Re: Lead Test Criteria Analysis Survey

Attached you will find the results of a survey we conducted in September, 1964 of individuals in state, city and regional government occupational health administration on criteria for evaluating industrial exposure to lead.

As you know, the analysis of biological fluids for lead, usually blood and urine, as an aid in evaluating industrial exposure is almost universal. However, the wide variety of tests used, as well as the wide range of criteria used for judging the results, has caused a certain amount of confusion when attempts are made to compare diagnostic efforts in one jurisdiction with those made in another. Accordingly, this survey was made in an attempt to provide a better comparison for judging by assembling such information as the types of tests and some of the criteria, or standards, that public agencies are presently employing in their evaluation of lead exposures in industry. The following questions are suggestive of the type of information that was intended to be secured by means of the survey:

- What test (or tests) do you use in the evaluation of industrial exposure to lead?
- What judgment criterion, or standard, do you apply in evaluating the results of these tests?
- Are these test results used in legal (compensation) situations?

A table showing the detailed information received from those responding to this survey is attached, together with a separate general summary of the total response. For your information, the spaces in the table under the heading titled "Tests and Standards Used" that are marked only with an "X" indicate that the respondents reported conducting such tests.

*Look Ahead with Lead*

Lead Test Criteria Analysis Survey

Questionnaire mailed to 61 individuals in state, city and regional government occupational health administration. Respondents totaled 54, including: 39 from state organizations; 3 from county organizations; 11 from city organizations; and one from Puerto Rico.

Thirty-seven respondents reported utilizing blood testing, a majority adhering to the standard of 80 μ g of lead per 100 grams of blood.

Forty-two reported using urine testing, a majority adhering to a standard ranging between 150 μ g and 200 μ g of lead per liter of urine.

Respondents indicating use of neither blood nor urine consisted almost totally of those depending on other associated departments or labs to supply or carry out such testing or who indicated no need for lead testing (e.g. Wyoming, Idaho). While other test criteria are employed, no respondents indicated their use to the exclusion of blood, urine, or both. Such other criteria include: urinary porphyrins - 7 respondents, basophilic stippling - 4 respondents.

Respondents parenthetically indicating use of air samplings to determine lead content numbered 19. Only one reported that it analyzed paint for lead content.

Seventeen respondents indicated that no use is made of their findings in compensation cases. Ten respondents indicated that their findings are used, though they are not necessarily binding, and may be used in a supporting basis in relation to other medical evidence. Twelve respondents reported that their findings are not intended for use in compensation cases, but may be used under certain circumstances.
