejudiced observation leads to the belief that up to this time women's associations have coöperated willingly rather than capably, and the fault seems to be due to divided objectives. Undoubted good has come from the effort, however, and if once the women workers themselves can be made to understand that their own coöperation is necessary for best results, future progress will be greater.

Apathy toward any help used has been disappointingly common among women in manufacturing plants, and may not wear away fully for some little time. Well-meant but very patronizing manners on the part of the "social uplifters" is responsible for a large proportion of the resentment that follows concerted effort to improve working conditions. Too often the good intentions of the uplifters have been nullified by their investigating-committees assuming an attitude somewhat as they would take during a slumming party, on the theory that women work-

ers are of baser material. Jealous and sensitive as is the American workman toward anything that even remotely resembles charity, the working women show these feelings more strongly than their brothers—and it may be taken as a fact that women workers will not stand for being patronized; because it seems like being looked down upon.

Carefully planned programs, upon which concerted action is based is the only means by which the women's interests will be cemented to those of their well-wishers in the achieving of results worth while.

GOVERNMENTAL COÖPERATION

With cessation of actual war work, the Government's chief interest in sponsoring women's work was naturally lessened. When the semi-official organizations were demobilized, the opportunity—and perhaps some of the incentive, as well—began to be circumscribed.

Perhaps it is the Government's proper mission to undertake positive measures in improving labor conditions (for men as well as for women); but I incline to believe that if the Government will obtain the necessary statistics, and verify them so they will be compiled promptly and distributed soon enough to make their data usable in a practical way, the present non-Governmental agencies will be able to make the actual utilizations to excellent advantage.

Therefore, as the Governmental bureaus arrive at a post-war basis, I hope there may be a closer interchange among them of all important data that possess "secondary" or deferred value. By means of such interchange other departments can handle current industrial information in much the same way as the Department of Agriculture now distributes statistics of regional accomplishments and forecasts of tendencies.

To make such information generally public (and not merely to make it available to a limited number of persons) will allow both employer and employee to cultivate personal opinions upon all the facts instead of upon a few facts and unlimited surmises.

Since surmises encourage suspicions and suspicion breeds enmity, only a fair, full, and free presentation of essential industrial data can induce intelligent study and use of it. The importance of the subject demands nothing less.

CONCLUSION

Throughout our entire prospective consideration of women's industrial activities let us not overlook probabilities of Governmental use of men for army and navy service. Opinions are not yet settled as to whether America is likely to have a comparatively large standing army or whether the policy of universal military service will call from industrial life for a short term every able-bodied male during his military training. Personally, I incline to favor the latter plan because a large army may naturally turn to thoughts of war; while a large ready-trained force goes no further than the degree of genuine preparedness which (had we possessed it in 1914) might have deterred Germany from inciting the great war.

To withdraw the young men for such military or naval training is equivalent to a labor shortage for the time being; and to supply this shortage by industrial use of women serves a twofold purpose:

1. It occupies the girls after their school days and before the normal marriage age—thus increasing the industrial worth in the country as a whole; and
2. It broadens the young men under training by teaching them the value of method and the real meaning of organization—thus encouraging them to develop ability.

CHAIRMAN COFF: Our next speaker, is Miss Mary Anderson.

THE WOMAN'S BUREAU

MISS MARY ANDERSON, DIRECTOR, WOMEN'S BUREAU, U. S. DEPARTMENT OF LABOR, WASHINGTON, D. C.

A great deal has been said this morning about the women in industry and how care should be taken that the greatest possible efficiency may be had from women workers. From that standpoint, when Miss Van Kleeck was with the Women's Bureau, U. S. Department of Labor, we thought out a standard for women working in industry. We got this standard out from the experience gained during the war and before the war, and also with the fact in mind that the number of women in industry is growing larger and larger every day,—we have now approximately twelve million women in gainful occupations.

In 1910, when the last census was taken, there were eight million women in gainful occupations. It might be safe to say, and we will know next year after the census is taken, that probably one-third of the workers of the country are women. It behooves us, then, to see that some standards are made for the employment of women.

THE EIGHT-HOUR DAY

The first standard we got out was the eight-hour day. I am happy to say that since the Armistice was signed a great many industries and a great many factories where women are employed have instituted the forty-four-hour week, and the eight-hour day. We have the great garment trade working on the forty-four-hour week. Some of them are working five days a week with Saturday and Sunday off; some of them are working five days a week and some of them are working six days a week, with a half holiday on Saturday. The textile industry—an industry that employs women to a very large extent, has in a great many instances gone to the forty-four and the forty-eight hour week. The boot and shoe industry, with which I am connected, where one-third of the employees are women, now have the forty-eight hour week and in some cases the forty-four hour week.

You speak of the married woman in industry. In most all cases now the women when they marry finally come back to the factories at some time or other, and there is a growing need, I believe, for part time work. If we have the institution of the forty-four hour week, and we work five days a week, we find the married woman doing her work on Satur-

day, with possibly a little rest on Sunday. I believe we have to realize in this country, as other countries have realized, that the married woman is the worker, whether she works in her home or in the factory.

WAGES OF WOMEN

I want to speak about the wages of women. I believe this is a Safety Congress, and to my mind there is nothing that is more safe than good wages. The question of equality of wages comes up—wages of equality, whether of men or women. I am going to repeat this story—probably many of you have heard it, but it was a personal experience and I think it illustrates the point very well. Just now there are some States that have prohibition of night work. During the war one manufacturer, in particular, applied for permission to work women at night, and I was sent out to inspect the factory. They were doing very essential war work. Both the superintendent and the general manager in the factory assured me that the women had made good; that the women were the best workers they had in the factory, and they stayed on the job and came in every day and worked very thoroughly; and together with that, they showed me a barrel of parts of machinery that had been spoiled in the night because he said he had men working at night and they were no good at all, and if he couldn't employ women at night, he would give up the night shift and the Government would have to do without the very essential commodity. I asked him what he paid his workmen at night. "We pay them 40c an hour, with a 7c a hour bonus." "What are you going to pay the women you want to work at night?" "Well, we will start them out with 25c an hour." I told him then that he had just told me that the men couldn't do the work and that the women were better—and asked him if he didn't think that he ought to pay them the same wage that he was offering the men, and he said, "No!" He said they never did and if they did it would bring on revolution in industry, and he added, "Furthermore, the women have not the same family responsibilities that the men have." I asked him if he knew what family responsibilities the men had that were working there. "No, I don't—I haven't gotten into that phase of it." "Do you know what family responsibilities the women have?" "No, but I do know that we have one or two widows working here that have families to support."

I know that younger women who stay in their homes take much more family responsibility than the younger brother working right beside the girl, and they are usually the ones who are left in the home to take care of the old mother and father when the boys go off and get married and get their own homes. In the report issued by the Department of Labor some years ago, this question was investigated. They took in part of the garment trade and part of the glass works and they found that 6 per cent of the women had family responsibilities, and either supported in whole or in part, families or other dependents. They found a very small percentage of the boys that had any such responsibilities, and they also found that the men employed in those industries, only 57 per cent of those men had family responsibilities. Now the question that we

face all the time is the question that the wage of women ought to be fixed on the individual and the wage of men ought to be fixed on family. It is a very serious question, and in order that we sometime will get an equality of pay that industry ought to give to both sexes, we have to know exactly what part the women are taking in the family life. It's very serious to the family life of the nation to have women underpaid and have the very large responsibility they have to their family curtailed by the low wage that they are receiving.

I want to say something about the Women's Bureau in the Department of Labor. We are working in very close cooperation with the State Departments of Labor and we want to see that a square deal is given to the women in industry.

CHAIRMAN COPP: Mr. Sanford, of the General Electric Company, is here to talk to us informally this morning about some of the experiments that they have tried, and following his informal talk we shall resume the very interesting discussion of Miss Wright's paper and add to it the discussion of Miss Anderson's paper.

MUSIC IN INDUSTRY

MR. G. E. SANFORD (Safety Expert, General Electric Company, Lynn, Mass.): If any one had suggested fifteen or twenty years ago that pianos be placed in plants doing general manufacturing for use of operatives, he probably would have been gently led away by a couple of husky men in brass buttoned blue coats and taken to some place where his sanity could be tested. At such time the words "factory" and "work" were synonymous and little if any thought was given toward bringing harmonious spirit or a feeling of good fellowship into the rank and file of the organization.

A few months ago some of the employees in one of the departments of the Lynn Works of the General Electric Company received permission to put a piano in that department for use during noon hours and at other times outside of regular working hours.

The idea met with enthusiasm among the employees in general, especially in departments where a large percentage of the employees are women, and the employees of other departments also purchased pianos. There are at present sixteen of these pianos in various departments of the Lynn Plant, all being in rooms where girls work. The noontime concert is a regular thing now and it is not uncommon for employees in some of the departments occasionally to request permission to hold dances for a while in the afternoon at the close of the regular working period.

Before the pianos were put in there seemed to be more or less of a tendency among those who carried their dinners and stayed in the factory noontimes to get together, knock the high cost of living, and air their discontent in other respects and now such people forget their personal troubles and gather around the piano as soon as their dinner is eaten. From time to time a department will advertise that a special concert will be held and on such days it is noticeable that a large num-

ber bring their dinner who do not ordinarily do so. The music idea has spread so that in addition to the pianos, some of the large departments are now forming orchestras and where practicable dancing at noon is frequently in favor. Small departments may also take care of themselves, if the employees so desire, by phonographs and in such cases those who have subscribed to the purchase of records may obtain permission from proper authority to take such records home for an evening for the benefit of the family. One small isolated department of five employees has recently put in a phonograph.

Many of the women employees work entirely on routine or mechanical operations without having to use any brain work to accomplish results, the jobs being a matter of habit after they are once learned. Many of these girls operate machines and occasionally are idle for a short time for such reasons as machines break down, finishing an operation where machine adjustment for the next operation is necessary, this having to be made by one of the male employees, or running out of stock temporarily. These girls who are idle under such conditions have been given permission to play the piano if they so desire during working hours. At first there was a noticeable slowing up in the work due to the extreme novelty of music during working hours and the other operatives stopped to listen, but inside of a few days the novelty completely wore off and there appears to be no reduction in the amount of work, in fact one or two of the foremen estimate that there is a noticeable increase in the amount of work. That matter, however, I have no definite figures on as the subject is entirely too new for sufficient authentic data to have been collected.

I do not wish to convey the idea from these remarks that the pianos are continually in use during working hours for such is not the case, but a piano may be in use for approximately one hour per day during working hours and on many days there is no occasion for any one to use it. The playing of pianos during working hours is not and should not be permitted in departments where persons have to do mental work, or otherwise concentrate their attention on the work, such as punch press operation for example. The machinist too would have a hard time to read his drawings or micrometer and get out his work safely and efficiently if there was a piano ten feet away from him playing rag time, but where the operations are purely mechanical there appears to be no objection to occasional music during working hours. It seems to break into the monotony which is otherwise experienced and appears to rest the nerves of the girls at the machines.

I was in one of these departments recently in the middle of an afternoon where a popular song was being played on the piano and thirty or forty girls were all singing without even any slowing down of their machines.

DISCUSSION

Miss Wright: I believe that most industrial nurses in large towns are coming rapidly to the idea that they must in some way arrange

coöperation with local agencies so that they do not overlap. In my work I see it more and more that the industrial nurse will refer cases to local agencies.

I don't think it's any of our business how the people live in their homes or how they conduct themselves, except as it would be our business to render assistance to our friends, and if we are friends we must know how people live and in a friendly way change the method of the workers so that they may be adjusted to different conditions. The nurse goes to the home because there is a need. She is employed in the plant to manage a First-aid Room, and if she sends a girl home because she is sick, her very human sympathy will force her, perhaps after hours, to see what happened to that girl after she got home.

Some people say that you map out too large a program for the industrial nurse, but within the last week I have seen several industrial nurses who have said they weren't busy enough and would like to go into some broader program where they would have more to do. Personally, I believe they have plenty to do.

MR. BISHOP: I am very much interested in the five-day week for married women, perhaps from a very different point of view than you may have in mind, and that is not only that the married woman may be overworked or that she may neglect her baby but the fact that after all, the woman is the mother of men of tomorrow, and if the mother isn't at home on Saturday, her children run wild. I think we are continually alarmed at the prevalence of crime and viciousness among the youth. The criminal or vicious youth, I am told by social workers, is the result of an unwise training or an unwholesome home atmosphere, or no home atmosphere during the early years of his youth. You people are dependent upon the city's tomorrow for the success of your industries and for the well-being of the nation.

MISS EDWARDS: I think there is one point in that remark which is absolutely dangerous. If our industries need women so badly, pay them enough to have a housekeeper—let them have a housekeeper seven days of the week.

MR. C. B. AUEL (Westinghouse Electric Company, Pittsburgh, Pa.): May I tell you a few of the things we are attempting to do, whether successfully or not we can only judge? At our East Pittsburgh works we have close to 3,000 women in the various departments and all those women are required to undergo a physical examination not for the purpose of rejecting them but to endeavor to keep from putting a square peg into a round hole.

The women have the same hours as the men except that we dismiss them a quarter of an hour sooner in order that they may reach the street cars and trains and avoid the crowd. We actually pay them for that fifteen minutes away from their work, but you can see that that is a small item for a single individual, but at the same time, a total of from 2,500 to 3,000 women at ten or fifteen minutes amounts to something like \$75,000 or \$100,000 in a year.

We have so-called Relief or First-Aid Departments scattered through-

out our works where all of the women are perfectly free to go at any time for advice from our nurses or from our surgeons. We have a sickness association and that is divided into a half a dozen classes and no employee is allowed to join that association except in a class commensurate with his salary, taking the highest class where the dues are \$1.50 per month; in the event of sickness that woman will receive over \$75.00 a month; if she was hopelessly disabled for the rest of her life, she would still receive that \$75.00 a month up to the age of seventy years, when she would eventually retire. We pay our women workers exactly what we pay the men. We have visiting nurses but we do not attempt to intrude into the home, and only act upon receipt of word from departmental foremen that so and so has been absent the previous week and is again absent on Monday morning. We at once send a surgeon or nurse to see if we can be of any assistance in any line.

We have a number of restaurants for our employees and I may tell you that if anybody goes without, it is the men and not the women. We have a small restaurant at the present time that accommodates 300 men; We have a lunchroom for women that accommodates 1,200 women. We give them all the coffee, tea, milk and sugar gratis, and it costs us about \$1,200 a month to do that. In one particular dining room the women bring their own lunches. We have another dining room in which we feed 1,750 women every day and their lunches average from 17c to 22c a meal—less than the cost of the food alone, and in that particular dining room we give the supply of the coffee, sugar and milk gratis, and it is operated at a loss of \$5,000 a month. We are now putting up what we believe to be the largest dining room in the world, with a seating capacity of over 3,000 places at one time, and the best we can hope to do is to incur a small rather than a large loss.

A LIVING WAGE

DR. F. E. SCHUBMEHL (General Electric Company, Lynn, Massachusetts): A living wage for women in industry—would that differ from the living wage of the man in industry? Not at all! What is the living wage or what shall the living wage be of one man who has a family of one or two children and another man who has a family of ten or twelve children? Will it be the same for the man with one or two children as the man with ten or twelve children? You can chase this living wage up one stairs and down the other and cost of living will follow, and when you get through the cost of living will be upstairs and the wage downstairs. The living wage isn't the problem—it's the wage and conditions that will permit people to live. I feel very strongly about this thing. I am just a doctor, spending my time in the conditions that arise in industry and with the employees that I come in contact with every day. I see the problem both from the standpoint of women in industry and men in industry and the nurse in industry, and I want to say that industry as such is not a convalescent hospital. Don't forget that! It isn't running a hospital for the benefit of the community. Industry has a function to create material for the world that needs it and it should

pay whatever an individual is earning in the industry, whether man, woman, boy, or girl.

The question of wage is a serious thing to get into, because people that are interested in it as much as we are have been going after this thing for years and years, and we are still further away from a proper wage than we ever were before—we are getting nowhere, and it's a question of a general misunderstanding. If I give a man \$5.00 or \$6.00 more today and charge him \$10.00 more tomorrow for the things that he needs, you know where that will end. The more money the people get, the less they can buy with it, and it increases the whole problem—they get less in proportion to the increase.

The fundamental thing underlying this whole problem and the reason we are here today is because we are beginning to feel that there is a human problem in industry that hasn't been taken care of. It's the human thing that is in industry that industry has just begun to recognize, and they are recognizing it, and they are doing very well. Industry doesn't need a nurse—it needs something that can put into industry that element of human relations that has been neglected, and we hope that the nurse in industry will bring that thing into industry and make the managers and the men who are busy creating large things see that there is an element that they can utilize to a very much better purpose than even their steel, iron, coal, or wood, or whatever they use. If they begin to recognize the qualities of the human element our production will begin to increase and wages will be sufficient to take care of it and everybody will get what they earn. If they don't earn much, you can't expect to give them what the men and women who are capable are earning, but we can correct inefficiency—it's more or less a question of misunderstanding. I am delighted to have heard this discussion because it convinces me that we all have our ideals of what ought to be done and I believe that many of these discussions will centralize us and correct some of these misunderstandings that are constantly coming up, and if there is a human being that is essential in industry today, it's the man or woman who can see the two points of view and centralize them—bring them together, and when you can bring them together and give them both an opportunity to say what they have to say or show what they have to show, you will find the problem will be easily solved.

Mr. J. M. Eaton (Continental Motors Company, Chicago, Illinois): I think I have had a unique experience with women in industry in a plant where some 1,200 women were taken in and trained in a very short space of time to do very important work, and I think that we have looked upon our women in industry, in the particular plant which I represent, in that we put the man on one side and the women on the other. I rather agree with Mr. Ashe in the great necessity of educating the men, and yet I think that the big thing that industries have to keep in mind is the fact that women ought to have, or must have equal pay for equal work, and I am rather inclined to think if we stick to that principle we will pay our women just as much for the work which they do, and if we did that, we would have mighty little trouble. We have a lot

of so-called welfare work, but it seems to me that the thing that industry has to do for women is that one thing—give them equal pay for equal work.

MISS ANDERSON: During the war one of the women from London went down and talked thrift to the women in the munitions plant, saving, etc., and when she got through with her speech she asked if there was any one who had anything to say, as it is the custom in England, and one of the girls said, "I am Maggie, and I have something to say. You talk about thrift and the large wages. I do get large wages to what I used to get and I am making more money than I used to, but this is what happens to that money: The first wages that I got I went out and bought a whole roast chicken for my Mother on Sunday. My Mother had never seen a whole roast chicken before in her life, and I am going to buy, as long as I have the money, a whole roast chicken every Sunday for my Mother." Then she said that she went out and bought a silk blouse and "he" came home from the trenches, meaning her fellow, and "he" said, "Why, Maggie, you look so different to what you used to", and as long as he says I look different, I am going to have a silk blouse as long as I can buy it", and the manufacturer added that it showed that better standards were being obtained by these women, better home conditions, and better citizenship, and that's all there is to it.

CHAIRMAN COPP: We have run over our time. May I remind you that this session continues tomorrow morning in this room.

FRIDAY MORNING SESSION

CHAIRMAN COPP: Mrs. Burdick has not arrived as yet. With your permission I am going to change the order of the speakers this morning and put the second speaker on first. Miss Maynard Downes, who is the Service Secretary of the Robert A. Johnston Company, Milwaukee, will speak to you this morning about the employment, training, and supervision in her factory. It gives me great pleasure to introduce Miss Downes.

SUPERVISION OF WOMEN INDUSTRIAL WORKERS

MISS MAYNARD DOWNES, SERVICE SECRETARY, ROBERT A. JOHNSTON COMPANY, MILWAUKEE, WIS.

The company which I represent in Milwaukee is a candy and biscuit manufacturing concern. At present we have about 1,000 employees of which 700 are girls and the remaining 300 are men.

In putting in such a department, and in all of our work conducted by this department, we had in mind the business as well as the philanthropic viewpoint. It pays us, and it pays any concern to do all the things that are necessary in order to keep their workmen or girls in good condition. Every bit of the money that is expended in improving health conditions in

the factory, in making more sanitary surroundings, in giving the employees an opportunity to perfect themselves in this work, will come back to the firm in greater production. More competent employees means larger production and anything we can do in order to make our employees more competent will benefit not only the employees but the concern as well.

HEALTH SUPERVISION

First of all, in the health supervision, we have a very well equipped First-Aid Room with a trained first-aid attendant. Our work being all hand work, we don't have major accidents, and being situated within the city limits, we are within ten minutes' automobile trip to the hospitals and doctors, so we don't feel it is necessary to have a trained nurse in our First-aid Room, instead we use a girl that is trained in first-aid work. To our First-aid Room come all of our accident cases. Of course there is where the compensation law comes in—we have a very fine compensation law in Wisconsin and it pays any employer to put in a first-aid room, because having such a room and arranging it in such a way that the employees will come to this room means that he is going to save its cost in compensation which otherwise would have to be paid out. It is also going to save the employee lost time, lost wages, and suffering. I try to make our First-aid room as attractive as possible. I want the First-aid Room at the Johnston Company to be used by every employee in that plant whenever he has any need to come to us. No employee is scolded for coming with a trivial matter. We want every one to come, because that means we can anticipate troubles and we can make our First-aid Room of real value in the plant. Our foremen have explicit instructions that if at any time an employee asks to come to the First-aid Room he has no right to question him—he simply must give his permission to that employee to come. Also, we permit no first-aid in the different departments; no foreman or forelady is allowed to administer first-aid work. We can really avoid a great deal of waste time by judicious first-aid rooms. No girl is allowed to go home on a plea of illness without first getting permission from the First-aid Room. I think that also does away with a great deal of a girl getting away from work after she comes to work.

Not only in providing for first-aid do we provide for the health and comfort of our employees but we also provide, to a certain extent, medical supervision. We have partial medical supervision and I hope that some time in the near future we can arrange medical supervision for all employees.

As Director of the Service Department I make inspections of the factory and I have made a great many suggestions which have been followed out along different lines in which we can improve equipment so as to make for greater comfort, and with comfort, greater efficiency and more work. If a girl is sitting on a high stool which has no back, she becomes tired and her work slackens. If by providing a comfortable chair for that girl we can increase her efficiency and production, I think

that money expended in that way is well spent, and that is one thing the Service Department is responsible for. We ought to see that the proper working conditions are provided, that the rooms are properly ventilated, and so on. I know it takes a ventilation expert to determine the ventilation of a room, but you or I can determine whether the air in that room is good or bad and then we can refer it to the proper authorities. Proper dressing rooms, proper washrooms, proper toilets—all of these matters should come under the care of the Service Department.

CLEANLINESS

Another matter which concerns us very keenly at the Robert A. Johnston Company is the cleanliness of the factory and the cleanliness with which our food materials are handled, and that is a matter which requires constant watching.

I am supposed to make a daily inspection of the factory to see that everything is clean. Our floors are scrubbed every night and our other work places are kept clean. We want to make our factory as clean as a home can be kept. It means that there must be some one constantly on the job, keeping after the foremen, foreladies, and even the higher officials, in order to keep the food factory in a clean condition. That work falls upon the Service Department.

SOUP AND COFFEE KITCHEN

Another function of our work which also is planned to give comfort to our employees and to improve the health of our employees is the lunchroom, or, as we have it, a soup and coffee kitchen. We have not space enough in our building at present for a lunchroom; in the new factory which we are building and which we expect to be in by Easter, we will have a well-equipped lunchroom. We are supplying our employees with hot coffee or hot soup every day—it is only a supplementary lunch. Our kitchen is run on a self-supporting basis—we charge our employees cost price for the food. Our coffee sells for 1c a cup, which is almost a pint in size, and our soup sells for 3c a bowl, and we do it without a deficit, and in the operation of our soup and coffee kitchen we are supplying something to almost every employee in the plant. It is impossible for all of the employees to get to the coffee or soup kitchen located centrally in the building, so we have to send our coffee or soup to the employees. We have percolators and those are sent to the different departments throughout the factory, thus making it possible for every employee in that factory to get a hot drink at noon, either in his own department or by going into the next department.

EMPLOYMENT DEPARTMENT

Under our service work also falls the large problem of employing. I do all the employing of the girls. An employment department must be well organized and then, too, it must have authority: your employment

department, unless it has the proper authority, is worse than useless, and I think I can safely say that in our employment department at the Robert A. Johnston Company we have the earnest support of the management, and that's a thing that is necessary in order to make an employment department a success. The management stands back of us in all things that we wish to do in the employment department. In the employment department you must have an adequate record system. I try to make our system as simple as possible. I have an employment card with the bare facts as to residence, age, place of birth, and previous employment. In previous employment it is sometimes very difficult to get any information because it is a sad fact that some girls cannot remember a year back where they have been employed—so far as any real information is concerned, I feel that it is not of much value, especially when we ask an employee why she left. We have a space showing the reason for leaving her previous place of employment and frequently I ask that question but I don't attach much real value to the answer I get because nine out of ten times the employee "left because she was being mistreated or because she wasn't properly appreciated," and that answer is not always a true one, but knowing the places where the girl has worked before does enable one to place her with some better accuracy into the different departments.

We also have a production card and dispensary card. Our production card and dispensary card are used only when the employee leaves our employ. I have an envelope system and into this envelope I put her original employment card, her production card and the number of hours she worked for the four weeks previous to leaving our employment, and also the dispensary card which is taken out of the dispensary files in the First-aid Room. I keep that production card because our work is all piece work and the production card will enable me, if that girl comes back to us and asks for employment, to see at a glance whether or not she was a skilled worker at the time she left us.

In Wisconsin at present we have a minimum wage law which sets the lowest limit that an employer can pay his employees, and I think our production card will be of value to us on that score in avoiding taking girls back who were not good workers when they left us.

After you get your records all in, or your department well organized, then I think you want to forget them. Some departments are so organized that there is so much red tape connected with it that the employment manager or secretary has little time for anything else than to keep records, and I want to use our records simply as a means to better the people we have in our employ. For that reason we need accurate help in taking care of our records. It is an impossibility for the employment secretary to be loaded down with the employment work in keeping absentee records or the employment records. After we have the record system well planned and after we have the proper authority in the employment department, we can then start in the actual working of the employment department, and first of all is the selection of the employees.

At present, with the labor situation as it is and with labor so scarce, we can hardly make a very careful selection of employees. The best thing we can do, of course, is to give every girl or woman a chance—some are always ruled out, but we are more inclined to give every one a chance, and the best selection I can make is after I get that girl into the department to try to put her into the department where I think she will be able to do the best work. Our work is of such variety that if a girl doesn't do good work in the candy-packing department, she may be able to do well in the cookie-icing department, or in the chocolate-dipping department, and so I am enabled to put her into the department where she will do the best work and where she will be most happy and will stay the longest.

FOLLOW-UP WORK

After a girl has been placed in a department, the next thing to do is to follow up her work. We have a sliding scale in our work in the teaching of the girls. We have no vestibule schools but we do have in each department a certain girl who is not a forelady but who is simply a teacher. It is her business to teach the new girls that we put into the department. This teacher devotes her entire time to the new girls; she instructs them not only in their work but also instructs them in regard to the customs of the factory, where to find the First-aid Room, where to get soup, and all the different things she ought to know in order to feel at home in our factory. On our sliding scale we start the girl in at a flat rate; the next week we cut that flat rate and give her a certain amount per hour plus everything the girl can make. The third week we drop that amount a little per hour and by that time her skill should have increased in that work so that her earnings will run above what we guarantee, and so we continue this gradual dropping until a certain time when we feel the girls should go on piece work altogether, and the result has been that very few of our girls will ever drop if they are any good at all. In order that the girl herself may see that she is gaining every day, that she may see that increased effort on her part is bringing her increased earnings, we keep a day record of every person in our employment so that we can see at any time how much that girl has earned for the day. I can go into any department in our factory in the morning and find out what every girl made the day before and I wouldn't have to consult the payroll. Every foreman has the record and every girl knows the next day what she has made the previous day. There is no uncertainty with her as to how much she ought to have in her pay envelope at the end of the week and I think that in keeping such a daily record it acts as an incentive to the girls to bring up their earnings day by day, and it also enables us to check up on our work and it is especially important since we have a minimum wage law because we can know at any time if a girl is falling below the minimum wage scale at any time, and our minimum is higher than the minimum wage law as set by the State, but we have our standards set of what we wish each girl to earn

during the day and if we find that it is dropping below that standard then we can take steps to find out why that girl is falling below the standard and correct it.

The employment department also receives all complaints regarding shortages in pay. I think that is one cause of trouble in the factories. We also receive all complaints of dissatisfaction and dislike of the foreman, trouble with other girls, and anything that may come up which will disturb a girl in her work. Formerly, before we had service departments or an employment department there was no one to whom a girl could go with her troubles—she could not very well go to the foreman or superintendent with these troubles, but now she can come to the Service Department and we can many times clear up all of these little difficulties in which otherwise she would have no other alternative except to leave.

No person should be discharged without passing through the employment department. In fact, the foremen should not have the right to discharge. They should only recommend discharges, and the employment department should hear both sides of the story—the girl's side and the foreman's side—and the employment department should judge from the merits of it. Any one who quits voluntarily has to pass through the employment department and no person can receive her pay without first receiving her time card O. K.'d by myself, and that is where we can check up all the difficulties. A system like that is useless unless you are really getting the fundamental reason for the employee leaving the department. The interview of the employee at the time of quitting is of no value unless you win the confidence of the employee, and then it is of infinite value because you can prevent a recurrence.

We keep a turnover record and we have an absentee record and these are of great value to us because we find a number of employees are leaving for certain reasons which we can remedy.

Our employment department is not perfect as yet but we are working, we are trying, and we want to make our employment department and our service department something that is of real benefit not only to the firm but to the employees as well. We want to treat our employees as human beings and we want to consider and put in all the things that we can that will make for the comfort, for the wellbeing, and for the happiness of our employees, and we feel we also benefit ourselves as well as the employees, because we will get more efficient employees and it will result in a bigger production throughout the plant.

DISCUSSION

Mrs. WASHBURN: (Printz, Biederman & Co., Cleveland, Ohio.) In speaking about the records kept in each department, are those records figured in the payroll department and sent to each department?

Miss DOWNES: Those reports are figured in the different departments

and we have rather an elaborate cost system and in the departments where we have this cost system the one who does the cost work figures them. In other departments the work is done by one of the girls who is chosen for that class of work, and in some departments the girls figure their individual earnings and report to the foreman who enters it on the card and the cards are then sent to the cost department. We have one or two errors which come from the girls figuring their own records but it doesn't amount to more than two a week, and we figure that the percentage of errors is so small that it isn't worth counting.

Mr. S. W. ASHE: How many of your employees do you serve with coffee and soup a day?

Miss DOWNES: I think we are now distributing coffee to at least 350 a day—we rarely sell soup and coffee to the same individual. During the winter we sold our coffee to as many as 500 a day, and at present we are serving soup to over a hundred a day. In our kitchen we also sell ice cream and we make a few sandwiches, not many, and among the coffee, soup, and ice cream, I am confident that almost every one in the factory receives something from the kitchen every day.

Miss FLORENCE S. WRIGHT: In your interviewing the girl, do you have any questions that bring out the economic status of the applicant, for instance, as to whether the girl lives at home or whether she boards?

Miss DOWNES: We have very few girls who are boarding. I always ask the applicant if she is living at home or if she is boarding, but I never ask her what her previous income has been. Most of our girls do live at home and very few of the girls are boarding unless they are with relatives.

Miss BROCK: When a girl boards she has to have a larger wage than if she lives at home.

Miss DOWNES: Well, our rates are so set that we couldn't make any distinction for that girl if she is boarding. We are paying what we consider a living wage for a girl. We don't take into consideration whether she lives at home or not. The only distinction that is made is on account of age: the girls at 16 are started at a certain rate, and the girls at 17 are started at a certain rate, and so on.

There is one point that I failed to bring out in regard to the Service Department and that is that the head of the Service Department ought to be the person who assumes all responsibility regarding hours of labor, the ages of the workers, the minimum wage, the compensation, and any other State laws that touch the health and the welfare of the employees.

CHAIRMAN CORP: I shall have to interrupt this discussion in order that we may have Miss Tarbell speak to us. Dr. Cutler will speak to you now on a paper which we have not heard. I have asked Dr. Cutler to confine her words to a very few minutes in order that we may have a recess before Miss Tarbell speaks to us.

(Mrs. Burdick, who was unable to be present, sent an abstract of her paper, which is here inserted.)

ABSTRACT OF PAPER ON

TRAINING AND UPGRADING OF WOMEN FACTORY
WORKERS

MRS. ANNA LALOR BURDICK.

SPECIAL AGENT FOR TRADE AND INDUSTRIAL EDUCATION FOR GIRLS AND
WOMEN, FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.

- I. Employment of women during the war was but an acceleration of a normal development.
- II. An immediate demand for increased production and a shortage of experienced workers exhausted our usual "labor reserve."
- III. Women were the only members of the community from which large accession to the ranks of industry could be expected.
- IV. The extent to which women were employed in basic industries—textile, garment making, metal trades, and transportation—shows rapid increase during the four months preceding the signing of the armistice.
- V. The employment of large number of untrained women in war essential industries has resulted in:
 1. The establishment of employment service departments dealing with
 - (a) the personnel of the working force.
 - (b) standardized conditions of employment necessary to safeguard the health, hygiene, and safety of the workers.
 2. Improvement in processes of production. This necessitated:
 - (a) Realignment of tasks suitable to workers in order that quality may not be sacrificed for speed.
 - (b) Increased subdivision of processes.
 - (c) Multiplication of inspectors.
 - (d) Increase in number of supervisors.
 - (e) Increase in number of foremen and forewomen.
 - (f) Changes in construction and equipment, such as, the installation of lifting and transporting devices, conveyors, etc., with the ultimate aim of making the job hazard-proof and error-proof.
 3. The inauguration of systems of training or inducting unskilled women workers into industry and upgrading them during their period of employment. The larger the plant the greater the tendency for these functions to become departmental and specialized into
 - (a) The employment service, or personnel department, supervising the hiring, placing, and releasing of workers.
 - (b) A production division, and
 - (c) An educational and training department.
- VI. A description of a few types of training departments instituted in different establishments manufacturing widely diverse products will

illustrate types of training which may be expected to persist under normal times:

1. Experimental shops under the railroad administration
2. The government school for training precision optical operatives.
3. A vestibule school for women employed in the manufacture of aeroplanes.
4. Training machine operators and metal workers on the production floor.
5. A combination system of training women workers in the textile industry.

1. An interest in women as a possible supply of labor on the part of certain railway officials including the shop foreman, the superintendent of motive power, and Federal manager has resulted in successful experiments in organizing a shop force of women and training them for a department requiring a high degree of skill and technical knowledge necessary to carry on their work. The result is recorded in the annual report of the director general of railroads in the section devoted to labor.

2. A government school for training precision optical operatives is organized under governmental control, maintained by funds appropriated by Congress, conducted in a private school, the president of which acts as director. The student learners are employed for pay during the instruction period and are assigned to the operations for which they are best fitted mentally and temperamentally. The instructor was chosen from one of the plants for his experience, skill, and ability to instruct. A committee from the five local plants co-operating in the enterprise determined the processes to be taught. The expense of materials is prohibitive of productive work for beginners. The graduates are pro-rated to the co-operating firms.

3. A plant under contract to provide motor trucks for the army faced the problem of producing a standard product with a constantly diminishing force of experienced workmen and the addition of woman labor. The problem was handled in two ways: first, by the establishment of a three-weeks' course of training for inspectors and machine operators. Tool room attendants and other workers all took an initial course which covered thorough instruction in the system of organization in the plant itself, involving such practices as the use of time clocks, method of checking work in and out, terminology of parts needed for work, routing of work and interpretation of operative cards.

The learning for the manufacturing division included blue print reading, the operation of automatic and special machines which would enable a transfer to be made according to the needs of the plant.

The inspection group were taught the reading of blue prints, the use of precision measuring instruments, decimal equivalents, and such auxiliary information as would enable them to understand the underlying principles of the job.

This presents the best type of a vestibule school.

4. The need of space, the production demands and the foremen's insistent call for workers forced the abandonment of this method and the new worker was immediately put upon the production floor, and given only such instruction as was necessary to do the specific job at which she was employed. To note the product and report any deviation from the normal, the number of supervisory foremen was increased to one for every seven workers. The efficiency of the training on the production floor depends upon the instructional ability of the supervisory foremen.

5. In the cotton industry supposed to employ lesser skilled operatives, the change of product in the mills and the taking on of new workers has led to a system of inducting new workers and readjusting the experienced ones to changed conditions in the plant and upgrading them in their labor. This system provides for a combination of training on machines designated for the learners on the production floor. This is necessary in some processes because of the long line of spindles they must tend. The worker progresses in degree of skill at the same operation and passes through progressive stages or grades with corresponding related rewards. After maintaining a stated production rate for a given period she becomes a regular worker.

VII. A liberal interpretation of that section of the Federal Vocational Act dealing with part-time education admits that persons who are definitely scheduled for employment in a trade or industrial occupation by a written agreement with the employer may be given instruction in a class fitting them for advantageous entrance to such a trade or industrial occupation—subject to the provisions of the law.

DR. ALICE S. CUTLER: Mrs. Burdick's paper was on the training of women factory workers.

As I said yesterday, by the first of the year the Government expects there will be about 4,000,000 men going back to Europe—there is an acute shortage of women. When I got up yesterday and told the audience there was an acute shortage of women in the West, Dr. Schubmehl jumped up and said there was always a shortage of women in the West, but let me tell you there is a shortage in the East. I was in Boston, where we have 50,000 more women than we do men, and the condition there was just the same, so it isn't only in the West we are having a shortage of women but all over the country and why? Simply because there are so many men going abroad and we have to assimilate women in our industry.

I believe in vestibule schools—they are one of the biggest assets we have and you certainly have to train your women if you are going to assimilate them in jobs that men are doing, but the thing is that you want to have the right kind of instructors in your schools because if you don't have the right kind of instructors, in the first place, the majority of women are timid.

CHAIRMAN COPP: I have the honor of presenting to you Miss Ida M.

Tarbell, who will talk on the subject of "The Future of the Woman Industrial Worker."

THE FUTURE OF THE WOMAN INDUSTRIAL WORKER

MISS IDA M. TARBELL

I have been asked to prophesy—and prophesy before experts. I possibly do it with more facility and assurance than I would be able to command if I knew more of the subject. I am not going to attempt to make a thrilling prophecy but rather to call attention to certain things that have come out of the intensive experience with women in industry that we have had in the last five years—things which I am convinced will be influential in shaping the future. This experience was striking in the countries of all the belligerents—and similar.

NUMBERS OF WOMEN AND VARIETY OF THEIR WORK

No doubt the two facts which have most impressed observers of women in the war industries have been the numbers drawn in and the variety of work which they have undertaken.

No sooner had France begun to mobilize in August, 1914, than we began to hear amazing reports of the way French women were instantaneously taking up the work that had been left behind by the men. Almost at once street car lines, the Paris subway, the street-cleaning department, the taxis were taken over by women. A little later we began to hear of women in French factories, where they had never been seen before, and particularly great numbers in munition works. At the end of 1914 there were 44,161 women in French munition factories. Three years later, 1918, there were 399,631. The same thing happened in England. There were towns that were entirely women-run, and there was no industry where they were not used. We all remember, I am sure, the English shipbuilder who declared he could build a ship from start to finish with women's labor. In our own country, we had them going into such unlikely things as the lumber business. The general observer was inclined to feel that the like had never been seen in the world before; but if the general observer had been a little more inclined to compare what he saw going on with what has gone on in every country in the past in war time, he would have been less amazed. War has always forced women to fill places vacated by men. Study our own Revolution—the war of the Rebellion, and you will find women doing all kinds of unexpected things. You see the same in past French and English wars. The difference this time has been the scale on which the great enterprise was carried out, the number of countries engaged in it and, too, the great difference in the operations now and in previous wars. That is, in spite of the fact that these are the two things that stand out most prominently in any consideration of women in war industries, they are simply the things that were to have been expected. They do not, in my judgment, affect the future nearly as deeply as many people are inclined to think. As we

return to a normal peace basis, the numbers of women in industry will drop back. That is, many women will not stay and not want to stay. There are no doubt many of the industries in which they have been active and useful from which they will entirely disappear.

There are, however, certain phenomena in the experience which are bound to have a permanent and important influence on the future.

WOMEN DO HIGH-GRADE MACHINE WORK, AND LIKE IT

Among these are the fact that for the first time in the history of industry, women have proved themselves to have the capacity to do high-grade machine work—and not only to do it, but to do it well. And, what is quite important, to like it. It has generally been believed by men and I think no less by women that they could not handle machines. And yet the War was not many months old in England before employers were seeing with surprise that women were being taught to handle machines and to handle them satisfactorily.

There were difficulties to be overcome in the way of training. One of the most interesting reports that I saw from any country during the war of experiences in preparing women came from Mr. John Upp of the General Electric Company.

TRAINING OF WOMEN IN INDUSTRY

Mr. Upp wrote with surprised enthusiasm. He had foreseen that he would be short of help, decided that he must use girls, and realized that he must train them. He notes some of the difficulties that had to be overcome. One very interesting and important one was the fact that a woman, as a rule, has no sense of measurement, that she does not distinguish between an inch and a quarter of an inch. Another is her lack of appreciation of the sharpness of a tool. She will go to work with a dull tool as quickly as she will with a sharp one, and have no sense of what is hindering her. But, having overcome her feminine blind spots about certain common things, having trained her to the technique of an operation, Mr. Upp's experience was that she was a more exact workman than a man. She did what she had been taught to do in the way she had been taught to do it.

If the men were surprised to find that a girl could be taught, I think there has been no less surprise on the part of women that they could go into machine shops, do the work satisfactorily,—and like it.

Possibly the greatest effect on the future of any of the experiences of women in industry during the War—that is, the greatest effect on the woman herself, will come from just that, that many women have found that the higher processes of industry interest them—interest them more than certain ~~tasks~~ ~~that they have been accustomed to doing~~. If this be so, now that the war is broken, I believe that it means that in the future a certain ~~number~~ ~~of women~~ at least will be seeking work which they have always ~~regarded~~ ~~as closed to them~~. That is, the war will have opened a new field of labor to women.

STANDARDS GOVERNING WOMEN'S WORK

Another development in the war that is bound to have much influence is the strides that the standards governing woman's work took in every country. From the moment that it was realized that she was bound to play a large part in war production, that she was being called into many trades and positions where women had never before been seen, the public began to demand that she should be protected in her new undertaking. England's experience of course is familiar. A year had not passed before the Government had a commission at work observing the effect that the unusual labor was having upon the health of women. The result of the investigations there was drastically to change hours and conditions. This was done, primarily, for the sake of production. It was found that the long hours which she had been willingly working for the sake of the cause were not so productive as shorter ones. And England went on through the war developing regulations, prohibitions, adjustments which should protect the woman in her new tasks. The same thing happened in France. Altogether the best set of regulations and ordinances governing women in industry that France has ever had was worked out in the years 1916-1917 in order to meet the public demand that women should be cared for. We had the same thing happen in this country. From the opening of the war, one of the grave concerns of the country was the protection of women. The Women's Committee of the Council of National Defense, which was organized by the government to pull together all of the great organized bodies of women in this country in order that they might carry out coöperatively the requests that the Government might have to make of women, established in May, 1917, a department of Women in Industry in order to stimulate all of the great women's agencies to keep an eye on the conditions under which women were working and to aid in correcting them if they were wrong.

As soon as the Government had approved a set of standards for women in shops and factories, the Women's Committee undertook to make these standards generally known. It was able to put them before ten or twelve million women, and it is probable that in nine-tenths of the cases these women for the first time were put face to face with a high set of standards and were made to feel that they had a personal responsibility in supporting them. That is, all over the country there was an enormous expansion of the ideas of what proper industrial conditions are for women and a tremendous pressure was brought to bear upon all sorts of people to see that these conditions were secured.

Now, it is inconceivable that after such an education in this matter as England, France, and the United States had during the war that we should ever fall back to where we were before the war. Certain standards have been made known and accepted. The whole future of women in industry will be influenced by this. The tendency will be to improve and extend these standards. That is, in the future women are bound to be more thoroughly safeguarded than they have ever been before. Every ten years, in my judgment, is bound to see a very substantial advance in this particular over its predecessor.

THE FACTORY WELFARE WORKER

Another important development from the war that cannot but affect the future profoundly is the general recognition that has been given to her that we sometimes refer to as the factory welfare worker,—the woman employed not only to supervise the health of working girls, but to train them to better habits of life and to lead them into a happier and more civilized manner of living. Most of us are familiar with the way in which a few women in this country, thrown into factories, neither they nor their employers knowing very definitely what could be done, and yet all feeling that there ought to be a kindly and intelligent supervision of the girls, have developed their positions to what might be called a professional standpoint. They have proved of the greatest service to both management and workers.

One of the most intelligent undertakings of the Government in its effort to bring the management of war industries up to the highest point of scientific and humane efficiency, was training women for these positions.

TRAINING CLASSES FOR WOMEN FACTORY SUPERVISORS

In the Spring of 1918 the War Industries Board started classes in industrial management. Women were admitted to these classes. Many more applied than could be accommodated although the requirements were severe. One requirement of admirable good sense was that no woman would be admitted who had not had two months' actual experience in a factory. Here in this city of Cleveland women of education and social position sat at machines in one of the great factories through the summer of 1918, getting this preliminary experience. Many employers of large bodies of women in different parts of the country who had trusted women working their way more or less blindly trying to develop the position, hearing of what the Government was doing, asked permission to send these women into the classes.

The thing that our Government realized and attempted in this very thorough way to meet, was realized in other countries. England and France both developed training classes for women factory supervisors where bodies of girls were employed.

Now, I cannot believe but that the future of women in industry is bound to be very profoundly influenced by this experience. In past years it has been the habit to collect great groups of girls helter-skelter and throw them together in great work rooms. They came in without instruction, they passed their days without any particular supervision. If they were ill they must drop out or be dismissed. Nowhere was there an effort to prepare them for the work which they were to do, to see that their health was properly cared for, to try to explain things in the shop that would reach out to their life at home. The occasional modern employer has, as I have said, tried to meet the very obvious need if he were to build up a stable body of working girls.

A NEW PROFESSION FOR WOMEN

But the War came. Its needs were so great that every effort had to be made to improve and stabilize labor. The value of these women supervisors was immediately recognized, and what had been a sporadic, private enterprise suddenly becomes a government policy. This not only means much that is of value to the working girl herself but it means the introduction into industry of a high-grade woman whose vocation will be not only that of a physical and intellectual but a moral teacher and leader. It is hard to conceive of a position in which a woman can be of more genuine value to society than in this relation to 500 or a thousand girls whose opportunities in life for health and decency and for future usefulness and happiness are so limited. It means much to the girls, to society, and it is a great thing for the women themselves. It literally opens a new profession for women.

Now these are very fundamental gains for the future.

(A rising vote of thanks was given to Miss Tarbell.)

CHAIRMAN COFF: Miss Tarbell's time is limited with us but she will be glad to answer any questions you may have.

DISCUSSION

MRS M. H. VARNUM: The Michigan University is establishing a department to train women to become teachers in trade schools. It is doing this for the express purpose of standardizing women in industry and putting her on par with the professional women and the women who are not in business. It is operated by funds, part of which are furnished by the United States Government, and it is to be established in Detroit where they have the temporary courses and there are hopes of being able to establish in all of the big industrial plants in Detroit trade schools so that the work will go on in industry, and that will eliminate a great deal of this timidity and cautiousness because she doesn't know what to do, and she won't spoil a lot of material and she will be taught to use her natural facilities in the best way. I believe the same funds are available to all universities and all schools.

MARK M. JONES (Edison Industries, Orange, N. J.): While Miss Tarbell found most of those women to represent the leadership in those countries, the same thing has been somewhat general among the women in this country. In other words, it seems to me that the ability among the factory workers is something that wasn't appreciated by women as generally as it might have been. Was that the situation in the foreign countries?

MISS TARBELL: I think to a good degree, yes. In England there has been a strong feeling about it and that has been very largely due to the very bad conditions under which women have worked and the very low pay they have had in the great industrial towns like Manchester. There isn't any doubt that there has been a strong feeling against it, and I think that feeling had something to do with England's activities, where a good many women went into industry and said that things had to be

changed. In France the attitude of the women is different, but in any kind of business or occupation, to the French women it doesn't make any difference—if the thing is to be done, she does it, and she has always been accustomed to doing exactly those things—she works on the farms and she works on the streets. Her great occupation in France is the sewing trade; but women rushed out to get into the factories to a surprising extent and one of the interesting things I noticed this Spring was the difficulty they had in getting the women back into the sewing trade—they said very frankly they didn't want to sew any more, the factory being more interesting. They knew that they wouldn't be getting the wages they had been getting, but they didn't want to sew any more and they wanted to stay in the factories. Whatever prejudice there was against the factories as a place of work for women in France was, I think, pretty nearly overcome. There was some objection on moral grounds.

MR. S. W. ASHE: I would like to ask about the physical examination of women in industry. In some places I understand the women are rather averse to having physical examinations, at the same time, I believe it is absolutely necessary to have the physical examination in the factories into which they are going in order to ascertain their condition and know the kind of work which they are capable of doing. I would like to get some information on that subject.

MISS TARBELL: Miss Copp, I think that question ought to be answered by some one who has had more experience in that line. I have had that question come up in different factories and my observation has been that while the women when they had this thing sprung on them might object, if the employment manager was tactful and if she explained to them why it was and what it meant, it could be brought about.

MR. S. W. ASHE: Did you find, Miss Tarbell, in France that the introduction of women in industry had any bad effects over them in any way—whether they lost any of the home atmosphere and what means was taken to prevent that?

MISS TARBELL: In France, in the munitions factories they were pretty well scattered and a good many of the workers were brought to Paris. It was in the munitions factories around Paris that I made most of my observations. There were two classes, a great many married women that came in from the provinces and there were also a great many girls—girls that had never been in the big city before—they had always lived in small towns at home before and they were working night and day shifts. In general there was an enormous amount of recklessness—I think that is war psychology, at least, part of it—you see everything going to smash. Now that did happen to some extent but only to a comparatively small extent. A surprising number of these untrained girls got the idea they could go into clerical work. I spent some time in the Government Employment Bureau and I was perfectly surprised by the number of untrained girls that came there seeking positions. They had a little bit of typewriting, they could read and write, and they thought that was all that was necessary.

MR. ARTHUR T. MOREY (Commonwealth Steel Company, St. Louis, Mo.): You will be pleased to know that at the Executive Meeting of the Council yesterday a woman was elected Treasurer of this organization. (Applause).

Miss Hunt will not have a small job inasmuch as the receipts and disbursements are in the neighborhood of \$100,000 a year.

Another matter that you will be interested in is the matter of whether or not we should elect a woman as an executive on the committee of the National Safety Council. It was left in this way—under our organization the chairman of a section automatically becomes a member of the committee and it was felt that if the women themselves felt that there was a need, and the women were interested enough, we could organize a woman's section.

ORGANIZATION OF A WOMAN'S SECTION

The organization is a very simple one, and has its chairman, vice chairman, and secretary, who, with others, would be the executive committee to adopt by-laws, etc. We have in the Council a sectional service and this section would be expected to develop its own problems and work out its own salvation without any assistance, if possible, from the headquarters staff.

MRS. M. H. VARNUM: Who would be eligible to the women's section—what are the qualifications necessary for membership in the section? Is it necessary for the women to represent industrial establishments or may they join as individuals?

MR. ARTHUR T. MOREY: Both memberships—memberships individually and as representatives of companies.

MRS. M. H. VARNUM: Would there be a separate financial burden on the women's section?

MR. ARTHUR T. MOREY: No! The individual membership is \$7.50 per year and the company memberships are based on the employer and the number of employees. I presume the officers would have to be members of companies who are members of the National Safety Council.

I might add that in other sections I spoke to they have got together in a group and formulated their organization, and have already adopted a form of by-laws and felt enough interest in it to present that to the Council for its approval, and to see to its programs.

MRS. M. H. VARNUM: I move that Mr. Morey's suggestion as to the method be adopted for preparing a permanent organization.

(The motion was seconded and carried unanimously.)

MR. A. T. MOREY: I think the thing to do is for those of you who are interested to call a meeting and go through the temporary form and proceed.

MRS. M. H. VARNUM: I move that the Chairman be empowered to call such a meeting and that she be temporary chairman of the meeting so called.

(This motion was seconded and carried unanimously.)

CHAIRMAN CORP: The chairman announces that there will be a meet-

ing this afternoon at five o'clock for the women who are interested in establishing a permanent section for women in the National Safety Council, and you will find the place of meeting by inquiring at the Registration Desk. Let me remind you, ladies, that our interest in this program will be shown first by our attendance this afternoon.

FRIDAY AFTERNOON SESSION

ORGANIZATION COMMITTEE MEETING

THE meeting convened at 5 P. M., Miss Tracy Copp presiding as Chairman.

CHAIRMAN COPP: As I understand it, our meeting this afternoon is perhaps more of a formality than anything else, that the real work is to be done after the officers are elected. May I just repeat what was said this morning by Mr. Morey that by taking the action which we expect to take today we make of this a permanent section. There goes with that the responsibility of providing the National Headquarters with material for bulletins. It is not necessarily a section for women only. It is a section for the interests of the employers of women.

Now what is your pleasure?

MISS NESTA C. EDWARDS: Madam Chairman, I would like to offer the following resolution:

RESOLUTION

"RESOLVED that this meeting here and now organize itself into the Women in Industry Section of the National Safety Council, and that the Chairman of this meeting, Miss Tracy Copp, appoint a committee of which she herself shall be Chairman to work out the details of the organization of the section, with the authority of said committee to adopt By-Laws for the section in conformity with the Constitution and By-Laws of the National Safety Council, and that those at this meeting be considered the initial members of the Section who shall be advised of the progress of the Section's organization and its duties and work to be accomplished, and that this meeting now proceed to the election of the necessary officers of the Women in Industry Section who shall be the officers for the first year under the Section's By-Laws."

I move the adoption of that resolution.

(The motion was seconded.)

CHAIRMAN COPP: It is moved and seconded that we consider this the establishment of a permanent section for women, that your Temporary Chairman for this afternoon be instructed to appoint a committee to draw up the Constitution and By-Laws that the people here present shall be considered the initial members of the Women in Industry Section. All those in favor of this resolution will say "aye"; opposed "no".

(The motion was adopted.)

ELECTION OF OFFICERS

MISS MILDRED M. HICKMAN: In recognition of the very splendid service which has been rendered us this year I should like to present the name of Miss Tracy Copp as Permanent Chairman.

(The motion was put and carried.)

CHAIRMAN COPP: We are now ready to receive nominations for Vice-Chairman.

(The name of Miss Nesta C. Edwards was placed in nomination, seconded, and carried.)

CHAIRMAN COPP: We will now proceed with the election of a Secretary.

MISS MAUD SWETT: I should like to nominate Miss Hickman of Cleveland.

(The motion to elect Miss Mildred M. Hickman of Cleveland as Secretary was carried.)

CHAIRMAN COPP: The duty of naming a committee to draw up the Constitution and By-Laws devolves upon your new Chairman. It is clear that the officers of the Section will be a part of that committee. I am wondering if I might just get from you informally a little expression of your feeling in this matter of selecting a committee. I had thought that perhaps we need five members on that Committee, and my first thought on it was that it might be well for us to ask a man to act with us on that Committee in drawing up the Constitution and By-Laws, and in preparing a program for next year. What do you think of it?

(The meeting collectively signified their concurrence in the suggestion.)

CHAIRMAN COPP: I am sure that you will have occasion to do something during the year as members of the Section. May I ask you then to keep me informed on the subject of the employment of women and all of the new things that are being published, and anything that can be presented to the official headquarters for publication in their very interesting bulletins.

MRS. HUMPHREY VARNUM: Do you want us to send you papers that have been presented publicly, papers that have been published, or do you want reports of the various movements that are going on in the different cities in regard to labor? Just what is your idea?

CHAIRMAN COPP: We should want all of those. I don't know that you are familiar with the publications of the National Safety Council. We shall be more familiar with them, but they are branching out into the subject of industrial relations and the employment of women. Their work is not now confined only to mechanical safeguards and the education of workmen. So that whatever we have that is good material should be sent to headquarters so that it can be summarized and given out officially through the Council to the members.

MRS. HUMPHREY VARNUM: Are you familiar with the bulletins that are sent out by Miss Tarbell from the Council of National Defense? I was Michigan Chairman of Publicity and we sent in newspaper clippings when they were vital to the subjects at hand even though they came

from small towns. We sent in articles from local magazines like the Michigan Manufacturer and Financial Record and other material of that sort. A great deal of it was used as the basis for formulating articles, but we don't want to swamp you with the wrong kind of material, and yet we would like to know just how much material you would like.

CHAIRMAN COPP: Miss Hunt and Miss Edwards are both here. They are very much more familiar with the mechanics of the office than I am. I imagine they would be glad to have all kinds of material from which to make extracts and make notes for publication. Am I right in that?

MISS HUNT: Yes.

MISS NESTA C. EDWARDS: The Library would like to have photographs or things that will be of value to the Women's Department. You may come across good blue prints and good drawings. I know they would be welcome.

CHARTER MEMBERS OF THE WOMEN IN INDUSTRY SECTION

The names, business connections and addresses of those present were as follows:

Miss E. Mae Haas, Employment Department, The National Cash Register Company, Dayton, Ohio.

Miss Anna M. Atherton, Supervisor of Women, The National Cash Register Company, Dayton, Ohio.

Miss Bernhard C. Riffel, Hyatt Bearings Division, General Motors Corporation, Harrison, N. J.

Mrs. Humphrey Varnum, Publicity and Advertising, Michigan State Telephone Company, Detroit, Michigan.

Miss Anna K. Koutecky, Women's Department, Morris & Co., Union Stock Yards, Chicago, Ill.

Miss Nesta C. Edwards, Consultant in Industrial Service, 168 North Michigan Avenue, Chicago, Ill.

Miss Naomi Neill, Supervisor Nurses, Aetna Life Insurance Company, Hartford, Conn.

Miss Maynard Downes, Robert A. Johnston Co., Milwaukee, Wis.

Mrs. S. M. Galaty, 508 North Humphrey Avenue, Oak Park, Ill.

Miss Mary Lapsley, R. N., Ohio Lamp Division of National Lamp Works of General Electric Company, Warren, Ohio.

Miss Clara L. Ruchti, R. N. Gisholt Machine Co., Madison, Wis.

Dr. Alice S. Cutler, The Printz-Biederman Co., Cleveland, Ohio.

Mrs. Flossa R. Washburn, The Printz-Biederman Co., Cleveland, Ohio.

Miss Stella Gonsior, National Safety Council, 168 North Michigan Avenue, Chicago, Ill.

Mrs. L. Luella Cox, Director Department of Women and Children, Industrial Board of Indiana, Indianapolis, Ind.

Miss Kathryne Hunt, Treasurer, National Safety Council, 168 North Michigan Avenue, Chicago, Ill.

Miss Mildred Middleton, Manager, Operators' Training Department, Michigan State Telephone Company, Detroit, Mich.

Miss Florence Swift Wright, National Organization for Public Health Nursing, 156 Fifth Avenue, New York City.

Dr. Marian A. Weightman, Willys-Overland Co., Toledo, Ohio.

Miss Harriet V. Condie, Employment Supervisor, Michigan State Telephone Company, 29 Madison Avenue, Detroit, Mich.

Miss Jeanie E. Hughes, John Schoonmaker & Son, Newburgh, N. Y.

Mrs. Lillian A. Brown, Glynn-Clarke Co., Cleveland, Ohio.

Mrs. Arthur T. Morey, 5565 Bartmer Avenue, St. Louis, Mo.

Mrs. C. A. Hamann, 2036 East 89th Street, Cleveland, Ohio.

Miss Muriel Mackay, Dominion Rubber System, Pt. Dalhousie, Ontario, Canada.

Miss Virginia H. Evans, Kimberly Clark Co., Neenah, Wis.

Miss Maud Swett, Assistant Secretary, Industrial Commission of Wisconsin, Madison, Wis.

Miss Mildred M. Hickman, National Acme Co. (Employment Manager), Cleveland, Ohio.

Miss NESTA C. EDWARDS: I move that these names be listed and that each one of us get a copy of that list.

(The motion was seconded, it was put to a vote, and carried.)

On motion the meeting adjourned.

Woodworking Section

October 3 and 4, 1919

J. E. RHODES, Chairman

Secretary-Treasurer, Southern Pine Association, New Orleans, La.

F. A. BARKER, Secretary

Resident Manager, Lumberman's and Manufacturers' Insurance Agency,
Milwaukee, Wis.

MEMBERS PRESENT:

David W. Teachout, Vice-President and Treasurer, The A. Teachout Co.,
331 Prospect Avenue, Cleveland, Ohio.

D. F. Hatch, Superintendent, The A. Teachout Co., 331 Prospect Avenue,
Cleveland, Ohio.

R. F. Milne, Lumbermen's Safety Association, 19 Castle Bldg., Ottawa,
Ontario, Canada.

F. G. Lovett, Inspector, Industrial Accident Prevention Association, 892
Excelsior Life Bldg., Toronto, Ont., Canada.

James H. Parks, General Accident Insurance Company.

Robert B. Howe, Safety Dept., Goodrich Rubber Co., Akron, Ohio.

L. B. Alsey, J. F. Hasty and Sons, Stave & Heading Mfg., Paragould, Ark.

Frank W. Schoof, Safety Equipment, Willard Storage Battery Company,
691 East 128th St., Cleveland, Ohio.

F. D. Ensminger, The Prest-O-Lite Company, Inc., Indianapolis, Ind.

W. H. Rohr, S. H. Smith Co., Publishers "Woodworker," Indianapolis, Ind.

C. H. Gram, Commissioner of Labor, Salem, Oregon.

C. W. Tellier, Eastman Kodak Company, 333 State Street, Rochester,
N. Y.

E. B. Jacques, Goodyear Tire and Rubber Company, Akron, Ohio.

Warren Hilleary, Royal Indemnity Company, 84 William Street, New
York.

W. F. Proper, W. F. Stewart Company, Automobile Bodies, Flint, Mich.

M. L. Henwood, Maryland Casualty Company, Baltimore, Md.

G. D. Bragdon, General Accident Corp., Philadelphia, Pa.

C. B. Allen, Mfrs. Liability Ins. Company, Jersey City, N. J.

Alfred Struck, President Alfred Struck Company, Louisville, Ky.

O. F. Behm, Standard Accident Company, Detroit, Mich.
 Wm. A. Marshall, Chairman, Oregon Ind. Accident Commission, Chairman, Safety Com. Pacific Logging Congress, Salem, Oregon.
 E. M. Hamlin, Mgr., Maine Mills, The American Thread Co., Milo, Maine.
 A. B. Cowfer, Safety Engineer, Ocean Insurance Company, 912 West 21st Street, Erie, Pa.
 Paul M. Bowen, Standard Accident Insurance Company, Detroit, Mich.
 R. H. Platts, Standard Accident Insurance Company, 906 Penobscot Bldg., Detroit, Mich.
 Holger Jensen, Maryland Casualty Company, Baltimore, Md.
 J. L. Naylor, Bureau of Labor, Manitoba, Parliament Bldg., Winnipeg.
 R. W. Patmore, East End Mfrs.' Association, Cleveland, Ohio.
 Charles N. Young, Acting Supt. Dept. of Sched. Rating & Inspection, National Workmen's Com. Serv. Bureau, 13 Park Row, New York, N. Y.
 John L. Bartlett, Safety Eng., Maryland Casualty Company, Baltimore, Md.
 Martin J. Flyzik, Olympia, Washington, Member of State Medical Board and State Safety Board.
 W. Graham Cole, Director of Safety and Industrial Relations, Southern Pine Association, New Orleans, La.

FRIDAY MORNING SESSION

THE meeting was called to order by the Chairman, at 9:30 A. M. CHAIRMAN RHODES: Although the Woodworking Section of the National Safety Council appears to be considered as one of the least important of this great organization, I am sure that with the active participation in this conference of those present, we can make the proceedings of this section not only interesting but extremely valuable to greet you, and to invite you to take part in this conference in a strictly informal way, in order that we may have the benefit of your suggestions and judgment concerning the questions which have been placed before us for discussion.

THREE BRANCHES OF LUMBER INDUSTRIES

The Woodworking Section really involves three different branches of the lumber producing and consuming industries. As I see it, we include first the manufacture of lumber; second, its distribution, and third, its consumption as represented by woodworking plants. Addresses from representatives of these three branches are scheduled to be delivered today and tomorrow.

Speaking for the lumber manufacturing industry, with which I am personally connected, I am pleased to say that there is an increasing interest on the part of employers in the work of eliminating causes for personal injuries. Our attention has been most forcibly called to the fact that the record of the lumber industry in the matter of accidents and fatalities is far from satisfactory. I am informed that on the basis of the number of injuries sustained by employees, the lumber industry stands third among

the great vocations in which men are engaged in this country, railroad-ing and mining leading the lumber industry. If this situation is true, and the lumber manufacturers during the coming year will make an effort to ascertain whether or not it is, I can assure you that they will make every effort to improve the record, but frank to say, personally I feel ashamed about it, and I know that many of our associates also entertain the same feelings.

SAFETY DEPARTMENT OF SOUTHERN PINE ASSOCIATION

The Southern Pine Association has inaugurated a Department of Safety First, for the express purpose of doing what it can to reduce the number of accidents sustained by employees in the woods and mills of the Southern states. Mechanical appliances, so far as they will protect life and limb in sawmills, have been perfected about as far as it seems possible at this time; hence, it would appear that little improvement can be made in that direction. The greatest number of accidents incident to the manufacture of lumber occur in logging operations, and I am informed that in this respect the operations of the Southern states show a better record than those of the far Western states, where logging is more largely done by machinery and where the timber handled is of a much larger and heavier character. At the session of this conference a year hence, we shall endeavor to present statistics which I feel certain will show a very gratifying decrease in the number of injuries sustained by employees in the Southern mills and woods, and I will not take your time by rehearsing the efforts which we are exerting to bring this about.

So far as the distribution of lumber is concerned, the number of injuries sustained by employees is undoubtedly very materially less than that in its manufacture, and I am pleased to note that a representative of the wholesalers and retail lumbermen will address us on this subject. The handling of lumber involves generally heavy manual labor, and it is hence impossible to entirely eliminate the physical hazard.

SEEK COÖPERATION OF MANUFACTURERS OF WOODWORKING MACHINERY

There are a vast number of industries throughout the country which produce articles made of wood. There are, of course, the manufacturers of sash and doors, boxes, and other exclusively wood products, but in addition there are a vast number of plants which have a woodworking department, such as manufactories of automobiles, batteries, and so forth. These operations involve the use of a large amount of woodworking machinery, upon which safeguards have generally been installed. The chief cause of accidents in woodworking plants is due to the fact that the employees do not use the safeguards which have been provided, and the management is frequently careless or indifferent. It is possible that the manufacturers of woodworking machinery can coöperate by incorporating these safety devices as an integral part of the machines, so that they cannot be removed. I think that some discussion upon this phase of the matter would be helpful, and to that end would suggest that the manufactur-

ers of woodworking machinery be invited to participate in future meetings of this section.

We are delighted to have with us representatives of our Northern friends, the Canadians, our worthy allies in the great war. We not only welcome their participation, but I feel that a resolution of thanks should be extended to them, expressing our appreciation of their interest in this great work.

By reason of the size of the lumber industry, as compared with many others represented in this Council, I feel that we should make an effort to make the sessions of this section at the next annual meeting among the most largely attended of all, and that steps should be taken at this time for the preparation of a program which will result in bringing out representatives of the lumber industry and affiliated branches, so that instead of being the smallest of the sections we may become one of the largest, if not in point of attendance at least in actual results achieved. In this connection, I wish to extend my thanks to Mr. Barker, Secretary of this section, for the keen interest which he has taken in the work during the past year. The success of work of this kind really depends more upon the Secretary than any other officer. I will appreciate it if you will consider this meeting in a strictly informal manner, so that our discussions may be of the most intimate and helpful sort.

(Chairman exhibited safety bulletins and forms as used by Southern Pine Association in their safety promotion work.)

SECRETARY'S REPORT

I am going to dispense with any unnecessary talk as regards the secretary's report with reference to our previous meetings, and devote my entire time to a direct appeal to you members present, for your full cooperation in increasing the membership of our Woodworking Section.

I was very much surprised to receive figures from the National Safety Council as regards the present membership of this Section, especially in view of the fact that lumbering, logging, and lumber-working represents more industries in the United States than any other prominent class of manufacturing, and frankly speaking we should have right from Ohio a greater number of members than are represented as a total for the United States, and if agreeable to the Chair, I wish to have each and every one of you register your name upon the booklet which I will pass around and by so doing I wish to consider it a partial pledge by each of you to secure at least one new member before our next Annual Safety Congress.

As we review the accidents occurring in the lumber and lumber-working industries, we cannot help but feel that a progressive accident-prevention campaign for these industries would eliminate a number of the so-called preventable accidents. My personal experience in the sawmill industry takes me back to a time when I remember frequent accidents by reasons of kick-backs on edgers, and speaking for the territory in which I am now interested, I am very glad to say that we have practically eliminated this class of accident, which has proven to be preventable and was usually fatal to the injured. Such was accomplished by applying sim-

ple and practical guards to the machine. Surely work of that character must interest any lumber manufacturer.

I can also go back a few years, and bring to my mind a vivid recollection of frequent finger and hand accidents on jointers, and today by the use of the round cylinder head instead of the square head in these machines, we have almost entirely eliminated any further loss of fingers or hands, and furthermore, the round cylinder head in the jointer has been found in addition to its wonderful safety feature, capable of doing the same and even more work than the square head can do.

Our every indication is that this Safety Congress is going to be the best one that we have as yet held for the woodworking section. As for next year, we are already planning to have prominent men of our industry deliver addresses, and I petition you all once again to cooperate fully in making our next Congress a successful one in membership as well as program.

Chairman Rhodes introduced Mr. David W. Teachout who delivered the following address:

SAFETY IN THE LUMBER AND MILLWORK INDUSTRY

DAVID W. TEACHOUT, VICE-PRESIDENT AND TREASURER, THE A. TEACHOUT COMPANY, CLEVELAND, OHIO

The work which the Council is doing in America we believe is of the greatest importance to the future of our people and the development of our Nation's life.

The Eighth Annual Safety Congress in Cleveland this week has been a source of great education to our own "local family" of almost one million people. This Congress has taught us to "be more careful to wait at the crossing, and not spend so much time waiting in the cemetery."

While it seems that we have many accidents to report in our daily papers, statistics indicate that we are a long way from heading the list of accidents in our large cities. Usually Cleveland aspires to be at the top but in this respect, in which you and I are vitally interested, we prefer to be at the bottom,—in other words have the fewest accidents possible in proportion to our population.

We feel indebted to this Congress in Cleveland and trust your stay in our midst has been both pleasant and profitable.

The subject assigned to me of safety in the lumber and millwork industry is one in which I have always been vitally interested. Perhaps this was first developed by my early experience in the manufacturing end of the lumber business at our North Carolina Mill. It was necessary to start with a very crude affair and practically no safety appliances. A few days after we started the mill I cautioned one of the few white laborers, one who was working with the log chain which came up into the mill to be careful with some gear wheels near the saw-carriage. Less than twenty-four hours after that time I saw this same man catch his arm in this very place and tear it off at the wrist. From that date I resolved that

whenever and wherever I could take some precautionary measure I would do so.

While in the South logging in the woods, slipping the logs down-stream by tide to the mill, ripping up the logs and then shipping the lumber north I came to know the conditions and the environments of the lumberman, in fact what is more vital. I came to *know workmen*. Never shall I cease to be grateful for this experience. I came to recognize the human side of men in the act of labor. "The humanizing of business is the beacon light of our country," as a prominent lumberman of the Central West has so well expressed it. Reasonable precaution in protecting life and limb is recognized today, not only as a duty under the law but is realized as a common-sense thing to do to save the corporation or partnership from great loss, and under some circumstances, financial ruin. And in addition there is the higher law. The Christian viewpoint is developing and there is the moral responsibility and duty which we must frankly face as we meet one another in industry as *associates*. Note that I do not say employer and employee.

Usually a man's word growing out of his own experience is more acceptable and I trust mine may be to the point in this message.

The first consideration in establishing a yard is the public hazard. From the standpoint of public safety all yards should be fenced in and the gates carefully closed at night. Lumber should be neatly piled and well stacked. This avoids boards and dimension falling over in case a truck strikes the corner of a pile. Every platform in a lumber shed should have a substantial rail. "An ounce of prevention is worth a pound of cure," as a maxim, applies in this line and especially around the planing mill. So far as I can learn we have never had any serious accident around any of the ten yards in which we are interested in the City of Cleveland. In the sash and door business we have had four deaths resulting from accidents over a period of forty-five years—two were sustained by falls in the elevator shaft, one from blood poisoning and one resulted from accident on one of our millwork machines. Danger signs and gates were present in the case of the former. Our experience, therefore, shows that an air of independence on the part of the workingman is usually at the bottom of these serious accidents.

Personally I believe that the conscience of corporate management is aroused to the peril of such accidents and that the majority of concerns are only too willing to accept suggestions for additional safety and install the apparatus at once, even at considerable cost or I might even say—no matter what the cost.

SAFETY SUGGESTIONS

Five concrete suggestions should be borne in mind.

1. Place "Danger" cards at every critical and dangerous place, and especially at elevator shafts. Have these in metal and nailed up so they cannot easily be torn down.

2. Where there are laboring men who do not understand English, have safety signs put up in their respective languages, and frequently call their attention to such notices.

3. Urge foreigners to study English so that in the time of emergency or accident our language as a medium may be readily understood.
4. Use guards on all machines. Do not allow the poor argument of "too much trouble" to stop improvements short of the most complete and up-to-date.
5. Watch safety of health in office and plant.

DISCUSSION

This paper was discussed by: Mr. D. F. Hatch, Supt. of the A. Teachout Company; Mr. M. L. Henwood, Maryland Casualty Company, Baltimore, Md.; Mr. C. H. Gram, Commissioner of Labor, Salem, Oregon; Mr. Wm. A. Marshall, Chairman, Oregon Ind. Accident Co., Salem, Oregon.

Chairman Rhodes thanked Mr. Teachout for his excellent paper and exhibit of safety appliances. One in particular attracted the attention of the section. It was a red flag with firm name and safety first on it, which is attached to the extreme extending part of a load of lumber while in transit on trucks. This was considered very effective in attracting attention of pedestrians when truck would be turning a corner and have the probability of extended lumber swinging into persons near by.

Program was continued by introduction of Mr. Holger Jensen, who delivered an address.

METHODS OF SECURING COÖPERATION OF WORKMEN IN USING SAFEGUARDS

HOLGER JENSEN. MANAGER, ENGINEERING AND RATING BUREAU, MARYLAND CASUALTY COMPANY, BALTIMORE, MD.

If it were within the power of those interested in Safety to look into the minds of men, it would, no doubt, still be impossible to lay down any specific method for obtaining the use of safeguards which would be satisfactory in all cases. However, it is not an impossibility to obtain the general use of safeguards by workmen, if sufficient consideration is given to eliminate the objections. These objections are generally due to faulty construction of the guard, which does not give the *maximum amount of safety*, or which *curtails the output*, and also due to the *state of mind of the workman* who is to use it. This last objection, however, so closely interlocks with the first two that it is, to use the late Andrew Carnegie's illustration, similar "to a three-legged stool." It is necessary to consider and deal with all three objections, in order to obtain the desired result.

The responsibility for obtaining the workmen's coöperation rests mainly with the employer in the providing of efficient guards. Guards should be substantially constructed and as near automatic in their action as possible, where adjusting is necessary, due to size and nature of material. Any operation possible with an unguarded machine should be possible with a guard, at least, the guard should not interfere with any necessary feature of the work during operation. When ordering a machine from a manufacturer, the buyer should insist upon it being constructed so as to give the maximum of safety in its operation. If this demand were a gen-

eral practice, more machines would be safeguarded by machine manufacturers. Where machines are sent out unguarded by the manufacturer, the proposition of guarding the machine is up to the buyer. The present practice of guarding the belts, shafts, and gears is more or less uniform, and by no means difficult, but when it comes to guarding the danger zone of operation, which, no doubt, produces more serious accidents in connection with the operation of woodworking machines than anything else and considering that the types of guards in use at present for guarding the danger zone of operation are in most cases very easily removed, these types of guards demand special and most careful consideration.

REPORT OF WISCONSIN INDUSTRIAL COMMISSION

The report of the Industrial Commission of Wisconsin as to Industrial Accidents in that State for the years 1915, 1916, and 1917 shows that 981 accidents were on circular saws, 64 on band saws, 150 on saws not classified: in all, 1,195 accidents on saws out of a total of 2,365 accidents on woodworking machines, or 50 per cent of the accidents occurred on saws. Attention is not called to these figures with the idea in view that the State of Wisconsin shows an especially bad record: on the contrary, the State Department of Wisconsin has been exceptionally active in the reduction of accidents on woodworking machines, but it is one of the few State Departments which has tabulated industrial accidents by industries. These figures would indicate that circular saws are the greatest producers of accidents of all woodworking machines. This is first due to the fact that saws, no doubt, comprise the largest percentage of any one kind of woodworking machine. It may, however, be interesting to note, that, for instance, of the 981 accidents on circular saws, 143 were permanent injuries, divided as follows: 4, deaths; 2, arm cut off at elbow; 3, loss of hand; 76, loss of one finger; 36, loss of two fingers; 13, loss of three fingers; 5, loss of four fingers; 1, loss of foot; 3, loss of eye; and 1, facial disfigurement. This shows the necessity of protection. In the majority of cases, it would, no doubt, be found that the accidents were due entirely to the lack of safeguards, but to say that all of these accidents were due to the fact that safeguards had not been provided would be folly. While the statistical data throws no light on this, it can reasonably be assumed that in a great many cases safeguards were provided, but were inadequate, or where a fairly good guard was provided, its use was dispensed with at the time of the accident, due to special work being done; repairs or adjustment having been made, which necessitated the removal of the guard and same not having been replaced. In some cases, a very good guard is removed, due to the operator's personal dislike to it, or to the fact that it prevents him from turning out the desired quantity of work.

CAREFUL MAN AND GUARD, BOTH ESSENTIAL

The necessity of safeguards on woodworking machines is obvious and is recognized by all employers. Argument is often presented that a careful workman eliminates the need of a safeguard. A careful workman is only obtained through training and education and is probably a more

superior condition in operating a dangerous machine without a guard than a careless man operating the same machine guarded, but the most careful man forgets at times. Experience has shown that both the careful man and the guard are essential. The two are inseparable and it is difficult to state which one stands first in preventing accidents. The guard should first be provided.

To discuss the construction and suggest standard safeguards for machines, such as jointers, circular saws, planers, shapers, etc., is not considered necessary, as most men engaged in the operation of woodworking machinery are familiar with guards which are on the market and which are looked upon more or less as standard guards. These, however, cannot always be accepted as a "cure-all", even for these common types of woodworking machines, but guards have to be designed with due consideration as to the class of work done and material used. This, of course, also applies to other types of woodworking machines for which there are no guards on the market. At a meeting recently held, at which the possibility of standardizing safeguards was discussed, it was brought out very strongly that it would be impracticable to do this at the present time, due to the great difference in design of machines and requirements demanded in guards and that the great bulk of machine guards used were designed and made in the individual plant or mill in which they were to be used. In such cases, the construction of the safeguard must have the most serious consideration of the man in charge. The guard must be of substantial construction and should be the best money can purchase.

THE WORKMAN SHOULD BE CONSULTED

The providing of such a guard is a big step towards getting the cooperation of the workman in using it, but in order to be sure of this attitude, the workman should not be looked upon in the same light as the machine on which the guard is to be placed. Human nature is very much alike, whether the man wears a white collar and tie and spends his time at a desk, or he wears overalls and puts in the day operating a machine. When a man has an opportunity to express his individuality and takes some part in the purchasing or creating of a new venture, he is sure to take a great deal of interest in making it a success. It has been proven time and time again that the cooperation of the workmen is vitally essential, if anything like the majority of preventable accidents is to be eliminated and the workmen, therefore, should be consulted in the purchasing, designing or installing of safeguards on machines which they operate.

The use of certain safety devices oftentimes means the learning anew of the operation of the machine. Human beings get into habits. They do not like to change their ways, especially when they become older. It appears to be human nature to oppose a change, unless good reason can be shown for making it. The employer, by his attitude, can show the workmen that he is interested in safety, is anxious to provide safe conditions, and that he further desires and appreciates the workmen's best opinion from their practical knowledge. It is true that many helpful suggestions are made by workmen in reference to safeguards, which, in

the form presented, are impracticable, but which need only the application by others more skilled and experienced to be used to good advantage. A great many safeguards in woodworking operations remain unused a number of times because the workmen feel that they are not practicable in the operation of their machines. The guard may give full protection, though interfering with the output, and the employer may be willing to suffer this loss, but the loyal workman resents any curtailing of output. No guard should be considered satisfactory unless it gives the maximum of safety and provides at least the same output obtained by the unguarded machine. Safeguards not interfering with operation increase production, due to the workmen's sense of security. A guard affording full protection, without interfering with the operation, is sure to appeal to the workman as being practicable and if he has had part in the designing or installation, it is certain to be used at its maximum of service. Unjust objection and criticism to a guard is generally made at the time of installing, so that later on when a change is made in the operator, the guard is accepted as a fixture.

RESPONSIBILITY

The placing of new or inexperienced persons on dangerous machines, needless to state, will produce accidents, even with machines which, in the hands of experienced workmen, would be satisfactory. This is where the foremen or superintendents should use discretion. They can also greatly aid in getting cooperation of the workmen from a safety standpoint, as well as from the point of production, in maintaining discipline. This can always be obtained if a sense of responsibility exists in the minds of the workmen. May it not justly be assumed that the secret in obtaining the use of safeguards can best be covered by one word. *Responsibility*—responsibility of the employer, his superintendent or foreman towards the safety of the workmen, and workmen's sense of responsibility towards their own safety, as well as the best interest of their employer? In former days when the employer and his small number of workmen worked shoulder to shoulder and knew each other personally and were concerned as to each other's best interests, they both realized fully their responsibility towards each other. With the plants and mills being increased in size, the employer and the workmen have naturally drifted apart. This is, no doubt, the cause for lack of cooperation shown in many places at the present time. This fact is being recognized in general and sincere efforts are being made to correct this unfortunate situation. In the large mills and plants the employer, on account of his duties, is unable to keep in close touch with the individual workmen. The superintendent and foreman become his substitute, and they must be considerate of the workmen under them. They should take an earnest and sympathetic interest in the welfare of each workman, but with it all, they should maintain a certain amount of dignity. The right type of foreman will find the workmen ready and willing to follow his instructions in spirit, as well as in action. This makes discipline easier and carries with it a

sense of responsibility in the minds of the workmen as to prevention of accidents, as well as responsibility towards production.

The answer to the question "How to Secure the Cooperation of Workmen in Using Safeguards" is A PRACTICAL AND EFFICIENT FOREMAN AND SAFEGUARD.

Mr. Jensen's paper was discussed by Mr. Cole of the Southern Pine Association, Mr. C. H. Gram, Commissioner of Labor, Salem, Oregon, and Mr. F. G. Lovett, Inspector, Industrial Accident Prevention Association, of Toronto, Ontario.

Mr. Jensen advises that he has a number of photographs of various woodworking guards, and that he will be pleased to give practically any of these to members making request. The Secretary has made a note to have Mr. Jensen contribute to a safety bulletin board for the next Safety Congress.

The subject of hazards in box manufacturing plants was assigned to Mr. C. R. Miller. Mr. Miller was not present and his paper was read by Chairman Rhodes.

SOME OF THE BOX MANUFACTURERS' PROBLEMS

C. R. MILLER, OPERATING MANAGER, RATHBORNE, HAIR, AND RIDGWAY,
CHICAGO

The future of the Safety movement in the Wooden Box Industry is, in a large sense, linked up with the problem of developing automatic and semi-automatic machinery. There is a great field for such development and an urgent necessity for it.

The Industry, as a whole, seems to have taken a great interest in the work of guarding plants for the protection of employees, and in the short space of five years has made wonderful progress in affording conveniences for the comfort of workers. It is a common thing, nowadays, to find in plants of almost any size, stations where hot coffee and sandwiches may be had at nominal prices; rest rooms very well fitted up and many like provisions for comfort.

But now I want to get to the subject that I consider most important.

We are sawing boards today about as we did twenty-five years ago. It is true that recently a new nail driving machine has been introduced for making up certain types of boxes, but the principle of all the machines for general work, now in use, has not changed in thirty years. About ten years ago, a new type of box, which has since come to be known as the —4—ONE WIREBOUND BOX, was introduced to the consuming public. This box is made very largely of Rotary Cut Veneer and even though nine or ten years have elapsed we have not yet a satisfactory sawing machine for ripping this veneer. I could extend the list to considerable length but think that these will be sufficient examples to convey my thought.

When we consider the modern automatic machine for working steel and iron products, such as plates, bolts, screws, tin cans, etc., our average machinery seems to be woefully ancient and inadequate. Then, too, our

chief competitor, the manufacturer of fibre containers has machinery that is well abreast of the times generally. A recent investigation showed me that in an average establishment for making fibre containers, twelve persons can produce as many containers in a given time as would require 65 to 70 persons in the average wooden box factory.

Perhaps some one is wondering where all this joins with the safety movement as most of us usually think of it. We all know that in the designing of machinery today, safe operation is one of the fundamental thoughts with the designer. Therefore, it is fair to assume that new machines will be well guarded. Those of us engaged in this section of the wood working industry must give more and more serious thought and study to this subject, if we are to hold our own and do our part in the great work of reconstruction.

Another great work for us, coming under the caption Safety is picking the right man for the job, and seeing to it that each person is instructed and learns to do his work with the least effort necessary. This is the only way to increase production and at the same time pay more wages for shorter hours.

Some of the great manufacturing institutions working in steel, iron, and metal are conducting training schools for workers, teaching them how to do their work with the least number of movements for each operation and at the same time are finding the misfits and placing them where they can be of the best service to both themselves and their employers.

I think our box factories are, in most instances, important enough to warrant some movement of this kind.

Discussion was entered into by most of the members with reference to box manufacturing hazards, and it was unanimously decided that this important subject should be gone into very carefully at the next sectional meeting. Mr. Miller's paper gave the members present a number of good pointers as to how to conduct safety work for this industry.

DISCUSSION

Chairman Rhodes announced that a general discussion was in order on any matters pertaining to papers read or safety in general for the lumber and lumber working industries. This discussion was entered into freely by all members present, and the exchange of ideas was very beneficial to all.

A very interesting discussion was on photographs of hazards and safety appliances and the following members very kindly consented to contribute in a reasonable way to any member present, or to the section for its next exhibit, photographs which they have and which they will take from time to time:

F. G. Lovett, Inspector, Industrial Accident Prevention Association, 802 Excelsior Life Bldg., Toronto, Ont., Canada.

R. F. Milne, Lumbermen's Safety Association, 19 Castle Bldg., Ottawa, Ont., Canada.

C. H. Gram, Commissioner of Labor, Salem, Ore.

Holger Jensen, Maryland Casualty Company, Baltimore, Md.

Mr. Cole of the Southern Pine Association brought up a very interesting subject relative to the standardizing of accident classification and the subject was referred to the secretary and Mr. Cole for a further investigation as to how insurance companies and states could be brought together for such standard classification.

Mr. R. W. Patmore, East End Mfrs. Association, suggested that this council should go on record with reference to the purchasing, only, of machines that had approved guards. The subject brought up some very interesting discussion and the chairman advised that he would take action by appointing a committee on resolutions to handle this matter.

Chairman Rhodes appointed the following committees, to report at the meeting on Saturday morning October 4.

Membership Committee:

Wm. A. Marshall, Chairman, Oregon Industrial Accident Commission, Salem, Oregon; D. W. Teachout, Vice-President and Treasurer, The A. Teachout Company, Cleveland, Ohio; W. D. Keefer, Safety Engineer, National Safety Council, Chicago, Ill.

Resolution Committee:

F. D. Ensminger, The Prest-O-Lite Co., Indianapolis, Ind.; R. W. Patmore, East End Mfrs. Ass'n., Cleveland, Ohio; M. L. Henwood, Maryland Casualty Co., Baltimore, Md.

Nominating Committee:

R. F. Milne, Lumbermen's Safety Association, Ottawa, Ontario, Canada; Holger Jensen, Maryland Casualty Co., Baltimore, Md.; Fred A. Barker, Resident Manager, Lumbermen's Mutual Casualty Co., Milwaukee, Wis.

Adjournment at 12:30 P. M.

SATURDAY MORNING SESSION

THE meeting called to order by the Chairman at 9:30 A. M. Chairman Rhodes announced that in the absence of Mr. Boyd, Secretary Barker would read his paper.

ACCIDENTS IN LOGGING OPERATIONS AND HOW THEY MAY BE REDUCED

JAMES BOYD, EDITOR OF THE "LUMBER TRADE JOURNAL," NEW ORLEANS

Logging operations procure the source of supply for the lumber manufacturing plants. Accidents happen, but in most instances they result in minor injuries. It is rare that many men suffer injury at one time, because as a rule they work in groups of two or three. Still, one operation reports 183 personal injury cases in 1918.

The best statistics on the subject have been prepared by Henry Burr, Vice-President of T. H. Mastin and Company, Kansas City. The experience of this organization over a series of years, which insures lumber

companies only against liability and workmen's compensation, is that 39 per cent of all accidents in lumber operations are in the logging department of which 21 per cent are in the woods and 18 per cent on the logging railroads. The cost of the accidents in the logging departments is 21 per cent of the cost of all the claims in the lumber industry and that in the railroad department is 20 per cent, or a total of 41 per cent of the entire cost of personal injury.

Mr. Burr has prepared the following figures showing causes of accidents in percentage to the total number of accidents reported:

	Per cent
Log cutting	45
Skidding by power	15
Loading by power	18
Skidding by animals	2
Loading by animals	3
Hauling by animals	8
Swamping	4
Unclassified	5

In the operation of the logging railroads the following causes contribute in the percentage shown:

	Per cent
Operation of cars	26
Maintenance of way	46
Unloading logs	8
Accidents in pond	5
Coupling cars	8
Boarding and alighting	4
Unclassified	3

Bulletins of the National Safety Council have done good work in lessening the number of accidents in operations where they have been used. A company began posting bulletins in 1916; that year it had 272 accidents; in 1917 the number was 225, and in 1918, 183.

Those companies which do not change men often have few accidents. Some of them avoid putting green men in places where there is a possibility or likelihood of an accident, using the new men in places where there is not a great deal to be done, and practically no risk, until they become sufficiently acquainted with the requirements of the work so they can throw around themselves the necessary precaution. Others employ only competent men, and require those in charge of operations to keep a careful watch over their men and see that they take no unnecessary risks.

The Choctaw Lumber Company, Broken Bow, Okla., maintains a Welfare Department under the direction of J. W. Clark. Part of the duties of this department relate to a reduction of accidents. Each employee is given a small book which gives directions for the prevention of accidents. Here are the instructions for The Woods Operations:

OPEN LETTER TO WOODS FOREMEN

1. Instruct every man who is new in your crew regarding his duties and point out to him where he may meet with danger. New men are more liable to accident.
2. The ax and the saw teeth are the cause of most minor injuries to logging men. Keep this idea before your men.
3. Falling trees with the cutters is the cause of most all deaths from accidents in the woods. Keep the men on the lookout.
4. Catching logs on the move injures men and may cause death if the cant hook should fail. Stop this practice; some one on POLLY the year 'round from this carelessness, two at the present.
5. Keep the safety idea before your men all the time and make a record for your crew.
6. Coöperation among the men in the woods, as the swampers and the teams, the saws and the haulers, and the men and the foremen, is of absolute importance; foreman see that this condition is maintained.
7. Men who refuse to use ordinary precaution among their fellow workmen will have to be replaced.
8. Keep the women and children in mind when you think of Safety First and it will be easier.

OPEN LETTER TO WORKMEN IN WOODS

1. We have a desire to see every man on his feet and making his own way in the world and wish to help you.
 2. Carelessness causes 90 per cent of the accidents of industry. Cut out your part of the carelessness and you have done your part.
 3. The ax, the saw, and the falling tree are the arch enemies of the woods department.
 4. Always strike with the ax aimed out and from the body and there can be no injury with the ax.
 5. Don't treat the Safety idea lightly; it may save your life and keep your children from being orphans.
 6. A crippled man is not a man; he is only part of a man. Be a whole man.
 7. Industry needs every man of us. Let's work together that all may be happy.
 8. We have SAFETY FIRST rules now and I am asking every one of you to coöperate with each other and with the foremen to make your department free from injury. We should all be better for the rule.
- Mr. Clark publishes a monthly paper as part of his work. Following is the "SAFETY FIRST DEPARTMENT" from a recent issue:

SAFETY FIRST

The accident record for the month is very good. One hand badly hurt in the Bismarck planer mill, due to "carelessness and awkwardness," as the injured man puts it. It might have been a wrist as well as the two

leaders in the hand. Be on the lookout at all times and stay away from danger.

The new floor in the machine shop is a much needed improvement and will aid in preventing accident. Uneven floors are dangerous.

W. L. Douglas was hit by a falling limb at Broken Bow camp. This is a type of injury that can't well be avoided at times. Eternal vigilance will help.

One man injured at each camp by ax cuts. These appear too frequently. The foremen should point out this danger and then the men should quit chopping toward the feet; chop out from the body and you can't cut your foot. It will take more time to do this, but it will save you a foot, perhaps.

The cleanest place on the job is the car shed of the Bismarck car repair men. These men could keep a house neat and orderly.

A health pamphlet and a safety first pamphlet will be sent to each working hand this week. Read these and then take them home and keep them. I have done several weeks of hard work in preparing them and I know the material they contain is authoritative. We mean to send much of this to your home and ask you to keep it and try to get good from it.

The one remedy that is a certain preventative of all accidents is carefulness.

Mr. William A. Marshall, Chairman, Oregon Ind. Accident Commission, discussed Mr. Boyd's paper and read from an article which he had prepared to be delivered before the Pacific Logging Congress.

ACCIDENT SEVERITY IN LOGGING OPERATIONS

WILLIAM A. MARSHALL, CHAIRMAN, COMMITTEE ON ACCIDENT PREVENTION,
PACIFIC LOGGING CONGRESS, SALEM, OREGON

If statistics are to be of greater value in connection with accident prevention work in logging operations, the information should show, not only the number of accidents occurring in the various occupations or divisions of the work, but also the average severity resulting. The fact that there has been a reduction in the number of accidents during a given period is not conclusive evidence of a real reduction in the total injury to the workmen or in the total of compensation benefits paid to injured workmen.

A study was made for the Pacific Logging Congress of logging accidents in Oregon for the year ending June 30, 1919, and I am taking the liberty of presenting two of the condensed tables and some of the conclusions drawn from them. The principal purpose of this study was to show the causes resulting, not in the greatest number of accidents, but which represented the greater total loss to the injured workmen in temporary and permanent disabilities and in fatalities.

In comparing the relative hazards of the various occupations, or the severity of injury resulting from the different causes of accidents, the total amounts paid in compensation are often unreliable, particularly in

the logging industry, where a considerable number of fatal cases leave no dependents. For these reasons an additional basis of comparison has been inserted in these tables and such disability is measured and the result converted into a common denominator of "days lost". In temporary injuries the actual days lost from employment are counted, while the injuries resulting fatally or in permanent disability are arbitrarily weighted in terms of potential work-days lost according to a table of weights adopted by the International Association of Compensation Boards and Commissions.

A study was made of the causes of accidents by occupations or occupational groups. The following is a summary of the original table:

The value of the study was enhanced by the fact that in the more important respects the conclusions were in harmony with tabulations of previous experience. Some of the deductions made are as follows:

Fallers, Buckers, Sealers, Swampers, Rivers, Peelers and Tie Hackers: Falls of trees and limbs caused but 18 per cent of all accidents and 66 per cent of all fatal cases in this group. This one cause, however, was responsible for 55 per cent of the total severity. Rolling logs caused 17 per cent of the total injury. On the other hand, the use of hand tools (saws, axes, wedges, and sledges) accounted for 43 per cent of all accidents in this group, but was responsible for but 11 per cent of total severity. These three causes represent 83 per cent of total severity to workers in these occupations. Machinery caused less than 2 per cent of accidents in this group.

Snipers, Rigging Slingers, Chasers, Hocktenders, Choker Setters, and Whistlemen: Two hazards again appear as factors in this group, falling trees and limbs causing 21 per cent and rolling logs 9 per cent of severity. Trees felled or objects set in motion by moving logs being pulled in caused 9 per cent of accidents and 21 per cent of severity, while the breaking of or pulling loose of lines or hooks caused 10 per cent of all accidents in this group and 15 per cent of severity. One-half of all fatal cases in the group resulted from the last two causes. Workmen being caught by lines or struck by logs going in caused 21 per cent of accidents and 30 per cent of total severity. These five causes account for 96 per cent of total severity resulting from injuries in this group.

Loaders and Deckers: The two outstanding hazards in this group were rolling logs, causing 46 per cent of severity, and workmen being caught by logs while being handled by machinery, the severity in the latter cause being 21 per cent of the total.

Donkey Engineers and Firemen and Pumpmen: While over one-third of accidents in this group are caused by contact with the donkey engines and their parts, the injuries resulting from the operation of hauling in the logs represent greater total severity.

Wood Bucks, Wood Splitters, and Drag Saw Operators: Here, again, hauling in of logs causes over one-third of total severity, notwithstanding the fact that over 50 per cent of accidents are from use of hand tools.

Rafters, Drivers, and Boommen: Drownings are responsible for 99.3 per cent of total severity to group.

Woodworking Section

X-Animals			2		14	16	.88	2,964	3.01	2,542.12	.67									
XI-Miscellaneous	8		3		19	30	1.64	51,719	3.41	26,778.56	7.05									
Total	62	6	135		1,627	1,830	100.00	583,216	100.00	\$379,752.11	100.00									

Logging Railroad Conductors, Brakemen, Engineers, and Firemen: Brakemen suffered 58 per cent of total accidents to trainmen, with resulting severity 53 per cent. Operation of hand brakes, falls from trains, and runaway trains are the principal hazards to train employees.

Logging Railroad Maintenance and Construction: The two principal hazards to employees in this group are operation of trains and blasting.

In the following summary of the cause table, using the material irrespective of occupation, a number of important deductions are to be found. Using "days lost" as the basis of comparison, it will be noted that accidents caused by machinery, logging trains and falling or rolling objects caused the greatest severity. On the other hand, the use of hand tools and the handling of objects caused one-third of all accidents but only 6 per cent of severity and only 7 per cent of total compensation cost.

In consideration of the very interesting points raised in both Mr. Boyd's and Mr. Marshall's papers, a motion was made by Secretary Barker to the effect that each of these papers be prepared in pamphlet form and distributed to all loggers in the United States. Mr. Barker's motion was seconded and unanimously carried.

Chairman Rhodes announced that the printing and distribution of these pamphlets would be placed before the Executive Committee of the National Safety Council, and should they deem it too expensive for them to undertake, that he as Secretary of the Southern Pine Association would have his organization prepare these pamphlets and see to the distribution of them.

Members present suggested that Mr. Marshall and Mr. Gram be delegated at next year's Congress to deal with the subject of logging on the Pacific Coast and further suggested that representatives from the South and North be selected, and the very interesting matter of logging accidents be thoroughly gone into. The Chairman and Secretary promised to take this matter up with the Executive Committee and see that representation in these localities was on the program for next year.

Chairman Rhodes expressed his pleasure to the Canadian members who had come from their great distance to attend this Congress, and requested a rising vote of appreciation by all members present. This was unanimously endorsed with enthusiasm.

Response in behalf of the Canadian members was delivered by Mr. Lovett, Inspector, Industrial Accident Prevention Association.

Chairman Rhodes expressed his regrets that Honorable T. J. Duffy, Chairman of the Ohio State Industrial Commission, Columbus, Ohio, was not present to deliver the address assigned to him on the subject of "Does It Pay to Employ Safety Engineers in the Woodworking Industry."

Mr. Frank Hawkins, Secretary, Lumbermen's Safety Association, Ottawa, Canada, was unable to attend the meeting and his paper was read by Secretary Barker.

APPLICATION OF WORKMEN'S COMPENSATION ACT IN
CANADIAN SAWMILL AND LOGGING OPERATIONSFRANK HAWKINS, SECRETARY, LUMBERMEN'S SAFETY ASSOCIATION,
OTTAWA, CANADA

It is no longer necessary to apologize for safety work nor to explain what safety work means. It not only counts for the amelioration of suffering—the humanitarian bond of sympathy between the injured and those in a position to help—it counts for increased efficiency in the workshop or mill, and increased efficiency means increased production of better goods for less money, which in the last analysis means a larger opportunity to compete in the world's markets, in other words that "Safety is a paying proposition."

I think every one will concede this to be the case.

The question, therefore, resolves itself merely into one of method: that is, of law and its administration.

When Mr. Price invited me to address you he suggested the subject.

"Accident Prevention in Canadian Woodworking Plants."

In Canada we have our Provincial Workmen's Compensation laws just as you have here in the United States. The Association with which I am connected is the Lumbermen's Safety Association of Ontario. I therefore speak only from the point of view of that Province, and of our particular group, Class 1, which embraces lumbering, sawmills, manufacture of veneer, excelsior and cooperage stock, lumber yards in connection with mills, creosoting of timber, and kiln drying of lumber.

A further explanation is due to you in that our group does not take in Woodworking factories. We have 34 classes or groups of industries operating under the Workmen's Compensation Act of Ontario.

It is reasonable to believe that a comparison of laws and their administration adopted by various states and provinces may be of practical value. This is my apology then for referring only to the Ontario Workmen's Compensation Act and to Class 1 thereunder, in the hope that other papers presented at this Conference may, by inviting comparison and discussion lead to betterment in law and administration.

WORKMEN'S COMPENSATION ACT OF ONTARIO

The Workmen's Compensation Act of Ontario came into effect the first of January, 1915, and at that time could only be regarded as legislation of the most advanced type. It completely abolished common law rights in so far as damage suits for accidents are concerned; it vested arbitrary powers in a commission appointed by the provincial government from whose ruling there is absolutely no appeal. It exempted railways from the operation of the act under schedule one, putting them in a separate class, together with Dominion Telephone, Telegraph and Express companies, Municipalities, etc. The whole cost of awards made by the Commission is payable out of the group funds contributed by each industry. The industries also pay a large proportion of the expenses of administra-

tion. Whether or not this whole subject of compensating the injured is a matter for Federal rather than State or Provincial Legislation is a subject which might easily be considered in the near future.

It is to be conceded that where the bread winner is incapacitated through accident some form of compensation is due not only for the injured himself but in order to relieve suffering and want on the part of his wife and children or other dependents. From the point of view of the workmen, legislation of this character is much to be desired because under the old law he had to prove negligence on the part of his employer, otherwise he had no right to recover damages. If through negligence he contributed to the accident or if he were injured through the negligence of a fellow employee, or had he assumed the risk of the employment he was barred.

Under the old law if the employer and employee did not agree upon a settlement the remedy was an action in court. This meant long delay, annoyance, and great expense to one, or both of the parties, and, with the technicality and complication that prevailed, much uncertainty as to the result. The ordinary workman or his dependent widow shrank from such a proceeding or feared the danger of an appeal, or perhaps had not the money with which to proceed. Upon the other hand employers often suffered from vexatious litigation by irresponsible claimants. Under the new law, with its simple provisions and methods of procedure, settlements are made expeditiously and without expense to either party, and payments go direct to the person entitled.

On the other hand the employer was forced to defend all suits, with the possibility of a Court judgment that might mean practically ruination and the consequent ill-will of both employer and employee. The employer is now relieved from all anxiety on this score as he can neither sue nor be sued for damages.

Representations made by the Lumbermen's Safety Association with regard to the Safety Associations being recognized by the Board as representing the respective groups of employers have been acknowledged, and favorably considered.

The Association has also urged the necessity that an appeal to some judicial tribunal should be had on certain general principles. We do not seek to appeal to such tribunal on the matter of awards made by the Board. This suggestion, however, is opposed by the Board as they are not prepared to recommend legislation of this character.

RECENT AMENDMENTS

A recent amendment to the Act includes clerical employees, and on and after January 1, 1920, their salaries will be assessed just in the same way that the workmen are included. In similar fashion an employer or partner, or executive officer of any company, or a member of his family, if employed by the company, may be covered in precisely the same way as the workman by including a reasonable amount as salary in the pay roll, and so notifying the Board.

Another recent amendment increases pensions for widows and children. On April 24, 1919, a widow's pension was increased from \$20.00 to \$30.00,

with an increase from \$5.00 to \$7.00 for a child, the maximum for all dependents being from \$40.00 to \$60.00 per month.

We have persistently urged against the building up of large reserves to provide for deferred liabilities and the Board has abandoned their former position in this regard. In other words, the Current Cost plan is now practically adopted by the Board. When it is considered that under the Act the Board may assess upon all industries or any one industry for any amount, and as often as the Board may deem fit, the necessity of building up large reserves is not apparent.

Merit rating also is a settled policy of the Board. A workman cannot contract himself out of the operations of the Act.

Medical Aid must be provided for as long as is necessary and an employer is prohibited from collecting any sum from any employee in any way toward medical aid; nor can any doctor collect anything from the workman for services covered by the Act. The employer must also furnish the necessary transportation for an injured employee to the doctor, the hospital, or the man's home. The cost of Medical Aid has added practically 15 per cent to the amount of the assessments.

The gross revenue for the year (all classes) in schedule 1

amounted to.....	\$4,319,439.98
Expenditures	3,474,769.09

Leaving a provisional balance of.....	\$ 844,670.89
---------------------------------------	---------------

The various classes may appoint Inspectors to examine and report on industries within their group, and persistent failure to carry out the betterments suggested by the Inspector renders that industry liable to pay individually the whole amount of any damages awarded, at the discretion of the Board.

Last winter our Inspector visited a number of camps and in addition to ordinary safety work his inspection covered hygienic and sanitary conditions, also first aid to the injured. It is proposed to extend this feature during the coming winter.

In the year 1918, owing no doubt to inexperienced labor, the number of accidents in Class 1, increased to 1,160 as against 975 in 1917. But the number of permanent disability cases was reduced in 1918 by seven and of deaths by four as compared with 1917; leaving 1,069 temporary disability cases in 1918 as against 873 in 1917. The year 1918 was the first full year where medical aid was in operation, there being 212 that received medical aid only—i. e., there was no compensation paid—so that it was impossible to compare this with only part of 1917, when there were only 63 cases in which medical aid only was given.

The average rate (over all industries) per \$100 of Pay Roll for the first year's operations in 1915 was \$1.64 subsequently adjusted to \$1.27; for 1916 the average rate was \$1.09; for 1917, 98 cents which is expected to be still further reduced for 1918. The rates charged for lumbering operations are per \$100 of Pay Roll.

Sawmills	\$1.60
Logging or lumbering.....	1.20

It is claimed by the Board that a full measure of compensation has been provided and every reasonable effort has been made to avoid imposition.

Where work is sub-let the principal is responsible for reporting to the Board and is to see that all assessments are paid, and all returns made to the Board.

In this condensed fashion I have endeavored to carry out Mr. Price's suggestion to give you some idea of the operation and also some of the results obtained in the application of the Workmen's Compensation in the Province of Ontario, Canada.

While industries do not agree with the commissioners on all points it is only simple justice to say that the Board has administered the Act in a fair and impartial manner.

LABOR—CAPITAL—PUBLIC SERVICE .

We are finding out that the safe-guarding of machinery, printing of bulletins, the holding of safety conferences, and indemnifying the injured is not the sum total of safety work. However estimable and just these things may be we must henceforth take a larger view of the human being. Our intercourse with one another now must be on the basis of "Man to Man." The old order has passed away or is rapidly passing. No longer may the arbitrary and overbearing manner of the capitalistic employer or the equally intolerant attitude of the labor agitator be able to hoodwink and deceive. An intelligent and fearless public opinion must enforce the rights of both capital and labor—it will supply the necessary ingredients whereby the wheels of progress may be efficiently lubricated and the great public service be uninterruptedly maintained. This is a great triumph: Labor—Capital—Public Service; and we must fully appreciate that what injures or affects one injures or affects all. We shall learn presently that a closed factory is a public loss, and the employer who interferes with public service by closing his factory must open it again at the public demand; and similarly the human factor must be brought to realize that the threat, "We will get 'ours'—or quit work"—will have to be replaced by something that will keep the workman at his bench, while at the same time giving him a contented mind and a fat pay envelope.

We must cultivate a community spirit between employer and employee—a spirit founded upon the rock of mutual confidence and esteem—every one must feel that the new order of things means justice and the square deal. This, I conceive to be a work for which the National Safety Council is eminently manned and equipped to perform.

Explanations were given by the Canadian members with reference to the Government's working principles of the Compensation Law.

Mr. J. A. Dickinson of the Bureau of Associated Mechanical Engineers of Washington, D. C., was in the room and was called upon by the chairman to speak with reference to the standardization of accident classification. Mr. Dickinson delivered a very interesting discourse as to the Government's plan for this work, and it is hoped that universal methods may be applied for the standardizing of the various elements which enter into

accident prevention work. Mr. Dickinson suggested that steps had already been taken with the manufacturers of woodworking machines with reference to their standardizing guards for their machines, but so far very little had been accomplished.

Mr. Cole of the Southern Pine Association made a suggestion that our section should endeavor to secure uniform classification of accidents. This apparently met with the approval of the members, and the chairman appointed Mr. Cole and Mr. Barker as a committee of two, to investigate and report as regards the manner in which this work is now handled by insurance companies and state departments.

Chairman asked for the report of the committee on resolutions. This report was delivered by the chairman, Mr. F. D. Ensminger, of the Prest-O-Lite Company, Indianapolis, Indiana as follows:

REPORT OF RESOLUTIONS COMMITTEE

We, the members of the Woodworking Section, of the National Safety Council, in Eighth Annual Congress assembled, having given considerable thought and discussion to the Woodworking machines now being used in the industry, are of the opinion

First, that these machines are not built with safety devices sufficient to protect the operator from serious injury.

Second, that because of this serious defect, it is hard to attract employees to operate these machines.

Be it resolved, therefore, that purchasers of woodworking machines specify that such safety devices be attached to and sold with the machine that will give adequate protection to the operator.

And be it resolved that the National Safety Council call to the attention of the manufacturers of woodworking machinery this resolution.

And be it further resolved that the Secretary of this Section be instructed to forward these resolutions together with a list of Woodworking machine manufacturers to the headquarters of the National Safety Council.

Signed—F. D. Ensminger, Chairman
R. W. Patmore
M. L. Henwood

Mr. Gram, Commissioner of Labor, Salem, Oregon, made a motion that a copy of the above resolutions be sent to the association of Woodworking Machinery Manufacturers by the National Safety Council. This was seconded, and unanimously voted to be so carried.

REPORT OF COMMITTEE OF MEMBERSHIP

Mr. Marshall, Chairman, recommends that each member should forward to the Council a list of prospective members. This action is to be taken by the Council and the Membership Committee to be advised of the progress.

Mr. Gram suggested that the National Council send its field representatives to Washington and hold meetings in the various territories which

he feels positive would be an incentive for increasing membership in that territory. General Manager, Mr. Price is to be notified of this request.

REPORT OF NOMINATING COMMITTEE

In view of the very excellent manner in which the present officers have served their particular position, we the nominating committee recommend the reelection of Mr. Rhodes as Chairman, and Mr. Barker, as Secretary for the coming year.

Signed—R. F. Milne, Chairman
Holger Jensen
F. A. Barker

Chairman Rhodes and Secretary Barker expressed their appreciation of reelection and assured the members present that the next year's council will be bigger and better than ever before, it being particularly proposed to have in addition to papers by interesting speakers, picture exhibits of safety appliances and bulletins, and also motion pictures and stereopticon slides.

It is hoped that the membership will be very materially increased, and that the woodworking section will grow to a proportion that will place it in the eyes of the safety world as second to none.

Mr. Marshall mentioned California's accident prevention department's logging film as being of special interest, and suggested that this section endeavor to have the film at its next Congress for review, by the attending members. This will be acted upon as per his request.

Mr. Flysik from the State of Washington gave a very interesting address as to the new move in that state with reference to safety conditions.

Adjournment 12:30 P. M.

Respectfully submitted,

F. A. Barker, Secretary.
