Incidentally, I think a word of caution might be in order on safety communications: We must guard against the clever approach which completely obscures the point we are trying to make. There have been examples of this in television commercials . . . notably the Piel's Beer commercials which were very cleverly done. The "Bert and Harry" commercials won numerous awards from art directors and TV critics, but they did not make an appreciable contribution to the sale of Piel's Beer. I think the same rule should apply to safety communications—our objective is to prevent accidents, not to impress employees with our cleverness.

One more point on this subject of cleverness: There probably isn't a safety director alive who doesn't dream of the day he'll coin a safety slogan with the impact and appeal of "The life you save may be your own." I'm sometimes inclined to think our safety efforts today are too wrapped up in slogans . . . that we're too dependent upon slogans as a substitute for a well-rounded, effective communications program.

7. Tell the bad with the good.

This, like most of the other points, I've listed, is a basic tenet of employee communications. We don't like to talk about fatalities; we don't like to show that our frequency or severity rates are on the rise. But we must face these facts of life and communicate with our employees about them. When employees are given a two-color four-page report of a decreasing frequency rate, they're entitled to some form of communication when the rate takes a climb.

Some people shy away from comparative listings of frequency and severity rates. They feel that this makes one plant or one department "look bad" if its rates are higher than those of other departments or plants. It's true, it makes one department look bad in comparison with others. But failure to use these listings is failure to give credit to those departments or plants which are doing better than your company-wide average. In order to give credence to the good, you must also publish the bad.

8. Get employees into the act.

Employees want to feel that they are a part of the company's safety promotion efforts. Poster contests, monthly quizzes, discussion meetings are all part of the employee participation program. At Allis-Chalmers we've distributed silver dollars to employees who could correctly identify the safety "theme of the month," with additional dollars for the employee's supervisor when a correct answer was given, and even dollars for the employees' wives if they correctly answered a telephone quiz on the same theme.

9. Localize the message.

An advantage of monthly safety themes in multi-plant safety promotion campaigns is the volume printing and the resultant lower cost-per-unit of handout materials, posters, etc. This is offset, however, by a big disadvantage—if your monthly theme is electrical safety, the message may be pretty well lost on employees whose work is primarily concerned with material handling, or machining or any number of non-electrical occupations.

To compensate for this flaw, we have gone to a "library" of employee handouts on a variety of subjects. Some are of a

general nature. Some are of a very specific nature, of interest only to specialists in certain phases of our operations. But the result is that our supervisors can order the handout folders they think will be of greatest value to them in a given month. They are not saddled with printed materials on electrical safety while trying to combat accidents resulting from poor housekeeping practices.

10. Spend money on safety communications, but keep your program under a magnifying glass.

Like any other staff function, the safety department is under scrutiny by line people where costs are concerned. An old-line general superintendent is not going to look too kindly on an apparently fussy safety

promotion campaign at a time when he is being asked to cut his department's cost.

On the other hand, it takes money to do an effective job of communicating . . . printed matter, motion pictures, banners and other promotional materials cost money. In addition, employees' time costs money, when it means taking people off the job to view a new movie or to attend meetings and other presentations.

The best advice I can give you here is to forego the flashy materials and concentrate on good, tested communications devices—the employee publications, the posters, the handouts, and the other techniques, which your experience has shown to be effective communications. Be prepared to spend money when you have to, and to justify the expense if it becomes necessary.

SAFETY ENGINEERING—A MODERN CONCEPT

By JOHN J. AHERN

Dir. of Security, General Motors Corp., Detroit, Mich.

- I. You can't steal second with one foot on first:
 - A. All progress involves risk.
 - B. Engineering and scientific progress have raised our standard of living beyond fondest dreams of our forefathers.
 - C. Each new conquest of nature's secrets accelerates industrial activity and adds to the burden of the safety profession.
 - D. Few timid souls
 1. Governors on cars
 2. Restrictions on reactors
 - E. Safety engineering must be ready to meet the challenge
 1. Move forward—we can never stand still
 - F. This means a higher degree of technical competence
- II. Approach
 - A. How does safety engineering meet this challenge?
 1. Education
 - B. Research
 1. Great impetus by ASSE Committee on Cooperation with Engineering Colleges in early 1940's
 2. Joe Stennett, chairman
 - 1) Suggested curriculum—graduate primarily
 3. Conferences with engineering administrators
 4. Schools
 - 1) Illinois Institute of Technology
 - 2) Texas A&M
 - 3) Georgia Tech
 - C. Phenomenal progress—very few engineering schools today without some safety instruction
 - D. Our goal—every graduating engineer safety oriented
 - E. Research
 1. Weakest part of our approach

2. Some improvement but the surface hasn't been scratched
 - Equipment
 - a. Safety shoes
 - b. Wire rope
 - c. Safety goggles
 3. Transportation
 - a. Seat belts
 - b. Highway construction
 - c. Aircraft crash
 4. Industrial
 - a. Very little on ordinary industrial accidents
 - b. Explosion features in ovens
 - c. Exotic fuels
 - d. Automatic Sprinkler Co.—fast acting sprinklers
 5. Accident analysis—lengthy reports on statistics
 - a. How many? — But why?
 - b. Let's not be record-keepers but be analysts
 - c. Statistics are only good if they can prevent future accidents
 - D. Intelligent application of present knowledge
 1. First—what is an accident?
 2. Heinrich "An accident is an event in which (a) the contact of a person with an object, substance or another person, or (b) the exposure of a person to objects, substances, other persons or conditions, or (c) the movement of a person causes personal injury or
- suggests the probability of such injury."
3. Webster: "An event that takes place without one's foresight or expectation, esp. one of an afflictive or unfortunate character; a casualty . . ."
4. Is this modern accident prevention?
 - a. Trim press—new job—old guard—fingers severed?
 - b. Is this an accident? Was it an unexpected event?
 - c. Only unexpected feature—turning!
 - d. Working on machine without locking-out. (same questions above)
 - 1) "Accident" marks our inability or reluctance to think through all the possibilities in an operation
 - 2) Better term: "predictable event"
 - e. Example: high pressure, airless spray guns
 - 1) Potential there from the beginning—good manufacturer — good development — no safety research
 5. Basically we are not doing as good an engineering job as we are capable of—nor are we communicating what we do know to the people who need the information

III. This meeting is an opportunity to take stock and by improving our performance to enhance the stature of safety engineering.

DYNAMIC SAFETY CRITERIA—AN ENGINEERING APPROACH

By WILLIAM A. McADAMS

Mgr.-Industry Standards, Industry Standards Service, General Electric Co., Schenectady, N. Y.

With world tensions at the peak they are today it may be a little difficult to focus our attention on the dream world of the future. But that is what I would like to do. I would like to paint a picture—a picture which may seem more like a fantasy

than anything else—but a picture which I believe will be a reasonable facsimile of our world of the next generation.

Most of us will be in this picture—probably in retirement—and we will have some trouble recalling just how things were back in 1961, because our whole pattern of work and play will be completely changed.

Our homes will be masterpieces of convenience with replaceable walls, luminescent ceilings, wireless appliances and completely automatic temperature, humidity and ventilation control. We will wear disposable lounge and work clothes and use ultrasonics to wash our fancy clothes and dishes. We will have specially processed foods in concentrated forms which will be cooked in minutes by electronic ovens.

Our morning mail will contain letters written only moments before and transmitted electronically to a neighborhood message center. Guided missiles will provide us with almost instantaneous transport of packages and freight.

Guided missiles will also replace our jets for long distance passenger travel. We will solve our local transportation problems by personal land-sea-air vehicles that can be keyed to automatic routing systems by dialing the point of destination.

We will be well on the way to controlled climate. This will be accomplished through the development of methods for retaining or dispersing the heat of the sun. We will harness the winds, the waves, and the tides.

Atomic energy will become our chief source of energy and we will use it for all forms of transportation. We will have compact atomic power plants in our homes and factories. We will also develop new sources of energy and methods for direct conversion of one form of energy into another.

Advances in medical science will all but eliminate the major diseases such as cancer and heart disease. Better and more complete medical records plus data processing equipment will make it possible to diagnose and prescribe treatment for illnesses with greater accuracy and more effectiveness. New techniques for handling injuries will reduce fatality and permanent disability rates.

Our progress in plant chemistry and biology will be equally spectacular. New fer-

tilizers and growing techniques will permit us to harvest huge crops from small areas in shorter growing cycles, and with a variety of substitutes for soil. We may even find a practical biological or biochemical generator to produce energy, food, and raw materials simultaneously.

As we continue to use up our natural resources we will be faced with all kinds of shortages in materials. We will solve these problems by new synthetics and, eventually, by modern alchemy in which we change basic elements to others of our choice by transmutation.

Maybe these predictions of things to come seem like delusions, but almost all of them are known to be technically feasible right now, and many have already been demonstrated at least on a small scale. Maybe we won't accomplish it all in the next generation, but the chances are good that we will do this and more besides.

It would be nice to say this wonderful world of the future will be devoid of safety hazards. Much as we would like this to be true, it is not a very likely prospect. Nevertheless, if we make our safety criteria as dynamic as our technology, every year ahead will be safer than the previous one.

Now, what do we need to do to develop the kind of safety criteria that will enable us to keep abreast of these rapid changes in technology?

Few men in the past have had the sagacity to see the scientific and industrial growth that was immediately ahead of them. As a result, advance planning has rarely been adequate even for relatively short periods, and we have grown accustomed to a constant race to keep up with the times. In this respect the performance in safety has been no better than in any other field.

Therefore, we must be future-minded. We must know where science is leading us and we must understand the fundamental principles involved. It is obvious that none of us can become expert in all of the many scientific disciplines, but we can learn enough about the new developments to visualize their future applications.

Once we have a basic understanding of the new scientific developments we can then begin to recognize the potential hazards of the future. The world I have described will be full of new materials, strange phe-

nomena, and unnatural forces of all kinds. There will be new poisons, new irritants, new noises, new vibrations, new radiations and new traumatic hazards which we will have to identify and deal with. We will have to know how the human body will react to each of these changes in environment before we can prescribe the proper criteria for safety. The earlier we comprehend the hazards of the future; the sooner we can prepare for them.

Safety is no longer an "after the fact" proposition. We used to pay little attention to hazards until someone got hurt. Later on it became common practice to seek out the hazards and to find the best ways to keep people from being injured by these hazards. Under this kind of a safety program the emphasis was on personal protective equipment, safety training programs, and special devices added to facilities and equipment after they were installed. There was little real safety engineering.

Now this situation is beginning to change. We have started to "blueprint" our safety. Consider the atomic energy industry as an example. From the very beginning, the scientists and engineers recognized the hazard of ionizing radiations and took them into account in all of their plans. Not only did they design the reactors to be safe during operation, but they provided built-in maintenance equipment and emergency devices as well. They also planned for safe disposal of wastes and for safe handling and processing of the radioactive products and by-products removed from the reactors. This philosophy of engineered safety has continued throughout the expansion of the atomic energy industry and it is the primary reason why there have been so few radiation injuries in the industry.

Our rapid growth in technology will give us tremendous opportunities to have "blueprint" safety. The technology itself will furnish us with unlimited new safety techniques which we can exploit to the maximum as present facilities and equipment become obsolete. Furthermore, the automatic systems of the future will be ideally suited for built-in safety devices.

This trend toward blueprint, built-in, safety does not mean that we should discontinue all of our traditional safety meth-

ods. We have only to picture the U. S. astronauts, Alan Shepard and Virgil Grissom, to recognize that the best of built-in safety will not always be enough. Shepard and Grissom were provided with quite a collection of personal protective equipment and were given thorough training for every conceivable hazard they might encounter. There is no question that personal protective equipment and training will continue to be important parts of our safety programs, but they will become, more and more, a second line of defense.

As far as protective equipment is concerned, most of that in use today will have wide application for many years ahead. However, some items will have to be redesigned and made more efficient. For example, I can see quite a need for respiratory masks in the next generation, but they will undoubtedly have to be equipped with canisters for different kinds of dusts and poisons than we have now.

Also if we can believe our space researchers, face masks may have to be designed for beards, because spacemen may not be able to shave. According to the experts, shaving soaps will harm the bacterial digestion system of the space ship and whisker fragments from an electric razor will create a major dust problem. Of course, there is a good chance that our expanding technology will solve this problem with a way to keep whiskers from growing.

There is one great pitfall in all of this talk about the novel and unusual hazards of the future. If we are not very careful, we will become so involved with the glamorous new problems, that we will overlook the familiar hazards that have plagued us for generations.

For example, every year 18,000-20,000 persons in the United States are killed by falls. The frequency rate has declined slightly over the years but the total deaths from this cause is about the same as it was half a century ago. It is also interesting to note that, in the atomic energy industry which I discussed a moment ago, more people are injured by falls off ladders than by the radiation which has been given so much publicity.

Thousands of other people are killed each year as a result of burns, suffocation, drown-

ing, falling objects and other accidents common in everyday living and largely the responsibility of the individual. Life in the future may be more comfortable, but many of these same hazards will continue to exist. So in the technological growth ahead, let us be sure to give attention to the commonplace.

One of the most difficult problems in establishing safety criteria is the determination of acceptable risk. Some persons will insist that we are never justified in taking any risk which may result in loss of a single life, but it is obvious that a world predicated on this philosophy would not only be stagnant, but it would be less safe at the same time. On the other hand, we are not justified in taking a risk if there is a practical way of avoiding it. It requires considerable good judgment to decide what is practical, and time and cost are probably the most important factors involved.

Let us consider the hazards of electricity as an example. Every year about 1000 persons in the United States die as a result of electric shock—a death rate of about 0.5 per 100,000 population as compared to about 21 for automobiles, 10.5 for falls, 3.6 for drownings, 1.3 for firearms, and 0.6 for poison gases. This is truly a remarkable safety record when we consider the extent to which electricity is used in the United States.

But are we willing to accept this death rate as an acceptable risk for the use of electricity? The answer is not a simple yes or no. We are constantly eliminating electrical hazards but we are also constantly expanding the use of electricity with more applications, higher power levels, and greater distribution of electrical equipment. The death rate has been going down, but we may soon reach a point where a further reduction can be achieved only by a significant increase in cost of electrical products and services, or by a delay in promising new electrical advances. In this case, the public will consider the alternatives, and decide if the risk is worth taking.

In our pursuit of the invisible and the unknown, the determination of acceptable risk will become extremely complex. We will not always be able to perceive the hazards, and we may not even be sure that there are tangible benefits ahead. There

are bound to be disagreements as to whether risks in a particular situation are justifiable, but I think we must accept the fact that we will have to take some risks—even some blind risks—to make any substantial amount of progress. After all, our aspirations for the future lie in our investigations of the things we do not understand now.

I am not suggesting that we plunge ahead carelessly without any regard for hazards. I think it is rarely necessary to do that. The first nuclear reactors were built for military purposes at a time when the country was at war and at a time when there was a good chance the enemy might produce an atomic bomb before we could. This was a case where we had to be first—and we were. But we were first—and safe—at the same time.

I believe that we can achieve most of the wonders of the future with no more risk than we have taken in the atomic energy field, but there will be situations where it will not be possible to do this without intolerable delays. The promising world of the future will surely be a safer world and we can afford to take a few short cuts to get there.

Now I have described a fantastic world for the next generation and I am convinced that we have an excellent chance to make this amount of progress. Several years ago David Sarnoff, the well-known chairman of RCA, made the statement that our technological achievement during the last 100 years was greater than in all the thousands of years that preceded. Certainly we should expect an equivalent achievement in the next 20 or 30 years, for knowledge breeds more knowledge and growth in knowledge is a geometric progression or more.

In the face of this progress we must reappraise our whole safety effort. In the course of doing this we must be future-minded and comprehend the hazards of the future.

We must blueprint our safety, but in doing so, we must not abandon our old-style safety, and we must give attention to the commonplace.

Finally, throughout all of this we must develop a proper risk philosophy.

If we do these things, our safety criteria will become as dynamic as our technology and we will be able to survive our progress.

MECHANICAL ACCIDENTS

By ROBERT P. BARROWS

Safety Dir., Underwood Corp., Hartford, Conn.

We do make progress in the ever-present war against industrial accidents, but slowly! Take for example the case of germ warfare. It was right after World War I when we first started hearing reports from the scientists about germ bombs which could annihilate an entire city's population through pestilence. With each passing year, the science prospered and the threat grew worse. Yet, despite all this progress, even today we are faced with germ warfare in only one area; on the screens of our television sets.

I have been able to develop some information concerning mechanical hazards at Underwood Corp. in Hartford which I believe you will find helpful.

The accidents we are going to talk about will all contain an unsafe mechanical condition, but will often be augmented, or even triggered by a thoughtless action, an unsafe act, of an individual. It is well to keep in mind that substantially 88 per cent of all industrial accidents arise from unsafe acts and about 11 per cent from unsafe mechanical conditions. . . . By eliminating the mechanical hazard, we not only prevent the 11 per cent but make important inroads into the 88 per cent caused by improper acts.

For the purpose of our talk this morning, I would like to break down mechanical accident situations into five categories. First we will discuss the "point of operation" accident, then, those associated with machine set up and repair; next "power transmission" accidents, those arising from materials handling and storage operations, and finally "process control" injuries.

Now, as we talk about these five areas of mechanical accidents, we will be talking about guarding a great deal. Guarding is in many respects like the industrial engineer's "one best method." Those with an I.E. background know that there is really no such thing as the one best method. Any method is the best one only until a better one can be found. Omniscent perfection is unobtainable in methods work. The same is

true for mechanical guarding. There is no such thing as a perfect guard, nor is there any guard that cannot be improved upon.

In developing any guard, we first look over the work place, watch the operation, study the machine tool, look for the hazards and then determine mechanical means of minimizing them. But this is only the very first step. Improving that guard means calling on all of the talent available for improvement. The next man that comes along to look at your idea may have just enough of a different outlook to come up with a substantial improvement. So never become over-sold on the ultimate superiority of your own guards.

Now let's look at some examples of the five types of accidents and see if we can develop some general rules from the specific solutions offered.

Specific Examples

As I mentioned, the first example will be concerned with "point of operation" accidents. Our first case deals with a drill press injury, more specifically, burr removal using free hand methods. In all metal working operations, it is generally necessary to remove the accumulation of flash or excess metal which builds up on the far side of a punched or drilled hole. Such de-burring jobs are usually very fast light operations where only a minimum of effort is required to break the burr. Often it becomes desirable to hand-hold the part as it is brushed against the working surface, rather than going to the cost of locating it in a fixture each time. In this particular injury, however, a common twist drill was being used as a burring tool. The part caught on the drill, tore out of the operator's hand, spun one revolution and struck the back of her hand.

Injury in this case resulted in lacerations and contusions to the middle and ring fingers of the left hand. Various solutions are available to prevent recurrence. Dial or automatic feeding of the parts or special fixturing of the part might be feasible

depending on production costs. The cheapest and easiest way would be to use a safer tool. Use of a sleeved drill, a burr, or a Weldon tool would maintain high production rates and yet protect the operator.

The next accident involves milling cutter guarding and two-hand controls. Actually there was no accident here but a "close call" incident was reported by a time-study observer. Here the operator was running a two-sided miller. The first piece was loaded on side A, the fixture jaws were closed mechanically and the milling cut started, thus automatically opening side B where the operation was repeated. Because of the single switch used to activate the machine, it was felt that greater safety was needed. As a result of the investigation, full enclosure guards were developed, and two-button control was substituted, requiring that both hands be out of the machine before it could be activated.

As a result of this change it was no longer felt necessary to stop the machine after each cut, and as a bonus for this improvement, an 1100-dollar per year savings in production cost was realized. The company fared well here in terms of a reduction in the cost of operations. The operator fared even better, inasmuch as this task was made less fatiguing and also considerably safer, thus reducing the level of tension.

The next example concerns non-standard operations of a power brake. This improvement came as a result, not of an accident, but of a potential accident turned up by an inspection committee. Here the operator was cutting steel strip stock to various predetermined lengths, using the single start button furnished by the manufacturer to activate the shear. Because of the varying nature of the stock in terms of width, thickness and length of cut, barrier guarding became very difficult. The guarding requirement was for relatively universal application, easy set-up and low cost. Such guarding requirements are not unusual.

Many safety directors find themselves faced with the proposition that 85 per cent of company profits are derived from about 15 per cent of the tooling. These tools are usually high performance multi-stage tools which can absorb relatively high costs for proper safeguarding without budgeting diffi-

culty. The problem arises with the much larger number of low production tools. Some of these tools may make a contribution to gross earnings of only five to fifty dollars per year. Yet they must be retained in the line because of customer demand, need within the product, or other reasons.

Here guarding becomes a more difficult problem from the financial standpoint. It is unprofitable to spend 250 dollars to guard a tool which possibly contributes only 25 cents to net profit. This is where the universal guard comes into play. Such a device would be permanently attached to a machine, not a tool. It can be rapidly re-adjusted as various tools are placed in the machine. A type of universal guard proved to be the answer to this power brake problem. Attaching a pull-out device to the lever arm of the brake, which was connected by wristlets to the operator's hands, it was possible to maintain an adequate degree of safety without a profit-cutting investment in hardware.

Machine Set-Up and Repair

Our next area of discussion is machine set-up and repair operations. Here we are getting away from the very repetitive easily guarded operations, but rather a collection of very unrelated tasks. However, by studying accident trends, we see that injuries here result from rather similar portions of activities. Take for example the screw driver that slips and causes a laceration of the hand. We see this injury cropping up time and time again. Generally, there is no injury or at least no serious injury. But each time, it happens because of the same two causes. First, the screw driver did not properly fit the slot. Secondly, the operator was not sufficiently aware of application of pressure and safe placement of his other hand or body part.

Preventions here can be obtained by:

- 1) Regular inspection of screw drivers for condition and training of screw driver users in proper fit, and
- 2) Development of risk awareness in the use of a screw driver.

The first goal could be much more easily attained if there were specific standards to work to, but unfortunately, although the screw driver is probably the most common hand tool in daily use by millions of our

citizens, there is not an accepted standard at the present time governing the width of screw slots or the dimension of screw driver blades.

The next accident concerns the use of an adjustable wrench. Here the wrench slipped while the operator was tightening a bolt, causing his finger to strike a sharp edge. In this case the result was a serious abrasion and contusion to the right little finger necessitating several days' lost time. The solutions to the problem are several.

First, special purpose tools, such as end wrenches, rather than adjustables would eliminate the mis-adjustment problem. However multi-purpose tools certainly have their place. The requirement is to properly indoctrinate the need for accurate adjustment and maintenance of condition. The second requirement is training in the proper use of tools, so that pressure is exerted in the direction of the shank rather than outwards from the jaws.

Power Transmission

Next we come into the area of guarding shafts, spindles and other power-transmitting hardware. The first example concerns the guarding of powered rindles on drill presses. Currently most of these machines are being built so that most revolving and reciprocating parts are pretty well guarded at the factory. But many machine tools in use today are far from being new. Also adaptations to special use require removal of the furnished guards. Consequently, a potential for hair and scalp involvement injury is developed.

I am happy to be able to say that a search of our records showed no recent injuries that the guard was designed to protect against. Hair nets, of course are another possible answer to this type of injury, but we have found that they are quite unpopular and therefore it is difficult to maintain 100 per cent enforcement. We find it is easier to remove the apple from the Garden of Eden, rather than to hang up a sign saying "Do Not Eat."

The infedding end of power roll conveyors always poses potential hazard if unguarded. On a floor conveyor used for removing cartons of finished machines, we discovered, following installation, a point where a foot could be inadvertently placed and drawn in under the conveyor. Installing

a steel shield was quick and inexpensive. It did not interfere with operation in any way. Yet it meant the elimination of a potentially serious accident which could have occurred at any time.

Material Handling and Storage

Our first example in the area of material handling involves the loading of a trailer truck. Here gravity fed sections of a portable conveyor were set up inside the trailer to facilitate the loading of finished machines. The operation was safe in all but one instance. The regular dock board used to bridge the small space between the platform and the truck had been temporarily removed. A make-shift piece of boiler plate was obtained and used in its place.

After completing the loading, the operator forgot the makeshift condition. He backed out dragging the last section of conveyor with him. Since there was no curb on the boiler plate, he missed his footing and stepped off into air between the truck and the platform. The space was only about eight inches wide. His leg slid down its full length and the conveyor landed in his lap. He suffered from very painful strain to the groin and abrasions to the thigh and stomach. A more proper awareness of the danger of make-shifts would have made this trip unnecessary.

Storage of grinding wheels can become a delicate problem. At Underwood, many of our tool grinders like to maintain their own inventory of grits and shapes of wheels dressed to their own particular "feel" or taste. This is socially desirable, since it contributes to pride of workmanship. However, storage of these wheels at the workplace can constitute a problem. If they are not carefully protected against shock, cracks can develop which can cause a wheel to explode when it is started up.

Consequently, special storage racks were developed for each tool grinder so that safe storage could be maintained. These racks, of course, do not reduce in any way the need for the other grinding safe practices, such as the use of front guards, vision shields, safety goggles, and the need for "ringing out" a wheel with a wood mallet prior to each installation.

The third item under material handling concerns an operator who was checking out an overhead conveyor on a trial run, prior

to installation of the guarding. He moved under a descending section of conveyor to more closely inspect the action of one of the moving carriers. While thus preoccupied, the next carrier came along and struck this maintenance man lightly on top of the head, causing him to lose his balance, fall against the wall and onto the floor.

This was not a serious injury in itself. In fact it was hardly more than an incident. But it served to put everyone concerned on notice of the potential hazard of even temporarily unguarded conveyor.

Control-of-Process Type Operations

We next come to the area of process type operations, such as electro-plating and heat-treating.

The first case concerns the handling of highly corrosive acids in carboys. For many years, we have been purchasing our sulphuric and nitric acid in wooden cased glass carboys. No unusual incidents had been reported until one day we heard that a trucker, while setting a carboy down from his hand truck, heard the glass begin to crack. He stepped back away from the acid so that the only loss was from parts and equipment damaged by the acid and time spent in clean-up. However, a cursory investigation of alternate methods turned up a new piece of equipment which could prevent a repetition with more serious results: a polyethylene liner contained in a steel drum. This new type of carboy makes possible better handling methods and more efficient storage with no added cost and, most important, no potential breakage.

Conclusions

We have now seen the specific examples. What can we develop from these in the way of general rules? I would like to suggest the following, starting with the simplest possible rule, and proceeding to the more complex:

- A. Change the Operation
 - Eliminate the job
 - Alter the part design
 - Change the method of performance
 - Improve the job layout
- B. Improve the Tooling
 - Automatic parts feeding (vibration, air, etc.)

- Improved loading devices
- Better handles on fixtures
- Easier nesting
- Reduced cutting surface
- C. Keep the Operator's Hands Out
 - Remote feeding devices (dual, slide, chute, automatic)
 - Barrier guards (covers, duckboards, etc.)

Two hand controls

D. When Guards are Necessary

1. Make them simple and cheap. The fewer the parts, the fewer the failures. Obvious purpose discourages misuse.
2. Let them help the operator. They should not make the job more difficult or awkward.
3. Don't build in booby traps! Avoid additional pinch points such as machine part that closes on guard when cycled, or hole between truck and platform.
4. Design them to be fail-safe. Plan for one in ten thousand or one in a million failures. Design guards so the operator is still safe when the failure occurs.
5. Plan two independent mechanical or other devices. Require simultaneous failure of both to result in incident.
6. Keep up the good work. Use the three "e's" of safety, engineering, education and enforcement. Once the guards are developed, (engineering) and the operators are taught their use (education), be sure to take advantage of the third "e" (enforcement).

Summary

Safety only starts in the safety office. Desirable follow-through requires effort on the part of everyone. Make sure that you are taking full advantage of all of your allies in the accomplishment of the safety effort. Some of your allies will be found in the line, for example the plant manager, the foreman, the set-up man or mechanic and most important, the operator himself.

Utilize fully the available staff organization. Such specialists as the time study or methods engineer, the tooling engineer, the

tool maker, and the machine repairman, even the janitor, can make invaluable suggestions to improve the safety effort in terms of better guarding. Just as the twelve Disciples were fishers of men, a good safety coordinator is a fisher of ideas to make operations safer.

You can never afford to have the superior attitude which says, "Joe, with his routine

job and low I.Q., sure can't tell me anything about doing this job." Maybe Joe, from his vantage point has made the one observation necessary to turn a good guard into an excellent one. Take the time to listen to the people that want to tell you something. It never hurts to give people recognition, and their advice will help you in avoiding the safety head-boggle.

REVIEW OF SIGNIFICANT ACCIDENT CASE HISTORIES, ELECTRICAL ACCIDENTS

By HERBERT J. METZGER

Safety Dir., Orange & Rockland Utilities, Inc., Nyack, N. Y.

Electrical accidents occur in many varieties, some of which are spectacular, most are not. This talk could have been made very interesting by describing and picturing spectacular high voltage accidents and their results. This type of accident and exposure is confined principally to a comparatively small part of our population, utility men and others who deal with these voltages.

We are here not to be shocked or entertained but to learn more about the business of preventing injury and death. We must therefore deal with the type of accidents most likely to occur to the greatest number of people. These are not spectacular but the results can be deadly.

The daily use of millions of appliances by practically every man, woman and child in the country produces a field of exposure greater than that of the automobile. It is a compliment to the built-in safety of these appliances that the death rate from all electrical accidents, including high voltage, is only about one fortieth of that caused by automobiles.

In spite of this inherent safety, misuse of appliances and ignorance of the characteristics of electricity can be the cause of accidents.

As I do not know the extent of your familiarity with electrical behavior, I must assume that in an audience of this size, it will range from complete understanding to none at all.

I hope therefore that I may be given the liberty of departing from technical accuracy in order to try to make certain points clear.

Electricity is a form of energy and as such it will perform work, useful or destructive. A hammer will drive a nail or smash a finger, electricity will drive a motor or cause destructive effects in the human body. It is all a matter of control.

Unlike most other forms of energy, it is not perceptible to human senses at a safe distance so we must assume that certain equipment and wires possess an electrical charge or potential.

The earth is considered to be at ground potential and we can think of it as a receptacle for electricity, with unlimited capability to accept electrical current from any source of higher potential. We should consider any conductor of electrical energy to be at higher potential than the earth.

Electricity is kept within safe and useful bounds by insulation or isolation. When insulation fails or contact is made with another conductive body, that body becomes charged or raised to the potential of the conductor. If it is also connected to some body of a different potential, the earth for instance, a current will flow.

This is what happens when a fault occurs in an electrical appliance. The frame of the appliance becomes charged and a person holding it, and at the same

time in some manner electrically connected with the earth, as for example through plumbing will form a conductive path and receive a shock.

Let us look at a few such accidents. First, a case history taken from an insurance company file. The victim was engaged in installing sheet metal covering over the lagging on a pipe at a power station. He had been working from a wooden scaffold but had shifted to a sitting position on an eight-inch steel pipe. It was a hot day and it is probable that his clothing was damp from perspiration. An electric drill, one-quarter-inch capacity, was handed to him by another workman. He put it in place to drill and pulled the switch trigger. Sparks flew from the drill and the victim stiffened. A co-worker pulled out the extension cord and lifted the victim back to the scaffold. Artificial respiration was started at once but was ineffective.

Upon examination after the accident, evidence was found that the bushing which normally took the strain of the cord was broken and had been ineffectively repaired. The strain thus transferred to the binding screws probably pulled one of the power wires loose, causing it to make contact with the drill housing.

This drill was fitted with a three-wire cord with the green grounding wire properly attached to the case. After the accident, this wire was found to have broken off at its connection with the case. This probably occurred when the drill fell after the accident.

The three-wire cord was properly connected to a three-wire grounding type male plug. The three-wire fifty-foot extension cord was equipped with a three-wire female receptacle at one end and a three-wire male plug at the other. It was plugged into a three-wire grounding receptacle.

Why then did this accident occur? Closer examination of the extension cord revealed that it had been lengthened by splicing twenty-nine feet of two-wire cord into its middle, leaving the green grounding wire open for that distance. Had this grounding wire been continuous the potential on the faulted drill case would have been reduced to a safe level and the

circuit fuse would have blown, cutting off the current.

It was a clear case of safe and proper equipment being made deadly by poor maintenance and makeshift alterations.

Case number two, from a newspaper clipping. A young man was electrocuted while operating an electric drill in a church under construction. He was standing on the top rung of a ladder, supporting himself by hooking his arm over a small metal I-beam and brought the drill close to his arm. His employer, standing on the floor, said he saw a blue flash and heard the youth scream. He pulled the plug of the drill and the victim fell off the ladder into his arms.

The coroner said that the self-grounding device on the drill may have been circumvented by the way the victim was holding it. He also said the tool worked perfectly on later examination.

I mention the coroner's remarks as typical of uninformed investigation. This tool must have been faulted, and could not have been properly grounded, which is frequently the case on construction jobs. Further, a faulted drill, isolated from the ground, may still operate perfectly. I wonder if this drill is still in use, waiting for another victim.

Here is a somewhat similar case. A man was doing some alteration work on his house, in the course of which he was installing a four inch sheet metal duct in an attic room. His wife on the lower floor heard his electric drill running and became curious after several minutes as to why the drill should be running so long without any sound of other movement. She investigated and found her husband stretched across the attic beams, the running drill still in his hand. She pulled the plug and called for help but her husband was dead.

This accident may be reconstructed from the evidence found.

On test, the drill was found to have a very high resistance fault from the windings in the case. There was no third, or ground wire, attached to the frame. It is not known how long this fault had existed as the tool could have been used indefinitely in this condition so long as the case and the user remained isolated

from ground. Working in the attic on a wooden floor, he might have been considered reasonably safe even with the faulted condition of the tool.

There was a slight burn on the tip of the drill and another on the duct, which was grounded. This would indicate that he had attempted to drill a hole in the duct and a small flash occurred causing him to pull the drill back quickly. Being in a kneeling position, he was thrown off balance and grasped the duct for support, forming an electrical path from the drill case to the grounded duct. It was hot in the attic and his perspiration lowered his skin resistance to a minimum. He had a small second degree burn on the palm of his right hand.

The exact nature of the fault in the drill was not determined but could have been from a loose strand of wire, insulation breakdown or even a drop of perspiration in the right place.

Another clipping relates that a woman using an electric massager in a bathroom was found dead on the floor near the sink. Another faulted appliance and a grounded victim.

Illustrative of a fairly common type of accident is this description. The victim was found in the bathtub. The coroner said that she had probably plugged in an electric razor and was holding it in her hand when she leaned over to feel the temperature of the bathwater. The force of the resultant shock caused her to fall into the bathtub. She apparently then dropped the razor into the tub and was electrocuted.

We hear once in a while of a person being electrocuted when an electric appliance such as a heater or a small radio falls into the bathwater. You may perhaps wonder how this can happen when the water is already grounded. The truth is that a bathtub is a glass-lined vessel and therefore is insulated. The only grounds are the drain and plumbing fixtures. An appliance dropped into one end of the tub charges the water, causing a flow of current to the drain fitting at the other end. If there is a person in that water, part of the current will flow through his body, perhaps enough to be deadly.

I have one more clipping, this one associated with higher voltage. Two accidents, resulting in three fatalities were reported in this article. Both were crane contacts. In the one case "authorities reported that both men were tossed from the cab by 2400 volts of electricity." I find this hard to believe as it is rarely that the man on the crane is injured unless he tries to get off.

The resistance of the machine, upon which the man is riding, is usually so low as to form a protective bridge around him. If he tries to get off, he will probably become a conductor between the charged machine and the earth. Even if he jumps off, which is the safest way to leave, there is the possibility, in some cases, of receiving a shock from two points of contact on the earth itself. In the other case, police said DeBouno jumped into a length of sewer pipe being lowered into an excavation and grabbed a steel cable attached to the crane.

"The crane came in contact with an overhead power line and the electric current passed through DeBouno."

The information given here is very sketchy and an accurate analysis is not possible. We can only know that all three men in some manner became conductors between the charged cranes and the earth.

Important lessons can be learned from a study of these accidents.

A very small current, as low as fifty milliamperes, may kill.

Practically the entire electrical resistance of the body is in the outer layer of skin. This resistance is very high when the skin is dry and cold and very low when it is warm and moist.

Under conditions of low skin resistance, and good contact, a potential as low as fifty volts could cause death. Low voltage contacts resulting in a small current through the heart muscles may result in ventricular fibrillation and almost certain death.

The belief that electricity takes only the path of least resistance can be deadly. Electricity will follow all conductive paths from one potential to another in direct relation to the conductivity of each.

A properly connected protective ground-

ing conductor can reduce the potential of a faulted appliance to a safe level and may cut off the current by blowing a fuse.

What protective measures can we take? All electrical equipment should be kept in top condition by frequent inspection and skilled maintenance. Extension cords and makeshift portable lights should receive particular attention. Makeshift wiring and repairs should be avoided not only because of the danger of shock, but also because of the fire hazard involved. All non-current carrying parts of fixed electrical equipment should be grounded through a low resistance grounding conductor.

All portable tools and appliances, particularly if used in damp locations, should be equipped with three-wire cords and a grounding-type plug.

Extension cords for use with such appliances should be three-wire, with ground-type plugs and receptacles. All new installations or replacements of receptacle outlets should be the grounding type. In locations where portable tools are likely to be used, such replacements

should be made at once. If necessary to use as an adapter to a two-wire receptacle, the grounding pigtail of the adapter should be firmly attached to a good ground.

Generally speaking, the bathroom is no place for electrical appliances. When used, bodily contact with plumbing fixtures should be avoided and no electrical appliances should be touched while in the tub. Some appliances such as electric razors cannot readily be grounded. These are usually encased with non conductive materials. This protection may be lost if the appliance becomes wet.

Isolating transformers with six or twelve volt output are available for portable lights in wet or otherwise hazardous locations and should be used where much work of this sort is done.

Never permit your body to make contact with two electrical conductors or with an electrical conductor and any conductive object connected with the earth.

Modern electrical appliances and tools are safe when properly used and maintained.

SAFETY IN MULTI-PLANT OPERATIONS

Presiding: LEWIS R. MORRISON, Corporate Mgr.-Safety, ACF Industries, Inc., New York City

MULTI-PLANT SAFETY ADMINISTRATION WORKSHOP

ROBERT H. ALBISSER, Safety Mgr., Merck Chemical Div., Merck & Co., Inc., Rahway, N. J.

FRANK R. BARNAKO, Mgr., Compensation & Safety Dept., Bethlehem Steel Co., Bethlehem, Pa.

JOHN A. O'DONNELL, Mgr.-Ground Safety, American Airlines, Inc., Flushing, N. Y.

DMITRO A. PATRICIAN, Administrator, Accident Prevention & Safety, Radio Corporation of America, Camden, N. J.

Morrison: The Multi-plant Program at the National Safety Congress started about 1954. This is either the seventh or eighth session. Don't be surprised at the infor-

mality—panel members sometimes ask their questions of the audience. Mr. Albisser will begin with a discussion of the problems of measurement.

Albisser: We must measure our safety performance to know how much to budget and how we are performing. (At this point Mr. Albisser turned to the blackboard and presented figures showing a hypothetical company's compensation and medical expenses, including the insurance company loading, fire damage (again showing the insurance company loading), and off-the-job injury expense. This he compared to the industry average. He pointed out that the costs of safety administration should be added to one's own company expenses before comparing to the all-industry average.

Barnako: A program that is effective across the board is what is wanted—one bad department or one good one can change the total result and distort the picture. We have a plan of evaluation which we use to size up the effectiveness of distant operations. Here are the main points of the plan:

1. Safety meetings.
2. Indoctrination of new employees
3. Personal contact.
4. Job safety analyses.
5. Personal protective equipment.
6. Tools and equipment.
7. Accident investigation.
8. Reports and statistics.
9. Signs.
10. Inspection.
11. First aid training.
12. Gas training.
13. Safety codes.
14. Safety literature & posters.
15. Equipment & process developments.
16. Outside contractors.
17. Off-the-job.
18. Forms.
19. Office safety.

Some of our men who travel and rate plants use a chart which gives an arbitrary rating showing four grade levels from "good" to "poor."

Others use a more subjective type of report. They submit a verbal statement of what needs attention. These reports enable me to understand what is going on and get behind the frequency and severity figures.

O'Donnell: We have more than 23,000 employees from coast to coast who work in

a variety of types and sizes of operations. They all claim to be unique. However, we believe there is one thing they have in common—safety is a management function. I once heard a manager tell the supervisors under him that he had been refused a raise because his safety record was bad, so no raises were in prospect for the supervisors themselves until their record improved.

We use safety contests in the different operations in which the units either compete against their own previous record or on a point system.

We believe our main job is to supply technical assistance and a "needle." This is the best way to get local management to do its safety job.

Patrician: We sometimes have noticed a breakdown in communications. We have had this situation: a safety man complains that he has no support from management. The same management of which he complains asks "what more can we do?"

To bridge this gap we require a progress report prepared quarterly. This report shows:

1. Accident trends—a clear and accurate picture.
2. Outstanding accident causes—it provides target areas and focuses attention where the attention will do the most good. Some reporters have a tendency to list too many causes as "outstanding."
3. Include accident costs—let management know what accidents are costing.
4. What is being done to control exposure.
5. Obstacles preventing progress.

We give these instructions to reporters on how their reports should be prepared:

1. Make it brief.
2. Submit it periodically.
3. Exclude irrelevant matter.
4. Include exhibits.
5. Summarize the contents.

QUESTIONS

Q. to O'Donnell: How is the pay raise withheld from a supervisor who has a bad record?

Answer: The manager considers the safety record as part of operating efficiency. This is not a company-wide policy. It is not formal.

This questioner then directed the same question to Mr. Albisser.

Albisser: Our company has incentives. Safety is a factor in the appraisal of performance, and this is a well known fact in the company.

Q. to Albisser: Are your costs allocated to the branch plant?

Answer: Yes.

Q. to Albisser: Is equipment (such as sprinklers, etc.) part of your safety administration expense?

Answer: No.

Q. to Albisser: Do you pay the entire cost of off-the-job accidents?

Answer: Some of our off-the-job accident victims get full pay and others get $\frac{3}{4}$ pay.

Q. to Entire Panel: What is being done to develop a serious injury index?

Barnako: We are using it.

Albisser: We are using it.

Patrician: Severity and frequency are meaningless to us. We have thrown out severity—it is a matter of luck. We concentrate on accident prevention, not lessening of injury. We use an "all-injury rate." We base it on injuries per 100 employees. An employee, for this purpose, is 40 hours of work a week. An employee, if he should work 60 hours in one week, would count as an employee-and-one-half.

Barnako: You can get into trouble with an all-injury rate. It can be overdone. There are infections that are reported late, and unreported accidents.

Morrison: Every injury that requires more than two calls to the dispensary is counted in our company.

O'Donnell: You need a firm measure in a scattered operation—it is hard to control otherwise.

Q. to Entire Panel: We had an accident that apparently had no cause and there was nothing to correct. A woman fell on a clear, unobstructed floor with good traction. How do we charge it? The woman was out for five weeks.

Albisser: As a disabling injury.

Q. to Barnako: Do your traveling central office men evaluate the safety men in the field?

Answer: We don't hire and fire them, but we can't help making personal judgments

about their efficiency. We judge what a man is trying to do. Sometimes local plant management can hold back the effectiveness of a potentially good program.

Q. to Entire Panel: I look upon extremely low frequencies with suspicion. Some of these plants can't possibly have such records if they experience rain and snow, use parking lots, and their people have to walk on floors. Do you believe the Z-16 has gone too far? Is the frequency rate reliable?

Patrician: One of our plants that had 17 million man-hours without disabling injury, after it went on an all-injury rate, went down near the bottom of the list.

Albisser: I'm happy about the present method, but we do need some emphasis on severity.

Q. to Entire Panel: How do you relate safety to production?

Volunteers from the audience answered:

"We relate it to feet of oil well drilled."

"The brewing industry relates it to barrels of beer."

"One company shows it in cents per share of stock."

Q. to Barnako: How long does it take your man from the central office to evaluate a plant of, say, 20,000 people?

Mr. Barnako called upon Mr. Nolan, who was in the audience, to answer the question since he had recently evaluated such a plant. Mr. Nolan replied that it took approximately 3 days the first time, and he now thinks he can do the job in one day.

Q. to Mr. Barnako: If the evaluation is unfavorable, what action does the plant manager take?

Answer: Evaluation is for the safety office; we talk to the plant manager, but don't show him the report.

Q. to Entire Panel: How is the best way to make use of the services of insurance company engineers?

Answer: (By member of the audience) Our insurance company engineer discusses problems with the plant managers, and gives us a copy of his report.

Q. to Patrician: If there is more than one major cause, how do you direct attention to the cure?

Answer: We attack the high-cost areas

first. There is an unfortunate tendency to go overboard on isolated serious injuries. We had a broken leg caused by a fall on some pebbles in the parking lot. The large sum that was spent resurfacing the parking lot could better have been spent isolating electrical hazards.

Q. to Barnako: How close is safety to research and development?

Answer: Very close. We see reports, and sit on committees that give us information on hazardous projects about to be attempted.

Morrison: We ask for reports on capital expenditures to detect where research and development is beginning.

Barnako: The purchasing department can tip you off on this.

Albisser: In our company the safety department meets with the director of the development laboratory once a month.

Patrician: Plans are approved by the safety administrator and the plant engineer.

Q. to Both Panel and Members of the Audience: Should the safety man be an engineer?

Answer: 1. We will be here all week answering that one. 2. We must take a human approach—I am always pleased to see an author in the NATIONAL SAFETY NEWS advocate a human approach.

Albisser: 3. If you phrase the question with the word *should*, the answer is "no." If you phrase it with the word *can*, the answer is "yes."

ARE THERE TOO MANY SAFETY RULES?

By J. E. NICHOLS

Dir. of Safety, Reynolds Metals Co., Richmond, Va.

When an unsafe condition gets into proper position with respect to an unsafe act, most of us in safety work know that an accident will result. In the course of our daily work all of us are confronted with many different kinds of safety conditions and many different kinds of unsafe acts. All of them need to be controlled or eliminated in whatever ways we can devise.

The unsafe conditions are usually the physical conditions of plant and equipment. They are countless in number and may exist because they were created when the plant was designed and built or later remodeled, or they may have been created by the natural wear and tear on facilities which are in production. We usually find that it is easy to become aware of these unsafe physical conditions, through inspections, through information from others and from the occurrence of accidents which they have caused. They are usually not too difficult to correct and control by repair or maintenance, or by engineering revision.

There is rarely any thought of using a "rule" to control unsafe physical conditions. The proper control of dangerous fumes contaminating the atmosphere in which our employees may have to work is

not usually a "rule." It is engineering revision. Similarly, we do not think of a "rule" as being the best answer to a stairway with slippery treads.

Most of us learn early in our careers as safety engineers that people do not always do the expected thing under a given set of circumstances. How to control the unsafe acts of human beings is the question that keeps safety engineers on the payroll. There are many ways of accomplishing the necessary results in control of unsafe acts of people. One of these ways is by the use of rules.

The degree of success which a safety engineer achieves is largely measured by the degree to which he can control the unsafe acts of people under conditions which cannot always be predicted. There are safety programs which have been effective using a large number of "rules" and there are others which have been effective with very few rules. There must be some point in between at which the optimum of effectiveness is reached with just the right number of rules.

Just what is a safety rule and what does it do that cannot be done better by other means? Haven't we all been tempted at

times to devise rules for action which we thought would accomplish something for safety that couldn't be done by other means? And then we called this a "safety rule." Haven't we all sometimes wanted to fire or lay off an employee for a few days when he is caught violating some common sense safety practice? Haven't you felt sometimes that if only you could make a few more safety rules in your plant and be sure of their complete enforcement, it would be easy to produce a zero frequency rate every month?

Evidently some safety engineers have believed that rules were the answer to accident prevention. In one rule book, of several years ago, which I have in my office, and which came from one of our great corporations, here are two examples of safety "rules":

"Short cuts must not be taken over dangerous places where other ways are available."

And another example from the same course this being their rule No. 4007:

"Employees must look in each direction before stepping upon, crossing or standing too close to tracks."

This one, from one of our safety rule books originating in one of our plants several years ago, reads:

"Do not work with tacks in your shoes."

It is evident that the thinking about what a safety rule should do has varied quite a bit in the past. The need for rules is governed by different conditions under which accidents could occur. One of these conditions is the intelligence level of the employees with whom you are dealing. For example, a different approach is necessary for the staff of a laboratory doing research than for employees doing underground mining.

The degree and kind of hazard encountered will also affect the number and kind of safety rules that are used. For example, the manufacture of very fine metallic powders can usually be done with safety only when a complete and rigidly enforced set of specific rules of procedure is in effect. No such set of rules is necessary for general office employees, however.

We would all probably be happy to get along with safety instructions rather than safety rules, but sometimes just plain instructions, no matter how carefully given, do not seem to be quite enough to insure getting the idea across. So we make our instructions more forceful and perhaps call them "rules" and in addition, there is usually a penalty attached for their violation. It is the penalty, apparently, which makes a "rule" out of the instruction by making it painful or costly for the employee to forget or neglect it, all this of course, assuming that he can be caught if he does not obey the rule, and assuming that the penalty will actually be assessed.

It is these two "ifs" that really cause this entire subject to be discussed here at this safety congress. If we could always catch those who violate our safety rules and if they were always punished in accordance with the penalties prescribed in the rules, the problem would be greatly different, and so would the entire profession of safety engineering. Since this matter of enforcement is to be discussed in a later part of this program, I shall not touch on it now.

I would like to discuss further, however, the matter of safety rules and how they apply to human behavior. Have you ever violated a speed law or parked in a no parking zone? Have you ever smoked under a sign reading "No Smoking"? I shall not ask for a showing of hands—I merely ask that each of you examine your own conscience in this matter.

Our daily lives are circumscribed by such a mass of rules, laws and regulations, both written and unwritten, that it is doubtful if any of us can pursue our ways of ordinary daily existence without breaking some law everyday, either knowingly or unknowingly. It is said of one of our fifty states that there is a law on the books which was designed to prevent train wrecks where one set of tracks crosses another. When two trains meet at such a crossroad, the law prohibits either train from moving until the other shall have moved on!

We almost seem to be at such a crossroads and facing such a deadlock in some of the safety programs which are in effect today. With a large number of rules, trying to control human behavior, the inevitable result has occurred: We build up more and

more resentment against rules as they are put into effect, and finally we try the natural escape of disregarding those which we can without getting caught.

In accident prevention, the use of too many safety rules is the use of a crutch and a substitute for something that takes more ability and ingenuity—instruction and training. Teaching, convincing, demonstrating and selling of safety to employees is as yet the best known way of securing from them the kinds of reactions wanted when the emergency arises, or when a non-routine situation develops. It is my belief that there is no good substitute for teaching employees that their own safety is largely their own responsibility.

There are some situations, of course, in which the needed instructions must be so emphatic and positive that they should probably be called rules and have penalties attached. These are few in number, probably

less than ten altogether and they apply mostly to special situations.

On the sturdy and reliable DC-3 airplane there are 15 items on the "check-list" which the pilot and co-pilot must check together before takeoff. On the new all-jet DC-8 there are 76 of these items! You may call them rules if you wish or just safety precautions, but few of us would want to see the list decreased in either airplane.

The real trick then comes in knowing how to make your plan secure the results you want from, by the use of the fewest possible "rules" rather than by the opposite course of trying to formulate a new rule for each new hazard as it causes an accident or each newly found unsafe act of an employee. The safety engineer who is unable to make safety effective in his plant may be the same safety engineer who is relying too heavily on a long list of "don'ts"—with penalties.

ACHIEVING AND MAINTAINING RESPECT FOR COMPANY RULES

By JAMES F. VAN NAMEE
Administrator, Accident Prevention Services
Westinghouse Electric Corp., Pittsburgh, Pa.

There are many things which require serious consideration if a business is to be operated successfully. The management of safety is one of the most important of these items, along with cost and quality.

We in Westinghouse recognize that the safety and well-being of our employees is dependent upon the degree to which the prevention of accidents is aggressively pursued. Success in accomplishing this has an important effect upon the ability of our workers to perform efficiently while on the job.

Among the many features essential to optimum safety performance is the establishment and application of practical and enforceable safety rules. The rules and regulations that govern orderly conduct in a factory do not differ materially from those imposed by society in general. They

are merely adapted to the needs of a particular situation.

The word "rule"—as we use it in the term safety rule—is defined by Webster as "the usual method or way of doing something; as, it is the rule to rise at seven."

As stated previously, rules—safety and otherwise—are essential to the orderly conduct of business. Without them we would operate in a state of utter confusion. With them we have a roadmap that can be used to guide us down the highway of orderly and safe operating practices.

In order to generate respect for safety rules—it is essential to recognize that most Americans possess a basic resentment against rules and regulations. They feel that any regulatory mandate infringes too much upon their freedom to satisfy

follow rules, it is impractical to expect that workers will comply.

Generally speaking—any rule that can withstand an honest appraisal of its worth is enforceable and is worthy of respect. The comments made concerning some of the shortcomings of safety rules are intended to point up some of the general areas of fault that contribute to workers having a lack of respect for them. Consequently, if you are finding a general disregard for your plant's rules—may I suggest that you take a hard look at them to see if you find similar symptoms of weakness.

Another important thing is to acquaint employees with the nature of the rules they are required to observe. In short, these guides to action must be sufficiently publicized to make them part of the "working knowledge" of every employee.

While the educational approach will lead to the observance by a large segment of the work force, unfortunately, there is always a small minority that will insist upon violating rules. Thus, where education fails, supervision must be prepared to take proper disciplinary action.

I believe that the following statement—made by Emile F. du Pont of the Du Pont Company—sums up the whole story concerning enforcement of safety rules.

"We believe strongly in the philosophy of preventive safety rather than after-the-fact correction. We place great stress upon safety violations rather than upon injuries as such. We are tough toward willful violators, as we are more interested in eliminating the chance for injury by working safely without violations of good practice than in setting records. Where we are reasonable but firm on violations, a safety consciousness is gradually developed among the entire work force."

This brings us to the all important problem of enforcement and discipline. If rules are to be enforced they must—as has been said before—be clear and known by the employees. They must be fair and undiscriminatory—and they must be uniformly applied—otherwise you may find them contested by union representatives.

The need for acceptance of safety rules by union representatives is mentioned because under the terms of some labor-management contracts a company may find that improper rules can become a basis for the

filing of a grievance—or even arbitration. Two examples will illustrate this point.

A union local in Trenton, New Jersey, filed a grievance against management's newly inaugurated rule which required 100 per cent compliance with an eye protection program. The following statement is taken directly from a report that the union local made to its membership concerning the outcome of action taken on the grievance:

"The 100% eye protection program—the union argued that many areas in the plant did not require safety glasses. Management insisted and have modified their program accordingly. The areas and jobs not required to wear glasses are—purchased parts crib, receiving docks, salvage building, main stock crib, overhead crane operators, steel bay area, yard area, parts checker, tool room, mixer, waste material disposal operations, car washing activity and drivers not working in production areas."

"Management's unilateral promulgation of a safety rule presents an arbitrable grievance."

On a question brought against a company by the Oil, Chemical and Atomic Workers' Union an arbitrator said: "The company had issued a regulation which the union challenged, requiring all employees to wear hard hats and toe guards. The company argued that it had the unquestioned unilateral right to establish reasonable safety regulations—such as those being challenged. The union contended that safety regulations involving special protective devices, which employees were required to wear, constituted conditions of employment for which the union had been recognized as the sole and exclusive bargaining agent. The union held that these were matters for joint consultation between the parties in the first instance and subject to review in the grievance procedure in the event that a job was described and classified in a manner with which the union did not agree. The arbitrator held that although the employer ordinarily has the right to determine for itself rules for protection of employees, there are circumstances in which the union may challenge the imposition of certain types of rules as well as the reasonableness of particular rules and that the union's protest in these cases presented an arbitrable grievance under a contract which defined a grievance as any disagreement between the company and union involving interpretation or alleged violation of contract."

While I do not wish to invade the subject of discipline, there are a few precepts concerning discipline that also may have a bearing on the respect tendered to safety rules. Briefly they are:

First: Disciplinary action under some labor-management contracts may be subject to arbitration. When such is the case—remember that an arbitrator may determine whether there was just cause for the discipline, and also whether it was overly severe.

Second: The burden is usually yours to prove that your rulings are proper—and that the penalty given wasn't too severe.

Third: Discipline and discharge are serious matters. Consequently, be sure to have the answers to such questions as: "Did the employee know he was violating a rule?"—"Was his violation intentional?" and "Were previous violations condoned?"

Fourth: Discipline must be the same for bargaining and non-bargaining employees.

From the foregoing discussion, three basic principles emerge as being the basis for creating and maintaining respect for safety rules. They are:

1. The rules themselves must not be at fault.
2. Employees must be educated concerning the needs for the rules—and the benefits to

be derived from compliance with them.

3. When all else fails, enforcement and discipline must be resorted to, but on an equitable basis.

In summarizing this discussion, I would like to stress that:

First—Safety rules are essential to the attainment of both production and safety objectives.

Second—Ways must be found to make employees want to abide by safety rules.

Third—The rules must not be unreasonable or improper—for if they are they won't be respected or accepted by the workers—and without acceptance they are doomed to failure.

THE CONSTRUCTIVE USE OF DISCIPLINE IN SAFETY VIOLATIONS

By STANISH C. RIDDLE

Senior Safety Eng., Cleveland Foundry & Engine Plants
Ford Motor Co., Cleveland, Ohio

One of the too many things aggravating the world situation today is the different interpretations applied to identical words by various persons or cultures. I want to consider the term, "constructive discipline," with a common and single interpretation of its meaning and implication.

First, let's look to Webster, who says,

"Construct (verb) 1. To put together the parts of something. To build. 2. To set in order mentally, to arrange."

"Discipline—1. Training (to train). 2. Punishment—(to punish). 3. Orderly Conduct. Synonyms are—educate, teach, chastise and correct."

Second, let's toss out these words and concepts: *punishment, to punish and chastise*. They have no place in our philosophy. We are not running penal institutions! We are operating business organizations where we are attempting to *instruct* our employees to perform their assigned duties to the best of their ability and with the least possible hazard to themselves and their co-workers.

Third, now, let's look at what we have left from Webster's definitions:

1. To put together the parts of something. To build.

2. To set in order mentally.

3. To arrange.

4. To train.

5. Orderly conduct.

6. Educate, teach and correct.

Fourth, from these concepts, let's construct our definition of "Constructive discipline"—to arrange by educating and correcting to motivate our employees to conduct themselves in an orderly fashion, both mentally and physically.

What this means is that we must strive to reach the minds of our employees and move them to conform to the standards of conduct as represented in the Ford Motor Co. safe practices rule books. This is not always an easy matter, for a man is not a simple organism, like some of the lower animals. A man can be very complex.

He is what he has lived. He is what his ancestors have been.

Keeping this in mind, we must consider that, just as no two individuals have identi-

cal fingerprints, so too, no two individuals have identical thinking processes. Because this is true, we must remain very flexible in handling this matter or discipline.

We must keep in mind that the old days when a "straw boss" kept order in his crew by developing the hardest knuckles, the biggest biceps and the loudest mouth, are long gone. Possibly a few cases of straw bosses also developing the widest toothless grins might have had something to do with this. Seriously, though, we do not believe that physical or severe mental or emotional force has any real place in today's application of corrective discipline to industrial employees.

The concept of discipline at the Ford Motor Co. is that it must be *corrective*. This concept also dictates that only as much corrective action be applied as is necessary to result in the desired correction. In other words, it is the expressed philosophy that all personal feelings be divorced from the case and only the *facts* are to be considered. This is what we mean by the term, "constructive discipline." Discipline that is *constructive* through reasonable and fair *correction*.

We do not mean to imply by what we have said up to this point that we do not want our supervisors to maintain control over their employees. To the contrary, it is insisted that they do. It is insisted that they be firm. Point No. 6 of the 14-point Ford Motor Co. Safety Program states, "Maintain firm plant discipline." Please distinguish between firm and harsh. These two words are poles apart in our philosophy.

As a matter of fact, if you think of it in the right light, being firm and insisting on strict adherence to the requirements of safety rules is actually being kind to an employee. Being kind to him to the extent that you force him to avoid having an accident. He may not appreciate your kindness in applying corrective discipline when it is merited. It is, nevertheless, kindness of the first water.

Speaking of the 14-point Ford Safety Program, points No. 4 and 5 are also worthy of note here. "Sell safety to the new employee," and "Re-sell safety repeatedly." It might appear that there is a discrepancy of terms here. Is there really a conflict

between "selling" an idea and using "discipline?" We think not. Remember what Webster says? Discipline is education. Selling, too, is education. Therefore, Selling is a form of discipline.

Regardless of what we call it, or how we define it, it means nothing unless it is applied.

I am reminded of a story I read sometime ago in a magazine. The story told of a rather large company that had been experiencing numerous serious accidents and injuries to employees with an ever-increasing frequency. According to the story, this went on for several years. (Hard to believe, but that is the story.) Numerous meetings to find causes and remedies were held but always wound up with someone saying that they hoped the "bad luck" would make a turn for the good, soon.

Finally it got to the point that someone at the top decided to bring the thing to a head. He called the managers of the various departments together and told them that it was up to them to find ways of controlling the situation or he would find someone who could. Rather drastic but a very effective form of discipline.

It turned out to be very constructive, as well. The top man's ultimatum finally made them realize that, far from their running the organization, the organization had actually been running them! Finally jolted out of their false sense of job security, each manager passed the jolt on to his subordinate supervisors. Each man was told to tender his resignation right then if he didn't think he could stop his employees from injuring themselves.

"Wow! The bosses are really mad now," they all thought, as they started scratching heads in search of ideas. It didn't take much scratching to come up with the idea of opening the safety rule books that for so many years had lain uncopied in the desk drawers. One after another got the bright idea of starting to insist that the rules must be adhered to.

There were no changes in normal work procedures, no supervisors lost their jobs. The supervisors just started to supervise within the framework which already existed in the organization. The foreman started to be the "boss" and exercised his almost forgotten responsibility to discipline

employees who violated the rules. Accidents fell off sharply and other benefits were also realized. Morale was strikingly improved, absenteeism decreased and not too surprisingly, there was also a significant increase in productivity.

Let's go back again to Webster. Remember—he says that discipline also means "to teach." Ford Motor Co. accepts this meaning wholeheartedly and considers the teaching and training of its employees to be one of its most important functions. Sure, we realize that our prime function and reason for existence is to serve our customers with a top quality product at a price they are willing to pay.

But, to do this we must have a *trained, disciplined* work force, at all levels of the organization. For the purpose of this discussion, however, we are considering only how this policy affects our program to prevent accidents, with particular emphasis on the enforcement of safety rules.

In order for established safety rules to have any meaning, it is a prerequisite that the persons to whom they are to apply, have a thorough knowledge of their context and meaning. This is accomplished through a very thorough system of training for both supervisors and hourly employees.

These training techniques take many forms, and include:

1. A six months training period for new supervisors.
2. One-hour weekly training meetings with required attendance by all supervisors.
3. Frequent contacts between supervisors and plant safety engineers.
4. Wide distribution of safety rule booklets, to both supervisors and hourly employees.
5. Requirement that all supervisors of hourly employees hold weekly safety talks with their employees.
6. Indoctrination program for new employees which requires that the supervisor go over pertinent safety rules with the new man to insure he understands them. A check sheet and card which the employee signs must be returned to the safety office for each new employee.

But that is enough of detail. I think

you have the idea that the Ford Motor Co. has an excellent training program and does a good job of educating its employees on how to do a good job safely. We have given our employees the knowledge, now we must see to it that they use that knowledge to the best advantage—to the advantage that employees will not suffer accidents and injury from someone's disregard of safe practices established and spelled out in the rule books.

Let us take a quick look at how "constructive discipline" of a progressive nature works in cases which demonstrate the principles we have been discussing.

First, consider a simple theoretical case. Suppose that one of the plant safety engineers observed an employee working at a machine while he was not wearing his safety glasses, as is required of all Ford Motor Co. employees. The safety engineer contacted the employee's foreman and verbally informed him that the employee was exposing himself to the hazard of a potential eye injury.

Thereupon the foreman, knowing the employee has just returned from lunch and merely has forgotten to put safety glasses back on, approached the man and reminded him to do so. The man, being a cooperative individual, did so, with thanks to the foreman for reminding him. (This man knows which side of his bread has the butter).

This man required very little correction since he realized that the eye protection rule was for his benefit. Just a word of caution was all the discipline (motivating education and correction) that was needed in this case and that was all that was applied. Mission accomplished!

Let us now consider a little more complicated and still theoretical case. Again, the plant safety engineer reported a worker, not wearing the prescribed eye protection, to his foreman. This individual was resentful and expressed himself bluntly, indicating he did not want to comply with the rule requiring him to wear safety glasses.

In this case the foreman realized that positive action was needed to change this individual's thinking. The foreman, therefore, called the man into the department office and, explained to the employee that the Ford Motor Co. safety rule requiring all employees to wear approved types of

eye protection was established to prevent serious eye injuries, himself included.

The man was then informed that because his record did not show any previous citation for rule violations the disciplinary action report resulting from this case would show that he had merely been given a reprimand and warning without the loss of any time. The warning indicated that he had been informed that any subsequent violations of the rules might result in increased corrective action on a progressive scale.

Here again, the case was dispositioned with only enough "constructive discipline" to arrive at the desired correction of the employee's attitude and performance.

This program of scaled action to fit the case is carried out through the whole range of cases which might occur. Each succeeding time that it is necessary to apply disciplinary action to an individual employee, his previous record is taken into consideration. In those cases where it is clearly evident that the previous actions have not resulted in the expected improvement in the employee's attitude and behavior, additional motivation is applied, each step being progressively more severe.

In a few very serious cases, the end result may finally be a discharge. I am glad to be able to say that very few cases go to this extreme. The lack of extreme cases indicates that the system of progressive actions takes hold and does the job somewhere along the line before the final stage is reached.

Since a disciplinary penalty is imposed solely to obtain improvement of future behavior, follow-up is important in determining whether it has been effective, or whether further action is necessary.

Up to the present time we have dwelt extensively on the techniques utilized in the "constructive use of discipline in safety violations." Now, let's give a little consideration to the end results of such actions. This is the meat on the menu. This is the payoff. While we do not, by any means, give our company program of "constructive discipline" the whole credit, we are sure that it played a very important part of the recent accomplishment of the Cleveland Foundry of the Ford Motor Co. in establishing a new all-time National Gray Iron

Foundry Best Record of 3,421,133 man-hours of exposure without a disabling injury.

We also are sure that this technique of using discipline for *corrective* purposes played an important part in the record of our two Cleveland engine plants. These two plants have, within the span of less than ten years, posted periods of over 3,000,000 man-hours of exposure without disabling injury on *several* separate occasions.

The use of "constructive discipline" can never be the answer to all problems. It can, however, help in the efforts to create a *safety awareness* in our employees which we all are striving for. Safety awareness? Now there is a term I like! Turn that over on the tongue of your mind for a minute! Get the taste of it? Let me give you an example.

Recently, while I was walking through an aisle in our foundry at Cleveland, an hourly man walking in the same direction but some distance ahead, noticed a small length of pipe lying in the aisle where it had apparently fallen from a passing scrap truck. The man, with scarcely a pause, stooped down, picked up the pipe and tossed it into another scrap truck and continued on his way. It was done in such a casual manner it appeared to be an act of habit.

That is what we want! We want safety so ingrained in our employees that they exhibit similar thoughtfulness in all their actions. Thoughtfulness that is a *habit*! And there is no contradiction of terms in *this* instance.

Here was living proof of the "safety awareness" we are striving for. Here was evidence of one of the factors which helped the foundry set a new record, helped the foundry exceed the old record, which had stood for five years, by a margin of well over 300,000 hours. Here was evidence that, properly motivated, employees can be moved to consider the "other fellow's" welfare as well as their own.

This man's action may well have prevented the next man coming along from taking a bad spill. Such patterns of thought can cause a man who, in the past, had been guilty of leaving a guard off a machine, to now pause to replace it upon completion of his job. Development of such *safe* work habits can truly make a man become, almost unconsciously, his "brother's keeper."

We do not know whether this man had ever had occasion to have "constructive discipline" applied to him. We have no way of determining since the man was not identified. We like to think, however, that this is the sort of attitude which can be developed by the technique of applying discipline in a corrective sense, rather than in a punitive sense.

You all know what happens when you push a pendulum. You give it a push and it swings right back at you. If you give a man a push he also has the same reaction; he has a tendency to take a swing at you in return, in one way or another. It is our thinking at Ford that much more can be accomplished by *leading* a man onto the right road by correcting his errors in a constructive manner. This leading, nevertheless, must be firm to avoid being misunderstood as weakness.

Someone says, "Nuts! There are some guys you can't reach with anything but a big club and a size 14 boot." There may be some truth in this statement, but, (and that is a *big* but) these cases are few and far between and we should not fall into the trap of accepting this as a dump for all of our problem children. It costs money, a *lot* of money, to train employees to perform today's complex jobs. It costs money, a *lot* of money, to have our employees suffer industrial injuries.

It is our job to save our employers from the unnecessary expense of discharging errant employees. It is *also* our job to save our employers from the unnecessary expense

of accidental injury. It is even more our job to discharge our moral responsibility of preventing the human misery to the employee and his family which invariably results when the bread-winner is laid low because he or his fellow-employee failed to heed the safety rules.

In nearing the conclusion of this discussion, let us remember that the old days of the woodshed as a symbol of discipline are gone and past. More enlightened thinking and the teaching of experience has opened a better door. A wider portal with brighter vistas; "constructive discipline," based on correction, not punishment.

It is a prime tenet of psychology that the human animal has a greater tendency to remember pleasure than pain. How many of you can remember the occasions on which your Ma or Pa beat the bejabbers out of your little hind-end? I'll bet not one of you can, or, at most very faintly. On the other hand, I'll also wager that many of you can still clearly remember the old swimming hole, how much fun you used to have at the County Fair or many other pleasures of your childhood.

Not that we mean to imply that applying even "constructive discipline" to our employees will be a pleasure to them. Rather, we should attempt to remove as much of the pain as possible from our corrective action to lessen the tendency to forget unpleasant experiences. *Educate, teach, correct* that's the ticket. Punishment for punishment's sake belongs to the Dark Ages.

SAFE APPLICATION OF ELECTRIC CONTROLS ON MACHINE TOOLS

By F. C. PEREGOY

Supervisor of Safety, Westinghouse Electric Corp., Baltimore, Md.

By definition, machine tools include all power-driven equipment performing cold-working of metal by progressively removing metal in the form of chips. The National Association of Machine Tool Builders has classified some 200 types of machine tools under five basic functions—turning, boring, milling, planing and grinding.

Authorities agree that injuries from machine operation are likely to be more severe than injuries from other causes; and more likely to result in permanent disability. For example, Accident Facts shows machinery to be the source of 10 per cent of all injuries, but the source of 19 per cent of permanent disabilities.

Material in reference books emphasizes that although many machine injuries result from lack of proper guards, the majority have their sources in unsafe practices; and that, therefore, is the area requiring concentrated attention.

Safe working procedures—operation, adjustment and repair of machines only by trained personnel, and supervisory responsibility for enforcement of established policies—are the weighted important factors in such reviews.

Other literature, stressing the soundness of correcting unsafe conditions first, provides lists of safeguards, such as drill vises, spring-loaded chuck wrenches, chip shields, tool guards, stock tubes, enclosed tanks for cutting-compounds, pinch-point guards, enclosures and ventilation.

However, it is most difficult to find informative material on the subject of providing protection against machine-tool injuries through use of adequate electrical controls. Although progress has been made through the years in the development of machine tool safety, the incidence of high severity in injuries dictates the need for closer examination of the problem. Perhaps there is no better place to start than to consider the feasibility of applying electrical controls for more efficiency and greater safety.

To prepare this article, many technical publications were reviewed. Although they covered the techniques of manufacturing without mentioning safety, safety is inherent in their operation because the operator is removed from the danger point. While safety handbooks serve their purpose adequately, there is an ancillary field ready to be explored: the field of technical publications on programming for machine control.

However, certain control methods developed in recent years mark beginnings in this direction. One of these is programming and control of machine tools by means of magnetic tapes.

Manual control of a machine tool means that both the tool and the operator are subject to physical limitations and to human

error—in interpretation of prints, in setup, in process of operation, in misjudgment of distances, in adjustment to light changes; and to other variables. Such problems repeat themselves for each run.

However, with the use of tape controls, decisions and checks are made at the time the tape is prepared. And so, errors and scrap go down; there is no fatigue problem; lead time is reduced; tooling is simplified; manufacturing time is cut. Such control permits infinitely repeatable precise machine operation, besides providing the optimum in personal safety. Manufacturing cost savings more than pay for the system: even one-shot parts are accurately and economically produced with such controls.

Additional accomplishments include the introduction of contactors to replace switches; the use of volt-meters and indicator lights for machine control; load meters and overload devices.

There is still a problem, that of a high incidence of permanent disabilities. Much effort has been devoted to mechanical guarding and safe procedures. Striving to improve machine tool safety, we must realize the limits of the past approach and the room for human error.

In an age when hospitals can wire patients to record pulse, respiration, blood pressure, temperature and heart action, cannot the individual safety engineer and organized safety groups probe more deeply into modern technology and demand a wider application to machine tool control?

THE ASA DISABLING INJURY FREQUENCY RATE IS A GOOD MEASURE OF SAFETY PERFORMANCE

By E. R. WALLACE

Sr. Safety Engineer, Eastman Kodak Company, Rochester, N. Y.

Shortly after World War I, the U. S. Bureau of Labor Statistics published Bulletin 276, "Standardization of Industrial Accident Statistics." A revision of this bulletin was requested by a resolution adopted at a National Conference on Industrial Accident Prevention in Washington in 1926. The resolution requested that the American Engineering Standards Committee, which is now the ASA, undertake this revision by means of a sectional committee. A sectional committee was organized and on it were representatives of the various national associations concerned with safety, as well as representatives of many other international and national organizations, including insurance companies, petroleum groups, steel groups, metal groups, departments of labor, accident commissions and various departments of the U. S. Government, as well as many state agencies. Other industrial groups were represented as well.

As a result of the work of this committee, the ASA Standard Z-16 was developed and was originally approved in 1941.

Prior to this time, there were many suggested methods of compiling accident statistics for use by the safety engineer. The one common denominator that has held true through the years is the method for calculating frequency of industrial accidents which, even though we all know it well, I am going to quote for you:

"Frequency is the number of disabling injuries times a million divided by the employee hours of exposure."

There is hardly a safety engineer, inspector or even neophyte who cannot quote the formula for frequency.

Since the establishment of the ASA Standard Z-16, many other methods of compiling accident statistics have been developed by one company or another. Most of us in safety have tried to evaluate these

other methods in an attempt to determine values from them which might better serve our needs in accident prevention work. However, we have found that our comparisons are made to the established standard with which we are all so thoroughly familiar.

The main point of contention and the main point of discussion in any appraisal of accident statistics in relation to the Z-16 code are that of the determination of what a disabling injury is.

"A disabling injury is a work injury which results in death, permanent disability, permanent partial disability, or temporary total disability." (The definitions of disability are found in Section 1.2, Page 6, Z-16.1)

If one is to use accident statistics as a basis for winning contests, for creating a pseudo-safe atmosphere among the employees and management, or to prove on paper that their organization has a better safety program than someone else, it might be possible to interpret the ASA Z-16 code definition of disabling injury in such a way as to give a frequency rate which can accomplish all the previously-mentioned points.

However, if the Z-16 code is used as a good measure of safety performance by an industry and the safety organization, and if the evaluations of their injuries are made on a basis which, I am sure, the original ASA Committee felt was just and honest, the Z-16 code could become an effective tool in accident prevention work.

There are many safety engineers who feel that, because they have been associated with their industry and the accidents therein for a number of years, they can make an instant appraisal of those places where the greatest effort in safety should be placed. This may be true; however, I recall sitting with a safety engineer of a large chemical industry not too long ago who, with a certain degree

of amazement, asked, "How come in a chemical industry we have more finger injuries than we have chemical injuries?"

If this question is an indication of what is going on in the minds of many safety engineers, it appears that some of us are not using our statistical analysis to its best advantage.

The beauty of a standard such as Z-16 is that comparisons can be made by the segments of an industry, even though those segments may vary in employee population from four or five men to units of several thousand. This type of comparison can be shown on a chart.

Such a chart, for departments of a large industry which vary in size from approximately 30 men to approximately 2500 might show department "C" as having a very high frequency rate in the year 1959 and an extremely low frequency rate in the year 1960-61, the other departments having slight variations over a three-year period.

As an example of the effectiveness of the Z-16 code as a measure of safety performance, I am going to tell you something about department "C."

It is a chemical manufacturing area of a little over 200 employees. It makes proprietary mixes of both dry and liquid chemicals; it fills, packages, blends, mixes, receives, ships and does everything else a normal manufacturing plant does, including its own maintenance. In 1959, the frequency rate took a bounce upward; the severity rate traveled up as well. As a result of the statistical analysis made in accordance with the ASA Code, it was readily determined that this area was one in which concentrated efforts should be put by the safety engineer responsible for the area. Such concentrated effort was put to use within the department, using the statistical information as a criteria for discussion with top management. It was established that economically, as well as from a humanitarian standpoint, increased safety emphasis must be placed.

In previous years when the frequency rate had risen, attempts had been made to sell management on the fact that increased emphasis should be placed on safety; however, because we did not have the statistical backing to be able to show economic justification, because we were unable to prove

production loss, because we were unable to show the potential of increased production with an adequate safety program, we had no more than token safety emphasis within the department.

Today, however, the picture is completely reversed. The management is aware of their accident record; they are jealous of that record; they are not using the record in any other way than to increase the morale of the employees within the department; they are concerned with the maintenance of the record on the basis on which it was established. They know that disabling injuries included in their frequency rates are evaluated on the true and honest basis as established by the ASA Code; they know that lost time is calculated as established with the Z-16 code and so in the employees; and, this is an important point. In order to use effectively the statistical information of a code such as the Z-16, it is important that the personnel within the department or industry be advised as to what the statistics mean.

Department "D" is a department of approximately the same number of employees. This department, over a period of six years, has maintained a notoriously bad accident record.

It follows without saying that, under conditions such as these, this is the next place where greater emphasis shall be placed on safety performance, philosophy, safety engineering, and last, but not least, accident prevention.

To set an entire safety program on the compiling of statistical information alone and to feel that job is done is a rare, ineffective way of preventing accidents; however, in order to utilize the Z-16 code as a measure of performance, one must evaluate the criteria for determining disabling injuries — must evaluate with the greatest degree of honesty and then, following the analysis, must establish an accident prevention program in keeping with the facts which can be found. In doing this, a safety engineer cannot only utilize his current figures, but he can also pull from his records his accident reports, of years past, evaluate these on the same standard basis, and show by a chart, by graph, or by any other known statistical means, the trends over a period of years. If this is done, and

the standard becomes established as a useful tool, then performance can be measured and measured well.

In two departments where the records have been maintained according to ASA Standards over a period of six years, it is easy to see those places where safety programs were instituted, where safety engineering was effectively utilized; where changes in safety philosophy on the part of personnel are apparent. Such information in the hands of your boss can be a second measure of safety performance—your safety performance. I am sure that every safety engineer in this room is responsible to management for the reduction of accidents within his industry. Management measures safety performance on the basis of the facts that we give them as well as on the basis of compensation costs with which they are already too familiar. In order to establish our effectiveness as a member of the management team doing our job in the prevention of accidents, we must have established criteria for reporting to them our day-to-day, week-to-week, and year-to-year progress in the prevention of accidents. The ASA Codes, of which there are many, have long since been established in the minds of management as the basis for evaluation of their position with others in the manufacturing business or the evaluation of types of material, of procedures and practices, the purchase of supplies, and other miscellaneous parts of the business world.

It seems logical to have to present to management in language that they understand and know, reports of performance on the basis of long-established standards which have stood the test of time.

There are those who feel that in order to maintain active interests or, in order to show improvement to management or to their employees, that it is necessary to change our methods of recording and compiling statistics. This may be necessary in some cases; however, change or modification of a standard statistical system can result in a false sense of security perhaps, in confusion on the part of the employees, and management as well and can result in no permanent gain.

Some years ago, an industry with which I am very familiar, established a statistical procedure for reporting injury experience

which was somewhat different from the ASA Standard. This method used weighting factors for average number of employees, for types of injuries, for practically everything under the sun. The reports were somewhat unwieldy to prepare; the interpretation of those reports was practically impossible for anyone less than a statistician. Because in each case, in order to obtain full evaluation of the statistical evidence, one would constantly be required to refer to the weighting factors. The employees could not understand the new system; however, they were favorably impressed in the first months or so because the charts prepared from this statistical evidence with those weighting factors were able to show an improving line on the graph almost constantly. The accident reports of this industry were analyzed according to the basis of the ASA Z-16 Code, and some startling information resulted. It showed that, by eliminating the factors, both frequency and severity fluctuated greatly over the period checked. It showed that their record was not the constantly improving record, and it showed that there was need of more than a new system chart to improve the safety of that industry.

Arthur P. Johnson, Vice President in charge of Engineering, American Mutual Liability and Insurance Company, in the May, 1961 issue of "Standards Magazine," published by ASA very appropriately summarizes my comments:

"Statistically, the total picture is much improved; however, fatalities and serious injuries are continuing as a result of accidents in which physical factors have not been brought up to a safe standard. This is of serious concern to employers as well as to employees. More and more, third-party suits for very high damages, alleging negligence by failure to make the operation safe, are being filed following industrial injuries. In these cases, evidence of failure to comply with codes and standards can be very damaging. Accident prevention, it should be remembered, is a process of management aimed to prevent recurrence of accidents. It is urged that management use standards, especially American Safety Standards, as criteria for the safe control of work environment and operations."

The ASA Disabling Frequency Rate is

a good measure of safety performance; the employees can understand it; management can understand it because it is the kind of information with which they are most familiar; the safety engineer can understand it because it establishes standards and limitations which, if used properly, can be the greatest assistance to him in his accident prevention work.

In order to play the game "according to Hoyle," we must have these standards. Deviation from the standard makes a new game.

Z-16.1 is no longer a research project. It is a regular code for day-to-day safety evaluation—for active safety engineers.

A MORE DYNAMIC APPROACH TO THE PREVENTION OF BACK INJURIES IN AN INDUSTRIAL ENVIRONMENT

By C. F. MARTIN, M.D.

Plant Physician, Electric Typewriter Div., International Business Machines Corp.
 Lexington, Ky.

Under this "wastebasket" term—the sore back—fall many common medical diagnoses and fancy National Safety Council classifications. Mark Twain's remark that, "Everybody talks about the weather and nobody does anything about it," might seem to apply to this sore back problem. However, as we know, this is not entirely true. In the field of medicine there is not a single large medical meeting presented anywhere without at least one discussion centering around the mechanisms and treatment of back complaints.

It is safe to say that almost everyone in this room has had a sore back. For reasons of understanding, let us define some terms so that we will be better able to understand each other. First, the disabilities in the back—with concern to safety people—can most simply be divided into two classes:

- (1) Those due to injury.
- (2) Those due to injury.

Those conditions due to injury we speak of as sprains, strains, bruises of ligaments, muscles, and joints. Those not due to injury can be wear and tear of age, or perhaps inflammation of muscles or tendons, best known as rheumatism.

From a safety man's standpoint, I think

it would be important to classify back complaint, emphasizing four points:

1. There should be some accident or some unforeseen event which suddenly occurs or produces a definite sprain, strain, or other recognizable injury. For example, a bruise.
2. Such an accident should lead to an immediate, or almost immediate interruption of the ability of the back to perform its usual work.
3. A thorough examination of the back would reveal some sign, or demonstrate some functional disturbance.
4. This disturbance should bear a logical connection to the accident or event as reported.

The term *strain* indicates stress greater than that which the supporting elements of the back are normally able to withstand. The fleshy tissues of the back are endowed with strength, elasticity, and vigor according to the development of each individual. When an abnormal stress is applied, whether suddenly or slowly, and the tissues are stretched beyond their normal resistance, this gives rise to pain, soreness, and disability.

Again, from a safety man's standpoint, occupational back strain as a result of fatigue is not usually classified as an injury.

However, as a medical entity, it is frequently seen and recognized.

When we refer to *chronic strain* we mean that an abnormal state has existed longer than the time estimated for the usual repair of the damage to the back. The word *strain* is a term applied when a joint has suddenly been twisted or wrenched and the ligaments around this joint have become torn or separated. Sprains are a more serious condition than strains, and the disability and time for improvement are much longer.

One of the most popular diagnoses made today is the rupture or protrusion of the intervertebral disc. This simply means that for some reason the padding between the bodies of the vertebra is pushed out of its normal position, causing some pressure upon the nerve roots. When this happens, there is pain, muscle spasm, and notable disability. Treatment for this condition is long-termed and quite involved.

Another perplexing term that we come upon in the medical discussion of the back is the *lumbosacral instability*, which in most practical terms means that there is a weakness in the cornerstones and/or the cement of the cornerstones of the base of the back. This leads to chronic soreness, weakness, and subsequent disability.

Most medical forms of treatment for back conditions are directed toward one end—that is, to allow the body to repair itself. This is done by restriction of the use of the back, medication, rest, and support.

In our location, our experience can be divided into three phases:

1. First, we were offered an unprecedented opportunity, by the building and opening of a new plant, to observe, examine, and collect data on the physical work required for a perplexing variety of jobs. Not only the physical work required for the job, but, more importantly, how the man on the job was actually performing this work. Observation such as this can be made only one way, and that is to see it firsthand; not once for two minutes, but repeatedly at varying intervals.

2. Second phase: the Medical Department collected patients, while the Safety Department collected the case histories of back accidents. Our data and observation

were sorted and studied. Engineering methods were used to devise improvements in the mechanics of the job. Patients with back complaints were instructed individually on proper back care and advised to tell others of their painful experiences.

These first two phases are completed, and we have learned much from working through them.

In a third phase, prevention, strong emphasis must be placed on education and group participation; the effects of which will reach beyond the plant and work situation.

In an attempt to bring all the medical information and experience into focus under one study, the medical department did what was called "The Statistical Evaluation of 215 Back Cases in the Medical Department, Oct. 1957—April 1960."

TABLE I

Total number industrial cases.....	130
Total number non-industrial cases.....	108
33 per cent industrial back injury	
44 per cent non-industrial back injury	
61 cases filed for Workmen's Compensation	

We see of the 215 people followed, approximately half were industrial injuries; the remainder occurred outside work. Of the 130 people who reported that they injured their back while at work, 61 (or less than half) were filed on through Workmen's Compensation.

It is important to remember, we were able to take care of more than half of the industrial injuries in the first aid area, using simple treatment measures. We will say a great deal more about the fact that half of our number of cases were injured outside the plant.

By listing the 10 departments having the largest number of cases, a finger is pointed to sore spots.

TABLE II

Ten Departments Having Greatest Number of Cases	
1. Dept. 108	11 (Assembly)
2. Dept. 102	10 (Machining)
3. Dept. 103	10 (Machining)
4. Dept. 104	8 (Machining)
5. Dept. 113	7 (Assembly)
6. Dept. 105	6 (Assembly)
7. Dept. 106	5 (Machining)
8. Dept. 110	5 (Machining)
9. Dept. 107	5 (Machining)
10. Dept. 101	5 (Assembly)
Totals	
Assembly	29
Machining	42
	71

In our pre-employment examination we ask the question in writing, and then again during the examination, "Have you ever experienced a sore back?" If the answer is yes, we ask, "Has this been severe enough to restrict your work activities?" Regardless of the answer, these people have been hired.

More recently, we have been asked these questions: Do people who have told you, at the time of pre-employment examination, that they have already experienced back trouble often have recurrences? How severe will their recurrences be? Will they demand jobs that are of a restrictive nature?

TABLE III
Comparison of employees who gave history of back trouble prior to employment as compared with those now having permanent physical (Class II) restrictions.

Previous history	57
Permanently restricted	10

When we compare the employees who gave us a history of back trouble with the total number who have permanent physical restrictions, we see that out of the 235 cases, 26 people are permanently restricted Class II.

Of these 235 cases, 57 people said that they had had back trouble. Of this 57 people, 10 people are permanently restricted (Class II)—that is 1 in 5.

TABLE IV
Comparison between those having previous history of back trouble prior to employment as compared with workmen's compensation cases.

Previous history	57
Total number compensation cases due to back complaint	61
Previous history and compensation	13 (21 per cent)

In this table, if we compare those having a previous history of back trouble, prior to employment, with workmen's compensation cases, we note: Those giving previous history were 57. Total number of compensation cases was 61. Those giving a previous history and becoming compensation cases later in employment were 13 (or 21 per cent).

I think it is logical to say that people with past history did substantially contribute: (1) to permanent restrictions—1 in 5, (2) to compensation cases—1 in 4.

50

TABLE V
How Long For Common Conditions

Average length of treatment for muscle strain	11.6 days
Average length of treatment for lumbosacral strain	21.9 days
Average length of treatment for disc (surgical)	106.4 days
Average length of treatment for disc (medical)	36.5 days

In this table you will see the average length of treatment of muscle strain, or lumbosacral strain, of disc disease that demanded surgery, and of disc disease treated medically.

A disc that will require surgery can return to some type of productive labor in three months, providing rehabilitation happens to be popular in your plant. If the disc seems to respond to conservative measures (that is, without surgery), you can get him back in two months.

TABLE VI
Warning of a Pitfall

Time for recovery of workmen's compensation cases cannot be compared with industrial back injuries not compensated, nor with non-industrial back injuries, because of the factor of severity. Those patients having the most severe, complicated, and protracted back injuries are filed on under Workmen's Compensation. The more simple, uncomplicated back injuries receive routine supportive treatment in the plant first aid and are not filed on. No comparison should be attempted.

At first glance, I thought we could compare workmen's compensation cases with home injuries, and draw some conclusions. Safety people, management people, and now medical people must be concerned with the amount of money spent on compensation cases, and the time required for recovery of compensation cases. The time for recovery for workmen's compensation cases cannot be compared with industrial back injuries not compensated, nor with non-industrial back injuries, because of the factors of severity.

Earlier, in the tables, we called your attention to the fact that we filed on less than half of those people who had industrial back injuries—that is, we filed on the severe ones. We took care of the ones that were not severe and would clear up in a logical time anyway. So, those patients having the most severe, complicated, and protracted back injuries were filed on under Workmen's Compensation. The more simple, uncomplicated back injuries received routine supportive treatment in the plant

first aid and were not filed on. No comparison should be attempted.

TABLE VII
Average Length of Treatment of Compensation Cases

Muscle strain	21.6 days
Disc	75.3 days
Lumbosacral strain	31.6 days

TABLE VIII
Average Length of Treatment of Industrial Back Injuries Not Compensation

Muscle strain	7.1 days
Disc	5.8 days
Lumbosacral strain	10.9 days

This table we present as a composite of facts (another warning of a pitfall) and not as a comparison: The length of treatment of compensation cases varies for muscle strain, disc, and lumbosacral strain, also for the average length of treatment for industrial back injuries not compensated. This may give us a picture, or perhaps an index of severity.

TABLE VIII
Back Cases 1960 Recurrent

Industrial	19
Compensation filed	15
No compensation filed	4
Non-industrial	26
	47

Now to be up-to-date, let us briefly review our experiences of 1960. Recurrent refers to some of our old buddies who have been re-injured and need further treatment at our gentle hands. Please note that industrial is now 19 and non-industrial 26.

From experience and from analysis, I have come to believe very firmly in the

TABLE IX
New (Acute) Cases

Industrial	49
Compensation filed	29
No compensation	50
Non-industrial	36
	85
Total cases 1960	132
Industrial	68
Non-industrial	64

third phase. You can see from this presentation that half of our back injuries happened in the plant and half away from work. So if we set about and spent all our time correcting all of the conditions in the plant that might cause any back trouble, and if perfection were reached, we would be able to show only 50 per cent improvement. Certainly we should—and we have—through individual training and through improved engineering techniques on the job, attempt to help this 50 per cent.

To achieve real success in the saving of manpower and in the lessening of pain and morbidity, we must have a group collective action. We propose to do this through an educational program of lectures (both medical and safety) and through printed material sent out with the plant newspaper and through management conference. We must train these people in groups, teaching them the mechanism of their back and the care of this system, and doing this in such a way that they will carry it from work and into their lives at home.

This has been the problem, the analysis, and the proposed answer.

SAFETY'S ROLE IN PREVENTING BACK INJURY

by CHARLES W. BOGGS

Safety Dir., Electric Typewriter Div., International Business Machines Corp.
Lexington, Ky.

One of the fastest-growing clubs in America today is the "Aching Back Club," an organization with millions of reluctant members. Thousands of industrial workers join this club every week by trying to lift subjects too heavy for them or by failing to lift properly. There's no waiting for membership. It takes no longer to qualify than it does to bend over and tie your shoe. Admission is free.

Many safety people are of the opinion that back injuries will occur regardless of what they do, so little is done to eliminate the cause of these injuries. There are causes, though, that can be eliminated. In tackling this problem at our plant, the first thing I did was to make a survey of all our compensable back injuries from January, 1957, through December, 1960. From this survey we found that our assembly

51

area accounted for the greatest number and that lifting typewriters from the work bench to the monorail conveyor or vice versa, was our leading cause. The next two leading causes, lifting pans of parts and handling machine fixtures, etc. occurred in our machining area. After reviewing all the facts and figures we decided to concentrate our efforts in these areas.

A typical work station on our assembly line has the work bench and roller conveyor the same height with a monorail conveyor directly above the roller conveyor. The carrier on the monorail is located 45" from the floor. When handling, the typewriter has to be held away from your body with the heavy part (motor area) away from you. There is a reason for this and it was one of the bad things about our original arrangement. To keep the typewriters in proper alignment the operator has to keep the keys away from him when handling.

This type of assembly line has been basically the same since 1950 when our plant was located in Kingston, N. Y. As a result of a study made there by the Liberty Mutual Insurance Co. we lowered the monorail conveyor 3 inches when we set up our new line at Lexington. We also became more conscious of the placement of people in regard to the location of female employees along the line.

You will recall that our leading cause of injury was lifting the typewriter to or from the monorail conveyor.

We found that the main reason for this was that employees were not following good lifting practices, such as waiting for the typewriter to be directly in front of them before removing it, and were not turning their feet, but only their bodies.

Realizing that as long as employees had to lift the typewriter we would continue to have injuries, we took our problem to plant engineering. In the fall of 1960 a "push along line" was installed into one of our three assembly lines. This initial installation was put in an area where most of our back injuries were occurring. We haven't had a compensable back injury in this area since the installation of the new line.

In January of 1960 we came out with a new model typewriter called the Model C. We were soon having injuries at our cover

operation where the typewriter had to be lifted twice; once to put the cover on and then again to be put back on the pallet after the cover was installed. Because of the design of the new cover it was hard to get a firm grip on the typewriter when lifting it back on the pallet.

As a result of a suggestion submitted by an employee performing this operation the pallet used to transport the typewriter on the roller conveyor was changed and locating stops were installed on the bench. This eliminated all the lifting, as the pallet is now pulled off the roller conveyor to the bench, cover installed, and pallet and typewriter are slid back in the conveyor.

Following the typewriter on through the line we realized that we had one more area that required a lot of lifting, our packing area. Here four people were required to lift all the typewriters that came down the assembly line. A change was made in the layout of this area whereby only one person was required to lift but this person had a lot more lifting to do as he had to lift each typewriter and place it in a carton.

We realized this was a problem at the time the layout change was made, so a temporary lifting device was installed. Now the operator would not have to lift the typewriter. This operation has been changed so that the operator now lifts only the carton (one pound) instead of lifting the typewriter, which weighs approximately 30 pounds. This device was designed by our engineering department and built by our apprentice toolmaking school.

The only other area in our assembly operations that had given us any trouble at all was a sub-assembly operation that required an employee to lift power frame baskets weighing approximately 40 pounds from a skid. Although these baskets aren't too heavy, they sometimes stick, and an employee lifting the top basket is lifting above his elbow height. One of the recommendations made by Liberty Mutual Insurance Co., in the survey mentioned earlier, was that a person should not have to lift repeatedly above their elbow height. (The range of elbow height is given as between 34 inches and 45 inches, the average being 40 inches.)

For this reason, the first thing we did was restrict the height of these baskets to

three feet high. Now the employee lifts below his elbow height. After restricting the height of the baskets we went to our materials handling department and requested that equipment be purchased to handle these baskets. With the equipment now in use the operator moves the skid of three baskets to his bench, performs one operation while the parts are in the basket, then removes the parts and places them on his bench for the next operation. He then places the parts on small pallets to be moved up the line on the roller conveyor. The only lifting involved now is removing the empty basket from the top of the pile. After removing the empty top basket the equipment can be raised bringing the next basket to bench height.

Before we leave the assembly area, I would like to mention the chairs used here. Our plant engineering, medical, and safety department investigated several styles of chairs, so that we might select the safest and most comfortable chair for our operations.

In the machining area, we have the usual material-handling equipment used when lifting, but we still have to lift many articles manually in the course of a day. We found from our survey that the biggest source of trouble here involved the lifting of pans. Although we have a rule that the total weight (pan and parts) are not to exceed 75 pounds, we found some instances where this was being overlooked, and some pans weighed as much as 150 to 200 pounds. In most cases the rule was being followed, but because of the size of the container being used it could only be lifted partly to stay within the 75-pound limit.

We had to use more containers, which naturally took up more floor space. As a result of an investigation carried out by machining, safety and material handling personnel, a smaller container has been put into use. Now we can fill the smaller container full, and with most parts it will not exceed the 75-pound limit. It also takes up less floor space.

Lifting problems in the machining area have been solved by the use of belt conveyors, and air lifts.

In one instance an employee developed back pain because of the awkward position he had to assume while performing his

operation. Investigation showed that he spent most of his time in a bent position. This was solved by raising the saw and table so he could work more comfortably.

Another source of help that may be overlooked is the purchasing department. Many purchased parts remain in their original container until the parts are used, so the container has to be handled somewhere along the line. By having the purchasing department notify vendors to ship parts in smaller containers, keeping the total weight around 75 pounds, it is possible to handle these containers without too much difficulty.

Here's an example of what I'm talking about. We used to receive main springs in cardboard barrels that weighed 300 pounds each. We now receive them in cardboard cartons, weighing 74 pounds. Each carton contains four smaller boxes weighing 18 pounds each. Although the cost of the springs were increased slightly, we eliminated many handling problems in the plant that more than overcame the increased cost.

In trying to solve our back injury problems we followed three basic steps:

1. Recognized that we had a problem.
2. Analyzed the problem for the how, when and where.
3. Used one of the E's of safety—Engineering.

Now we come to another E of safety and one I believe to be the most important—Education. As I pointed out in the beginning, people can become members of the "Aching Back Club" without too much difficulty. We can find out all the statistics, take care of all the engineering problems, and people will still hurt their backs if they don't understand the problem. Therefore we have to educate them, and this is what Dr. Martin and I have been working on. We have taken small groups of employees from the high-injury areas and, by using slides, we have discussed the basic structure of the back, how it works, and the importance of good posture when sitting at a work bench. We feel that if the employee has a chance to see how his back is constructed, and what it can and cannot do, they will be more conscious of good lifting habits.

Education must not stop at the plant gate. We know from experience that if we elimi-

nate all the problems in the plant we would still be left with 30 per cent of our problem because of the back injuries that occur off the job. Therefore it is important that we extend our education program into the home.

Even though many believe that the back problem is here to stay and there is nothing we can do about it, I hope I have been able to give you some idea of what can be done if you really want to lick the problem.

HUMAN ENGINEERING AND MATERIAL HANDLING SAFETY

By WILLEM S. FREDERIK, M.D., PH.D., M.S.L.H.
Director of Research and Development, Research Center,
Liberty Mutual Insurance Company, Hopkinton, Mass.
Lecturer, Harvard School of Public Health, Boston, Mass.

"Human Engineering" in its broadest meaning, or to use the modern term "Ergonomics," aims at the optimum use of the human being to serve the community and the individual in the best possible way. Ergonomics is the science which studies the "laws of work," emphasizing the capabilities and limitations of mankind, physically as well as mentally.

Technical developments are often so far advanced that the capabilities of the user, rather than the potentialities of his equipment, limit the performance of the two working together. Disregard for the human limitations results in an alarming number of fatalities and injuries caused by his own inventions. Because accident prevention is our goal, recognition of the pathological man-artificial environment relationship is paramount in order to undertake steps to cure the situation.

The industrial hygienist, safety engineer, physiologist, psychologist, industrial physician, traffic engineer, law maker, and gadgeteer, just to name a few, have in many instances devoted a lifetime to making the artificial environment a safe place in which to live. However, the magnitude of loss payments prove that much more ought to be done. The problem is basically simple: we have obviously a mismatch between man and environment and we must do something about it to improve the situation.

Ideally, we first must know man, machine, and environment before we can even try to

match them. The modern approach to this problem is basically to adjust the machine or the artificial environment to man and not man to the machine or environment. The latter approach may be acceptable to the armed forces where the human criteria, out of necessity, are different from peacetime standards.

The artificial environment and the machine are secondary to man. Disregard for this basic human requirement will create a health hazard. Research, as I see it, must and can contribute in a significant way by gaining knowledge necessary for the application of the principles of Ergonomics. Acceptance of the fact that better understanding of accident causation will result in better accident prevention, is of extreme importance to our society. The ultimate goal of Ergonomics is the determination of work procedures, machine designs, and environmental controls that will result in loss prevention.

It seems to me practical to concentrate safety research activities to a certain degree to those areas which have proven time after time to be significant accident producers. These areas can be selected simply by studying national accident figures, or our own statistics. A recent study made by our loss prevention department over a period of two years reveals e.g. that 23.8 per cent of all high cost workmen's compensation accidents are related to manual materials handling and are responsible for about 20 per cent of the total cost. These figures indicate

the need for better understanding of causation of accidents as a result of pushing, pulling, lifting, bending, twisting, carrying, etc.

The plant physician, as well as the safety engineer, would be greatly helped if we could supply him with answers to numerous questions such as: How much can the average man lift? What is the maximum daily allowable energy expenditure of woman? Is pushing more efficient than pulling? What is the proper relationship between the slope of a ramp and the total weight of the hand truck and the load? Many of these questions can be answered today because the research procedures and tools are available.

It is my privilege to discuss and to demonstrate a method which has been proven to be of great importance in the study of some of the human factors in material handling and equipment design.

One of the favorite tools of the physiologist interest in ergonomics is his equipment to measure metabolism. Because of the importance of this equipment, I have spent a good deal of time and effort in developing an instrument which will measure work efficiency more satisfactorily than most commercially available equipment. I would like to discuss this new instrument, called the "Differential Flamoxymeter." It enables us to obtain an accurate, continuous determination of the oxygen concentration in gas mixtures, information basic to the evaluation of metabolism and human efficiency.

Description of the Differential Flamoxymeter

In considering the development of a method to determine oxygen quantitatively and qualitatively in gas mixtures, it seems logical to utilize chemical or physical characteristics of oxygen, which are in degree, or essentially, different from other gases. Therefore, the fast oxidation of combustible substances as it occurs in a flame seems especially appealing because this reaction does not take place without oxygen in the majority of circumstances. Furthermore, the physical phenomena which accompany combustion will provide us with a variety of choices for quantitative measurements. The instrument must be designed in such a way that the oxygen concentration

of the gas sample is correlated with the chemical or physical characteristics measured.

A priori we did not expect satisfactory results from a method in which the heat production of a flame would be affected by minor changes in the oxygen concentration in the environment of the flame. One may expect that the limiting factor for the combustion under these circumstances will be the rate of supply of combustible material rather than the concentration of oxygen in the sample.

To make oxygen the limiting factor in the combustion we simply can "reverse" the flame. Because combustion is a physico-chemical process in which the combustible component is as essential to the reaction as the oxygen, it makes no difference whether a combustible gas burns in an environment of oxygen or whether oxygen burns in an environment of combustible gas. Therefore, if we were living in an atmosphere of hydrogen, we would call oxygen a combustible gas and the gas company would supply our gas ranges with oxygen.

By utilizing a reversed flame for the determination of the oxygen content in gas samples, it will be possible to produce heat in direct proportion to the oxygen content of this sample. In order to obtain this direct relationship, one must provide an excess of the combustible gas in the environment and at the same time one must keep the flow of the sample gas toward the flame at a constant rate. Under these circumstances, the instrument is specifically sensitive to oxygen and not to other gases. Notwithstanding the simplicity of the principle of the reversed flame it was found to be extremely time consuming to develop an accurate, sensitive, and practical instrument for the determination of the oxygen content in gas samples.

A differential method, using two flames, was chosen because it had some advantages over the utilization of a single flame, as will be explained later.

As combustible gas, hydrogen was found to be the best environmental gas of the group tested and has been used without experiencing any difficulty. FIGURE 1 presents a sketch of the essential parts of the Differential Flamoxymeter. Chamber A is kept under a constant low vacuum by means

ture, pressure and humidity of the patient's air. This is accomplished by means of a simple analog-computer in which we feed manually three variables: (1) Barometric pressure, (2) Dry bulb temperature and (3) Wet bulb temperature. The meter reading of this computer indicates the air flow correction necessary to compensate for the deviations from "standard" conditions of the patient's air. (Dry air at a temperature of 0° C and 760 mm Hg). Under these circumstances the patient's air supply is the equivalent of e.g. 3000 liters of air per hour, at 0° C temperature and 760 mm Hg pressure.

The flamoximeter indicates the percentage changes in oxygen in this standardized air flow, which now becomes an absolute measure of the volume of oxygen (under standard conditions) consumed by the test person per time-unit. Accepting a fixed respiratory quotient, which is permissible in metabolism determinations, based upon oxygen uptake, we now can express the difference in oxygen concentration of air going towards the patient and of air coming from the patient, in calories per unit of time.

This a priori correction of air flow makes time consuming calculations after the experiments are terminated, unnecessary and this is especially advantageous for field trials.

As I have mentioned earlier, I would like to demonstrate to you the importance of the evaluation of energy expenditure in the study of materials handling problems.

I have chosen, as an illustration, a very simple lifting experiment in which my associate will lift a box weighing 10 pounds every 4 seconds over a vertical distance of 1 foot. If he continues to do this work for 1 hour, his total work output will be $60 \times 15 \times 10 \times 1 = 9000$ ft./lbs. or about 29 Calories per hour.

We will see that his energy expenditure (to compare with "input") far exceeds this output value, because the human engine has a relatively low efficiency. The human efficiency, however, is not a fixed value and its magnitude depends upon a multitude of factors, some of which we will discuss today.

First we will "hook up" the test person with the Differential Flamoximeter while he is in sitting position, and we will notice

that his "rest" metabolism is about 75 Calories per hour. This value is somewhat larger than his so-called "basal metabolism." The basal metabolism is to compare with the energy expenditure of an idling engine. It is more realistic to calculate the efficiency of work after the basal metabolism has been deducted from the measured energy expenditure values.

We are now ready to start with the actual lifting experiment. We will notice that our instrument shows an almost immediate increase in energy expenditure, but we also will notice that it will take some time before a steady state has been reached. The total energy expenditure reads now a constant value of about 120 calories per hour or about 45 Cal/hr after deduction of the rest metabolism. We previously calculated that the actual output is approximately 29 Calories per hour: An efficiency of only $\frac{29}{45} \times 100 = 6.4$ per cent.

We now will repeat this experiment, varying only one factor and see what will happen to the efficiency of this test person under these circumstances.

In the previous experiment, we placed the box on a table which is about 30" high. The lifting took place, therefore, between 30" and 42", as measured from the floor.

In the second demonstration, my assistant will lift the same box at the same frequency and over the same distance of 1 foot, but starting the lifting from the height of 18" from the floor. The external work is still as in the first experiment, 9000 ft./lbs. or about 29 Calories per hour. The Differential Flamoximeter, however, indicates in the second test a higher energy expenditure and we read now a total metabolism of about 170 Cal. per hour. After subtracting the rest metabolism we find that the cost of this work is about 95 Cal. per hour. The efficiency is now reduced to $\frac{29}{95} \times 100 =$ about 3 per cent.

This simple demonstration reveals the importance of the area in which materials handling takes place. If time permitted also to vary the weight of the box, we could demonstrate that the efficiency of lifting could be made about 85 per cent by increasing the weight of the box to about 40 pounds and by starting the lift at approxi-

mately 4 feet from the floor. (Variables such as sex, age, body weight, height, etc., are purposely excluded from this table.)

This type of studies reveal that the human efficiency for many industrial activities has an optimal value if the circumstances are selected correctly.

This means that independent of the work output, certain design-environmental or other factors influence the energy expenditure of men. One of our goals is to find situations in which men work at this top physiological

efficiency or, in other words, expends the least amount of energy for his daily industrial physical work. This approach will reduce fatigue and stress, and consequently, injuries related to fatigue and stress. Much work has to be done in this field before we will notice the full effect of Ergonomics on the reduction of losses.

It is my firm belief that ergonomics will be of great help to the army of safety experts in their battle against our mutual enemy—accidents.

SAFE HANDLING OF LOW LEVEL RADIOISOTOPES

By E. R. HARRIS

Safety Eng., Missiles & Vehicles Dept., General Electric Co.
Philadelphia, Pa.

Radioactive materials continue to find increasing application and acceptance in modern industry. If you presently do not have radioisotopes in your plant, there is a strong possibility that at sometime in the near future you will. We are going to talk about some of the problems you, as safety engineers, will be confronted with when that day arrives.

The problems of control of radioisotopes may be reduced to essentially three factors: removal, or reduction of the hazard to lowest practical levels, guarding the hazard, and protecting the worker. Any program to use radioisotopes should be reviewed with the intention of applying controls in the above order.

A recent news note in a nationally circulated magazine (Life, 9-22-61) best illustrates the need for an adequate control system. Alarming amounts of radioactive contamination were discovered in a dozen laboratories at a Canadian university. The contamination was accidentally discovered by a graduate student while attempting to calibrate geiger tubes in the university's old physics building. Lab after lab proved to be contaminated. University officials and a decontamination unit of the Canadian Army were rushed to the scene. Subsequent investigation disclosed that the labs had been used by Ernest Lord Ruth-

erford and his associates between 1896 and 1907.

Lord Rutherford conducted much early research in radioactivity and is considered to be the father of atomic physics. In those early days little was known of the harmful effects of radiation, and a more relaxed view of laboratory cleanliness and order was permitted than could possibly be tolerated today. The legacy of Lord Rutherford's work habits has suddenly been handed down to us; and it points out a condition which we will not be permitted to pass on to our grandchildren, even accidentally. The law and common sense now dictate that you maintain strict control over the use of radioactive materials.

Radioactive materials, may appear in your plant virtually unannounced. Usually in micro-microcurie amounts incorporated in devices having little, if anything, to do with radiation work. Certain wave guide tubes used in radar installations are an example. Radium 226 is not covered by the Atomic Energy Act of 1954, and devices containing this material often only require registration with the proper state authority after being received. What control measures do you have which notify you when such materials are received? I am not implying that presence alone con-

stitutes a hazard, but rather that a lack of knowledge of intended uses of these devices; and more important, their ultimate disposition may indeed constitute a hazard.

Obviously the need for concern is greatest when you become involved in programs deliberately designed to utilize radioactive materials. These programs usually require licensing by the Atomic Energy Commission. Meeting the requirements of the A.E.C. at the time of application does not insure the elimination of problems after the actual work has started. The Commission, in Washington, can only act on what it reads; you must act on what you observe first hand. The forms in which radioactive materials will appear, and the uses to which they can be put are limited only by the imagination. The amount of control required may vary, but one thing is certain, a system must be established which will permit the required flexibility to do the job without sacrificing safety requirements.

Reams of material have been published documenting the potential hazards associated with the handling of radioactive materials. More reams of material—laws—have been published purporting to effectively control the use of radioisotopes and reduce hazards to acceptable levels. It is not my intention to discuss these laws, but rather to indicate how, within the framework of the law, an effective radiation control program can be administered.

An effective radiation control program requires the issuance of a policy statement of intention to control radiation. The statement should contain nothing which might later be subject to interpretation, and it should fix responsibility for control. Of uppermost consideration should be the health and welfare of employees and the public. All else is secondary.

Effective control of radiation begins in the design stages of the facility or equipment. A knowledge of the type and amount of radioisotopes to be used, and the effects that this will have on location, environmental restrictions, shielding and handling requirements is necessary. Here is the place to provide as much built-in safety as possible.

Selection of suitable personnel who will work directly with radioisotopes is of the utmost importance. Every effort must be made to provide for employment of individuals who are mentally and physically suited for this type of work. The medical department should establish standards for physicals at employment and determine the need for periodic re-examination. A positive system for reporting and clinically observing actual or suspected over-exposures to radiation is indicated.

Training programs and information courses are needed which will provide personnel with an understanding of the hazards associated with handling radioisotopes. All personnel should be trained in emergency procedures, including the use of radiation detection instruments. Emergency procedures should be clearly written and posted. To reduce the possibility of misunderstanding concerning the handling of radioisotopes a separate and distinct series of safety standards should be adopted and enforced. No one should be released for isotope work until he has demonstrated an understanding of the established safety requirements.

Documentation of all occupational radiation exposures is necessary. It is of utmost importance that these records be accurate and up to date. Individuals transferred from other companies should be required to supply documented previous radiation histories. An alternative to this is to assume that the individual has received the maximum allowable amount according to his age. The importance of always wearing personal monitoring devices cannot be over-emphasized.

Film badge programs are usually best administered by outside concerns who specialize in this field. They are usually prepared to provide rapid, accurate exposure records and, in addition, provide legal responsibility for their determinations.

Within the limits of whatever security restrictions you may have imposed upon you, it will be to your advantage to keep the appropriate civil authorities in your community posted. If the local fire company were to respond to an alarm unaware that it might have to deal with radioactive material, considerably more harm than good could be the result.

Constant surveillance would finish the list of general requirements. If radiation protection is to be your responsibility, be especially alert in this area. Under pressure from all directions to get the job done, you can't depend on the individual worker to always adhere to the best principles of radiation safety. Few accidents have as short a reaction time as an over-exposure to radiation. Even fewer have anywhere near the publicity value. The true facts in the case can easily be lost or distorted before anything worthwhile is learned, or corrective measures taken.

Research laboratories usually have more complex radioisotope programs than straight industrial application users. I will describe the program of one such laboratory.

The Atomic Energy Act of 1954, Title 10—Part 30, paragraph 30.24 requires among other things, that a committee be established "which will review and approve, in advance of purchase of radioisotopes, proposals for such uses and has appointed a radiological safety officer who will advise or be available for advice and assistance on radiological safety problems."

The committee's purpose is to establish and maintain accepted radiation safety and health standards. The committee must have absolute authority to pass on all matters concerning the safe use of radioisotopes, and to reject or modify any request for their use if, in their opinion, such use would jeopardize these standards. The committee does not sit in judgment on the relative merits of the work itself.

The plant physician, safety engineer, representatives of the various departments and a specialist in radiation protection are members of the committee. The medical doctor is responsible for establishing and maintaining a sound medical program and his presence on the committee insures adherence to strict medical consideration of all problems. The presence of the Safety Engineer prevents the sacrificing of sound safety principles as an expedient short-cut to a fast solution to a problem. This trick is not unique to the field of radiation as you well know. The representatives of the various departments often supply special knowledge which eliminates problems which otherwise would not have come to light until too late.

The work horse of a safety committee is the radiation safety specialist who should be someone technically qualified to give advice in this area. In addition, his duties will include most or all of the following:

1. Provide initial contact service for individuals wishing to use isotopes.
2. Discuss the overall program, evaluate the potential hazards, and provide necessary information to insure selection of proper isotopes by balancing radiation safety and health requirements against the job to be done.
3. Determine the background and training of the requester, with regard to previous isotope experience.
4. Provide for instruction as the case may indicate.
5. Examine the area in which the work is to be performed, and evaluate the potential hazard with regard to area personnel, equipment and environment.
6. Outline the personal protective equipment which will be necessary for the job.
7. Outline the work procedures insofar as radiation protection and waste disposal is concerned.
8. Supply necessary guidance for radiation requirements to be included in the normal request.
9. Arrange for full isotope group meeting to consider the problem, supply copies of request in advance of meeting for adequate consideration.
10. Record minutes of meetings.
11. Order radioactive materials. This is the only person authorized to do so.
12. Receive materials; again, the only person who can do so.
13. Store materials in a tamper-proof area. Test for leaks. Maintain inventory records.
14. Distribute radioactive materials as needed; label containers, areas, equipment.
15. Perform startup and regular surveys to insure proper procedures are being followed.
16. Dispose of radioactive waste through government-authorized channels.
17. Maintain correspondence with AEC and state boards.

18. Keep the full committee informed of all happenings of interest in this area.
19. Maintain radiation exposure records.
20. Conduct environmental surveys as indicated by the type of work performed.
21. Maintain professional contact with experts in the field.
22. Maintain contact with professional societies to insure knowledge of advancements in the field.

The committee's responsibilities cannot be overestimated. A decision to permit the use of isotopes is not lightly made, and cause for concern exists right up to the time that the material is finally disposed of.

In every field of endeavor the problem of dealing with people is important. This is especially true where you start talking radiation. The individual requestor often feels that you are being unnecessarily restrictive; you're standing in the way of progress. His associates in adjacent areas feel that you're too liberal and aren't exercising sufficient control. The manager is concerned with increased costs. Everyone wonders why so strict medical requirements if everything is so darned safe. And finally, if the project gets big enough,

the community starts to wonder about all that radiation floating around.

The solution to the problem of radiation lies in strict control of all sources of radiation and their use, based on current laws, and an understanding of the presently accepted theories of effects of radiation.

SAFETY RULE ENFORCEMENT—A KEY TO ACCIDENT PREVENTION

By RICHARD R. WILEY

Safety Eng., Bethlehem Plant, Bethlehem Steel Corp., Bethlehem, Pa.

In all of the many diversified activities of a large industrial organization like our Bethlehem Plant of the Bethlehem Steel Co., there are certain common basic principles. One of the most important is the principle that work should be done without injury to personnel. And one of the important elements in carrying out that principle is the development and enforcement of safety rules. The rules themselves are necessary, but unless they are followed—and followed consistently by everyone—they are simply a nice expensive collection of words.

Making sure the rules are followed is what is meant by "enforcement." By definition,

"enforcement" is "that which gives force, energy or effect; a putting into execution."

Our session is on "The Dynamics of Supervision." Again, by definition, "dynamics" is "the motive and controlling forces of any kind, and their mode of action."

My endeavor, therefore, will be to touch on some aspects of our program relating to modes of action, and those measures which give control, force, energy and effect to our safety rules and accident prevention program.

With this preface our stage is set, and the program begins. It must begin—I'm sure you will agree—with education, for education

is the impartation of knowledge, skill and discipline of character.

John Ruskin had this to say about people and education: "Education does not mean teaching people to know what they do not know. It means teaching them to behave as they do not behave. It is a painful, continual and difficult work; to be done by kindness, by watching, by warning, by precept and by praise, but above all by example."

At this point I would be surprised if everyone was not thinking to himself—"old hat stuff," because we should all know this general concept. But is it equally true of our employees for whose safety we are responsible? Specifically, do we, in our respective operations, employ every possible practical technique for promoting enforcement among our personnel at all levels? Or do we simply make a few standard selling approaches and go on the hopeful, but woefully mistaken, idea that all employees have been adequately schooled in safety? Then, with unjustifiable finality, we dust off our hands with the proclamation, "Well, that's that!" Make a mark on your calendar on the day that we agree that our enforcement cannot be improved. That is the day we start slipping.

You can have as much safety as you care to be responsible for. You can have little or none if the consequences do not bother you. After an accident happens it is easy to say, "The man knew better." We all realize, I'm sure, that it more realistic to swallow our pride and accept the fact that the man would have known better had he been better instructed.

To dodge responsibility is easy; the difficult part is to dodge the consequences of dodging the responsibilities.

The thought of simply talking to you about safety—whether principles, modes of action, or whatever—reminded me of the college professor in English composition. He would refer to a certain bit of work as "an unfinished Indian arrow"—long, polished, lots of feathers, but no point! To avoid being guilty of that very thing, it seemed to me that a maximum of specific action techniques and a minimum of theoretical principles is best.

In order to better identify and better acquaint you with our Bethlehem operation, let me lay a little groundwork.

Industrial Subjects Serious

The plant attains a force of 22,000 employees working 43 million hours a year. The average disabling injury frequency for the past ten years has been 0.64.

A successful program in any plant, regardless of size or nature of work, can result only with the unlimited backing of top management and the acceptance of responsibility by all levels of supervision. Our program begins here.

At a regular time each month, a general manager's staff meeting is held. The general manager's staff meets with all superintendents and their assistants. For one hour we discuss and illustrate with pictures the overall safety experience of the plant, and superintendents who have had serious accidents in their departments give an explanation of these to the group. Projected pictures of the re-enacted incident add realism and interest, and promote understanding for the responsibility and necessary preventive measures.

Within the next three days, 38 departmental safety meetings are held according to a fixed schedule. The superintendents meet with all of their foremen and cover all of the material presented at the first meeting. The foremen in turn pass the pertinent information on down the line to the men. Here again, to be at all effective, the message must be presented with enthusiasm. It was Emerson who so rightly said that nothing great was ever accomplished without it.

In order to develop in the foreman a keener perception of his operations and the importance of his function of supervisor in preventing accidents to the men, the job safety analysis program was adopted. This three-column worksheet is a detailed study of an operation by the supervisor in consultation with the workers for the purpose of determining how it is now being done, what the associated hazards are and how the operation itself can be improved to eliminate, minimize or control the hazards. When analysis has been completed and approved, it becomes a matter of record and is the only acceptable method for performing that particular job.

Rules and regulations are very necessary for safe conduct. We have 60 different booklets called safety codes. The green ones represent department codes. In addition, many workers are given other codes relating to

their specific jobs within the shop, such as crane operators, welders, and so forth. Violators of the provisions of the codes are subject to disciplinary measures up to and including discharge. Our supervisory safety code is designed intentionally on a broad basis as a guide for departmental safety programs and codes, and it outlines those things which should be covered by them in detail.

Certain other standards or guides are posted on bulletin boards. For example, an eye protection standard is designed to leave nothing to the imagination as regards the required eye protection. It specifies by picture the minimum type protection necessary when exposed to any conceivable job with eye hazard. It leaves no room for excuses for anyone.

All of us recognize the fact that the most effective way to sell any program is to offer constant reminders in the form of proof of the need and value of an item. We have been highly successful in stimulating interest through the dissemination of information on a variety of incidents.

A simple, letter-size "Safety News Bulletin" is promptly prepared on any incident of significance and interest, and run-off in quantities of about 1200 copies. These are sent out for complete plant coverage so that every foreman has a copy to use as material for his five-minute safety contact with his men. In order to insure that every man is aware of the incident, as well as being a follow-up reminder, copies are also posted on all bulletin boards.

The manual or mechanical handling of materials exacts a heavy toll in injuries to the fingers and hands and presents an infinitely more difficult problem than that of protecting the eyes. We do, however, provide hand hooks in great quantity and rigidly enforce their use when taking up, guiding, or setting down crane lifts of bars or similar materials subject to shifting. This program, although requiring constant education and enforcement, has been extremely successful.

An illustrated program on the subject of pinchpoints is presented at a safety meeting. We have developed a number of programs on a variety of subjects. The presentation consists of about 20 color slides and a prepared 15-minute commentary. In order to create realism, actual case histories are used. Visual aids, properly presented, are well re-

ceived and quite effective. It leaves an employee well informed and with no excuse for an unsafe act.

Supervision must recognize the fact that in order for a man to be safe around crane lifts there is considerably more to it than controlling his acts with respect to pinchpoints. The old adage, "A chain is no stronger than its weakest link," is a literal fact. In respect for this, we have an extensive chain maintenance program. All chains are sent to a centralized shop for periodic annealing, inspection and repair. In an average year about 8,000 chains are serviced and each one machine proof-tested before being returned to service. Each chain bears its own identification number and has a complete history file card. This chain servicing description is offered only as a typical example of a great number of rigidly enforced procedures employed to guarantee maximum safety.

In a typical year about 82,000 respirators are disassembled, washed, disinfected, dried, repaired, reassembled, packaged in cellophane bags, sorted and returned to the departments. The pick-up and return is done daily. A total of 17,000 pairs of goggles were similarly processed. The function of this central servicing is to encourage the willing use of this vital protective equipment.

Training of physically qualified men in symptom recognition, oxygen mask rescue and first aid for men exposed to gas is maintained at a high state of preparedness. Two scheduled two-hour classes per day, five days a week are held at either our central training school or under actual field conditions. Nearly 4,000 men participate in this training annually. Each trainee undergoes a refresher course every six months.

Any program, to be effective, must be policed. Therefore, every six months the school records are carefully reviewed and an appropriate form letter—either "satisfactory" or "unsatisfactory"—is prepared and submitted to each department superintendent advising the status of training.

The teaching of first aid is an essential part of our safety program. In addition to its general concept of providing emergency treatment and preparing the injured for transportation, it is also of intangible value by indirectly and subconsciously imparting thoughts of safety to both participants and casual observers as well.

Industrial Subjects Sessions

Our general plant minimum requirement is that 10 per cent of the shift personnel be qualified first aid trained men. This means certification by the U. S. Bureau of Mines for the successful completion of the 15-hour course. All foremen are also required to have this same training.

Here again, as in gas training, we continually check on the adequacy of the training. A supervisor from our central safety office conducts test drills at the rate of 28 per month among the departments. This means that every department is examined every other month.

When an employee is injured, no matter how slightly, we insist that he report to his foreman for referral to a dispensary. Four copies of the form shown are prepared, two of which accompany the injured to the dispensary. Three times daily all pink copies are collected by the Safety Department and immediately examined. This system keeps us currently informed of most incidents, and puts the departmental supervisors in a position whereby they must investigate the incident in order first, to prepare the report form, and second, to be able to provide additional information which is often requested.

A safety program is not any one thing or any one person. Rather, it is an aggregate of a great many things requiring the efforts of every person. This is to include a vast number of things, a few of which were touched on here—protective equipment, devices, controls, rules, regulations and procedures—and the enforcement of them to maintain effectiveness. Were it not for these techniques our personnel would, naturally, care far less about safety in general. Infractions do occur, however, and violators must be dealt with accordingly.

A typical discipline report for a safety violation is on the subject of hand hooks which were mentioned earlier. It reads "Man placed hand on lift of two and one-half inch liners to guide same, while placing lift on buggy. Explained to man that we insist on safe practices being followed, as all of these are for his protection. Pointed out to man that he was holding hand hook in his left hand while guiding lift with his right hand. He had the proper tool but was not using same." Discipline: "Warning."

In an average year we have occasion to

impose 357 formal written safety disciplines against employees' records. Of these, 83—or about one-fourth of the total—include time-off penalty, which in the average case amounts to slightly less than 10 hours.

Common sense reasoning will convince most employees that a safety rule should be followed. There might always be the small minority who insist upon ignoring the rules. Experience indicates that with such people disciplinary action must be taken. If corrective action is not taken, the regulation soon ceases to exist. It is the constant training and correction which in the end becomes self-discipline.

If the man on the job fails for any reason to follow known safe practices, he is taking a chance. If we in management condone his unsafe practices, then we too are taking chances, the only difference being that our chances are more serious since by condoning bad practices we are actually teaching disrespect for regulations. Consequently, we cannot excuse a poor accident record by accepting unsafe acts if we have failed in our duty to enforce safe procedure.

We believe that the many standards and procedures in effect at the Bethlehem Plant, a few of which were presented here, all play a significant part in the difficult role of developing proper attitudes on the part of all employees, including supervision.

The problem is to impress indelibly, through enforcement, on the mind of the individual that there is an approved safe way to carry on most activities. The various modes of acting are limited only by one's imagination and the unrelenting effort of enforcement to maintain liveliness.

The three essentials to safe practices—knowledge, skill and desire—can be developed through these media. The thorough preparation of the procedures can give us knowledge. The faithful application of them will develop skill. The rigid enforcement of their provisions will create desire. This last matter I associate with personal safety contact—those little five-minute discussions between the supervisor and the employee.

Personal safety contact in its conventional form is, to my mind, an artificial and unconvincing way to discuss safety unless the material is related to the daily doings of the supervisor or the worker. A supplemental approach to the general personal contact can

readily be based on an on-the-spot correction of something that an individual or group is doing incorrectly. This is dynamic enforcement. Simultaneously, to find a theme for a safety contact will be a challenge to the supervisor to detect a fault—and correct it!

To illustrate my point, I'll ask each of you to search your memory for an occasion when you listened to someone's remark or lecture on the subject of driving precautions on the highway. Can you recall such a session? If so, do you remember what was said? If not, I can assume that you were not impressed.

Now, another question. Have you ever been personally apprehended by the law? If so, can you ever forget what you did and what was said to you? I can now assume that you were impressed! A personal contact of this type is really personal and is most convincing. To the vast majority of individuals it creates a healthy respect for the law while creating a desire to abide by the rules and regulations.

The creation of a desire is commonly

known as "habit." Horace Mann, an American educator of a century ago, very aptly described it thus: "Habit is a cable. We weave a thread of it every day and soon it cannot be broken." This, in a nutshell, is what can be achieved through continuous enforcement of required practices.

We of Bethlehem wish to exchange ideas with our industrial compatriots. We hope to be helpful; we also hope that we can be helped. The problem of enforcement is a common one. Diversified action is the key. The task is simple, but not easy. There remains nothing but hard work.

In closing, I think it fitting to quote one of our superintendents who, in response to a general survey question on what more we could do to improve our plant safety program, said this: "Fundamentally, our program is complete. Perhaps what we need now is more backbone and less wishbone!"

This can be done in the very best American tradition: *enforce the rule, but never rule by force.*

DAMAGE CONTROL—A NEW HORIZON IN ACCIDENT PREVENTION

By FRANK E. BIRD, JR.

Supvr., Safety & Plant Protection, Lukens Steel Co., Coatesville, Pa.

The anticipated goals of the Accident Damage Control program at Lukens Steel Company in its planning stages five years ago were: first, a reduced injury rate and secondly, cost improvement. While both of these goals have exceeded all expectations, it is primarily the cost improvement aspects of the program that will be emphasized in this presentation.

While safety men can base the complete justification for their safety programming on the injury prevention potential, it is naive to underestimate the influence and role that sound economics can play in the further extension of safety efforts.

Cost improvement results were obtained last year at Lukens by the practical application of a very simple concept we have all ascribed to for many years—the fact that injuries can be prevented by controlling ac-

cidents. The larger portion of this presentation will reveal the programming methods involved.

Reference to our Company's Annual Report for 1960, that was sent to all stockholders and employees, reveals the economic highlights of plant operation. After all other distribution of the Lukens sales dollar was made, \$1,430,892.00 was made payable to stockholders in dividends and \$3,517,383.00 was retained to be reinvested in our business. Keep these two figures of one and a half million and three and a half million in mind in considering another small paragraph involved with this financial picture: "The first year's organized experience with a relatively new industrial safety approach to the area of accidental property damage was completed in 1960. The program's contribution to cost improvement

was estimated to be a half a million dollars."

To avoid confusion at this point, let me emphasize that the program required to produce this one year achievement took five years of careful planning and development. This planning and development began with the complete acceptance of the concept that engineering out all accidents, whether or not they involve personal injury, could only result in an improved injury performance at reduced operating costs.

The fact that a common denominator between personal injury and property damage exists is borne out by the accident relationship known as the Heindrick Theory. Statistics have indicated that for each disabling injury, 29 minor injuries occur; while 300 accidents (with no personal injury) that may or may not involve property damage have also resulted.

Suppose we consider a hypothetical accident case to show this relationship of property damage to personal injury—

1. A moment of decision (mule sitting down while hitched to vegetable cart).
 2. The approach—an un-aie act (farmer striking mule).
 3. Resulting in accident which may involve property damage (mule kicking wagon, vegetables and farmer into the air).
 4. Personal injury or both (mule heehawing while farmer looks on wrapped in bandages).
- To more effectively achieve our main objective of reduction in injuries to our employees, it was logical that greater emphasis be given to the control of all accidents. In addition to the humane aspects that had always been a vital concern, the economics involved with the anticipated all-accident approach indicated that any additional time and effort required would be more than justified. The four basic control methods to be described are:

- 1) Reporting;
- 2) Investigation;
- 3) Analysis;
- 4) Remedy.

Let's first explore the development of our reporting system in all accident control, since any accident prevention program is only as strong as its ability to discern the true nature of its problems. The first

method of reporting is through employee compliance with our revised general safety rules. In October 1956, a broad revision was made in our rules to include the reporting by all employees of any accident resulting in personal injury or property damage.

General safety rule No. 2 was rewritten to read: "Report immediately to your foreman or supervisor any condition or practice you think might cause injury to employees or damage to equipment."

The key to our whole program, general safety rule No. 5, was rewritten to read: "Whenever you or the equipment you operate is involved in any accident that results in personal injury or property damage, regardless of how minor, you must immediately report it to your foreman or supervisor. Get first aid promptly in a company dispensary."

In order to assure the success of the program, known violators of this rule have been equitably disciplined. Approximately six employees have been given time off from work for gross violations (since the adoption of this rule in 1956) while written and verbal warnings have been used more widely.

Fully recognizing the natural reluctance on the part of employees and supervisors to report the fact that they were involved in damaging company property, a simple report form maintained by the foreman of each repair shop serves as the same control to our accident damage program as dispensary records serve our injury prevention efforts. A damaged equipment repair tag was next introduced and required to be used by all employees whenever equipment was sent for replacement or repair as a "reporting" control to further pinpoint accident location, time, date and apparent cause.

One of the most effective methods of control is the investigation of each accident in order to determine corrective action and prevent recurrence. Mass collection of facts obtained from good accident investigations, properly correlated, formed patterns of common occurrence that were used effectively for further control. A new standard practice including personal injury and property damage was adopted as a tool to attain desired goals in proper accident investigation.

Essentially, the supervisor or foreman in whose area of responsibility the accident occurs is responsible for conducting a thorough investigation and submission of this official supervisor's accident report form. One form is used to cover personal injury, property damage or both. Since identical controls are used to prevent accidents whether they be personal injury or property damage, no conflict presents itself in the application of this two-purpose form and its broadening effect on the total accident control outlook of supervisory personnel.

Just as the disabling injury provides ammunition for drawing upon more extended management effort, so by standard practice any property damage accident of one thousand dollars or more is dealt with in the identical manner of a disabling injury. An immediate notice of serious property damage is delivered to all superintendents and managers. The superintendent concerned is required to hold a formal hearing of all persons involved in order to determine adequate remedial action. The results of this hearing are promptly forwarded to the manager, who then calls a final review meeting which includes the superintendent, key supervisors and myself.

This opportunity for top management to actively demonstrate its concern for accident prevention tends to keep everyone more aware of the accident problem and their individual responsibilities to maintain effective controls.

It might be useful to look at a few typical accidents in order to realize the importance of the remedial action resulting from these investigations. Accident No. 1 involved an ingot being lowered into No. 48 pit. The crane operator struck the front top of this pit with his ingot dog causing a key section to break off. The direct costs for brick replacement and repair were \$200. However, in order to make the necessary repairs this entire pit had to be shut down. Rehandling of the ingots that remained in the pit, reheating, rescheduling, and four hours of pit delay time added tremendous indirect costs.

Accident No. 2 involved our 206-inch Mill ingot buggy. The mechanical department personnel were changing rolls in our S & R Mill using a large "C" hook to grab the roll and pull it out. Electricians did

not tag the pulpit control that operates the ingot buggy. The operator sent the buggy down to service the 206 Mill (this buggy services both of our mills). Because of insufficient clearance between the buggy and the "C" hook assembly being used to remove the S & R Mill roll, a collision occurred that bent the main frame of the ingot buggy.

Three turns were required for temporary maintenance since permanent repairs would have required eight to 10 days of down time. The direct cost of temporary repair was \$1,250. It is interesting, however, that permanent repairs have still not been made because of the extended down time necessary. The maintenance bills for repair and replacement of wheels, axels, and collector shoes occurring as a result of the bent frame has continued for months, and is tremendous. On six occasions, two turns have been required to do this work.

Accident No. 3 involved an ingot dropping on our 206-inch steel yard crane scale. Although the replacement scale part cost \$175, it was necessary to ship the entire scale back to the factory for repair. During the week required for repair, all slabs formerly weighed on this scale had to be trucked to a scrap supplier's yard outside our plant and then returned for preheating. Delay time was estimated to have cost at least 40 times the direct costs of the accident.

Accident No. 4 involved a load dropping and destruction of a travograph machine. The old machine was originally purchased for \$6,000; however, a \$25,000 premature capital expenditure for the purchase of a new machine has been proposed.

Accident No. 5 involved a plate shears. The shear crew was trimming plates and allowed scrap to accumulate in the scrap trough. This caused the upper knife block to jam on the downward stroke and fracture the shear housing. Direct costs for repair were \$2,000.00. However, 15 turns of work were lost along with line slowdowns and customer delays. The indirect costs were estimated at \$12,480.

These typical accidents that actually occurred point out the tremendous cost involved in accident damage as well as the importance of an organized preventative program.

The more management is explicitly made aware that people will be hurt or property damaged through certain acts or conditions, the greater the possibility that action will be taken to prevent it. The accident analysis phase of our damage control program pinpoints specific items damaged repetitively and the agencies involved. Supervision concerned are thus equipped to place concerted effort on single specific objectives.

A detailed quarterly analysis is furnished to all key management personnel and includes a comparison of all accident damage costs this year to date to that of last year. It helps maintain a continued awareness of particular departments, agencies and items needing attention. A colorful barometer on the cover gives flash indication of action necessary on the report contents.

Just as compensation is considered a direct injury cost, damaged equipment repair or replacement is considered our direct costs for property damage. In order to show the big potential of cost improvement, our total costs include indirect costs estimated at a four-to-one ratio of direct costs. The estimated total costs of accident property damage for 1960 exceeded one and one half million dollars.

A breakdown by the agency or act inflicting damage revealed crane involvement with well over 60 per cent of our property damage accidents. Four departments stood out as shareholders in the greater majority of all damage costs. Further analysis revealed the cost of accidents by items damaged. A severity rate in dollars per unit of hourly rated manhours of time is used in our plant to indicate trends in control performance. Accident damage severity is expressed as direct costs per million hourly rated manhours worked. (All cost figures used in the remainder of this presentation are rounded off to facilitate understanding and retention.)

The severity rate for 1959 was \$62,000 per million hourly rated manhours worked. For all program purposes this was our base year. The 1960 year end damage severity rate of \$45,000 was substantially below the previous year's rate.

To realize more fully the cost improvement aspects of this comparison, let's examine more closely the 1960 accident

rate of \$45,000 per million hourly rated manhours worked. This was an improvement of \$17,000 per million manhours worked over the 1959 performance. Recognizing these are direct costs we are using, let's translate this into total cost improvement for the calendar year. This improvement per million manhours worked multiplied by the millions of hourly rated manhours worked revealed the direct cost improvement for the year. The value of our total effort becomes more evident when we apply the four-to-one ratio to determine indirect costs. By adding both direct and indirect costs, the larger figure of one half million dollars becomes a total estimated cost improvement for 1960.

Here are some new program examples of accident repetition highlighted by the analysis phase of the program with action taken that helped to bring about this cost improvement:

1. One door was damaged ten times in less than one year. (The door has been widened; piling in the loading area inside the door more effectively controlled.)
2. One railroad gate was broken 30 times in 1960. (The gate has been relocated and has not been damaged since.)
3. Better than 75 per cent of all narrow gauge railroad rolling stock maintenance is due to accident damage. (Spuds and ingot dogs have been redesigned, numerous procedural changes made.)
4. The guard railing on the top of seven shears were struck and badly damaged by material handling devices 38 times in one year. (Using solid plate guards instead of pipe railings and rounding of railing corners has greatly reduced catch points at these locations, reducing damage at least 50 per cent.)
5. At least 80 per cent of all cable replacement in the melting department is due to accident. (Methods have been changed, guards placed on sheave wheels, practices altered and inspection methods improved.)
6. The glass panel in this door was broken seven times in 1960. (It is now standard practice to use plastic in place of glass in shop doors throughout the plant.)
7. One thousand six hundred spindles on hand grinders were replaced in 1960. Investigation revealed that at least 25 per

cent of this was due to the unsafe practice of striking the locking nut to loosen it in order to remove the wheel. (All grinders are now provided with a special band wrench; the knowledge gained through the accident investigations also brought about improvement in the spindle quality and design, which has also reduced breakage substantially.)

8. Two thousand one hundred and six incidents of stators on hand grinders required repair and replacement in 1960. Accident damage investigation revealed that a minimum of 50 per cent of these "burn outs" was due to an unsafe practice of the operator. When the wall fuse would blow because of a "heat up," the common practice was to pull out the hot plug and connect to a cold plug and continue to use the grinder until it burned out. (We are now supervising better, testing local heat warning devices and new grinders.)

9. Thirty two oil lines on various pieces of equipment were damaged severely in 1960. (Standard practice is now to place all these lines in hideaway locations.)

10. One water pipe in the pickling department was damaged four times in one year. (There has been no repetitive damage in six months since the relocation of the pipe.)

To motivate key management personnel even further, an accident damage control chart is posted in a most conspicuous position in our superintendents' conference room where the general manager points to weekly trends each Friday. A weekly publi-

cation called *Safety Facts* is distributed weekly to all supervisors in our plant. The lower left side of this report gives personal injury facts, the lower right side gives property damage facts. A *total safety performance* rating is given each department in the right hand margin. This rating includes an evaluation of housekeeping, protective equipment, communications, actual injury experience, personal injury and property damage investigation.

It is the opinion at Lukens that the addition of damage control to our injury prevention program more truly represents a positive program approach to total safety. A final reason for the justification of this approach is the fact that a company desiring to earn 3 per cent net profit after taxes would have to sell six and a quarter millions in additional annual sales volume to compensate for accidents costing \$6,000 in damage per week.

In closing, I can say with a great deal of pride that this tremendous economic drain on our company's pocket book from accident property damage is fast coming unto control. Our safety personnel point with particular pride to the fact that ground will soon be broken for the construction of a new electric furnace.

In addition to the normal rewarding feeling that comes from any service to fellow man, they now realize how substantially their staff efforts contribute to the economic health and growth of their company through this new dimension in accident prevention—*total safety programming*.

TRAINING THE PLANT DEFENSE CORPS

By JOHN E. TWOMEY
Supt., Industrial Defense Planning
Western Electric Co., New York, N. Y.

With the threat of a nuclear attack, it became evident to the management of our company that a program would have to be established to provide for the protection of personnel, continuity of production and continuity of management.

Although all three are essential to an effective industrial defense planning program,

it was recognized that planning measures for the protection of personnel should receive primary consideration. This article will therefore focus on the personnel protection phase of our program with the main emphasis being given to emergency and disaster training.

In addition to stimulating a sense of re-

sponsibility on the part of the individual for his self-protection, it became clear that significant new dimensions in training employees in activities essential for their survival would be necessary. In organizing the training effort a three-pronged approach was decided on—expand existing protective forces—create new type protective forces—train employees in special action required to minimize blast and radiation injuries.

Before describing this three-phased personnel protection program in more detail, I would like to briefly describe our scope of business activities, as they greatly influenced the kind of training problems we were confronted with. Our primary function is the manufacturing and supply unit of the Bell System. We have manufacturing plants in fifteen metropolitan areas and thirty-three distributing houses located in or adjacent to major cities.

In addition our defense work on Nike, Titan, Dew Line, etc. further complicated our protection problems for employees based over a wide geographic area. Excluding our subsidiaries, we have approximately 140,000 employees. Because of the wide dispersion of our business operations, we realized that we had a more difficult job to develop appreciation for self-protection and to train workers in appropriate protective measures.

The first area of our personnel protection program on which we concentrated was the expansion of existing plant protective forces. Our major effort was to stimulate increased participation in first aid training and to form these people into teams with designated areas of responsibility. These teams were then set up to supplement the existing "cot" or "stretcher" crews that we use in normal emergencies.

Our objective was to train 10 per cent of our people in first aid. This objective has been generally obtained; as a matter of fact, some of our locations have more than 40 per cent of their people trained in this vital area of personnel protection. This is particularly gratifying to us because all of the training is given out of hours. The first aid teams devote several hours each year to practice exercises. These exercises, which are conducted during regular working hours, serve to train the employees to act as a team and also provide a more realistic test of their skills in a simulated emergency environment.

The fire crew was another protection group that was expanded. Where needed, fire auxiliaries were trained to supplement existing fire crews. In establishing a program of this nature it must be assumed that there will be no help from the local fire department, since the holocaust following a nuclear blast will be greater than anything ever before anticipated or experienced.

The second major phase of our personnel protection program was the creation of new types of protective forces. In this area rescue squads were established to remove the injured from the debris. With the help of the Civil Defense people a group of our employees received expert training at Olney, Md., in the techniques of removing the injured from buildings destroyed or damaged by natural or man-made disasters. These people returned to their locations and passed their training along to others who were then organized into rescue squads. Special equipment was assembled for training and other equipment normally used in maintenance work was designated for training and emergency use.

Under this second phase of our program, we also organized radiological monitoring and detection squads. In establishing our radiological training program, we brought together a small group of employees skilled in training techniques or with a technical background. These people reviewed the problem and prepared an Instructor's Guide and a Problem Book to facilitate training. A Radiological Monitoring and Detection Manual was also prepared for the squad members to be used as a guide and reference to aid them in performing their responsibilities.

Originally we purchased several sets of instruments and borrowed others from local Civil Defense units for training purposes. We recently completed the purchase of radiological instruments for each of our working locations. Each set of instruments, manufactured in accordance with Civil Defense specifications, consists of one geiger counter, one medium range survey meter, one high range survey meter, four dosimeters and one dosimeter charger. These instruments will be used to retrain our present monitors and train others as the need arises.

The third and final component of our personnel protection program is training our employees in the special action necessary to

minimize blast and radiation injuries. This includes such items as warnings, warden organization, shelter drills and shutdown procedures.

We receive our warning primarily by the bell and light system furnished by the local telephone companies. The warning is disseminated by various means—bells, horns, whistles, sirens and in some cases by public address systems—and is readily recognizable by the employees.

Our warden organization is generally made up of supervisors to whom people would normally look for direction. Our wardens are trained to see that employees move quickly to their assigned shelter areas, check to be sure that prescribed shutdown procedures have been carried out, and take any other steps necessary to minimize blast damage.

Shelter drills are conducted periodically. Drills of this nature are one of the best means of keeping our employees aware of the continuous need to prepare themselves to handle disasters effectively. Workers who are conditioned to shelter drills will show considerably more control when faced with a real disaster than those with little or no training.

While on the subject of shelter drills, a word about our shelter areas is in order. Specific areas in our building have been designated by our engineering organization as shelters and are well marked. Providing adequate fallout shelters poses a big problem and at the present time a survey is being made of our various buildings to determine the amount of protection that they will afford against radioactive fallout in the event of a nuclear attack on this country.

To aid us in this work, the Office of Civil and Defense Mobilization conducted a two-day fallout shelter survey workshop at their operational headquarters in Battle Creek, Mich., for 22 of our building engineers providing us with the necessary information, procedures and techniques for making such a study. These surveys, when analyzed, will enable us to determine the most suitable shelter areas for our employees. The important thing in any shelter program is that some positive action is better than none, as more people will be in areas outside the blast zone where fallout will be a major problem.

The fourth and last item of training employees in special protective action is the establishment of shutdown procedures. We have established detailed procedures for shutting down operations as quickly as possible when a warning is sounded and individuals with the responsibility for taking action have been trained in the necessary steps that are to be taken at that time. Where possible the actual shutdown of equipment takes place; however, if this is not feasible we conduct simulated shutdown procedures by tagging the equipment. These drills occur simultaneously with shelter drills for the rest of the employee population.

Although we have made progress in our personnel protection program, further work is necessary. We still need additional equipment for our various squads and the problem of providing refresher training in all phases of the job is a continuing one. We are presently reviewing the possibility of acquiring additional Geiger counters to be used by our first aid squads in monitoring the injured, to be sure they are relatively free of radioactive particles, before being brought into the receiving area. Another item that is receiving close attention at this time is the creation of decontamination squads to remove radioactive fallout particles from our manufacturing areas, machinery, and equipment so that we can get back into production at the earliest opportunity.

One of the big problems in personnel protection training is to have the workers recognize their responsibility and participate in the training that is made available to them. This requires a continuous educational program of providing them with information on the threat and the steps that can be taken to counteract it. The recurrent international crises also have helped to maintain this interest; however, one of the big problems is to overcome the apathy that is still prevalent.

One of the best ways to be sure that the individual does what he should about civil defense while away from the job is for his employer to demonstrate the awareness of the peril and doing something about it at the work place. This is accomplished by conducting shelter drills and other defense activities in which the employees participate while on the job. There are also many excellent publications that can be passed out to the employees which detail the steps necessary for survival.

If an attack comes, it will be "survival of the fittest;" it is therefore in the best interests of employee and employer to real-

istically face the problem of survival and cooperate in an active industrial defense program.

WHAT DO WE EXPECT OF THE SAFETY ENGINEERS?

By G. W. HARPER

Prof., School of Mechanical Engineering, University of Illinois, Urbana, Ill.

Before launching blindly into a detailed discussion, it seems to me that the third word in the title must be defined. Who is this "we" that is asking the question? To clarify this point I suggest that the "we" which we have in mind is that of top management. It might be both enlightening and valuable to discuss this subject from the standpoint of "we" being the safety man; in other words what do we expect from our fellow safety engineers. This might be very interesting indeed, and if carried to an extreme might even lead to bloodshed. However, I believe you will agree that we must approach this question keeping in mind that we had best understand what our bosses expect from us.

At this point, I could of course, refer you to several textbooks on industrial safety, and to the federal government's *Dictionary of Occupational Titles* and quote what has been written on the subject during the past forty years. While this might be enlightening in a historical sense, I believe sincerely that it would fall short in providing an adequate and useful answer for us.

Without taking your time to read the detailed list of what I consider to be a well done summary of the duties and responsibilities of the safety director, as outlined in fourteen specific items in Chapter 2 of the *NSC Manual of Accident Prevention for Industrial Organizations*, I want to pick out the action words from this listing. In these fourteen points we find the following: formulating, administering, reporting, advising, recording, investigating, supervising, training, delegating, correlating, inspecting, contracting, complying, initiating, and last, but not least, directing.

Now you will note that I have, up to

this point, not given any of the objects along with the above words. There are two main reasons for this. In the first place there are several objectives which have been and can be attached to each activity. Let me explain what I mean. For example, take the word "recording"—recording of injury cases, recording of unsafe practices, and the recording of the minutes of supervisory safety meetings, are possibilities.

But we will return to this train of thought in a moment. The second reason for not including types of activities is that I should like to pursue another line of thought as a foundation of further discussion.

Before attempting to pin-point what is expected of the safety engineer in detail, I think it would be well to review the areas of knowledge or the tools of the trade of safety engineering. A good many years ago, Joe Stennett, writing in the *National Safety News* had an article which was titled "The Double 'C' of Industrial Safety." In it he pointed out that the double "C" of industrial safety included the first "C," control of environment, and the second "C," control of behavior. Before a safety engineer can begin to do his job he must have knowledge of methods and procedures in both of these areas.

At this point I should like to refine and clarify these two items. For a number of years I have given a talk and a portion of it has been devoted to this phase of our present discussion. In it I have outlined some areas of information, study, and knowledge essential to accomplish the com-

"The Double 'C' of Industrial Safety by J. C. Stennett—*National Safety News*, December, 1959.

plete job of industrial safety engineering. The areas are defined in answer to the question, "What are the tools for the safety job?"

Item number one states that "A safe environment is obtained through engineering." A few of the tools with which we, as safety engineers, must have in our kit, include machine guarding, heating, light, ventilation, material handling, electricity, welding, materials processing, and a host of others. As you can see all of these areas concern the engineering background and tools essential to creating, maintaining, and controlling a safe environment.

Item number two covers a part of the second "C" and states "Safe acts and practices are obtained through training." Some of the tools in this kit are orientation or induction training, plant or general safety rules, job safety training, job safety rules, fire training, first-aid training, supervisory training and management conferences.

Item number three, in the talk I referred to previously concerns itself with a supplementary set of tools to reinforce the second "C." It states that "Safe attitudes are created and enhanced thru promotional activities." In this area in our kit of tools we find such items as posters and bulletin boards, contests, awards, certificates, stunts, campaigns, plant publications, signs, and suggestion systems. Let me be very explicit about this kit of tools. None of them ever directly prevented an injury but the whole kit contains supplementary and supporting activities. That "attitudes" are important is a fact that I am sure cannot be disputed.

It is evident in U. S. Steel's program, "knowing is not enough." Motivation is essential. May I insert at this point, that some safety programs, I have known about, are made up of such a high proportion of promotional elements, that the other two sets of tools are all but forgotten.

Now, let me summarize. Our top managements expect the safety engineer to have fundamental knowledge in the three basic tools of safety: engineering to make a safe environment; training, to eliminate unsafe practices; and promotion, to foster safe attitudes. The ways and means, of obtaining this knowledge through higher education, and as a continuing process, are the topics covered later in this program.

To quote a phrase already used, "knowing is not enough." The safety engineer is a doer. This fact was illustrated earlier by the list of action verbs. But this same listing covers such a diversity of activities that many safety engineers have jumped on their white chargers and galloped off in all directions. Many times to the detriment of their own jobs, and also to the safety movement in general. In all fairness, it must be said that these individuals have been few in number in recent years.

Let us now turn our attention to what management expects of us as safety administrators. In approaching this question I would for a moment or two like to dwell on the negative side; that is, a few of the things that they do not expect safety engineers to do.

I would like to direct your attention to a recent article in *Factory Magazine* titled "What's Wrong With Safety Management?" Let me say at the outset that I hope all of you will read this article, and I am sure you will be as angry as I was. Why will you get mad? Because there is so much truth in the article. Let me make just a few quotations to show what I mean.

The responsibility for making safety work must rest with first-line supervision. Safety men must learn to live as staff specialists, nothing else.

The management approach needs fewer, but better safety men.

Awards are absolutely worthless. Safety function has too often become a hiding place for "klunks"—men who are neither managers nor experts.

Here's where the safety expert comes in—as a staff specialist.

There is food for thought in these articles and I trust that you will all read it. But now let us turn to the positive side of the picture.

Russ De Reamer, writing in the *A.S.S.E. Journal* highlights what has been said before. "In the past the industrial safety specialist has been the doer. In the future he will be the catalyst, the advisor, the teacher who precipitates safety action on the part of live managers."

"What's Wrong With Safety Management"—by Lawrence F. Milien, *Factory Magazine*, September, 1961.

"A.S.S.E. Must Prepare Today For Tomorrow"—by Russell DeReamer, *Journal of the American Society of Safety Engineers*—January, 1960.

Along with this change in the type of activities we find a new challenge in the job that we must do. Just last Tuesday, Dr. John Grimaldi¹ called these to our attention when said—

First we must convey that safety is not a doctrine of risk avoidance. . . . It would be more appropriate instead, to emphasize that safety is controlled risk taking. In this concept the professional work of the safety specialist is implementing risk control so as to limit accidental harm to people, products and material. Prevention is not the key here, but limitation of hazards is. An effort to control hazards may produce their eradication, but not always.

There is much more that needs to be said on this subject, that I feel would be of help, but time does not permit. So in conclusion, I should like to summarize the major points I have made.

1. We must change our perspective and direct our energies toward a newer and higher goal—that of accident and hazard control—and stop becoming "follow-uppers."

2. We must realize that we can be more effective if we accept our role as staff safety specialists—safety consultants, planners, etc.—and stay away from the firing line.

3. We must equip ourselves with the

"Safety Engineering in a Changing World"—by John W. Grimaldi—at National Safety Congress—1961.

"Get Safety out of the Personnel Department"—R. G. D. Anderson, *Occupational Hazards*, March, 1961.

basic tools of our trade and know when and how to recommend their correct use in the control of hazards: i.e., in the control of environment, in the control of behavior, and in the motivation of safe attitudes.

4. We must emphasize the planning and control functions of our work. We must plan the safety programs, provide the necessary means to measure its application, be alert to the areas of weakness, provide assistance and technical information when and where needed and give leadership in safety work on the job and in other areas of our daily living.

DESIGN SPECIFICATIONS FOR A SAFETY ENGINEER

By T. H. ROCKWELL, Ph.D.
Associate Professor, Industrial Engineering Dept.
Ohio State University, Columbus, Ohio

With the growth of any profession there is always the need for that introspection called "soul searching." In the rush to get the job done we need to pause and ask the most humbling of all questions, "Where are we going and how are we going to get there?"

Certainly before we spell out the necessary ingredients to concoct the ideal safety engineer we must agree upon the end product. Doubtless there are countless versions

of the role of the safety engineer in our society. These role images will vary depending upon the viewpoint taken. Management, labor and the safety engineer himself will have different concepts of safety engineering, just as they will view the safety function itself differently.

For purposes of delineating this discussion and to pursue the main purpose of this address, namely the basic requirements of the safety engineer and suggestions for his ad-

vanced training, we shall stipulate the safety engineering role, "as the minimization of the losses associated with accidents and industrial hygiene hazards." To fulfill this role three prime skills—analysis, interpretation and communication—are required in the safety engineer.

While knowledge is essential as the backbone of any profession we must not confuse knowledge with understanding or the accumulation of facts with progress. Possession of knowledge is no guarantee of professional competence. Technical knowledge is indispensable to a scientific profession but at the same time detailed knowledge can be worthless without the skills to properly employ it or the ability to convince people that its fruits are worthwhile.

We don't want the modern safety engineer to be a walking encyclopedia—a roving handbook without the wisdom which must mediate knowledge. In fact, the exponential rate of growth in technology prevents anyone from being completely informed. This has led to specialization and subspecialization in engineering and still it is virtually impossible to keep abreast of a field.

The universal safety engineer—competent in all fields perhaps never existed even in early days of the safety movement. It is certain he does not exist today. Ionizing radiation, occupational noise, automation, the introduction of bizarre processes and exotic materials have forced the safety engineer to be concerned not with knowledge per se but with the problem of knowledge acquisition relative to a given problem.

The challenge of technology in the 60's has forced engineering educators to put less emphasis on technical details and more on skills, creative engineering and professional attitudes. While one has difficulty teaching an attitude he can imbue a student with the responsibilities of his profession and attempt to show him how he appears to others outside his discipline. The engineer must recognize that his assignments come from non-engineers and his results are used by "non-engineers." The safety engineer would do well to remember this in attacking accident problems.

In terms of knowledge requirements the safety specialist (at this point we should recognize that an engineering background is not the only preparation for success in acci-

dent control) must first know the process and operations for which he is responsible. This is just as important as the physical laws upon which engineering is founded. The safety specialist must also have knowledge of the vicissitudes of the accident phenomenon and the environments which precipitate accidents. He must be able to recognize the hazards in an operation before they result in accidents. He must be aware of pertinent safety codes and safety regulations.

Since he is a coordinator in many cases, the safety specialist must have some knowledge of cost accounting, compensation laws, union contracts, medical aspects of accident control, etc. These knowledge requirements are familiar to you all and as such the preceding statements are not very profound. What I do think is often overlooked is the emphasis in analysis, interpretation and communication.

The problem solving skills of the safety specialists are demanded with every accident in the plant and, indeed, with every man-machine operation. Such analytic skills are also required each time a new process is introduced since the safety specialist must know how to anticipate problems before they occur.

There is an obvious parallel between the criminologist and the accident investigator. Each must attempt to reconstruct conditions before the occurrence of the crime or accident. *Proper accident investigation is not something anyone can do.* It requires a trained mind—an inquisitive nature and a student of human behavior. This last point is one in which more training is needed.

All of us consider ourselves dilettantes in the behavioral sciences. In understanding accident causation, however, this is not enough. Too long have we left the psychologist in the laboratory and limited his discipline to research. The 20th century safety specialist must be familiar with learning, motivation, emotion, attitude, fatigue, boredom as well as sensory and motor skill capacities. These are not erudite subjects for the university climate. They are aspects of human behavior which impinge on the accident phenomenon.

Consider how slow the recognition of human engineering has been in the safety field. How many accidents have been ascribed to

operator error or carelessness instead of to the fact that certain kinds of equipment have been designed so that operator error is inevitable. Consider forklift accidents. Driving a forklift truck violates man's learned response from the automobile. With rear wheel steering, backing errors are common for the novice driver and even the experienced driver if he is in a stressful situation where he reverts to old learned responses.

A great per cent of the male population can't apply the forklift's brakes without striking the knee against the steering wheel unless braking is done with a slanting motion. I might add that present day autos have this same drawback. The auto industry has only in the last six to eight years begun to design cars for operator comfort and safety and I fear we have a long way to go. Thus, it is imperative that the safety specialist study the fruits of applied psychology if he really expects to properly analyze accidents.

The safety analyst must also recognize the danger signs of employees working in environmental stress. There is considerable evidence to suggest that sub-quality output, slight decreases in total output and a higher frequency of unscheduled breaks will occur during early stages of environmental stress such as heat, light, noise, airborne contamination, etc. This stage is followed by more direct quality errors by the operator and also increased susceptibility to accidents. Finally physiological damage and occupational diseases result with increased environmental stress.

Since safety is not a criterion in its own right but rather is intimately tied into production, the safety specialist must understand the principles of work design so that accident prevention complements production. In this regard, a safety specialist should be trained in methods improvement and work simplification. With very few exceptions, building safety into a job should increase output. None of the principles of motion economy, for example, contradict a principle of machine guarding. Indeed, the future of safety may depend on the justification of safety on the basis that it facilitates production *not* on the basis that accidents are costly.

It is precisely in the area of problem

analysis that the disciplinary training of engineering is useful. In safety, one must be able to organize facts, isolate the contributing factors, propose hypotheses and test them in the work environment. It is here that creative engineering is most pertinent. One must be forever curious in accident studies, for curiosity as Samuel Johnson put it, "is the permanent characteristic of a vigorous mind."

The fantastic complexity of the accident phenomenon obviates the application of simple homespun accident prevention remedies, such as the use of the ASA causal classification system. The safety specialist must be alert to new hazards, to new solutions, and to new ways to safeguard the operator. He can not afford to be straight-jacketed in this thinking.

Second to the analytic skill requirements of the safety specialist is his role as interpreter. He must be able to interpret the significance of accident findings to management and the worker. He must be able to interpret accident prevention measures in terms of company savings, better product and increased employee morale. He must be skilled at both descriptive and inferential statistics. The former will permit him to measure his progress and properly evaluate safety effectiveness in the firm. The latter will enable him to differentiate between real and chance changes in the safety level of the organization.

As a rule, safety specialists are mired in statistical averages and have little appreciation for the pitfalls that averages are prone to supply. How many safety specialists can perform or even interpret a statistical analysis of accident data; for example, the relationship between first aid and LTA accidents. Statistics are neither the work of the devil nor a panacea. They simply provide specialized interpretation of data.

An interpreter in the language sense is equally fluent in two or more languages. In safety, the specialist must be able to translate management policy into safety programs and translate accident data into management action. In addition, because of his unique position as coordinator in the firm, the specialist must be able to translate engineering into maintenance terms and vice versa. He must be able to translate medical recommendations into protection for the worker.

Moreover, the constraints as represented by safety codes must be related to the realities of production. Those interpretive skills must be mediated by wisdom and a sense of magnanimity, neither underplaying nor overplaying the function that safety must play in the company operations.

Finally, juxtaposed with interpretation is communication. Unless the safety specialist can make his findings and their interpretations known to management and the worker his efforts are wasted. To most safety directors this is the area of their prime concern, especially in their communication with management.

We often forget, however, that safety communication must be lateral, as well as vertical in the firm. Other staff functions are intimately bound to the safety functions since accident prevention measures are very likely to affect quality control, production control, methods and time study, sales, and accounting. Communication involves establishing channels and organizing the messages to be used in these channels.

Effective oral and written communicative skill is one of the real weaknesses in modern engineering education. Almost without exception our graduates complain that they wish they could have taken more English and speech courses while in college. To the safety specialist, communication is a constant challenge and a difficult art.

For example, he must convince his superiors that their support is indispensable and at the same time not inculcate the attitude that he does not have control of the situation. To the worker he must establish his authority and at the same time solicit from him assistance in combating accidents.

The safety specialists must above all else establish by means of the written and spoken word a sense of awareness and responsibility towards safety, from the hourly laborer to the plant manager. Unless the plant community considers safety a part of each individual job and is aware of accident producing situations it is questionable how much the most capable safety specialist can accomplish.

Up to this point we have outlined the general specifications for the ideal safety specialist. While none of us may ever reach perfection we can through self-education better equip ourselves for the challenges of

our work. Rather than emphasize more detailed knowledge I would like to suggest eight areas of advanced study which will assist the safety specialist in these functions of analysis, interpretation and communication. These areas of study might involve reading, safety seminars, advanced courses sponsored by local ASSE chapters and topics for ASSE national meetings.

I. *Work Simplification*—including work measurement, principles of motion economy, methods analysis and operational analysis. This ability to analyze elements of work is the foundation of job safety analysis.

II. *Human Factors Engineering*—The fundamentals of the design of man-machine systems for human use. This involves consideration of the cognitive, anthropometric, sensory and motor capabilities of man and their effect on equipment design.

III. *Descriptive Statistics*—The ability to organize data in meaningful ways and the subsequent ability to present accident data in clear and concise forms.

IV. *Inferential Statistics*—ability to draw proper inferences about statistical data. Of paramount concern here is the distinction between chance and real changes in accident statistics and the testing of hypotheses concerning accident causes and the relation between accident prevention efforts and changes in safety effectiveness.

V. *Environmental Stress and Its Effect on Worker Behavior*—included here are those environmental factors which not only accelerate accident producing situations but those which at the same time undermine quality output such as thermal stress, noise, lighting, airborne contaminants and toxic chemicals.

VI. *The Psychologically Safe Climate*—This is an area of psychology that has been abandoned in the past for emphasis on accident prone theory. Here we refer to motivational, learning and attitudinal factors which facilitate alertness and concern towards safety.

VII. *Creative Thinking*—one of the lost arts in engineering today. Because no two accident problems are the same we must develop ingenuity and unconventional solution methods. Creative thinking is a skill that can be developed as brainstorming sessions have demonstrated.

VIII. *Effective Communication*—The

ability to express concisely and completely our findings in safety and to spell out clearly the recommended action to management in terms which they can appreciate and understand.

What is needed is the development of these typical areas by talented individuals within and outside of our society and the publication of this material so that it is available

to the individual safety specialist. Lastly it should be clear that knowledge and skill are no guarantees of success in accident prevention if we fail to be genuinely motivated in our concern for our fellow man. If we truly possess this concern, face up to our own inadequacies and continually strive for self improvement, we will be a credit to ourselves and to our profession.

PREPARING THE SAFETY ENGINEER AND UPGRADING PERFORMANCE

By D. A. WEAVER

Training Div., Traffic Institute, Northwestern University, Evanston, Ill.

A hasty review of the literature reveals that we have been probing and discussing this subject for at least 10 years, and the question that first occurs to me is, "Why this recurring interest in this theme?" What are the needs that impel us to review and discuss this material and to seek new answers on frequent occasions in all of our professional meetings.

I believe there are four needs. Discussion of them will give us an opportunity to review some of the literature concerned with preparation of the safety engineer. In addition, I should like to present to you seven additional ideas concerned with preparing the safety engineer and upgrading performance. With this brief preview let us begin with the first need which motivates constant stirring and review of this question.

First, there is a need to clarify the question of whether a safety engineer must first be an engineer. I shall not discuss this issue, but merely refer to some of the literature, such as the 1956 item entitled "Preparing Tomorrow's Engineer and Safety Specialist"; or the 1958 item on the "Safety Engineering Profession"; or the fine paper by Heimreich, "Can Safety Stand On Its Own Feet"—a paper dating from 1953. At the 1953 Congress, there was a paper on "What Shall We Teach the Safety Engineer of Tomorrow"—in 1959 the question was discussed, "What Is A Safety Engineer?"—or the fine article in the current

issue of the Journal entitled "Engineering as a foundation for Optimum Safety Success."

One of our needs in our recurring discussion of this theme of education of safety personnel has been the need to clarify this question of the role of engineering training for safety engineers.

A second need has been to develop a university curriculum for preparing safety personnel. This has given us a fine paper at the congress in 1958 by Tom Rockwell, "Removing a Blind Spot in Safety Education." Or in 1955, a survey, entitled "The Safety Engineer in Industry." Or a paper from 1956, entitled "Recognition of Safety as a Profession." And dating all the way back to 1952, a fine booklet by Cutter and Elkow, entitled "Training For Industrial Accident Prevention," to which I shall return in a few moments.

I believe there is still a third reason why safety engineers find a need to consider and reconsider the kind of knowledge and training that goes into their job. I believe by such discussions we seek to avoid being swamped, being drowned, by the immensity of the knowledge and skills that seem to be unavoidably inherent in our job. We sense a need to know all things and yet we are aware of the fallacy of seeking to know all things, and are aware of the fallacy of creating an image of the safety engineer as a man who knows all things.

We have sought the core concepts around which to integrate our body of knowledge, to integrate our work, to integrate our safety personalities. The very vastness of the things we deal with, in chemistry, in physics, in engineering, in medicine, of plant layout, in industrial engineering procedures, in psychology, in teaching, in motivation, the very vastness of all this surrounds us with a chaos through which we seek guide posts.

This need gives us such papers as one in 1953, entitled "What The Safety Engineer Expects in the Safety Program"; or one in 1959 seeking guidance on policy, entitled "Safety Management Policy"; or in 1952, "The Place of Safety Engineering in Industry"; or in 1959, "What A Plant Manager Expects Of A Safety Engineer." We have sought guidance in the chaos of the knowledge and the skills of our job; we have sought to avoid being swamped by again and again asking ourselves what should be in our education and training.

Fourth, I believe there is another paradoxical need which motivates us to look at our training and background—the need to avoid being narrowed to the special aspects of our immediate job—to avoid becoming specialists in one plant, in one industry, or perhaps in just one department or phase of safety in a plant or industry.

On the one hand, we have the need to avoid intellectual chaos and on the other hand we have the need to avoid intellectual tunnel vision. This has given us such papers as the 1958 paper on "What is Wrong with Safety Engineers"; or in 1959 a paper entitled "Toward the Profession of Safety Program Management"; or in 1960, "Today's Safety Engineer"; or in 1960 again, "Our Society Must Prepare Today for Tomorrow."

These four thoughts provide a hasty review of some of the literature that exists on these topics. It may be comforting to you to know that whatever you are seeking here today and whatever you may acquire here today, can be augmented by the devoted efforts of many people extending back over many years. I believe we shall continue for many years to probe these questions, for by probing them we find personal guidance, personal integration, identification in our special role. We harness

ourselves and we harness concepts to the tasks of safety that surround us.

The American Society of Safety Engineers was the first organized group with an expressed belief that safety could be achieved by orderly application of principles. We still struggle to define ourselves and our body of knowledge. It is interesting to be aware of the fact that others deal in the same life-preserving and property-protecting tasks that we ourselves are in. But their identity has been different, their specialty has been different, the patterns of their thinking has been different.

Others have found it necessary to organize in groups and societies whose patterns of thinking are not satisfied in the things we have identified in the American Society of Safety Engineers. Just hastily there are the Fire Prevention Engineers, the Institute of Traffic Engineers, the Council of Safety Supervisors, the Campus Safety Association, the American Industrial Hygiene Association, and I am sure there are others.

I can perhaps close off this portion of my comments by referring again to the booklet by Dr. Cutter and Dr. Elkow, published in 1952 by the Center for Safety Education at New York University. In this 64 page booklet, Part I is entitled "The Industrial Accident Prevention Specialist and His Functions." Part II, "Training for Safety in Engineering and Technical Schools." Part III, "Training in Accident Prevention in Non-Engineering Colleges, Schools and Departments." Part IV, "Recommendations for Training in Industrial Accident Prevention." Those of us who seek for guidance in this field need not seek in vain.

Let us then consider some other aspects of preparation: the safety engineer and upgrading performance. Let us consider it from the view of the practical safety engineer doing his job, perhaps aware of the need to avoid both intellectual chaos and intellectual tunnel vision, and desiring further education and guidance to upgrade performance. The following seven ideas may have some merit in your thinking:

1. *Build your self-improvement around the specific hazards of your operation.* Define what it is you need to do in order to do your job better and seek opportunities for that kind of education. Do you have lad-

ders or flammable materials, window washers, an outside construction crew, explosives, or special hazards to which you might well give self-directed educational endeavor?

For example, one frequently overlooked is the trucking operation, which exists in many industries, and which at present tends to be growing at a rather rapid rate. What skills and knowledge do you need to reach out and exert an influence over that? Does your company have a sales organization, perhaps spread over a very wide area, directed by a sales manager whose sole concern is sales, and all of whose salesmen are driving passenger cars over which you have little influence?

This is what I mean when I say, "Build your influence, build your self-improvement around the specific hazards of your own operation." This I think is illustrated in a tale told to me by a safety director, who received a phone call about an explosion in a chemistry lab. Before he rushed over, he hastily thumbed through some chemical data sheets, and upon arrival was able to explain to the amazed chemist exactly what had happened, why it had happened, and how to prevent it. He said all of this very ruefully, for he realized that he was playing the role of the safety engineer as knowing all things. He knew that this is a satisfying role when you can get away with it, but you seldom can.

The real point of the story is that he was prepared to deal with the hazards of his chemical labs. It would require a chemical engineer to know all the facets that need to be known about the wide variety of chemicals that exist in most any of our industrial operations.

I submit that it would be a tall order for the safety engineer to seek to be a half-baked chemist. He performs his full function as a safety engineer, however, when he contrives procedures whereby he knows whenever a new chemical with unknown potential is brought into the plant. This gives him the opportunity to exert control and preventive measures. Self-directed improvement can usually be pointed by the specific hazards of our own operation.

2. *Through the literature and standards available, a flow of materials should cross your desks from the standard sources.* I mention this point because so frequently

a safety engineer mentions a problem, not knowing that a standard exists that would be helpful to him or that literature on it exists for pass-out materials for his supervisors. This again does not mean that we become all-knowing in studying all these things, but that we know what is available from the American Standards Association, from various insurance companies, from the National Fire Protection Association, National Safety Council, heating and ventilating engineers, industrial hygiene publications, chemical data sheets, and special publications pertinent to our industry, be it trucking, mining, petroleum, utilities, or whatever.

I believe it is a fair statement that you do not have a problem, you do not have any need for knowledge, that has not been reduced to writing and expressed in a pamphlet or a book somewhere. My point here is: keep your channels open to a flow of this material, learn to scan it hastily so that you know what is there, learn to read some of it and learn to study certain further choice items.

3. *Study your position and the position of safety in your organization.* This idea relates to the next one I am going to mention. My thought can be illustrated by this situation:

A safety man had been attached to the trucking department in an organization because that was their problem when they brought him in. He had, however, a sizeable background in industrial safety, felt the need to extend his influences further throughout the organization, and found himself strategically in a very poor position to exert influence throughout the organization.

It is further illustrated in a company I consulted with, in which it became a question of some import as to just where and to whom a potential safety director should report. The standard academic answers were there, but for reasons that would be difficult to understand without knowing the internal workings of the company, it just would not work in this case.

The idea is illustrated in a situation in which the safety director just isn't attached anywhere. He literally reports to no one. The person who hired him changed to another position, the safety director literally

did not know whom he reported to, and no one understood him to be a subordinate. He was a free-floating safety engineer. He was the most advisory safety engineer I have ever seen, and also in a position of least influence.

Can you extend your influence throughout the organization? Can you make it reach the sales department, the high-powered brains in the research department, the driver on the highway, the outlying plant in the other city, or the boss's son? We need to understand our position and the position of safety in the organization, in its total functioning, in order to advance and exert our influence for good.

4. *The fourth point is an old cliché of safety, to fix safety as a line responsibility—where it belongs.* It has been my observation that management does not expect this; is quite confused as to the functions of safety, even when they define it in words; is often rather vague in its application and, most importantly, that it is a long and difficult task to really imbue a whole organization with the idea of line responsibility for safety. I believe the whole philosophy, theory, and practice is revealed in a little vignette of the safety director who described a scene in which he stood talking to the plant manager one morning when the assistant plant manager walked up. As the assistant approached, the plant manager nudged the safety director and pointed at the shoes of the approaching assistant and said, "Look! No safety shoes—give him hell!" The safety director calmly shrugged his shoulders and walked away with the comment, "He doesn't work for me."

I believe these last two thoughts—to study your position and the position of safety in your organization, and to fix line responsibility for safety, are important in the development of the safety engineer. Your success and your skill in dealing with these last two items, I believe, make the distinction between safety management and safety inspection for some other lesser expression of safety control.

5. *Make the safety post a stepping-stone upward.* I believe this point has overlooked implications. It applies to you—it applies to your subordinates—and in a large organization it has special meaning for safety supervisors assigned in the field. As it applies to

you, let me suggest these thoughts: I believe that a man who leaves safety work for some higher responsibility in his company is not lost to safety—he is rather in a position of doing more for safety.

His higher position, with his safety background, makes him highly receptive to the safety needs of the organization; and his higher position puts him in a more influential position to accomplish something in it. I do not believe the cause of safety suffers when a safety man moves to a higher responsibility in his company.

This idea of making safety a stepping-stone has a special pertinence in many organizations which have gone through a rugged phase—a phase of rapid growth, of immaturity and development, of acquisition of other companies, of difficulty in applying good management procedures and hence good safety procedures. I have seen such organizations influenced by strong, competent safety men, who did a terrific job in safety and inculcated throughout the organization a deep awareness of safety fundamentals.

The more successfully they accomplished this task, the less it needed a man of such high competence and salary. I have seen such men become, shall I say, the victims of management's awareness that their tasks, now so well integrated throughout the company, could be done by somebody at half the salary.

I have seen other men in this same situation, perhaps more fortunate, who used safety as a stepping-stone. As they did this tremendous job for safety they also developed around themselves a set of related tasks—tasks in claims, in insurance and compensation, in wage administration, in pension programs, in any number of related tasks which are a developing part of the efficiency of the organization. I talked to one such man this week, who recently gave up the title of safety director to take on a higher title that encompasses all the tasks that he developed while still safety director. He now has reporting to him a safety director at perhaps one-half or one-third of his salary.

Safety suffers when highly competent men, who have staked their prestige, their status in the company, on masterful safety performance, suddenly have the rug slid out from under them. On the other hand,

safety gains when that safety engineer advances himself, exerting a stronger influence throughout the whole company, including his influence on safety.

This idea of safety as a stepping-stone applies to your subordinates. You may lose a man as you develop him to another company, or to another department, but let him go; let work in safety be seen and recognized as a stepping-stone upward deserving the best abilities and the most aggressive performance.

A special version of this applies in large organizations where at the plant level, or at the district or division level, safety supervisors are assigned by the line authority. These men are not usually professional safety men as you and I know them, they are not a part of the central safety staff; they report directly to the line organization.

In such positions you are apt to find one of two things: Sometimes you find an incompetent hiding behind the desk, left there because he is not wanted anywhere else, and he seems to do the least harm at the safety desk. Or sometimes you find an opposite picture—a capable, aggressive man who has done a fine job in safety and is left there because he has done a good job, while other promotional opportunities are passed on to other men. It is well to review the role and the functions and the prospects of safety supervisors in these positions.

These men are in a position to study the working of a whole operation, to travel throughout it, to know all its people, to deal with all of its people. It is a most wonderful opportunity for growth. We will get better safety performance in these safety supervisory posts when it is recognized that a post in safety is an opportunity for a step upward in the organization.

6. *Seek out courses and training opportunities to fit your needs;* become acquainted with the variety of courses available. Just thinking out loud—in a 150-mile radius of Chicago there are supervisor courses, courses in safety fundamentals, courses in plant ventilation and in industrial hygiene, in industrial security, in arson investigation, and I am sure there are many more. Know the sources in your own area of the kind of further preparation you need. This doesn't mean that the precise

package you want is always available, but the opportunities for the precise preparation you desire are available somewhere.

7. I suggest that each ASSE chapter should sponsor a professional-level course. When I mentioned this to George Harper he suggested two courses: one for safety engineers and safety personnel and the other for front-line supervision. I agree with him. I shall, however, at the moment, speak only of courses for professional safety personnel. Each chapter should seek out and establish university contacts. You will eventually find someone or some university or some department of the university that can work with you in putting on a program that will be helpful to you and to your chapter.

Let me offer four suggestions from my own experience in organizing and putting on these courses: (a) Put them on for yourself; don't develop them as a noble service to some other benighted soul who needs your help. Serve yourself. Serve your own chapter. Serve your own industry, and you are apt to find in the process that some other benighted soul is interested in what you're doing and will attend in greater measure than if you aim at him specifically.

(b) Put on your courses at the highest professional level. In part, this is an expression of the previous point, in that the greatest need for safety education is in the numerous small plants who have no safety director, who have little awareness of safety as an organized activity, who think of safety in terms of 5-600 dollars a year as insurance premium. These people we need to reach, but if you try to reach them directly, they will not come. If you put on a high-level course deserving of your attention and your earnest participation and attendance, and then promote it among these lesser folks whom you wish to reach, you will reach a higher percentage of them. This has been our experience.

(c) Work in fundamentals, even though your program is at a high professional level, because you wish to serve some folks who have less experience than you. Fundamentals are really worked in by the definitions and instructions given to your teachers rather than by the selection of titles themselves. Regardless of title, safety fundamentals, with forethought, by instruction to your speakers, can be worked into the

highest professional course, and what's more, can be presented in a way which will absorb the interest of the highest professional group.

(d) Look for an adviser. Somewhere there is a man who will work with you, who knows people in our field, knows the cross-threads of ideas, knows who can help to develop a program or present topics. In my work I always had the guidance of the Indianapolis chapter of the American Society of Safety Engineers, and beyond that I had phone contact with our longtime friend J. C. Stennett, who is an encyclopedia of guidance and help, and who I called on frequently.

Education for safety personnel—preparation of the engineer—upgrading performance—I wish I could tell you exactly where you can acquire the educational background that fits your particular needs, your particular personality, your particular intellect. Our particular company I cannot do that for we will never be able to. We do need constantly to upgrade ourselves and to seek new directions, especially new directions in self-preparation.

Bibliography

- Safety as a Profession*, by A. C. Blackman, Managing Director, American Society of Safety Engineers, Chicago, Illinois. (1958 NSC Transactions, Vol. 12)
- Is the Fuel Wagon the Deaf?* by Karl Schuler, Senior Safety Engineer, Western Operations, Inc. Standard Oil Company, San Francisco, Calif. (1958 NSC Transactions, Vol. 8)
- The Engineering Approach*, by William E. Tarranta, Instructor and Research Associate, Center for Safety Education, New York University. (1959 NSC Transactions, Vol. 13)
- What's Wrong with the Safety Engineer?* by Alfred Leitner, Mansueti, N. Y. (1959 NSC Transactions, Vol. 13, Sup. 2)
- What the Safety Engineer Expects in the Safety Program*, by Stanley F. Spence, Dir. of Safety and Fire Prevention, American Cyanamid Co., New York City. (1953 NSC Transactions, Vol. 11)
- What Shall We Teach the Safety Engineer of Tomorrow?* by William D. Kanner, Safety Supvr., Schering Corp., Bloomfield, N. J. (1958 NSC Transactions, Vol. 12)
- Recognition of Safety as a Profession—A Challenge to Colleges and Universities*, by H. W. Heinrich, Chairman, The Uniform Boiler & Pressure Vessel Laws Society, Inc., New York City. (1956 NSC Transactions, Vol. 24)
- The Safety Engineering Profession*, by Joseph C. Stennett, Dir., Accident & Fire Prevention, National Association of Mutual Casualty Cos., Chicago, Illinois. (1958 NSC Transactions, Vol. 15)
- Reports and Reporting Procedures*, by D. T. Mould, Safety Director, General Motors Corporation, Detroit. (1958 NSC Transactions, Vol. 16)
- The Safety Engineer's Major Problems*, by Myron L. Miller, Supervisor of Safety, Westinghouse Electric Corp., East Pittsburgh, Pa. (1958 NSC Transactions, Vol. 16)
- Problems of Administering Multi-Plant Safety Programs*, by D. T. Mould, Safety Director, General Motors Corp., Detroit; Earl H. Stockdale, Accident Prevention Dir., Gulf Oil Corp., Pittsburgh, Pa.; C. H. Hoopes, Supvr., Safety & Health Services, Continental Can Co., Inc., Chicago, Ill.; W. C. Mahalstedt, Safety Eng., Continental Baking Co., Rye, N. Y.; L. R. Morrison, Safety Mgr., A. S. F. Industries, Inc., New York City; J. E. Nichols, Dir. of Safety, Reynolds Metals Co., Richmond, Va.; B. A. Patrician, Staff Administrator, Safety & Accident Prevention, Radio Corp. of America, Camden, N. J. (1958 NSC Transactions, Vol. 16)
- The Safety Engineer's Responsibility with Management in the Far Reaching Aspects of Increasing Worker's Compensation Costs*, by Albert L. Anthony, Service Representative, Loss Prevention Dept., Liberty Mutual Insurance Co., East Orange, N. J. (1958 NSC Transactions, Vol. 2)
- American Society of Safety Engineers—Annual Meeting, Standards of Concern to the Safety Engineer*, by Arthur S. Johnson, Vice-Pres., Engineering American Mutual Liability Insurance Co., Boston. (1958 NSC Transactions, Vol. 13)
- American Society of Safety Engineers: Annual Meeting, What is Ahead for Engineering*, by John T. Retzlaff, Pres., Illinois Institute of Technology, Chicago, Ill. (1958 NSC Transactions, Vol. 13)
- Safety is Basic in Human Relations*, by C. G. Rousch, Mgr., Westinghouse Electric Corp., Kansas City, Mo. Vice-Pres., National Society of Professional Engineers. (1958 NSC Transactions, Vol. 13)
- Are Your Efforts Effective?* (A Symposium So We Want a Better Job), by H. E. Lambie, Safety Consultant, Kaiser Aluminum and Chemical Corp., Oakland, Calif. (1954 NSC Transactions, Vol. 12)
- Training for Industrial Accident Prevention*, by Walter A. Cutter and J. Duke Elbow, (Center for Safety Education, Division of General Education, New York University, in co-operation with The American Museum of Safety, New York, 1953)
- A Safety Job—or Job Safety?* by John W. Guiry, Safety Engineer, AVCO-Everett Research Laboratory, Boston, Mass. (National Safety News, May 1961)
- Working in the Shadow*, by Charles M. Brooks, Director of Industrial Relations, The Texas Company, New York, N. Y. (National Safety News, June, 1958)
- The Men Who Will Follow Us*, by William D. Reiser, Safety Supervisor, Schering Corp., Bloomfield, N. J. (National Safety News, February, 1958)
- Let's Not Sell The Safety Engineering Profession Short*, by H. E. Packard, Regional Safety Officer, Dallas Regional Office, Post Office Department, (National Safety News, October, 1958)
- What is a Safety Engineer?* by J. Robert McCullough, Supr. of Safety, Hunting Park Plant, Budd Company, Philadelphia, Pa. (National Safety News, February, 1959)

- Safety Engineering Comes of Age*, by T. H. Leadbeater, Safety Director, Todd Shipyards Corporation. (Supervision, January, 1954)
- Education Plus—What a Plant Manager Expects of a Safety Engineer*, by Lincoln B. Crosby, Director of Manufacturing, Eastern Operations, for the Plastics Division, Monsanto Chemical Company, Springfield, Mass. (National Safety News, September, 1959)
- Toward the Profession of Safety Program Management*, by Walter A. Cutter, Director, Center for Safety Education, New York University, and Thomas H. Wilkenson, Director of Safety, Department of the Army. (National Safety News, October, 1959)
- Our Society Must Prepare Today for Tomorrow*, by C. Russell De Reamer, Safety Manager, International Business Machines. (National Safety News, May 1960)
- Safety Comes of Age*, by John B. Dunne, Assistant Sales Manager, Borgwarder Manufacturing Co. (National Safety News, February, 1960)
- Today's Safety Engineer in Industry, Business and Government*, by E. Peter Marshall, Chairman, American Society of Safety Engineers, Special Committee on Membership Services. (National Safety News, August, 1959)
- Can Safety Stand on Its Own Feet?* by H. W. Heinrich, Superintendent of Design Engineering, and Loss Control Division, Travelers Insurance Company, Hartford, Conn. (National Safety News, November, 1959)
- Principles of Accident Prevention and Control*, by George F. Nuernberger, Safety Engineer, A. B. Dick Company, Chicago. (National Safety News, November, 1956)
- Causes of Ethics for Engineers*, prepared by Engineers' Council for Professional Development and adopted by the Executive Committee, American Society of Safety Engineers. (National Safety News, August, 1958)
- Management Safety Policies*, Published by the National Safety Council. (National Safety News, November, 1959)
- The Safety Engineer in Industry: A Survey*, by Society for the Advancement of Management, 74 Fifth Avenue, New York 11, N. Y. (Management Review, August, 1955)
- Preparing Tomorrow's Engineers and Safety Specialists*, by H. H. Fawcett, Research Laboratory, General Electric Co., Schenectady, N. Y. (National Safety Council, Library, October, 1956)
- The Place of Safety Engineering in Industry*, by C. H. Weiser, President, American Society of Safety Engineers. (National Safety Council, Library, January, 1954) (1956 NSC Transactions, Vol. 24)
- The Safety Engineer's Relationship With Management in Industry*, by E. C. McFadden, Vice-President, Texas Employers Insurance Company. (Engineering for Safety, No. 32, June, 1954)
- What is Wrong with Safety Engineers?* by A. B. Pettit, Supervisor, Industrial Health and Safety, The Davidson Chemical Corporation, Baltimore, Md. (National Safety Council, Library, April, 1951)

THE KINTZ AND BROWNE FIRE AND STATIC ELECTRICITY DEMONSTRATION

By

- J. M. KINTZ, District Supvr., Health & Safety, District G, Bureau of Mines, U. S. Dept. of the Interior, Dallas, Tex.
- H. F. BROWNE, Supervisory Safety Eng., District G, Bureau of Mines, U. S. Dept. of the Interior, Dallas, Tex.

The presentations which are designated "Interactive" deal primarily with the subjects of:

- fire and explosion, cause and prevention,
- the control of flammable and toxic gases,
- the hazards of static electricity,
- safety hazards in electrical equipment.

One of the highlights of the presentations is a demonstration entitled the "Magic of Fire," which has been enthusiastically received by large audiences in Canada, U.S.A. and Mexico.

All of the undemoted lecture demonstrations are authoritative, lively, informative and enjoyable scientific shows utilizing a unique combination of specially designed equipment and lecture demonstrations. The general technique of presentation is to describe an occurrence, a theory, or operating procedure and then by use of specially designed equipment, to reproduce the occurrence or apply the theory and show the results.

The first demonstration deals with the chemistry of fire and dust explosions, the fire triangle (fuel, heat and oxygen), explosions due to pressures, the extinguishment of fire by removing individually, fuel,

oxygen and the heat legs of the fire triangle. The strengths, limitations of various types of fire fighting equipment are shown and techniques of use are demonstrated.

The lecture further deals with the special and hazardous characteristics of light hydrocarbons including natural gas and gasoline. Factors which act to convert an explosion into a detonation are demonstrated. The special effects of different concentrations of gases and oxygen on flammable limits and explosive pressures are seen as is the migration of gases according to specific gravity. Ignition temperatures and various methods of developing these ignition temperatures are demonstrated, as are dust explosions and the factors affecting them.

Special methods of control of fire and explosion in industry, and in the home are demonstrated at length. Particular attention is given to discussion of individual and local problems.

The next lecture demonstration deals with the flammability, toxicity and explosive limits of gases encountered in industry. Examination is made of the composition and qualities of normal air and the special effects of the differing specific gravity of gases as well as detailed consideration of the special qualities of oxygen, nitrogen, carbon dioxide, methane, propane, butane, gasoline, carbon monoxide, hydrogen sulphide, sulphur dioxide and mercury. Diffusion of gases is demonstrated and respiratory equipment and its choice is discussed and the affect of gas concentrations on living organisms is shown. Permissible limits and the meaning of permissible limits are described and demonstrated.

The next lecture demonstration explains and shows the nature of static electricity. Its various manifestations are dramatically presented and specific hazardous occurrences are discussed in detail and repro-

duced in miniature. Means of control of static electricity and means of preventing serious effects are demonstrated and discussed. It is shown that static electricity cannot ignite flammable materials unless three conditions exist simultaneously. Means of preventing fire and explosion from static causes are derived in demonstration from this observation.

The effects of discharges of static electricity in operations involving such common place substances as gasoline, anaesthetics, natural gas, paint, varnish and commercial alcohol are demonstrated in memorable fashion.

The final lecture demonstration is of special interest to persons who are concerned primarily with electrical problems in areas in which explosive vapours and gases may be contaminants and particularly in conduits, ducts, and underground structures. It is also of wide interest to many laymen, industrial managers, architects, contractors, supervisors, and workmen. The need for maintenance of explosion proof and permissible electrical equipment is explained and demonstrated.

Special devices are used to demonstrate the behavior of flammable gases in conduits, and enclosures. The provisions of the Electrical Code dealing with these matters are discussed, explained and demonstrated. Flame and explosions are generated and propagated by equipment which permits observation, and study of the phenomena. Comprehensive demonstration is made of the differing performances of various types of equipment in explosive and flammable atmospheres.

This series of lectures provides an unusual training opportunity for accident prevention personnel, supervisory staffs, safety committees in industry, teachers, training personnel, fire department workers, hospital workers, civil defense participants and others.

BETTER DRIVING FOR THE WHOLE FAMILY

By WILLIAM F. SABOTA
Safety Advisor, Humble Oil & Refining Co., Linden, N. J.

Traffic accidents are the number one cause of accidental death and injury in the nation today. Bayway Refinery also learned that their principal problem in the area of off-the-job safety last year was traffic accidents. This is the story of the action taken and the results achieved by Bayway Refinery in reducing off-the-job lost-time traffic accidents. My talk is taken from our publication prepared as a guide to other organizations wishing to implement a similar program.

For many years Bayway Refinery has sustained a comprehensive and progressive safety program. They attacked the problem of off-the-job lost-time accidents because of their conviction that employees should "Be Safe Around the Clock" and that an off-the-job program contributes toward reducing in-plant injuries.

The success of the program was primarily attributed to the enthusiastic employee participation in the off-the-job safety activities. Some measure of its success was indicated by the fact that of the 1200 employees and members of their families who enrolled for the course, only 2 1/2 per cent failed to attend all four sessions. The reductions in off-the-job traffic accidents, as a result of this program, indicate that it was very worth-while.

During the past five years, Bayway made considerable progress in reducing off-the-job lost-time accidents. The year 1956 represented the first year that action was taken to bring off-the-job disabling injuries under control. It was found that 20 off-the-job disabling injuries were taking place for every plant disabling injury. Our accidents were reduced from 263 in 1956 to 63 in 1958. In 1959 we reduced the total number of accidents by four from the preceding year.

The problem was found to be that while the total off-the-job disabling injuries were reduced, no progress was made in the area of traffic accidents. Accounting for 18 per cent of our off-the-job accidents in 1956, traffic accidents steadily increased to 34 per cent in 1959. As significant was the increase

in days lost to 54 per cent of the total due to off-the-job traffic accidents in 1959. These increases offset reductions in other areas, such as home and recreation accidents.

Program Development

STEP 1: Bayway Safety Division developed a defensive driving program based on needs, with the cooperation of the Esso Safety Foundation.

STEP 2: Defensive driving program was presented to Bayway Central Safety Committee for approval.

STEP 3: The cooperation of outside agencies was obtained to participate in the course, such as the New Jersey Division of Motor Vehicles and Division of State Police and the New Jersey Safety Council.

STEP 4: A pilot course was presented to a sample group to develop the final program format before it was offered to all Bayway employees and their families.

A letter from the Manager of Bayway Refinery accompanied by this flyer was sent to employees' homes announcing the program.

A second letter from the manager of Bayway Refinery was sent to employees' homes accompanied by an information sheet and a kit of promotional materials, as follows:

Information and Instruction Sheet

"Who is eligible?"—All Bayway employees and members of their immediate families who drive. The initial program will be presented to the first 600 who register. Attendance tickets will be sent out for this program.

Place—Auditorium, Bayway Office Building.

Time—7:30 p.m. to 9:30 p.m.—4 sessions, 2 hours each.

Dinner—Starting at 6 p.m., a free dinner will be served in the Bayway Cafeteria to everyone attending the program.

Dates—Tuesdays or Thursdays through May.

This program will continue in future

months until everyone who registered has a chance to make part.

Registration and award card—Enclosed is a return address registration and award selection card. Please print your name, address and employee number. Check the box indicating that you will or will not attend. If you (the employee) plan to attend, look over the enclosed list of Employee Awards and mark the number of your selection in the box after your name on the card. To register members of your family who drive, print their names on the bottom of the card in the spaces provided. If you register family members, have them look over the enclosed list of Family Awards and mark the number of their selection in the box after their name on the card. If you (the employee) cannot attend, you may still register members of your family who drive.

If you prefer either Tuesday or Thursday sessions, please indicate your choice at the bottom of the card.

Driving skill rodeo prizes—A total of \$350 will be awarded to the three best men and women drivers of the Rodeo. Both employees and non-employees who attend all four sessions will be eligible for selection to compete in the Rodeo. The top 15 men and 15 women selected for the Rodeo will compete for the cash prizes.

Women Drivers	Men Drivers
\$100 First Prize	\$100
\$50 Second Prize	\$50
\$25 Third Prize	\$25

Employee and family awards—Employees and family members who attend all four sessions will be eligible to receive the award they selected from the two enclosed lists.

Certificates—Defensive Driving Certificates will be awarded to everyone who attends all four sessions.

Defensive Driving Pens will be given to all who attend.

DON'T DELAY—REGISTER TODAY

Program Coordination

Behind every smoothly run program is a hard-working staff with specific assignments. The coordinator for the course was William F. Sabota, Bayway Refinery Safety Division, who was responsible for all arrangements. This included publicity, enrollment,

scheduling guest instructors, resource people, visual aids and physical facilities. In addition, each session required the following staff assignments:

1. *One attendant at cafeteria door*—punch ticket stub of persons enrolled in course as dinner guests of management.

2. *One attendant at auditorium door*—collect tickets for attendance records.

3. *One guide at ground floor elevators*—direct people to the auditorium. Assist Motor Vehicle Inspectors during psycho-physical testing in cafeteria.

4. *One guide at first floor elevators*—same duties as item 3 above.

5. *Two microphone handlers*—assist in stopping distance demonstration. Assist Motor Vehicle Inspectors during psycho-physical testing in cafeteria. Usher. Handle traveling microphones during regular sessions.

Instructors included Dr. Herbert J. Stack, Department of Safety Education, New York University; Consultant, Esso Safety Foundation; Dr. Arthur Mahony, Education Supervisor, Fair Lawn Public Schools System; Dr. Nathaniel O. Schneider, Director, School and College Division, New Jersey State Safety Council; Richard Tossell, Assistant Director, Esso Safety Foundation.

Cooperating agency representatives included George Traver, Executive Vice President, New Jersey State Safety Council; Capt. Daniel Dunn, New Jersey State Safety Council; Gerald J. Driscoll, Chief, Bureau Traffic Safety, New Jersey Division of Motor Vehicles; William J. Ford, Budd Krayner, and Richard Stearn of the New Jersey Division of Motor Vehicles; Enaley Bennett, Traffic Engineer, New Jersey Division of Motor Vehicles; Col. Joseph D. Rutter, Superintendent, New Jersey Division of State Police; Lt. Peter Hausch, New Jersey Division of State Police, and Lt. Raymond Mockridge, New Jersey Division of Motor Vehicles.

Instructional Planning

Planning for the instructional program in off-the-job traffic safety was based on the purposes of driver education and on other practical objectives of the learning group. In determining details, instructors considered the needs and interests of the employees and their families and utilized every good resource available.

Industrial Subjects Sessions

The limitation of eight hours for the course required careful planning and judicious use of time. The participants attending the Bayway course represented a wide range of driving experience, age and income. Many family groups of two to five members enrolled in each class of nearly 300 people.

Inasmuch as the individuals in these groups were at various levels of learning readiness and driving experience, the course had to be structured to meet the more common needs represented. The following instructional objectives were established; however, the development of specific learning experiences was the responsibility of the qualified instructor working with the participants:

1. Develop the concept of "anticipation" and "early recognition" of hazardous traffic conditions.

2. Develop the concept of "personal responsibility" for preventing accidents.

3. Develop criteria by which participants can measure their own driving practices and habits.

4. Develop the relationship between traffic violations and the consequences of accidents.

5. Review effective evasive steps to avoid collisions and near misses.

6. Personally involve the individual through "participation" in learning experiences related to course objectives.

Methods of Instruction

Little attempt was made to standardize methods closely, since they may vary according to student needs, size of group, type of learning experience, teacher abilities, available facilities, and other local conditions. The methods selected for the Bayway course placed learning experience in meaningful and realistic settings which were familiar to the participants. The instructors used the following teaching methods and techniques:

1. *Class discussion* was an important means for determining the more common problems and involving a large number of people through participation.

2. *Instructors' presentations* provided essential background information and prepared students for planned learning experiences. Lectures were discouraged. Instructors skillfully organized their presentations using a variety of audio-visual materials and demonstrations suitable for large audiences to create and maintain a high level of interest.

3. *Visiting specialists and resource persons* (representatives from the State of New Jersey Division of Motor Vehicles, Division of State Police, and State Safety Council) backed up the instructor at each session by answering questions raised by individuals in the audience. The students also wrote their questions on the cards which were provided and collected at the end of the session. Questions not answered became the basis for the panel discussion during the final session. The panel members were representative from each of the cooperating state agencies. State Motor Vehicle Division Inspectors also participated by administering the psycho-physical tests and scoring participants in the Driving Skill Rodeo. Their participation gave the program an "official" atmosphere and improved the participants' understanding of the objectives of each of these agencies.

4. *Stopping distance demonstration*—a series of dramatic stopping trials were run over a roped-off area of asphalt pavement at the refinery parking lot. Two cars of the exact model and weight were matched against each other—one equipped with Atlas Bucron tires, the others were factory-equipped tires. The measured braking distances of the two vehicles at 40 mph on both dry and wet pavement impressed the audience with the fact that even with Bucron's added margin of safety—"You Can't Stop on a Dime!" Volunteers from the audience were invited to drive the vehicles at 20 mph and make emergency stops.

No attempt has been made to present a detailed course of study in this manual. The following outline and sequence was developed as a guide in organizing instructor presentations to achieve the course objectives.

Outline of Course

A.—First Session:

1. Informal greeting to group by top management.

2. Group orientation—purpose of the course and seriousness of the traffic accidents with particular emphasis on local problems; introduction of guests and instructor by coordinator.

3. Audience interviews to familiarize audience with discussion technique and use of microphones, by instructor, "mike" handlers, and audience volunteers.

4. Discussion on basic causes of traffic accidents and meaning of "defensive driving," namely, avoiding mistakes of others by anticipation and early recognition, using transparencies.

5. "Seven-tenths of a Second"—strip film with tape recording.

6. Development of proper seeing habits using transparencies and trapezoidal window demonstration.

7. "Smith System" a motion picture for developing driver alertness.

8. Discussion of film and question and answer period, conducted by instructor, audience, State Motor Vehicle and Police representatives.

9. "And Then There Were Four," a motion picture. (Note: Interest can be stimulated by not revealing the ending of the film until the next session.)

10. Summary and assignment (*You and Your Driving booklet*) by coordinator.

B. Second Session:

Prior to this session, the group met for a demonstration of stopping distances by the New Jersey Safety Council.

1. Summary of previous session and introduction of guests & instructor by coordinator.

2. Demonstration of psycho-physical testing and significance of tests by audience volunteers, using transparencies.

3. Tell Them the Truth—the alcohol story showing physiological function—no warning signs at time drinking becomes dangerous, using transparencies.

4. "And Then There Were Four" (if not completed prior session)—motion picture.

5. Discussion of film.

6. "To See Ourselves," a motion picture

7. Discussion of film.

8. What Makes Us Tick, by Dr. Arthur Mahoney—discuss how emotions are related to attitude development and show how attitudes influence our actions in practical situations—using transparencies.

9. Questions and answer period—instructor, audience, State Motor Vehicle and Police representatives.

10. Summary and assignment (vehicle safety checks)—coordinator.

C. Third Session:

For 30 minutes previous to this and the fourth sessions, four sets of psycho-physical testing apparatus were operated by Motor Vehicle Division License Examiners and assistants.

1. Summary of previous session and introduction of guests and instructor—coordinator.

2. "Freeway Driving Is Different," a motion picture.

3. Discussion of film to emphasize important differences.

4. Discuss safe driving practices and specific steps in meeting the more common driving emergencies; show transparencies.

5. Improving perception in driving—discussion illustrated with color slides to provide practice in "early recognition" and "anticipation" principles, using color slides.

6. Question and answer period, conducted by instructor, audience, State Motor Vehicle and Police representatives.

7. Summarization and assignment (prepare and mail in questions on "what I want to know" for panel discussion).

D. Fourth Session:

1. Things I Would Like to Know—question and answer discussion around questions submitted on cards prior to or during the session, conducted by a panel: State Motor Vehicle Division, Police, Safety Council and Course Instructor. (Transparencies were utilized for illustration.)

2. Summarization of course by the instructor.

3. Objective Driver Knowledge Test (20 minutes).

4. "You and Your Driving," a motion picture.

5. Discussion of film.

6. Closing remarks by coordinator and management.

Instructional Materials

There are many audio-visual resources in driver education to aid the instructors to more fully motivate learning among his students. The following aids were used at Bayway for the purpose of illustration, stimulating discussion, and for holding the students' attention and interest:

a. Motion pictures especially related to the course content.

1. "Smith System"—9 min. B&W, 16 mm sound—Training film on proper habits of seeing—Ford Motor Company.

2. "And Then There Were Four"—25 min. B&W, 16 mm sound—Inspirational film showing faulty attitudes—Socony Mobil Oil Company.

3. "To See Ourselves"—15 min. color 16 mm sound—Provocative film on personality factors—Aetna Casualty and Surety Company.

4. "Freeway Driving Is Different"—15 min. color 16 mm sound—Training film showing how to drive on freeways—American Automobile Association.

5. "You and Your Driving"—14 min. color 16 mm sound—Defensive driving film with a refreshing "positive" approach—Esso Safety Foundation.

b. Transparencies used with overhead projector. Large enough to be easily seen at the rear of the auditorium. Utilized like a blackboard. Allows instructor to face his audience. Stimulates greater degree of student participation.

1. "Driver Safety Education," 7" visual training transparencies suitable for 7" or 9" overhead projector. Shows specific traffic conditions.—Porto-Clinic Instruments, Inc.

2. Transparencies may be made up to suit the needs of the instructor.

c. Slides and strip film were specifically related to course content. A synchronized sound recording also was used with a strip film.

1. "Seven-tenths of a Second"—4 min. 35 mm color strip film with tape-recorded narration and music. Shows the effects of a collision in tenth-second detail.—Bell Telephone System.

2. Perception slides—taken with a 35 mm camera in color, showing local traffic situations. Individual scenes were flashed on the screen for 3 seconds to improve "early recognition" of traffic hazards and to stimulate discussion.—Center for Safety Education, New York University.

3. Seeing habits—35 mm B&W slides taken from "Observation Perception"—E. I. duPont de Nemours & Co.

d. Psycho-physical testing device—each student was afforded the opportunity of being tested on a Porto-Clinic by a uniformed motor vehicle inspector on the following: visual acuity, depth perception, color vision, peripheral vision and stopping reflex. Each of the items were demonstrated and related to safe driving practices during a regular session.—Porto-Clinic Instruments, Inc.

e. Reading material—the Esso Safety Foundation *You and Your Driving booklet* and tests and the New Jersey Department of Law and Public Safety Driver's Manual were the basic reading materials. Other appropriate reading materials from various sources were distributed at each session.

f. Trapezoidal window demonstration—particularly effective demonstration to show how we do develop seeing habits that can produce errors in the interpretation of what we see on the road.

(Note: The materials used in the Bayway course are only representative of the many fine educational aids available in the field. Consult your state safety council or other traffic safety agency in your state for assistance in obtaining these aids.)

Driving Skill Roadtest

Eligibility of contestants in the men's and women's divisions was based on attendance at all four sessions of the Defensive Driving course and placement among the top 15 scores of the Driving Knowledge Test administered at the end of the course. Dr. Nathaniel Schneider, New Jersey State Safety Council, assisted by eight New Jersey State Motor Vehicle Inspectors, conducted the contest.

The score sheet for the Driving Skill Contest was based on New Jersey State Teen-age Road-test.

Program Evaluation

Approximately 1200 employees and members of their families who drive attended the Defensive Driving Program. Nearly 25 per cent of our employees were in this group. Those employees who did not attend were made aware of the course objectives by favorable newspaper coverage published by the refinery and local communities.

The reactions of employees and relatives participating have been gratifying. On a course evaluation questionnaire completed at the end of the last session, 99 per cent of

the participants rated the program "excellent" or "good" on its educational value and helpfulness. More than 85 per cent of those who attended voluntarily took the Driver Knowledge Test at the end of the course. Scores on the 50 questions based on course material averaged 82.5. This indicated the participants learned their lessons well.

The benefits derived from this program were not limited to the area of improved traffic accident performance. Bayway is now experiencing its lowest off-the-job and on-the-job disabling injury frequency rates ever recorded. These results support the belief of Bayway management that the course not only contributed toward making our employees safer drivers but also made safer workers.

Many other benefits were derived from the program which cannot be converted into frequency rates. The program added to the prestige of Esso in the community and impressed upon all employees and their families that management was sincere about reducing accidents. The program contributed toward improving employee relations by providing representatives of management and their families an opportunity to meet on an equal and continuing basis with wage and salary employees and members of their families. It also strengthened management and union relations by their working together to promote the program.

In addition, it reinforced the relationship between Esso and the state agencies that participated, such as the New Jersey Division of State Police, New Jersey Division of Motor Vehicles and the New Jersey State Safety Council.

One of the primary justifications for this program is the reduction in off-the-job accident costs as a result of a decrease in traffic accidents. It is anticipated that the savings represented by the reduction of traffic injuries will pay for the Defensive Driving Program in one year. Like any good investment, additional dividends are expected in the future.

Recommendations for Future Sessions

1. Continue the four, two-hour sessions, inasmuch as a large per cent of the partici-

pants reported that the length of the course was just right.

2. The course should be conducted during the spring, summer or early fall months due to the longer daylight hours and warmer weather for outdoor demonstrations, namely the stopping distance demonstration.

3. Early planning is essential with regard to obtaining speakers, resource persons, state agency cooperation, facilities and audio-visual aids.

4. Instructors should utilize practical examples familiar to the audience along with as many visual aids as feasible. Straight lectures should be discouraged.

5. Discussions around specific points with decisions (voting) or conclusions drawn is highly desirable. However, questions or comments from the audience of a "gripe" nature and personal experiences not of general interest or directly related to the discussion tend to waste time and add little to the "learning" process.

6. Written questions from the audience should be encouraged because they contribute to the sense of "individual participation." Cards for questions can be given to the participants as they arrive. A specific time should be allowed for answering these questions during each session.

7. Perhaps the most important recommendation is that only highly qualified and interesting speakers participate as instructors and panelists. It is essential that each session be made as interesting as possible in order to continue a high level of attendance.

8. In the Driving Skill Contest a car should be located at each of the test areas. This expedites the completion of the testing, thereby improving the efficiency of conducting the contest.

9. It is suggested that incentive awards be continued, as they were effective in motivating attendance.

(NOTE: Copies of the course manual may be obtained by writing to Safety Department, Esso Standard Division of Humble Oil and Refining Co., Bayway Refinery, P.O. Box 222, Linden, N. J.)

GETTING PEOPLE TO UNDERSTAND LAW ENFORCEMENT

By FRANKLIN M. KREML

Dir., Transportation Center at Northwestern University, Evanston, Ill.

I am glad that the title of this talk asks for "understanding" instead of "liking." None of us really likes enforcement, especially if it is applied to us; but we all hope for acceptance of and support for enforcement.

Enforcement is, of course, an essential element of traffic safety—even as it is an essential element in industrial safety or in that matter, in virtually every aspect of life, from the maintenance of an organized, effective military arm to the rearing of children. In bringing up children or maintaining an army we speak of enforcement as supervision or discipline, but it is still enforcement.

Naturally, the more self-discipline we have, the less need there is to impose enforcement. If people generally can be made to see this—in this light—then we will have come a long way in "getting people to understand enforcement."

In a word, enforcement is the discipline that is imposed when lack of self-discipline causes anyone to intrude upon or violate the rights of others. To fail of enforcement under such circumstances, is to invite anarchy.

This would be the end of my speech if we were interested only in the philosophy of enforcement; but it isn't quite this simple in life and practice because public attitudes and misunderstandings create many difficulties. We are still quite immature, as a people, in our attitudes toward the enforcement of our own laws. Some people are truculent in their resentment of enforcement action, and with such people officers sometimes have difficulty in making even routine arrests.

There are many attempts to evade or beat the law, varying from the childish erasure of chalk marks on the tire of an overparked vehicle to the destructive device of having a child riding in the rear seat of a vehicle "look out for the cops." These unfortunate attitudes—this immaturity—

spring, in part, from our heritage of freedom; some come from widely held beliefs that are erroneous or from a lack of respect for the law and its officers. Let us look at these latter two for a moment.

One of the most common public misconceptions lies in the statement, "I have a right to drive!" People think that what they have is a licensed privilege and this concept may be too late to correct.

Another misconception is that "the use of radar, unmarked cars, concealed officers, etc. is 'unfair,' 'un-American,' and amounts to a speedtrap." Now the difference between the clearly illegal practice of entrapment and devices such as those just mentioned, which are commonly called "traps," is the difference between the securing of evidence of the violation by reliable though perhaps surreptitious means on the one hand and, on the other, actions on the part of an officer which induce the commission of an offense which might not otherwise have been committed, for the purpose of getting evidence thereof.

The means of securing evidence are unimportant so long as the devices are accurate and the officers honest. A change of method will not insure honesty. It would, of course, be extremely desirable to have a far-ranging, all-seeing patrol to insure the proper enforcement of laws, but this is completely unfeasible from the standpoint of municipal and state finance.

We hear, too, that "policemen enjoy catching erring motorists." This may be true in a few isolated cases, but one of the problems in most traffic departments today is the difficulty of getting officers to enforce traffic laws with sufficient vigor.

These three misconceptions—along with others—lead to a fourth—an attitude which sets the law enforcement officer apart from the rest of society. This is dangerous, for the policeman must become a respected member of the community. We cannot overcome misconceptions about enforcement if

we do not have respect for the law and its officers.

There is some real basis, in my view, for the lack of respect for the law and its officers. Traffic law enforcement has not always been carried through with that integrity, reasonableness, and intelligence which the public has a right to expect. Let us look at each of these.

Integrity. The "fixing" of cases by police officers, prosecutors, clerks and judges, while greatly reduced over what it was a decade ago, is still widespread. The effect of this upon the confidence of the public is incalculable and positively dangerous—particularly among our younger citizens. This is a serious weakness in the moral fabric of our society, reflecting a lack of both devotion and courage on the part of the officers and a cynicism on the part of the public which has lost its capacity for righteous indignation wherever these conditions are tolerated.

Reasonableness. The use of radar to enforce speed laws to within two or three miles of the limit; traffic violation bureau fine schedules and the crowded courts which deny a hearing; the fixed limits in chemical testing for intoxication; and the "point system" for drivers license revocation, while apparently "business-like and efficient" are substituting artificial standardization for judgment and reason and courage in law enforcement. This mechanization and efficiency are very handy for the politician, but the public has a deep sense of the unreasonableness of it all.

Intelligence. The aim of selective enforcement is to produce the safest possible con-

dition with the available resources. It is based upon accident investigation and good records—by time, place and type of violation. The public will understand and support such enforcement; but it is still not being done in even a majority of our cities and states; it requires the training of top people, both staff and line.

When the public knows that enforcement action truly reflects accident experience, then understanding and acceptance will follow.

What does all this add up to? We have seen that we must have enforcement; we cannot have enforcement without public understanding and support; the public will not support unless the enforcement is honest, reasonable and intelligent; and for such enforcement we need highly trained, well motivated, adequately supervised police, from top to bottom, to carry on a well-organized program which, in turn, is supported by an effective court program.

The initiative to achieve all this can come either from the official (court and/or police) or civic side (safety council, chamber of commerce), but initiative must be taken in the development of enforcement that meets these criteria.

Once the enforcement program has begun, then all of the citizenry must be informed by every means available, from the police officer writing a selective enforcement ticket, to the statements of the judge to the defendants, to the use of TV programs. This will be easier to do as the inevitable results of an effective traffic law enforcement program evidence themselves in a reduced accident experience; for in this, as in almost all human endeavors, nothing succeeds like success.

OFFICERS OF THE

INDUSTRIAL CONFERENCE

NATIONAL SAFETY COUNCIL 1961-62

Vice-President for Industry and Chairman—ROY P. HAMILTON, Supr. of Safety, St. Louis, San Francisco Railway Co., St. Louis, Mo.

Chairman Sections—CLYDE F. SCHLUETER (Chairman-Elect), Accident Prevention Mgr., Employers Mutuals of Wausau, Wausau, Wis.

Vice Chairmen—Sections—G. L. GOWELL, Mgr., Safety & Fire Protection, Monsanto Chemical Co., St. Louis, Mo.; M. F. BIANCARDI, Mgr., Safety Services Dept., Allis-Chalmers Manufacturing Co., Milwaukee, Wis.; M. C. M. POLLARD, Dir. of Safety, National Gypsum Co., Buffalo, N. Y.; J. F. LEGER, Safety Dir., Portland Cement Assn., Chicago, Ill.

Chairman Committees—J. S. QUENEY, Mgr., Safety & Fire Protection Div., E. I. du Pont de Nemours and Co., Inc., Wilmington, Del.

Vice Chairmen—Committees—R. H. ALBISER, Safety Mgr., Merck & Co., Inc., Rahway, N. J.; T. A. KRAKLOW, Dir. of Safety, Deere and Co., Moline, Ill.

Secretary—ROY G. BENSON, Mgr., Industrial Dept., National Safety Council, Chicago, Ill.

COMMITTEE CHAIRMEN

Audio Visual Aids—R. N. PAPICH, Safety Consultant, American Gas Assn., New York, N. Y.

Congress Program—W. M. KLEINMANN, Safety Dir., Johnson & Johnson, Chicago, Ill.

Contests and Awards—J. LLOYD, Safety Dir., Jersey Central Lines, Jersey City, N. J.

Executive—ROY P. HAMILTON

Industrial Safety Training—E. S. HANNAM, Safety Engr., Long Lines Dept., American Telephone & Telegraph Co., New York, N. Y.

Mechanical Safeguarding—K. S. HEDGES, Safety Dir., General Motors Corp., Detroit, Mich.

Nominating—W. E. MONTGOMERY, Safety Dir., Quebec Asbestos Mining Assn., Montreal, Quebec, Canada

Nuclear Energy—D. F. HAYES, Chief, Safety and Fire Protection Branch, U. S. Atomic Energy Commission, Washington, D. C.

Off-The-Job Safety—T. J. BERK, Safety Consultant, Safety and Occupational Health Bureau, Metropolitan Life Insurance Co., New York, N. Y.

Research Projects—S. F. SPENCE, Dir., Safety and Loss Prevention, American Cyanamid Co., New York, N. Y.

Small Business and Associations—F. LAUBER, Dir. of Safety, Nationwide Insurance, Columbus, Ohio

Standards—W. BURNIS, Phillips Petroleum Co., Bartlesville, Okla.

Technical Publications—C. RUDNICK, Pittsburgh Plate Glass Co., Pittsburgh, Pa.

It has often been said that anything taken into the body in too large a quantity may be considered a poison.

The problem then becomes one of defining the limits or quantity of substance a person can take into his body without producing deleterious effects on his health and well-being. For many of the dusts, gases, vapors, and fumes encountered in the environment of our workrooms in industry, there are limits that are referred to as maximum allowable concentrations (MAC). These limits are based on an eight-hour day exposure and are nothing more than bench marks or guides which enable an industrial hygienist to properly evaluate the extent of an exposure and to determine whether or not a potential health hazard is present.

The list of maximum allowable concentrations can be obtained from the American Conference of Governmental Industrial Hygienists, 1014 Broadway, Cincinnati 2, Ohio, or if you have access to the American Industrial Hygiene Association Journal of August, 1961, you will find it there.

When we say these values are bench marks, we mean that more factors are considered in evaluating an exposure than just the finding of a certain amount of contaminant in the air. Factors such as skin absorption, accumulative effect or sensitizing properties of the suspected material must also be considered for proper evaluation of the exposure. Now let us consider but a few of the many toxic materials one may be exposed to in different industrial environments.

Lead

Lead, I'm sure, we are all familiar with, yet it is this familiarity that gets us into trouble with this metal, because we choose to forget the fact that it is an accumulative poison. The maximum allowable concentration for lead is 0.20 milligrams per cubic meter, and the little we take into our sys-

tem today that is in excess of this value is added on to the little we take in tomorrow until the body can no longer safely hold the burden. Chronic lead poisoning will develop among employees exposed during the course of their work to excessive levels of lead dust or fume. Clinical manifestations may appear as loss of appetite, nausea, vomiting, general sickness, irritability, dizziness, and headache, and unless the afflicted person has biological tests taken for lead absorption, the diagnosis may be missed completely until more severe symptoms develop.

Taking appropriate action when blood lead levels indicate an absorption of 0.08 milligrams of lead per 100 grams of whole blood is essential for the prevention of lead poisoning. Recommended action is to remove the employee from further exposure and to review the area of operation to make sure that all engineering controls and safety precautions are satisfactorily in use. Obviously good engineering control is required to prevent the lead from being dispersed into the workroom. In addition, good personal hygiene is required to further reduce exposure. Finally, biological tests, preferably blood leads, are required to ascertain any shortcomings in either of the first two control measures.

Cadmium

Cadmium metal, either as a plating on parts or the solid metal itself, will volatilize when heated above 600°F to produce a toxic brownish-yellow cadmium oxide fume which has no pronounced odor or immediate effect but its inhalation may induce after a few hours or much less depending upon the concentration of exposure a painful and sometimes fatal pneumonitis. The maximum allowable concentration of this material is listed as 0.1 milligrams of fume per cubic meter of air and only by means of a well-engineered exhaust system are we able to control any operation generating the fume to a value below this level.

Beryllium

Beryllium metal is being used quite extensively in the aviation and missile industries. Exposure to minute quantities of fume or dust from this metal may also cause an acute chemical pneumonitis. The maximum allowable concentration is 0.002 milligrams per cubic meter of air and concentrations as low as 0.025 milligrams per cubic meter for thirty (30) minutes are hazardous. The toxicity of this metal can be attested to by the reports of non-occupational illness caused as a result of air pollution or home contamination resulting from dust carried home on the employee's work clothes.

Recommended control procedures are to enclose beryllium machining and finishing processes as much as possible and to ventilate by means of a local exhaust system.

Carbon Monoxide

From the time man first encountered fire to the present, when the automobile contributes gas to his environment, carbon monoxide has been with us as an insidious killer. You can suspect its presence wherever there is fire, but don't be fooled into believing that just because there is a lot of air present that carbon monoxide will not be formed. To illustrate this point, take the burning of newspaper in excess air as an example. According to the experimental work performed by Easton, the following analysis of the products of combustion was found:

Carbon Dioxide	7.6%
Carbon Monoxide	0.2%
Oxygen	7.7%
Nitrogen	77.6%
Unsaturated Hydrocarbons	1.2%

The maximum allowable concentration for carbon monoxide is 100 parts per million; the concentration obtained by the burning of newspaper in excess air was 62,000 parts per million, enough to kill a man in less than five (5) minutes of exposure. Sources of this gas are smoke from a coal fire, flue gas from boilers and house heaters, gas from charcoal briquets and from coke-burning salamanders, and whenever a flame impinges upon a cold surface—just to mention a few.

Carbon monoxide is not a protoplasmic tissue poison. Were it not for its affinity

for the hemoglobin of the blood, it would be classified with the simple asphyxiants such as nitrogen and hydrogen.

For some unknown and unfortunate reason, the hemoglobin's affinity for carbon monoxide is approximately 300 times greater than its affinity for oxygen. Its chief mode of action is to combine chemically with the hemoglobin and thereby deprive the body of its respiratory function. There is no further change in the system. The carbon monoxide remains thus combined until the victim is removed from the contaminated atmosphere to fresh air where the chemical process is completely reversed; that is, the hemoglobin gives off the carbon monoxide and takes on oxygen.

There are no cumulative effects from carbon monoxide for it is not a cumulative poison. The misconception expressed as "chronic carbon monoxide poisoning" is probably based on cases where there has been prolonged asphyxia which has damaged the brain too severely for complete recovery but not sufficiently enough to kill the victim. This same brain damage will result regardless of what the circumstances are that caused a deficiency in the supply of oxygen to the brain cells.

Plastics

Polyurethane foams and epoxy resins are finding wider use in numerous applications. The diisocyanates used in the production of the urethane foams are upper respiratory irritants and extreme sensitizers. Persons who have once become sensitized to these materials develop severe asthmatic attacks if they should again be exposed to extremely minute quantities of the material. Exposure to large initial concentrations will also result in an asthma-like syndrome. As a rule once a person has become sensitized, he can no longer work with or in the vicinity of this material. The best control measures for protection against exposure to the diisocyanates is to put in a well-engineered ventilation system before operations begin.

The amine hardeners used in the epoxy resin system are the principle cause of dermatological manifestations resulting from contact with these materials. We have a great deal of difficulty in trying to convince people of the importance of wearing adequate protective equipment in order to prevent skin contact with subsequent

sensitization. They are inclined to ignore the warnings because in many cases the skin reactions do not appear until several months after a person has started working with the resin. Once a reaction has developed, they must exercise even greater care then required initially in order to prevent a recurrence.

High Energy Fuels

The race for missile supremacy and the conquering of space has confronted us with increased problems of exposure to high energy fuels and their decomposition products. Among these are hydrazine and the boranes—diborane, pentaborane and decaborane.

Hydrazine finds its use as a propellant fuel, either alone or with other compounds such as nitric acid, hydrogen peroxide or oxygen. It has a maximum allowable concentration of one (1) part per million, and in addition to the inhalation hazard, the material is absorbed through the skin. It is primarily a central nervous system stimulant causing excitement, convulsions and cyanosis.

Diborane is a gas at room temperature and has a maximum allowable concentration of 0.1 part per million. Inhalation produces congestion, edema and hemorrhage in the lungs. Its toxicity is comparable to that of phosgene.

Pentaborane is a volatile liquid with a tentative maximum allowable concentration

of 0.005 part per million; however, it is recommended that the exposure be kept as near to zero as is possible since no medical preventive or therapeutic agent has yet been developed for this compound.

Decaborane is a solid having a tentative maximum allowable concentration of 0.05 part per million. Both decaborane and pentaborane attack the central nervous system. Protection is best afforded by the use of air-supplied respirators or cartridge-type respirators that are specifically designed and designated for protection against these compounds.

In concluding this brief discussion, may I point out to you that the services of your local, state, and federal health agencies are always available to you. Should you desire information on the potential health hazard associated with any material or process to which you or your associates are exposed in your particular place of work, feel free to contact any one of them for assistance in evaluating the problem.

OCCUPATIONAL HEALTH HAZARDS — MEDICAL ASPECTS

By HERBERT K. ABRAMS, M.D.
Medical Director, Union Health Service, Inc., Chicago

I would like to quote from a famous writer his description of a "modern" community:

It was a town of red brick, or of brick that would have been red if the smoke and ashes had allowed it; but as matters stood it was a town of unnatural red and black like the painted face of a savage. It was a town of machinery and tall chimneys, out of which interminable serpents of smoke trailed themselves for ever and ever, and never got uncoiled. It had a black canal in it, and a river that ran purple with ill-smelling dye, and

vast piles of buildings full of windows where there was a rattling and a trembling all day long, and where the piston of the steam engine worked monotonously up and down, like the head of an elephant in a state of melancholy madness. It contained several large streets all very like one another, and many small streets still more like one another, inhabited by people equally like one another, who all went in and out at the same hours, with the same sound upon the same pavements, to do the same work, and to whom every day was the same as yesterday and tomorrow, and every year the counterpart of the last and the next...

On every side, and as far as the eye could see into the heavy distance, tall chimneys, crowding on each other, and presenting that endless repetition of the same dull, ugly form, which is the horror of oppressive dreams, poured out their plague of smoke, obscured the light, and made foul the melancholy air. Strange engines spun and writhed like tortured creatures, clanking their iron chains shrieking in their rapid whirl from time to time as though in torment unendurable, and making the ground tremble with their agonies . . .

Before you try to guess which city this is, let me tell you. Charles Dickens wrote this in his book *Hard Times*, published in 1854, describing a typical city in England during the years of the industrial revolution (1760-1830). The description sounds too familiar for comfort to us in America in 1961, at a time when we are going through another industrial revolution: automation, atomic energy, space travel, and many powerful new chemicals. They are exciting developments. They offer a promise of a wonderful world of tomorrow. However, they also pose serious threats to our health and well-being, unless they are properly controlled.

We must ask ourselves whether we are better prepared to meet these threats than the English were 150 years ago. Certainly, we are better prepared technically. In 1800, except in a few instances, little was known about the health aspects of exposure to chemicals, to ionizing radiation, or the effects of long hours of work, poor lighting and ventilation. Today, however, our technical knowledge is sufficient, so that we can say with assurance that we know how to use any chemical with safety. We know how to set up proper protective measures to make every job safe.

The big question is, "Are we utilizing this knowledge?"

Perhaps you who represent workers in industry know the answer better than I do. Let me give you only two examples that will help provide the answer. In Illinois, in 1958, there was found "a drug packaging plant where 103 employees were subjected to a full body fluoroscopic examination each day as they left the plant as a check against pilferage. During the examination, the entire body from the top of the head to the bottom of the shoes was exposed to ionizing radiation. The firm had practiced this procedure on all employees for some 12 years, but discontinued it when advised of the hazards in-

volved." I am quoting from the Report of the Atomic Power Investigating Commission to the 71st General Assembly, State of Illinois, March, 1959.

In the same report, the study found that:

Gross contamination and excessive levels of radiation typify nearly all radium processing installations in Illinois included in the survey. These conditions result from a lack of adequate shielding of proper routing of materials, as well as poor housekeeping within the plant, as noted by the contaminated paper and rags littering the floors, the lack of local exhaust ventilation and presence of contamination in eating areas. In addition, it was noted that labels on containers of radium-luminescent compounds do not contain information as to the quantity of radioactivity included. In all radium plants surveyed, little or no use was made of personnel monitoring devices such as film badges and, therefore, there is no adequate record of radiation exposures received by working personnel.

This was Illinois, 1958—thirty years after the tragedy of the girls who painted watch dials: they pointed the brushes containing radium paint with their lips, and later died of bone cancer.

The role of environment on health grows in importance as we gradually control the infectious disease agents that caused the plagues of old, and as the chemical and physical hazards of our industrial environment become ever more important determinants of our health and our diseases. A recent report of the Public Health Service made for the House committee on appropriations states: "After hearing the evidence, the members of the subcommittee concluded that the health hazards resulting from changes in the environment are far greater than is generally realized and that all levels of government, industries, and research and educational institutions need to step up their efforts to deal with the problem."

The number of chemical materials man is being exposed to is increasing constantly. Over 600 chemicals are currently being added to food; over 600 million pounds of pesticides are used annually, in the United States. Approximately 500 new chemicals are introduced on the United States market each year.

The occupational environment is the basic element in our total environment. Our occupations largely determine how and where we as individuals will live, and, indirectly or directly, may actually influence our life expectancy and our mode of death. Our

industries, in addition to affecting the immediate eight-hour working environment, also largely account for the chemical and physical contaminants in the air we breathe, the water we drink, and in the food we eat.

One example will illustrate: recent studies show that people living in manufacturing areas experienced higher death rates than residents of non-manufacturing areas. The difference was greatest for cancer, and tuberculosis of the respiratory tract (mainly of the lungs), and for various forms of heart disease.

Air pollution was a major factor in causing this greater mortality, but socio-economic conditions also played an important role.

Occupational Diseases

Occupational disease hazards may be classified in various ways. For example, by the type of agent which causes the disease: chemicals, in the form of liquids, dusts, gases, fumes and vapors; physical agents, such as noise, ionizing radiation, abnormal temperatures and pressures, vibration, and physical strain; infectious disease agents, such as the germ that causes brucellosis in meat-packing house workers and farmers.

Or occupational diseases can be studied according to the part of the body affected or the kind of disease. For example, many toxic chemicals may attack the skin, causing an inflammation which we call dermatitis. These or other chemicals may affect the lungs, the liver, the kidneys, the bones, or various combinations of organs of the body, and, in many cases, the entire system.

Occupational diseases may be acute and temporary, or may be chronic and long-lasting. Brief exposures to certain chemicals may produce symptoms that are of short duration, and the individual recovers quickly. A good example of this is metal fume fever, arising from inhalation of the fumes produced when certain metals are heated to temperatures above the melting point. Among the metals which can cause this are zinc, copper, magnesium, cadmium, iron, manganese, and others.

More important, however, are the chronic diseases of industry. These are the diseases of relatively long duration arising usually from long-continued exposure to relatively small amounts of toxic chemicals.

Sometimes these diseases do not show symptoms until long after, in many cases years after, the exposure has stopped. A good example of this is beryllium, a metal which may result in serious and fatal lung disease up to 15 or more years after breathing the contaminated dust or fumes.

We must remember that diseases, like everything else affecting living things, cannot be put into rigid categories. Not all chronic occupational diseases need to result from long-continued exposure. Only a brief exposure to a large dose of ionizing radiation (X-ray or radioactive chemicals) may result in cancer. Similarly, a brief exposure to a sufficient dose of carbon tetrachloride may result in chronic kidney disease or liver disease. In other words, there are many variations and combinations of these conditions.

To attempt a detailed listing of all of the chemicals and metals which can cause disease would only be disturbing and confusing, and we would be in danger of not seeing the forest for the trees. Every industrial chemical is dangerous. It is merely a matter of determining how dangerous it is and establishing procedures for protecting against it. The time is past when "experts" can stand before a group of workers, or, for that matter, a group of physicians and scientists, and say without evidence that this or that chemical when absorbed into the body is harmless. I recall only a few years ago attending meetings of industrial physicians and being shown X-ray pictures of lungs of coal miners, black with inhaled coal dust, and being told that this dust was harmless. Yet, long before that time, British scientists had demonstrated that coal dust can cause disabling lung disease in miners. We in the United States were merely slow to accept the evidence.

Diseases of the Lung

The respiratory system (lungs, bronchi, and larynx) is the most frequent site of chronic diseases caused by industrial poisons. For a long time, we have recognized that silica dust, as it is inhaled by the metal miner, the foundry worker, the pottery worker, the tunnel digger and others, causes a disabling and often fatal disease called "silicosis." Similarly, we know that asbestos dust causes a serious lung disease called

'asbestosis.' And, there is a lung disease found in workers in the manufacture of alumina abrasives, called 'Shaver's disease' (after Dr. Shaver who described it). The dust has high concentrations of alumina and silica. Diatomaceous earth, a form of free silica, similarly causes serious lung disease. And there is byssinosis, resulting from the inhalation of cotton dust. Until a handful of years ago, some of the experts insisted that many dusts when inhaled into the lungs were inert; that is, they produced no effect on the body. However, as we learn more, we find that these so-called "nuisance" dusts are also capable of causing disease. For example, talc, corundum, feldspar, graphite, porcelain, barite, cement, mica, slate, kaolin, and many others.

Even farmers, as well as grain handlers in the holds of ships, suffer from a respiratory disability when inhaling large amounts of grain dust. They develop chronic bronchitis with shortness of breath, cough, etc. Chronic bronchitis can result from inhalation of irritating dusts, fumes and gases; for example: phosphorus chloride and other volatile chloride compounds, acid fumes, phosgene, nitrous gases, aldehydes, solvents and other chemicals.

One of the leading toxicologists in the country, Dr. Herbert Stokinger, of the Public Health Service, points out that:

...our experience with occupational lung diseases makes it difficult to escape the conclusion that all dusts, irrespective of their nature, if breathed in sufficient quantity and for sufficient time, may cause profound damage to the lung, and emphasizes the desirability of the physician's obtaining an accurate and thorough history on individuals suspected of pulmonary disease.¹

Other Chronic Diseases

Let me discuss a few more of the chronic disease hazards, since these are the chief occupational health problems of the present day. The chlorinated hydrocarbons, such as carbon tetrachloride, represent a large group of chemicals used in industry. These can damage the liver and the kidneys. The chemicals known as aromatic amines, represented by beta naphthylamine, used in the manufacture of dye and other commodities, have been proven to cause cancer of the urinary bladder. The central nervous system—that is, the brain and spinal cord—can be affected by many chemicals. Tetraethyl lead causes severe brain disease called encephalopathy. Manganese, one of the im-

portant industrial metals, causes a disease that is remarkably similar to multiple sclerosis. Carbon disulphide may cause severe nervous system effects, affecting the nerves, muscles, and brain.

Serious and sometimes fatal blood diseases may be caused by exposure to benzol. Of course, we know that ionizing radiation in any form—whether through exposure to X-rays or radioactive chemicals—may cause fatal blood diseases as well as various types of cancer. The bones can be affected by exposure to radioactive chemicals, fluorides, phosphorus, and other chemicals. Cadmium affects the lungs and kidneys.

The heart may be affected by the metal known as antimony, and possibly by nitroglycerin, and there have been a number of reports that the heart may also be affected by brucellosis infection, which occurs among slaughter house workers and farmers.

Nitroglycerin and related chemicals used in the manufacture of dynamite and other explosives make an interesting story and illustrate some of the problems in occupational medicine. Workers have been exposed to this group of chemicals for many years. They have known for many years the severe headaches this chemical causes. For years, also, we have heard reports of sudden deaths among workers exposed to nitroglycerin. We do know that this chemical has a powerful effect on the body. It causes profound reduction in blood pressure, severe headaches, palpitation of the heart, nausea and vomiting, fainting, dizziness, and other symptoms. It can also cause skin inflammation. Whether it can cause heart disease is disputed. Even though we have known this chemical for many years, there has been insufficient investigation of the health hazards, and inadequate preventive measures.

Cancer

Occupational cancer is one of our most serious problems. It also provides us with a remarkable opportunity to study cancer in general. The first breakthrough in the mystery of cancer came with the discovery of an occupational cancer. In 1775, in England, Dr. Percival Pott called attention to soot as a cause of cancer of the scrotum in chimney sweeps. These were little boys who climbed into the chimneys to clean them out. Years after working in this

occupation, they died of cancer of the scrotum, which was traced to the soot which penetrated their clothing. Similarly, for years we have known that an excessive number of uranium miners in Europe have died of lung cancer. (Recent studies in our own uranium mines reveal dangerously high exposures.¹)

Since then numerous other chemicals, in addition to ionizing radiation, have been demonstrated to be capable of causing, or contributing to the development of, cancer in various parts of the body. Some examples are beta naphthylamine, which I mentioned earlier, causing cancer of the urinary bladder, coal tars which can cause cancer of the skin, chromates which cause cancer of the lung, and many others. Recent studies have focused suspicion of lung cancer hazards in the work of welders, sheet metal workers and other metal workers.

Skin Diseases

Skin diseases are, as you know, the most frequent type of occupational disease which we see. Most of them result from direct irritation by chemical or physical agents. A smaller number result from an allergic reaction to a chemical. Almost any chemical contact can result in dermatitis. Many of the new chemicals are causing skin troubles. For example, the epoxy resins: These materials are being widely used in electronics, automobiles, pattern-making, die-casting, aircraft, and other trades—for surface coatings and paints, molding compounds, various plastics, and electrical insulation. Another group of chemicals which causes skin disease are the chromates. Chrome ulcerations of the skin are well known. The chlorinated hydrocarbons also may cause skin diseases. One of them is called 'chlor-acne' because it resembles acne. Machinists and metal workers often get a dermatitis from cutting oils. Coal tars produce skin changes, some of which may turn into cancer. There are a host of others too numerous to mention.

Protection

These are only a few examples of the occupational disease hazards arising from contact with chemicals. The alert worker will become acquainted with the materials he is handling and the process he is using, so that he can help to protect himself and his fellows. If he should suffer excessive

exposure to some harmful material, he will know what to tell the doctor who examines him. The alert doctor will be able to correlate the occupational history with the physical findings and symptoms and decide whether the patient is suffering from an occupational disease.

Very few occupational diseases produce such characteristic symptoms that they can be readily identified as an occupational disease. After all, the body can react to harmful stimuli only in a limited number of ways. For example, a worker may have severe pains in his abdomen. These might be caused by appendicitis or by lead poisoning. Leukemia may result from unknown causes or from exposure to X-rays. A person suffering a certain type of paralysis may have multiple sclerosis, a disease of as yet unknown cause, or it could be manganese poisoning. The person who has a cough, shortness of breath, and is losing weight, may have tuberculosis, silicosis, berilliosis or cancer of the lungs. A history including occupational history and a thorough examination is the only way of telling those conditions apart.

Prevention

All occupational diseases are preventable. If we were doing our job right, we would have nothing to talk about today. The fact is that unknown numbers of people are suffering from a great variety of occupational diseases because we are not adequately protecting against them. What are the protective measures which we should follow?

(1) *Education:* Employees should be given adequate training for their jobs, so that they understand the process, know the materials they are handling, and, therefore, can protect themselves and other workers from injury.

Key employees should be instructed in first aid. Management and labor both have responsibilities here. Shop health and safety committees can help in the health education of workers. There is no substitute for knowledge.

(2) *Protection of the environment:* This means from the air of harmful dusts, fumes, gases, vapors. This is accomplished by means of engineering measures, such as exhaust ventilation, enclosure of hazardous processes, wetting down methods for suppression of

dust, and substitution of less harmful for dangerous materials. Good lighting and reduction of noise, etc. are other environmental problems that the engineer can help to solve.

Only when engineering measures are not possible should respirators or other personal protective devices be depended on for protection against inhaling of harmful materials.

(3) *Good housekeeping and sanitary place of work.* This means a clean place of work, free of dirt and dust, and accident hazards. There should be adequate toilet, washing, shower, locker and eating facilities. Hand washing alone can often prevent dermatitis and other diseases. All containers of chemicals should be properly labeled.

(4) *Personal protective devices:* Whenever necessary, management should supply workers with respirators for protection against noxious dusts, fumes and gases in the air; suitable gloves and work clothing for protection from harmful chemicals; hard-topped shoes and hats for protection from falling objects; safety goggles, etc.

(5) *Medical protection:* This includes first aid facilities and a medical department. Every worker should have a periodic physical examination, not for the purpose of disqualifying him for work, but for the purpose of detecting disease early so that prompt measures can be taken to protect his health. The physician has an ethical obligation to inform the worker or his family of any finding important to his health.

In addition to first aid and medical care for work injuries, all workers and their families should have access to modern medical care. Unions throughout the nation are obtaining such care through collective bargaining. Union health centers and other plans, such as Health Insurance Plan of Greater New York and the cooperative health plans, are attempting to bring good care, including preventive medicine, to working people.

(6) *Plant health and safety committees.* Every place of work should have a committee of representatives of the workers concerned with the health protection of the men and women in the plant. This committee should have authority to make periodic inspections of the plant and make recommendations to management. The com-

mittee should meet regularly with the plant physician, the nursing staff, the plant safety and industrial hygiene engineers, and with other representatives of management to discuss health and safety problems and to plan programs of education of the workers in these problems.

(7) *Government safety and industrial hygiene agencies:* These agencies should be called upon for help, whenever the union believes that management is not adequately providing health and safety measures in any particular problem.

How We Are Doing Our Job

How well are we doing in protecting our workers? Let me cite a few facts. The prevalence and incidence of occupational diseases in the United States is unknown, because in many states there is no reporting of occupational diseases. And, in those states where there is reporting, it is incomplete and not uniform. Moreover, we know that numerous occupational diseases are not recognized because of medical ignorance, deficiency in medical education, deficiencies in workmen's compensation laws and health and safety laws.

Health services in many private industrial plants are inadequate, and most workers are employed in small plants where such services are not provided. According to the Public Health Service, 90 per cent of the labor force is not receiving proper industrial hygiene and health services.

The governmental agencies, federal, state and local, which are charged with responsibility for protecting the health of workers, are for the most part grossly inadequate in their resources and services. They suffer from lack of funds, personnel and even from lack of authority. At least seven of our states have no occupational health unit in their health or labor departments, and in all of the state occupational health agencies in the entire country, there are less than 40 physicians employed. There is no uniformity of industrial health codes and standards, and the states differ in the hazards regulated and in their regulations for the same hazards.

There is a serious and growing shortage of physicians and other health personnel both in and out of industry. Dr. Harold J. Magnusson, Chief of the Division of Occupational Health of the U. S. Public Health

Service, estimates that by 1970, industry will need 4800 physicians, but is expected to have only 2900; while 35,000 industrial nurses will be needed, but only 26,000 are expected; and 3400 industrial hygienists will be needed, but only 1600 are expected.

Workmen's Compensation

Good workmen's compensation laws are basic to the health of industrial workers. Without strong workmen's compensation laws, it is difficult to see how we can ever have really effective implementation of our industrial health measures. The fact is that although the workmen's compensation laws are the earliest form of social legislation in the United States, they are in almost all cases hopelessly behind the times. They are inadequate in their provisions for compensation, for medical care and rehabilitation, and most of them have not been brought up to date to permit equitable recognition and compensation for the injuries inflicted by radiation and chemical hazards which cause chronic diseases, usually after long latent periods between exposure and the first symptoms of disease.

Two states still have no occupational disease coverage. Nineteen state laws cover only specified diseases. Most of the laws exclude farm work, domestic work and casual employment. In over half the states, employees in small establishments which have less than a specified number of employees are excluded, and in 12 states the laws apply mainly to a list of "hazardous" employments. Many white collar workers are today excluded from the workmen's compensation laws.

Research

The level of our research in occupational health is correspondingly low. Research is largely in the hands of private industry, and it is guided substantially by the economic needs of the particular industry. Even where research is done in universities, much of this is subsidized for special needs by private industry. Governmental agencies sporadically have made excellent contributions, but their resources are chronically inadequate. There is an urgent need for a system of research and consultation facilities in various parts of the country where workers and employers alike can go for scientific solutions to their problems.

Hope for the Future

Last year, a subcommittee of the House committee on appropriations under Congressman Fogarty conducted hearings on these problems. These are published in a "Report on Environmental Health Problems," available through the Government Printing Office. It is interesting reading. These hearings raised hope that better appropriations would be made to the Public Health Service and other agencies for an expansion of services in the environmental health field.

In the meantime, there is a dangerous vacuum in the supervision of hazards from ionizing radiation as differences prevail among the interested agencies, AEC, U. S. Public Health Service and the states, over jurisdiction in this field. At the moment, controls in this field are a patchwork with good programs in a few states like New York and California, but poor or almost non-existent programs in most others.

The implications of all this should be obvious. Occupational health and workmen's compensation vitally and directly affect the health and life of working people. Yet the unions so far, for the most part, seem to be apathetic about this. Now that unions are deeply involved in health insurance, for the care of non-occupational diseases, perhaps there will be a resurgence of interest in the environmental factors which affect our health.

A few unions have begun to help themselves. Some have negotiated clauses in their collective bargaining agreements embodying a number of the preventive measures I outlined earlier, and have also asserted the union's right to bring expert consultants into the plant.

The United Auto Workers has a department of occupational health, staffed by two experts in safety and industrial hygiene. The International Association of Machinists has a medical consultant. The International Chemical Workers' Union also has a medical consultant and recently appointed a staff safety man. These people can be of great help to workers in providing them with expert knowledge and honest information. Obviously, however, every union cannot and should not hire its own corps of experts and set up its own research laboratories. We are dealing with big social problems, and they must be met socially.

Professor of Sociology of Columbia University, C. Wright Mills, defines the issue in this way:

No moral endeavor, no political orientation, no human study that does not pay close attention to man at work, can possibly be adequate for our time. For work is affected by and in turn affects all that man is and all that he might become. The question we must ask of any society or of any social program is what kinds of men and women does it select, encourage, create? And, in terms of this human evaluation, the most important question we can ask is whether work is a void in which men sacrifice themselves or whether work is a central feature of a style of life in which man may realize himself. . . .

SOME OBSERVATIONS ON OCCUPATIONAL DERMATOSES

By PAUL P. BOSWELL, M.D.
Senior Dermatologist, Provident Hospital, Chicago

Incidence of Industrial Skin Diseases

While there are at present no reliable statistics on the incidence of occupational dermatoses, their frequency is undisputed. Indeed, in World War II evidence indicates that there were more skin casualties than all other battle casualties in this very specialized occupation of soldiering.

In England, a three year study done between 1930 and 1932 inclusively, more than 72 per cent of all occupational diseases were found to be industrial or occupational dermatoses.

Reports from the compensation boards in seven states in this country indicated that 65 per cent of all compensable cases were occupational dermatoses. In a fashion more understandable to those of us accustomed to cost and taxes, this means an estimated loss of more than ten weeks per year with an annual cost of approximately one million dollars. This, in itself, a staggering figure.

Anatomy and Function of the Skin

With these brief statistics, it is well to ask something of their body area, so easily

disposed to such great measure of damage. And again it is felt that a most superficial look at the anatomy and function of the skin, as it is related to this question, is indicated especially for those not related to the medical sciences.

It is not always realized that the skin is one of the most important organs of the body. In its embryonic development, it represents the first of the three primary or basic tissues formed, the ectoderm. And from this ectoderm the largest sensory organ is developed, the brain. So the skin is not only a prologue to the brain, but remains the next largest sensory organ.

The skin is an organ, a very complex organ, constituting about one sixteenth of the total body weight. It contains, within its comparatively thin structure, muscles, blood vessels, nerves, glands, specialized cells such as those that produce pigment and appendages such as nails and hair.

With over-simplification, we can divide the skin in two major layers—an inner layer, called the corium and an outer layer called epidermis. The inner layer is tough, elastic and resilient, and its chief function

is to protect against normal and everyday injuries the more susceptible inner organs; and this is the skin layer which, on tanning, produces leather.

The epidermis, or outer layer, likewise protects by means of its outermost, insensitive, cornified layer, its oil gland and sweat gland secretion, and by means of pigment content. These elements are present in all normal skin and vary only by degree or quantity.

Of the many functions of the skin, the following are of particular pertinence to this discussion:

(1) It protects the underlying tissues of the body by the physical means of resilience and elasticity.

(2) It protects by means of the relatively insensitive outer "horny" layer of the epidermis by its resistance to noxious substances.

(3) It protects the integument from actinic and other physical radiations by means of its pigments.

(4) It receives and transmits sensations of many types to the central nervous systems such as pain, heat and cold.

(5) It regulates body heat so that extremes of external temperature changes can be neutralized.

(6) It secretes water and some waste products.

(7) Finally, it has a small role in respiration and gaseous interchange.

All of these functions are constantly being modified by internal and external influences designed to allow man to maintain some constancy in an ever changing environment.

Historical Background of Industrial Diseases

From a historical point of view, injuries suffered by the skin were known but not favored in medical writings for many years. Not until 1700 when Ramazzini published his *Treatise* was formal recognition achieved and many of his observations still hold true today.

In 1775, Percival Potts noted and described the chimney sweep cancer of the scrotum, as previously mentioned by Dr. Abrams.

Not until the early part of the nineteenth century were added interests and contribu-

tions made to this subject. Then English, French and Germans began to describe the occupational dermatoses of their era.

Not until World War I did American dermatologists begin their prolific and significant studies. At this time there was an intense revival and expansion of the chemical industries and many new areas in the field of industrial dermatoses had to be explained. These new areas are still being met with even today.

In 1928, the United States Public Health Service organized the Office of Dermatitis Investigation, which is exclusively concerned with occupational and other forms of contact dermatitis. This, in part, has led to formulation of laws in the majority of states designed to compensate workers for occupational diseases.

Predisposing Causes of Occupational Diseases

It is almost impossible to classify clearly all the professional and occupational damages to which skin is subjected. The new chemicals, the complexities of manufacture and the wide usages and the resultant chemical products increase this difficulty.

However, certain factors remain constant. I should like to summarize some of these among the predisposing factors that play an important role:

First—Illustrating the protective role of epidermal pigment, it is an accepted fact that negroes are less susceptible to certain skin irritants than other races. Thus they are the choice employees as grinders and dyers in dye factories, where irritating dusts as well as dyes are the major hazards. This is likewise true where solvents are the irritating factor as in dry-cleaning establishments. However, oils and their by-products are the chief irritants of negroes and an increase in dermatitis occurs in negroes chiefly in the form of oil acne.

Secondly—Types of skin vary markedly in individuals as well as in races. The thin, blood-skin individual has trouble obtaining employment in those industries that bring them in contact with potential irritants and, I may add, if those industries' pre-employment examinations are adequate.

Workers with thick oily skin can tolerate the action of fat solvents, such as soap,

turpentine, naphtha, benzol, etc., better than the workers with dry skin. It is universally true that in occupations where clothing may become soaked in oils, greases and waxes these individuals with hairy, scrobbled or oily thick skins are more likely to develop folliculitis and acne-like lesions.

And, as a final note, in the same individual, the skin of the inner arms are more involved than the palms.

Thirdly—Perspiration and sebum usually act as a protective by diluting irritating agents that are already in solution. But a third predisposing factor is in that individual who perspires excessively and works in solid substances such as calcium oxide. Here the moisture can produce a chemical change where the conversion to calcium hydroxide proves to be an irritant.

To affect the skin, materials must wet the skin, thus acting by chemical combinations or by extracting moisture and fat. Obviously, these are materials soluble or miscible in sweat.

Fourthly—Age of the worker can also influence the incidence of occupational dermatoses, another factor to be considered. Whether or not this is due to relative inexperience and lesser previous exposure in younger people, statistically they are more susceptible.

Fifthly—As in all fields, the matter of sex must be considered when discussing predisposing causes. The skin of women is usually drier than that of men.

However, during menses and pregnancy there is an increase in perspiration and therefore an increase in the sensitivity as before mentioned.

Likewise, women are more concerned and more prone to individual cleanliness in their habits and so fewer incidences are reported.

On the other hand, fewer women are engaged in hazardous occupations and there is an absolute statistical decrease in reported cases.

Women seek first aid more readily and sooner than men and so develop fewer chronic dermatoses reported as compensable.

Sixthly—The existence of previous non-occupational diseases is also a predisposing factor. There are workers more prone to develop industrial dermatoses than others. These are the individuals who have had

previous skin diseases. This may or may not hold true for those with mycotic, or fungus, infections. There is no real evidence that this is true. Illustrative are the diseases of psoriasis and lichen planus. In these individuals, though currently clear of the acute lesions, the development of trauma may cause recurrence or new lesions of these diseases completely unrelated to occupational dermatoses.

Seventhly—Cleanliness, or rather the lack of cleanliness, or its careless application is a most important factor. And cleanliness means not only personal but also environmental. This is particularly true where workers handle or are exposed to fumes, dust and noxious vapors. Moreover, the clinical substances used in cleansing must be chosen judiciously, since they too can cause a reaction. The subject of cleanliness will be mentioned later.

Eighthly—The question of allergy is being deliberately passed over, since there is little agreement as to specific definition of this term. Suffice it to say that most, if not all, persons can be or are allergic if exposed to the right allergens. Guarding against this possibility is a herculean task.

Actual Causes of Occupational Dermatoses
The actual causes of occupational dermatoses may be simply divided or outlined in five major groups:

- (1) Mechanical.
- (2) Physical.
- (3) Chemical.
- (4) Plant poison or irritants.
- (5) Biological.

Any or all of these factors may be encountered or predominant in any occupation. For example, the farm worker is exposed to most of these factors. There may be mechanical injury from farm machinery; there may be physical injury from heat, cold or the arctic rays of excessive sunlight; chemical irritants of fertilizers and insecticides may play a role; or the biological infections from fungus and parasite organisms from the effluvium of animal and plant materials are important and, of course, plant poison.

Mechanical agents which may cause callusities, tendon injuries, cuts and abrasions fall within this category. These in turn may lead to infection, or, as many investi-

gators think, may become the sites of malignancies. In those patients, previous sites of skin diseases such as psoriasis or lichen planus, new lesions or an aggravation of old lesions is common.

Among the physical agents that are likely to excite occupational dermatoses are the following most common:

High temperatures may cause excess perspiration leading to the common heat rash, intertrigo, or less commonly, erythema ab igne. More permanent skin changes may result. These are the afflictions of the workers, produced by prolonged exposures to heat occurring in such workers as stokers and steel workers.

Cold and electricity may also take their toll amongst outdoor and electrical workers.

The deleterious effects of X-ray, radium and ultra violet radiation is well known to all of you; as Dr. Abrahams has previously indicated, this is particularly true with medical workers or technicians, miners of radium and uranium, and laboratory workers in the new field of nuclear energy and atom-splitting.

Chemicals are of necessity the predominant villains in the production of industrial dermatoses. These can be divided into what are primarily skin irritants or skin sensitizers.

The primary irritant is defined as an agent which will cause damage by direct action on the normal skin at the sight of contact. Only substances which can wet the skin or be dissolved in its solutions of sweat or sebum are in this category. Unfortunately these primary irritants, under specific circumstances, may also become sensitizers. The sensitizer, on the other hand, may not produce demonstrable skin changes on first contact, but only after prolonged exposure of one or more weeks may cause changes that produce a definitive dermatitis.

Here, the field of allergy enters the picture and its varied theories are an attempt to explain the mechanics of this most common condition.

For a detailed list of those major groups, the readers are referred to the encyclopedic work of Rostenberg and Sulzberger in the Journal of Investigative Dermatology, Vol. 11, No. 3, June 1939.

What, in general, are the methods of preventing the wholesale occurrence of occupational dermatoses?

The ideal method, of course, is to safeguard the worker so that these noxious agents mentioned, do not come in contact with the worker's skin. This is obviously an impossibility.

The modern factory or laboratory, new in specific construction and automation, is coming closer and closer to this ideal.

The following basic precautions should be observed whenever at all feasible:

- (1) Cleanliness of working environment.
- (2) Personal cleanliness encouraged by shower baths, lockers for street clothing and work clothing.
- (3) Initial physical examination to be assured that the applicant does not have any predisposing skin ailment.
- (4) Insistence that workers report all irritations of the skin, no matter how trivial, to the medical department.
- (5) The use of protective clothing where indicated, as well as the use of protective medications.

But, whereas it is impossible to outline any few basic principles of prevention, there is an encouraging number of positive factors.

Train inspectors, sanitary and safety engineers who are usually employed by insurance carriers and municipalities are the front line task forces. These people train superintendents, foremen, and plant physicians, who in turn instruct the workers of any avoidable hazards of the occupational dermatoses.

While the problem of occupational dermatoses is complex and large, I, for one, am confident that American ingenuity will eventually solve it.

I believe in facing problems directly, and I believe in knowing just where you stand before you start any kind of discussion or action. So before we go any further, I think it will be good for us to take a quick look around to determine our condition and position.

We have done some good work in safety in the United States. We have accomplished much, but, we are not finished. There is still plenty of work to be done.

When we begin to look around, we find some rather appalling figures and these figures tend to disturb us very much. They also become the basis for marching orders for the day. Very quickly they tell us what must be done.

I am sure you know these figures, but let's get them before us again. In 1960, 93,000 people lost their lives in accidents. No matter how much this figure is improved over the years, it is still 93,000 too many. In dealing with the loss of human lives, even one is too many.

To express this loss in another way, every six minutes, twenty-four hours a day, year in and year out, somebody loses his life in an accident. This adds up to the 93,000 lives I mentioned. This is almost as many deaths as the United States suffered in World War I, and we thought the losses in that conflict were disastrous. This loss in life from accidents represents the entire population of Springfield, the state capital of Illinois.

But, there are still worse figures. We have been talking only about fatal accidents. In addition to the deaths, 45 million persons were injured in 1960. If you care to think in terms of dollars, these accidents cost over 13.5 billion dollars. Going beyond these figures, no one can measure the grief, the worry, the discomfort and the unhappiness caused by the accidents to the millions of people connected in some way with the victims.

We could go on and recite a lot of figures but these are enough to set the stage. There is still a big job to be done. These figures are a little bit cold because they are impersonal. They become more realistic when they represent real persons in your family, your neighborhood, or your plant.

I picked up a paper recently to make an experiment. I scanned the paper and I listed

the headlines and feature stories, from the one issue, that were concerned with accidents and safety. This is what I found:

jet plane crashes into store roof—pilot killed and 35 injured.

Six from area killed in auto crash.

Youth, 16, drowns in farm pond.

Indiana man killed in Ohio road crash.

Driver hurt, phones knocked out, in truck crash.

Grid star injured in freak accident.

Family of seven wiped out in tenement fire.

Here we had in one issue of a newspaper, 16 dead and 38 injured, and all within my community or population center. These examples bring the figures closer to home. They do not tell us that our job is done in safety.

I read these accident and fatality figures regularly, and I am sure you do, too. They have a great effect on me. They stimulate me to continue everything I've ever done in the interest of safety, and to step up the pace if possible.

Since our special emphasis today in this section is industrial safety, let's take a closer look at that level. I think we will soon see that there is no level that is not dependent on all other levels.

In industrial safety there has been some fine work done. The fatality rate in all industry has been reduced and injuries have been greatly diminished. I am going to use some facts and figures concerned with Firestone, because, first, this is the situation I know the most about, and secondly, it will serve as a typical example of industrial safety in action.

At Firestone, we have reduced our frequency rate from 6.3 in 1946 to 1.7 in 1960 and to 1.3 for the first six months of 1961. Our severity rate has been reduced from 970 in 1946 to 305 in 1960 and to 275 for the first six months of 1961.

Our company has received the Award of Honor of the Safety Council on a company-wide basis, several times and individual plants have been cited frequently for meritorious performance. Firestone holds the world's record for tire plant safety—a record when one tire plant went through almost 10 million man-hours without a lost

time injury. In the industrial rubber goods classification, a Firestone plant holds the record of 7 million man-hours without a lost time injury.

I give you these figures not only because I am proud of them, but because they indicate what is being done with definite safety programs and by instructional procedures that keep pounding home the value of safety.

Our point of emphasis here is that in spite of what has been done in industrial safety the figures for over-all accidents continue at very high levels.

Safety programs in industry have undergone great changes in the time I have been associated with them. The scope has greatly expanded. In the early years the emphasis was in the prevention of fatal accidents. Today, although the fight still goes on against fatal accidents, the program now includes prevention against even the most minor injury.

As safety programs in industry have developed into their present state, they have passed through several stages.

The first stage could be described as mechanical. This is the stage when we put guards on gears, stop rails on rollers, wire grilles to protect accidental contacts. It is the stage of guards, guides, grilles, and gimmicks to prevent injuries. It is the time of automatic stops and safety releases. We installed lights, we protected against flying objects, we painted, we smoothed, we roughed up—anything and everything—to make the environment reasonably safe. All these things helped but they were not enough.

The key word in the second stage is "attitudes." Industrial safety people found that in spite of guards, automatic warnings and all other devices, that men were still getting hurt, because safety was not in their thinking; it was something the safety man did. Safety programs were started to train men on safety. This program was not only to train supervisors but to develop safety attitudes in all employees.

Safety operating instructions were prepared; safety shoe programs and eye protection programs have been emphasized to influence the man to think safety. Safety scoreboards screamed at him to be safe, they were even made to move, rotate and

spin, so he would notice. There are safety contests, slogan contests, and awards of every type to impress safety indelibly on the mind of the individual.

The third stage is going on continuously. It includes the first and second but it goes further. It moves into every level of our split-level house of safety and it tries two advanced steps.

(1) Make every man his own safety expert with responsibility for safety on every level.

(2) Make every person think and act safely twenty-four hours a day.

Why is this necessary? Because in spite of all our gains in industrial safety, men still get injured and killed. Some of these happen in industry but many more occur when the individual worker is functioning on another level.

There is a story of a prize fighter who was slightly overmatched. During the first round, his opponent had his fists in our fighter's face most of the time. He was roughed up pretty badly. His second, or man in his corner, however, thought he should encourage him and when the fighter came into the corner between rounds, the second said, "Nice round, boy; he never laid a glove on you."

In the second round, it was even worse, as the opponent began to put more snap into his punches. By the end of the round, our fighter returned again to his corner, a little groggy and much the worse for wear. The second told him, "That was a good round, he never landed a solid blow." The fighter was a little bewildered because he felt the effects of several solid blows and he was not very optimistic. However, he kept going out for each successive round and coming back in worse shape each time. Finally, when he had been told again that the opponent had not landed any telling blows, he said to his second, "When I go out this round, I want you to keep an eye on that referee, because someone is beating the hell outta me out there."

So it is with safety. All the things that have been done are not enough. Someone is still beating the hell outta safety. In most cases it isn't you, it isn't you, and it isn't you. It isn't this group and it isn't that group, but the damage is still being done. There were still those 93,000 lives

lost and those 45 million injuries. Let's see if we can find who is doing it.

National statistics show that nearly 70 per cent of all fatal accidents among workers occur off the job and more than half the accidents resulting in workman disability take place away from the job. This leads us to a conclusion that the safety practices followed by the worker, while on the job, in many cases do not carry over after he passes through the factory gate.

Do you realize that in the decade 1950-1960, nearly three quarters of a million Americans were killed in motor vehicle, public and home accidents—the other levels?

We have been very interested in this off-the-job safety problem at Firestone. Twice each year we run checks of on-the-job and off-the-job accidents. The checks are made in May and December and cover the accidents in that given month. In the past three years, in these checks, we have found 31 lost time injuries on-the-job as opposed to 322 off-the-job. There have been, in these six monthly periods checked, no fatalities in the factory and three off-the-job fatalities.

We have a new challenge and we must face it. We must reach for that split-level type of safety that operates on every level.

A man may have a home workshop which has guards on the power tools; he may wear goggles and observe all the safe procedures when in his shop. But, if he has a fire hazard in his attic, or he smokes in bed, or he has a car in the garage with bad brakes, or he has objects piled on his basement stairs, or he paints his house using an unsafe ladder, he is the fellow who is beating the hell outta safety.

I read an article recently which made this statement, "Population is increasing rapidly. Since most fires are the result of human failure, the expected population growth will increase the number of fires."

This very plainly says, *the more of us there are, the more there are to be careless.* This is a pessimistic statement and tends to assume that you and I are not going to do anything about it. This statement concerned fires but it could easily apply to all accidents caused by human failure. Take another look at that statement.

The more people there are, the more there are to be careless.

My argument here today is that it does not need to be this way. We just have more work to do and more people to reach. Let's turn that statement into a positive one, full of challenge:

The more people there are, the more there are to learn and practice safety.

Of course this is a big job. Who is going to do it? I gave a title to my remarks—"Safety Is A Man-Size Job." I have built up to this climax. There are two meanings to this title.

First, it means that safety fits your person—it is your size as an individual. It is man size. It is not too big for you. It is not too small for you. It is true that safety is an over-all task, on which all groups and individuals must cooperate, but it is no good at all unless each individual assumes safety as his job. Advertisers talk about certain foods being bite size—the size of a bite. Safety is man size—the size of a man.

My second meaning when I say safety is a man-size job, is that safety is a really big problem. When we want to express the large proportions of anything, we say it is man-size. A man-sized cup of coffee is a big one; a man-sized appetite is a big one; and a man-sized safety program is a big one.

Safety begins at this man-size level. Every individual must practice and live safety. Someone has given us this very challenging statement—*Take chances and the chances are that you won't have many chances left to take.*

First, we all operate as individuals. We begin a full-size safety program by being safe ourselves—and not just on one level—on all levels. This, in itself, is a man-size job. You cannot stop a person from having an accident by telling him not to have one. "Don't have an accident," is as futile a statement as "Don't have an ulcer." Someone has said, "You can lead a man to safety, but you can't make him practice it."

In another comparison, you can put collection cans along the streets and highways, for the deposit of rubbish, but, whether or not people use them is largely a matter

of personal attitude. You can force persons, by law, to install safety belts in their cars but, whether or not they are used is up to the individual. Safety is man size.

I recently heard a very clever story on individual safety.

Let us suppose I put 331 pills in a bottle. Three hundred of them are simple bicarbonate of soda; thirty of them are harmless sugar pills and one is deadly potassium cyanide. The pills all look alike. Now, we shake them all up and offer you the bottle. Are you willing to take a chance, select a pill and swallow it? Not very many of us who love life would take the chance. Yet, traffic safety engineers tell us that these are the odds on running a red light. *Once in every 331 times there is a fatality.* I wonder why the individual looks at the odds so differently when he is behind the wheel?

I believe there are two key reasons why industrial safety has been successful. The first is concern. Management has been concerned and has taken every measure to make each person concerned, not only for his own safety but that of his fellow workmen. Labor has been concerned and has cooperated in industrial safety programs. Where there is no concern there is no safety program of any value.

The second key word is responsibility. Our safety programs at Firestone have been successful because we have placed responsibility. A plant manager is responsible for safety in his plant. He, in turn, makes department managers and supervisors responsible. Safety is a responsibility just like production, cost, and economical operation.

So, we are back to the individual. The only way we can ever accomplish split level safety is through the individual being concerned and accepting responsibility.

Safety is a matter of personal attitude. People work, drive and play with the same attitudes as they live. If we can teach people to embrace safety attitudes then they will drive safely, work safely and play safely.

If every individual tries to improve his safety attitudes then he will be safer and he will frown on all persons who do not behave safely. The unsafe individual can-

not be tolerated and those who work with him should be critical of his action.

I believe that with men thinking and living safety that there will be benefits all along the line. Workers will be interested in the quality of their product because such quality will contribute to safety. He will be interested in good housekeeping because it has a close relationship to safety. Most important to all, he will think safety and practice safety on every level of his split-level life.

If safety is to be a way of life, appearing in every level on which we operate, who is going to bring it about? I say the job is a man-size one. Management, labor and the individual must all work together in promoting the safety theme. And you must operate on every level of your life. More than this, you must operate consistently on all levels. We must be consistently safe. A safety attitude must be practiced at home, at work, on the highway and in the community.

Safety is non-controversial. There is only one side. So we do not need to cast ballots or hold elections. Management and labor have no argument on safety. So we can spend all our energies in promoting the safety attitude.

Certainly we need to continue all the mechanical means we have ever used in industrial safety. We need to continue our drive against industrial accidents but we must expand our vision and find a way to extend safety practices to all levels. Howard Pyle, the Council president, has said it very well, *"I've want every American home safe and safe at home."*

There is still a man size job to be done in making safety a full-time, around the clock attitude.

There is still a man-size job to be done in industrial safety, to hold our gains and to cut deeper and deeper into accidents and poor safety practice.

There is still a man-size job to be done on the public safety level.

There is still a man-size job to be done on the traffic safety level.

Attitudes are exposed by behavior. You don't have to be a psychologist to develop sound safety attitudes. You do this by the

way you act, by the things you do, by the way you talk. By your attitude you not only control yourself but you teach others. Each individual must have *concern* and he must accept *responsibility*.

I will close with a little verse that tells a story:

If everyone who does a job, would say
a little prayer,

And keep in mind those other folks depending on his care,

And make a vow, and pledge himself to never take a chance,

The great crusade for safety would suddenly advance.

The job is man-size. Now, let's do what we can to become men capable of a man-size job.

SAFETY IS OUR CHALLENGE

By GEORGE M. HARRISON

President, Brotherhood of Railway Clerks, Freight Handlers, Express & Station Employees, AFL-CIO, Cincinnati, Ohio

It is pleasant to be able to begin my remarks by noting that today's news on the safety front in American industry is the best we have had for some time. The last two quarterly releases of the U. S. Bureau of Labor Statistics, covering the first six months of 1961, have each reported that work injuries in manufacturing plants reached record low rates during that period. The rate of 10.4 disabling injuries per million man hours worked, which was set in the first three months of this year, equalled the all-time record low for any quarter, established in the last quarter of 1960.

In fact, according to a September release, the first six months of 1961 produced the best six-month average recorded, six per cent lower than in 1960 and 1961 may be the best year on record.

This optimism then is qualified by the injection of a note of caution.

"However," the Labor Department continues, "the greater-than-seasonal increase in May and June could indicate a rising trend resulting from increased industrial activity. Previous experience suggests that increased industrial activity is followed by an increase in injury rates."

Those words are worth repeating, for they certainly make clear that safety is, indeed, our challenge. "Increased industrial activity" says the Labor Department, on the basis of past experience, "is followed by an increase in injury rates."

Aren't the implications contained in this statement truly shocking? Aren't they a tragic indictment of the ethical standards—or the lack of them—which our industrial society exhibits in this area of industrial safety? Is it really necessary in order to reduce the killing and maiming of workers to have that happen only because of a decline in business which brings reduced industrial activity? In other words, are safety and prosperity incompatible?

The facts, based on past experience, would seem to indicate that this is the case. I would like, however, to challenge such a conclusion. I do not believe that prosperity and mounting accidents are necessarily related. In fact, I would contend that greater prosperity can make possible the necessary basic expenditures and greater care which will insure greater safety on the job, reduce the staggering economic losses resulting from accidents, and thereby make prosperity even greater.

In recent years, industrial accidents have accounted for only about one-seventh of the deaths and for about only one-fifth of the injuries of the more than nine million different kinds of fatal and disabling accidents suffered within our nation annually.

The shocking thing about these statistics is that they tend to reflect a gross indifference to accidents on the part of us as individuals. This is borne out by the fact that by far the greatest number of disabling accidents—four million of them

annually—occur right in our own homes. More than two million more accidents annually are of a nature which the National Safety Council classifies as public, and include such categories as those accidents occurring in hunting and swimming and other recreational activities, in transportation other than by motor vehicles, in public buildings, etc. Finally, each year motor vehicle accidents take a tragic toll of more than one and one third million victims and account for the highest number of fatalities, in the neighborhood of over 37,000 deaths annually.

Thus nearly seven out of every nine accidents occur either in our homes, on the highways or in recreational pursuits and other public activities. These are the kind of accidents where individual responsibility clearly is very high. Carelessness and selfishness as individual weaknesses account for most of this tragedy.

We find that the huge annual toll of occupational injuries and deaths has been running at the rate of about two million a year ever since the end of World War II. The yearly average for a ten-year period (1946-1955) was 17,040 killed or totally disabled for life, 83,600 partially disabled for life, and 1,893,000 more temporarily disabled—a yearly average of 1,994,000 injuries and deaths. The annual cost to employers of these accidents, according to a Labor Department estimate which it terms "highly conservative," is more than \$3.5 billion. When estimated annual wage losses to employees of \$1.4 billion are added, the total yearly economic loss to the nation of occupational accidents amounts to nearly \$5 billion dollars.

This needless toll of economic waste and death, pain and mutilation of workers has been going on for too many years. Over the 15 years which have elapsed since World War II ended, some 30 million workers have suffered from industrial accidents and the nation has paid some \$75 billion in economic losses to support this accident toll. When we recall that these industrial accidents amount to less than one-quarter of all accidents, the picture takes on an aspect of hopelessness which it may very well deserve.

However, the long-range picture can give us cause for courage and a hope for an

end to this tragic suffering and economic waste. The truth is that, over the years, real and significant progress in reducing work accidents is being made. Industrial accidents have been reduced steadily since the turn of the century through the elimination of some of the unnecessarily hazardous working conditions, through better laws for the protection of employees, and through joint cooperation of labor and management in many industries. This progress has even picked up speed in recent years. The casualty rate in American factories in 1951-1955 was 17.3 per cent lower than in 1936-1940. In 1956 the number of casualties in manufacturing per million hours worked was 20 per cent lower than in 1949, and in the first six months of this year it was down 30.6 per cent.

These figures indicate that real progress has been made, and is being made, in reducing the toll of accidents in industry. They show that the battle for safety is not hopeless. They prove that with proper concern by management, with joint labor-management cooperation to prevent accidents, and with adequate interest and action by the legislative and administrative arms of the government, accidents can be prevented to a remarkable degree. They show that where there is a will, there is still a way.

Before progress of this kind can take place, however, there clearly must be a will to do something about it on the part of both management and labor and government. Nothing proves this more clearly, in my opinion, than the tragic record of what has been happening in the railroad industry in recent years. I happen to know a little something about that industry, since I have spent most of my working life as either a railroad employee or a railroad labor union official intimately concerned about the condition of the industry and the working conditions of its workers.

I have already said that I do not believe that the rate of accidents in industry must be related to its rate of output, as the Labor Department press release quoted at the outset says "previous experience suggests." Certainly, experience in the railroad industry does not bear this out. Most of you are well aware that the current level of operations in railroading has not matched levels in recent years and therefore if the

Other splendid achievements are the distribution of over 400,000 Mouth-to-Mouth Resuscitation Instruction cards as a public service and the establishment of a radiation safety department at the international union level. The union's monthly periodical always carries a full-size safety poster on the back cover and consistently contains printed articles dealing with safety.

Many other factors were taken into consideration by the Awards committee when judging IBEW's activities, but the above should suffice as an indication of the excellent job this union is doing.

Here today to accept the Harry Read Memorial Award of Honor on behalf of the Brotherhood of Electrical Workers is Mel Boyle, administrative assistant to international secretary-treasurer, Joseph Keenan.

3. International Brotherhood of Operative Pottery, AFL-CIO, Local 89, San Pablo, California.

The Labor Conference is pleased to name another winner of the highest award for a labor organization—the International Brotherhood of Operative Pottery, AFL-CIO, Local 89. This local represents workers at the American Radiator and Standard Sanitary Corporation in San Pablo, California.

This local has received so many awards from the National Safety Council over the past ten years that it would leave you breathless to hear them all. Its safety activities are manifold, including such out-of-plant programs as instruction in the safe use of firearms for youngsters and participation in the "Swim to Live" program.

On May 8, 1961, the employees of this plant established a new "world's record" for safety in the clay and mineral products industry by completing a full ten years without incurring a chargeable lost time injury. For that they received an Award of Honor from the Council.

The Labor Conference is proud to present its top award, "The Harry Read Memorial Award of Honor" to Local 89 of the International Brotherhood of Operative Pottery, AFL-CIO.

Here to receive the award for the local union is Brother E. N. Steward, local union president.

4. General Industrial Workers Union Local 146 of the Distillery, Rectifying, Wine

and Allied Workers, AFL-CIO, Linden, New Jersey and a "Citation for Distinguished Service" to:

Joseph P. Shepherd, Local 146 safety chairman.

The fourth labor organization to win the Labor Conference's highest award is local 146 of the Distillery Workers union, AFL-CIO, which represents employees of the General Aniline and Film Corporation in Linden, New Jersey.

Here again is an outstanding example of a union that is concerned not only about in-plant safety but community safety, as well.

To give you a brief idea of the scope of its activities, this local union deeply involved itself in a Bike Safety campaign in the community, gave every employee copies of New Jersey Traffic Accident Facts prior to Labor Day, and copies of the Driver's Manual of the State of New Jersey. On August 26, 1960, a major goal was accomplished at this plant when 1,500,000 man-hours were worked without a lost-time accident.

These activities are an indication of the imaginative programs which this local union carries out.

To the local union we are happy to present "The Harry Read Memorial Award of Honor."

To the local's safety committee chairman, Joseph P. Shepherd, who sparkplugged those programs, we are proud to present the "Citation for Distinguished Service."

Here to receive the awards are Joseph P. Shepherd and the local's current safety committee chairman, Hayward Webber.

"The Harry Read Memorial Award of Merit" to:

United Steelworkers of America, AFL-CIO, Local 1010, E. Chicago, Ind.

"Citation for Outstanding Service to Safety" to:

Kenneth S. Kovack, United Steelworkers Local 1010 Safety Chairman.

An "Award of Merit" is presented to the United Steelworkers of America, AFL-CIO, Local 1010, East Chicago, Indiana, which represents workers at Inland Steel Company in East Chicago, and a "Citation for Outstanding Service" to Kenneth S. Kovack,

chairman of the local's safety and health committee.

Here to receive the "Citation" is Kenneth S. Kovack, who is also the local's recording secretary. Here to receive the "Award of Merit" on behalf of Local 1010 is Louis Chickie, treasurer of Local 1010.

"The Harry Read Memorial Award of Merit" to:

United Auto Workers, AFL-CIO, Local 837, Elkhart, Ind.

An "Award of Merit" is presented to Local 837 of the United Auto Workers of America, AFL-CIO, bargaining agent at the Taylor Products Division of the Tecumseh Products Company, Elkhart, Ind.

Here to receive the award on behalf of the local union is Alice Reed, the local's safety chairman.

"The Harry Read Memorial Award of Merit" to:

Local 5, Industrial Union of Marine and Shipbuilding Workers of America, AFL-CIO.

Local 90, Industrial Union of Marine and Shipbuilding Workers of America, AFL-CIO.

An "Award of Merit" is presented to local 90 of the Industrial Union of Marine and Shipbuilding Workers of America, AFL-CIO, and office workers local 5 of the same Union at the Quincy Shipyard of the Bethlehem Steel Company in Quincy, Mass.

Here to receive the awards on behalf of their respective locals are Mr. Fitzgerald, president, and Mr. Houruda, safety committee chairman for Local 90; and Mr. Olivero, president, and Mr. Switzer, safety committee chairman for Local 5.

"The Harry Read Memorial Award of Commendation" to:

Brotherhood of Locomotive Firemen and Enginemen, AFL-CIO-CLC.

In recognition of its nationally known Safety Awards Program for railroad locomotive crewmen, we are pleased to present an "Award of Commendation" to the Brotherhood of Locomotive Firemen and Enginemen, AFL-CIO-CLC.

Here to receive the "Award of Commendation" is Brother H. E. Gilbert, President of the Brotherhood of Locomotive Firemen and Enginemen.

"The Harry Read Memorial Award of Commendation" to:

International Brotherhood of Pulp, Sulphite and Paper Mill Workers, AFL-CIO.

To the International Brotherhood of Pulp, Sulphite and Paper Mill Workers, AFL-CIO, we present the "Award of Commendation" for their nationwide efforts during 1960.

The committee to accept this award is composed of Vice President Elmer Meins; International Treasurer Henry Segal, and International Representatives, Wellington Meyer and Edward Zeininger.

"The Harry Read Memorial Award of Commendation" to:

Independent Radionic Workers of America, CUA.

An "Award of Commendation" is presented to the Independent Radionic Workers of America, bargaining agent at the Zenith Radio Corporation in Chicago, Illinois.

Accepting the award on behalf of the organization is Eugene Raetz, president.

"The Harry Read Memorial Award of Commendation" to:

Local 1255, International Brotherhood of Electrical Workers, AFL-CIO.

An "Award of Commendation" is presented to Local 1255, International Brotherhood of Electrical Workers, AFL-CIO, representing workers at the Orangeburg Manufacturing Co., a division of Flintkote, Orangeburg, N. Y.

Here to receive the award on behalf of the local union is Arnold Smith, President, and Allan Kunz, Director of Safety.

"Citation for Outstanding Service" to:

Lois F. Malecki, Local 272, International Brotherhood of Pulp, Sulphite and Paper Mill Workers, AFL-CIO, Everett, Washington.

A "Citation for Outstanding Service" is awarded to Lois F. Malecki, safety director of Local 272, International Brotherhood of Pulp, Sulphite and Paper Mill Workers, AFL-CIO, representing workers at the Simpson Lee Paper Company, Everett, Wash.

We are pleased that Lois has come all the way from the state of Washington to receive this highly-deserved award.

"Citation for Distinguished Service" to:

P. L. "Roy" Siemiller, General Vice President, International Association of Machinists, AFL-CIO,

G. G. Grieve, Secretary, Labor Conference, National Safety Council.

And now we have two "surprise" awards to make to two of our associates in the Labor Conference, both of whom have made

outstanding contributions beyond the call of duty to the development and growth of the Labor Conference. It gives all of us in the Labor Conference the highest pleasure to present the "Citation for Distinguished Service" to Brother Roy Siemiller, General Vice President, International Association of Machinists, AFL-CIO, and to the Secretary of the Labor Conference, Gil Grieve.

HOW WE WORK ON A JOINT BASIS

By JACK MOYE

President, B. F. Goodrich Local 5, United Rubber Workers, Akron, Ohio

It is a thrill to be here speaking for thousands of our members throughout the United Rubber Workers and for many other unions that have benefited from the efforts of joint safety committees. A little over two years ago this would not have been possible, for the history of The B. F. Goodrich Company shows a continual fight by management against the endeavors of our local union and others to obtain joint safety committees. This was true of a good many of the Rubber Workers' systems throughout the United States and Canada.

However, our members in 1959 had made up their minds that they were going to fight for this committee, along with many other things, and the establishment of such a committee was brought about by the efforts put out through a 55-day strike. Our people fought to get it. They thought it was worthwhile, and realize it even more so today; for remember, it is their fingers, hands, feet, eyes and lives that have been saved through cooperation of this kind.

I am pleased to say that, to my knowledge, this fight against a joint committee was not led by management people who are directly responsible for safety in the Goodrich plants.

To make a committee of this type successful, we have found that it takes action by both parties (labor and management), not just words. We have that sort of action in the Akron B. F. Goodrich joint committee, for any time of the day or night, including Sundays or holidays, we individually and collectively are in the plant

looking at problems. We have found that our members get a "lift" when they see the joint committee in the department looking at their problems and attempting in some manner to solve them.

To make a joint committee really successful, I feel that the department committeeman should always have a part in the discussion when a safety problem is being investigated in the department, and that he should be kept informed of the handling that has resulted through the joint effort. Having the committeeman in on a problem, as well as the foreman, brings about better results. It does not leave it in one person's hands and one person's thinking.

Also, I strongly feel that you should make sure that a problem is one of safety or health. Believe me, you will lose the value of the committee if you allow other types of problems to be tied in with safety. There are other people connected with our union that handle personal problems or standards problems. Use your people that are assigned to those types of cases to take care of them. The safety committee's value greatly increases if this rigid rule is followed. Management of this plant realizes that if the joint committee makes a recommendation to resolve or correct some condition, that it is actually tied in with safety, that it bears looking into, and that they had better be about correcting it.

Our committee meets every week, at which time we not only discuss the problems going on in the plant, but exchange

ideas, speak freely to one another, and above all try to see ahead to prevent future accidents. This is one of the great goals of a joint committee. When you learn to drive for future results, you are on the right road.

A desire to help bring about true safety is another requisite. If your committee in its actions gets "humdrum" it will lose the spark that is necessary. Keep people working on the committee that have a mutual trust and that have the drive to make progress in safety.

One of the very profitable benefits brought about through our joint committee is that now dozens of problems are solved without their ever being put in the hands of the joint safety committee, for we have found that department management does not want to appear on the bi-weekly write-up that is distributed throughout the plant and

which is brought to the attention of the higher groups of management. This, in my opinion, is one of the greatest gains of a joint committee. Now the foreman in the department is making it his business so very often to be about resolving the problem and not just sloughing it off.

If you can make the people that work in the department realize that they can obtain great results by cooperating with and putting pressure on their immediate supervision, part of your battle is won.

We of the Goodrich URW unions fought long in 1959 to obtain, among other things, a joint, forceful safety committee. We have pledged, and are using the same effort, to make it the best one possible. Jointly we have corrected many hundreds of health and safety problems in the past two years. We are proud of our joint safety committee; we hope you are of yours.

HOW WE WORK ON A JOINT BASIS IN ACCIDENT PREVENTION PROGRAMS

By THOMAS J. CAIN, JR.

Director of Safety, The B. F. Goodrich Co., Akron 18, O.

Talking with you this morning as an industrial safety specialist for the B. F. Goodrich Co., which has eight United Rubber Workers locals using joint, or co-operative I like better, safety program activities, I want to emphasize that such participation has a very decided and definite plus.

Why do I believe that co-operative, management-labor or labor-management, accident prevention efforts are desirable? Let me tell you that such thinking was not always the case, even with my own company. I remember that for some ten years the URW and especially Local 5, pleaded, urged, and struggled for such a committee as part of the agreement. Finally, and thanks to the untiring efforts of Jack Moye, we have had co-operative committees in the eight plants with URW locals, for a little over two years.

The results have been splendid. I can report this to you with no reservations.

Our agreement states that problems which are not resolved to the satisfaction of the union members of the committee (three in number, with three company members) may be taken to the step immediately preceding arbitration for handling. We have had no such problems to date. Our goal is to see that we don't have any.

If you are one of the "doubting Thomases" as to the effectiveness of co-operative handling of safety problems, I can tell you that you may have overlooked one of the big advantages of such arrangements. Hundreds, yes thousands, of situations which might ordinarily be submitted as formal grievances requiring hours and hours of discussion and reams of paper work, are handled on an informal basis—solutions are arrived at with promptness and the time required for "labor problems" is greatly reduced. Remember, these problems normally require a great deal of time and expense for the members of your Local, too; so the ad-

That is the heritage bequeathed to us today by those sturdy pioneers of yesterday. Could we do otherwise but carry on the work that they started?

The conditions of a half-century ago that caused those men to rise up to action were by today's standards absolutely terrifying. Structural iron workers and electrical workers lost 10 per cent of their members each year in fatalities. Joyce Kilmer in his immortal lines wrote, "Only God can make a tree." God must have been fond of Oregon, for He covered millions of acres of the state with beautiful trees—pines, firs and hemlocks—the finest examples of His handiwork.

Those beautiful trees fell prey to the demand for lumber. Logging methods of fifty years ago were crude. Much of the tree was wasted; and worse yet, human beings were sacrificed in the process of converting the standing trees into marketable lumber. The wrath of God seemed to descend on the people for their wasteful methods of harvesting the trees that God had made. The terrible toll in human lives and broken bodies called to the higher instincts of men for a safer and better way to do it. Even so, change came slowly.

As the Industrial Accident Commission became better established, the safety program developed with it. The Legislature in 1939 entrusted the Commission with the administration of the Oregon Safety Law, giving the Commission complete charge of industrial safety. With that came the authority to promulgate safety codes which, when filed with the Secretary of State, have the force and effect of law. The annual budget for safety work is nearly \$800,000. Counting the fifteen girls in the office, this finances a force of 102 persons at this time. Everyone from the Director to the newest person is dedicated to making our state a safer place in which to work.

Labor unions started the movement for safety in Oregon, and it is only to be expected that their interest should continue. Union members serve unselfishly on code committees, supplying knowledge that only those actually performing the work can have. These committees, composed of the best informed persons from Labor, employers and technical men, aid the Commission in establishing safety codes for the industry of our state. Without the help of

these splendid union members, the Commission would find it very difficult to develop and revise the safety codes.

Our Commission believes in bringing the message of safety to the people we serve. Each year regional safety conferences are held in various parts of the state. Local rallies are held, sometimes in remote areas. Union members help greatly in promoting these affairs. For many years it has been the custom to have as co-chairmen for all conferences a labor man and an employer. We try to balance the program with employers and labor men. One of the best safety skits I have ever witnessed was acted out entirely by loggers dressed in genuine working and work-in clothes.

One of the really spectacular demonstrations, and one that is used quite frequently at our safety conferences, is a demonstration of safe handling of high voltage electric lines. These lines are not energized, but are handled as though they were. After that demonstration an accident is simulated: a flashlight bulb very graphically imitates an arc; a lineman drops over, only his safety belt holding him. His partner on the pole immediately goes to work applying artificial respiration. The ground men spring into action: the radio in the truck is used to call for an ambulance; tackle is rigged to bring the injured man down from the pole. Meanwhile the second man on the pole top continues giving the "victims" artificial respiration. If it can be staged outside, the wail of the siren on the approaching ambulance may be heard. The audience is tense; if they are seated you may be sure they are on the edge of their chairs.

This demonstration requires employer participation, of course, and I wish to pay a compliment to our Oregon employers in all industries: they are wonderfully cooperative. But this demonstration is almost always performed in off-working hours by union linemen, cheerfully and for free. Another example of union members promoting safety.

Time does not permit me to tell of all the examples of cooperation between the Commission and labor unions and their members. Several former union business agents and officers are now continuing to serve their brother members as safety representatives in our accident prevention di-

vision. Our people are welcomed at union offices and union meetings and conventions.

My presentation to you would not be complete without telling you of the program for safety in the pulp and paper industry. This was presented to the employers by labor people at a wage negotiating meeting more than fifteen years ago. The employers accepted and it was agreed that the safety program would be a joint affair. It works far better than when the employers tried to do it alone. I have attended their state meetings, and I have attended their joint meeting of the three west coast states—Washington, Oregon and California. All the delegates speak the same language; it is impossible to tell who represents the employers and who are the delegates sent by the unions. This joint safety program of the Pacific Coast Association of Pulp & Paper Manufacturers and their workmen, union members, has gained national fame and recognition.

In early 1944 I was a delegate from my local union to the Portland Building Trades Council. I evidently talked too convincingly of the need for a health and safety committee. It was formed, and I found myself to be the chairman. This committee still functions after more than seventeen years.

We asked the Commission to teach a basic safety course to all the business representatives of the Council, and for the next twelve weeks, every Tuesday from 11 A.M. to noon, the Commission's safety instructors taught the business representatives of the Portland Building Trades Council how to analyze the causes of accidents, how to look for unsafe conditions, the most successful methods of correcting unsafe attitudes, and all the other items that were taught to the Commission's safety representatives.

I am quite sure that it would be safe to say that upon the completion of the training course, the Portland Building Trades Council had the best safety-trained business representatives in the country.

I would not have you believe that in Oregon we have no problems. We have plenty. We have very few large employers, none of the huge plants that people of the eastern part of the nation are accustomed to. Most of our employers have less

than fifty workmen and many, many of them less than ten. To make this situation even more difficult, there is a tremendous turnover in these small employers. This is particularly true in logging and construction work.

The growing custom of subletting parts of the work has been a big factor in the increase of these small employers. We have found that working with unions is of tremendous help in coping with the problems present when workmen shift rapidly from one employer to another. We have our problems with employers who want to cut corners, but what troubles me most are the problems we have with workmen, our own union members. It is most distressing to have workers who for some reason seem to feel that they have put something over on someone when they get by with a violation of a safety rule. Fortunately, there is much less of this than formerly.

As late as fifteen years ago the Commission's safety men sometimes met with less than a cordial reception when visiting places of employment. I am pleased to say this has greatly improved. In fact, there is complaint now that our men do not get around often enough.

I try to attend all of the labor conventions in the state and bring some of the Commission's safety people with me. If for some reason I cannot be there, I have someone there to represent me. Our people are well accepted, and the acquaintances made are a great help in the future. It is much easier to transact business with a person who is not a stranger.

We still have far too many workers killed and maimed; last year the Commission paid \$25,844,000 to injured workers or for their medical care. I would hate to think what this figure would be if we did not have the excellent safety program that we have. The accident frequency for all industry of the state has shown a steady decline over the years. Last year the frequency was lowered by the phenomenal figure of 9.47 points. That is too great a reduction to hope to duplicate every year, but we will make every effort to reduce further accidental injuries.

Oregon's safety program has gained national recognition, and it could not have been accomplished without the cooperation

of union men and women. It is very difficult to measure just how many lives have been saved. A study made a few years ago showed that if the frequency of five years previous had been applied to the employment of 1958, the claim costs would have been about \$5 million more than they were. That savings of \$5 million of claim costs means that fewer persons were injured, fewer wives became widows, and more fathers came home to their children after the day's work.

No monetary value can be placed on the blood that was not spilled, the bones that were not broken, and the suffering that didn't occur. This is the real achievement of a safety program. This is the end for which dedicated people serve. Conservation of manpower and the alleviation of human suffering are being accomplished.

Oregon has witnessed a phenomenal improvement in the conditions that existed when Oregon citizens, aroused by the appeal made to them in the *Voters' Pamphlet* by those union leaders of more than a half-century ago, established the Employers' Liability Law by their campaign for votes for safety.

Although much progress has been made and we are encouraged by that progress, the job is not yet done. The number of widows, while smaller, is still too large. Fewer workmen are disabled, but there are still too many. The standards of the future must be higher than the standards of today. We of today must carry on the work begun many years ago by our predecessors and pass on to our successors an inspiration to accept as their motto, "One injury is too many."

OTHER PRACTICAL APPROACHES FOR WORKING TOGETHER IN SAFETY

By MRS. PAULEEN J. FIELD

Chairman, Safety Committee
United Auto Workers Local Union No. 652, Lansing, Mich.

I wonder just how many of you have joint industrial health and safety committees, partial cooperation—or none at all. We all recognize the fact that some large and small industries, with wise managements, do have joint labor-management safety committees. But very few companies with multi-plant operation enjoy 100 per cent cooperation between labor and management . . . in each and every section of the country."

Ford Local 600, for example, has a full-time safety director, at the union level, as well as a workable strike clause to take care of unadjusted industrial health and safety problems.

The West Coast Papermakers and Paperworkers enjoy cooperation with management in regard to safety.

These examples are but two, however, of a wide area which is as yet untouched by complete harmony or even agreement between management and labor in respect to the industrial health and safety movement.

Well-coined phrases such as "Safety is everybody's business," come to mind, let us say, instead, that "The safety movement cannot survive without active participation of all citizens, including labor and management, in whom dedication and selflessness are the prime requisites."

Our safety committee has approached management for a top level meeting to discuss areas of safety we could agree on, such as traffic and home safety, as well as protective equipment. We were promptly informed that management, and General Motors, maintain that planning and administering the safety program and providing adequate safety facilities is a management responsibility which they always have and always will continue to fulfill. This being the case, they could see no need for a labor-management safety committee.

There is none so blind as they that will not see.

In my opinion, opposition to joint effort

is a narrow-minded and shortsighted attitude. Insofar as our safety committee was concerned, this viewpoint added incentive and the necessary stimulus to continue to work in safety, with or without management's cooperation—not only to prove to management our sincerity in improving existing conditions, but also to do what we could to educate the membership and their families against fatalities occurring on or off-the-job.

How then do we operate without management's cooperation in safety?

1. Form your committee, as large or as small as your needs, depending primarily on plant size.

2. Conduct training classes for the committee so they may more readily recognize hazards. This should also include a Red Cross class. Resource people may be obtained through your international union health and safety division, the Bureau of Labor Standards, Washington, D. C., state labor and health departments, and the National Safety Council, all free of charge.

3. District committeemen, stewards, top committeemen, and the membership should also have education. If you are working without management's cooperation, safety committeemen just will not have access to every area of the plant, therefore liaison should be established between the shop committee and safety committee at all times.

4. Safety grievances in most instances are useless. No human being has the right to bargain another's life away. It usually takes fifteen days before the grievance is on the table to be discussed by labor and management. Untold injury or even death can be caused in the meantime. There is either a hazard or there isn't. The employee should have the right to refuse to work in unsafe conditions without fear of being penalized. Should this be in dispute, the international should be called in at once.

5. Provided you have all the facts, a very successful and effective method of keeping your membership informed is to publicize the case in the union paper.

For example, we were having trouble with an over-zealous foreman grabbing bumpers off the line that he thought had not been buffed enough. Result was, not only did a couple of bumpers get away from him,

thereby endangering the lives of the employees in the department, but he ended up being injured himself. This was contrary to all the training he had supposedly received. Employees in the department were greatly relieved and their morale boosted when the condition through publication was corrected.

Weekly or monthly articles on all phases of safety, bulletins from your state health department, National Safety Council, as well as safety cartoons, will attract attention and bring about an increased awareness to the membership and their families.

6. Where the local union consists of several units, each dealing with a small plant, every unit should have an industrial health and safety committee. The local union hall should be the focal point for all meetings. Safety material, training manuals, etc., would be on hand for all the committees to utilize. Safety posters from the National Safety Council can be placed on the local union bulletin board.

The chairman for each of these unit safety committees could meet every two months to discuss the different plant problems and have an exchange of ideas.

7. Wherever possible, make the entire membership part of your program. Set up a booth during local union elections or at membership picnics. Literature can be handed out concerning industrial safety, home safety, traffic safety. In fact, cover the whole field. You will be surprised at the interest shown. During the 1958 strike, for instance, our committee, with the help of the picket captains, gave out 5,000 copies of the Michigan traffic violation point system.

Ten or twelve-minute films on different phases of safety, are usually available which can be made part of the safety committee's report during membership meetings. The steward and committeemen's monthly meetings serve as an effective method for not only education but also as a source of information in regard to existing conditions in the various districts in the plant.

Above all—keep records. I'll go into this important area a little further on.

If, however, you do not receive satisfaction in correcting an existing hazard, after going through the foreman, general foreman, etc., we in the U.A.W. have found the most effective method to be the following.

Send direct to the international health and safety division: (1) the problem and what it involves; (2) the area; (3) the foreman's name; (4) the particular plant involved. The international industrial health and safety personnel will, in turn, send the information to the state labor department or health department; whichever is the most appropriate place. In this way, not only the international will receive an answer, but also the local safety committee. Depending on the reply, the committee can follow up to see if the condition is corrected.

Both the U.A.W. safety director and industrial hygienist also may enter the plant by request, through your international representative and/or regional director.

When management sublets a job to outside contractors, try to convince them to include the plant's safety standards in the contract. Nothing is more demoralizing to the regular employees than to work side by side with these workers when they are not required to wear the same type of safety equipment, such as safety glasses, etc.

It is not unusual to find that each management in G.M. has different ideas about safety standards and the wearing of protective equipment. While one plant has 100 per cent eye protection, another has eye protection in only what is considered hazardous areas. For their own protection female employees wear caps, glasses, short-sleeved blouses and slacks in one plant, while in another, dresses, skirts, no head protection are the mode. This can only lead to misunderstanding and an indifferent attitude on the part of the employee in regard to the safety program.

Joint labor-management safety committees can be of great use to management in both small and large plants. The foreman, a very busy man, is responsible for production, quality, and, supposedly, safety in his department. On top of this, he has to worry about efficiency. It is not unusual to have the foreman call the employee to the desk every so often and say—"Sign here." If the employee asks what I am signing for, the reply is, "I've just given you your safety talk," or, "You've had your good housekeeping talk for the month."

To further aggravate good working conditions and employee morale, it is not un-

usual for the employee who receives an injury to be given a reprimand for working in an unsafe manner, even though in the majority of cases, by having the proper engineering or education, the accident would not have occurred in the first place.

Safety committeemen trained to detect hazards could eliminate many of these accidents before an injury or death does occur. He also could talk to his fellow employee, should he, through ignorance or lack of knowledge of the job, be working in an unsafe manner.

Safety signs throughout the plant should be changed with ever increasing regularity. By signs, I do not refer to the monthly posters sent out by the National Safety Council, but to the large signs placed throughout the plant by management.

However, even the posters should be in a prominent place for all to see. Employees become so accustomed to the same old sign, it doesn't even register; thus the need for eye catching slogans.

Department-wide safety contests, with prizes, for the lowest injury rate should be conducted. A catalogue of prizes, sent to the home so the family can be made a part of the contest, would add incentive. Not feasible, you say? Why not, when thousands of dollars are spent on recreation prizes.

Management and labor could conduct a joint safety check on cars in both a spring and fall campaign, and certainly all steps should be taken to include labor in the local safety councils which are a part of each community and represent all segments of society except labor.

None of the previously mentioned points are going to be easy. It will take courage but, as Winston Churchill said, "Courage is rightly esteemed the first of human qualities, because it is the quality that guarantees all others."

Perhaps you have heard about the man who went out to play a game of golf.

After teeing off, he found that his golf ball had landed in a sand trap, right smack dab on the top of an ant-hill. Well, each time he took a swipe at the ball to get it out of the trap, he killed a couple of thousand ants. This kept up until there were only two lonely ants left. One ant looked at the other and said,

"I don't know about you, buddy, but if you want to survive, we'd better get on the ball."

This is what we must do, in labor. We have approximately 74,000 local unions throughout the United States. With 63,000 of them in the AFL-CIO, the potential for a working force for safety is great indeed. One of the reasons for organizing in the 30's was working conditions. Where do we find ourselves today? In most cases, at the bottom of the totem pole.

There is not enough concentration on prevention and the cure of industrial injuries or industrial caused illnesses. It does no good to put the cart before the horse, so to speak. Having industrial health and safety subordinate to Workmen's Compensation is equivalent to the American Medical Association deciding to eliminate medical research and investing in cemetery lots.

The four "E's" of safety should be: Education, engineering, enforcement and effort.

After an injury or illness occurs, \$100 or even \$200 will never compensate the worker or family for the lifetime of misery ahead. You are lucky if you receive \$36 a week, which cannot even begin to keep a family of three. The end result is welfare, with all taxpayers sharing the burden.

We in the union movement do not fully utilize the tremendous resource of our membership which is available. Even though our vice presidents, regional directors, international representatives, etc. recognize the importance of industrial health and safety, it is brushed aside in too many instances for what are considered more important things.

Must we continue to make progress in safety through tragedy? Has manpower become such a glut on the market that we can turn aside without a thought to preventing another occurrence?

Our own George Brown put it very aptly when he said, "Would you mind getting to the job, staying on the job, and still live long enough to collect all the benefits the union has won across the bargaining table? More of our people are being killed than we are organizing."

It is up to the rank and file, therefore, to go to work and put pressure on from the grass roots:

1. To make the industrial health and

safety committee a mandatory standing committee in every local union, in our constitutions, through convention action;

2. Through membership action, to request regional health and safety conferences at least bi-annually;

3. By requesting our regional directors to include a full week of industrial health and safety classes at our regional summer schools;

4. By taking out membership in the National Safety Council Labor Department.

Only by doing these things will we build the solid foundation which is necessary to grow on. In this way also we will eventually receive the language we so desperately need in our contracts and the legislation to back us up.

We must keep our international health and safety department aware at all times of industrial hazards. In the event of injuries, keep case histories. As U.A.W. Region 1C Director, E. S. "Pat" Patterson, said at a recent safety conference held in Lansing, "Each year we negotiate we are faced with the same problem. Management at G. M., for example, polishes all their safety awards and hangs them on the wall. Each time we bring up health and safety, they point to their wall. We realize that problems exist; the law today makes it necessary only to report lost-time injuries."

However, it cannot be emphasized strongly enough that if we continue to spread our adequately trained union safety personnel so thin, the rank and file have a stupendous job ahead. Most of our international unions have only one or two safety personnel to take care of the U. S. Other internationals have only part-time personnel, no established industrial health and safety departments, or even safety film libraries for the rank and file to go to.

In the state of Michigan we have to work with an antiquated 1909 industrial law, no building code, and we had 40 construction workers killed last year. Even our school hot water boilers are not covered under the law, to protect our children. For lack of adequate staff, the state labor department could make less than half of the annual inspections required under the horse and buggy law. There are approximately 16,000 industrial establishments in the state, with 22 inspectors. We need at least 144 more to

1961 National Safety Congress

do the job even under the present inadequate law. It is little wonder that workmen's compensation insurance rates jumped 11 per cent last year.

It was interesting to note that school custodians met in East Lansing recently. While there, one minute of silence was observed for a fellow custodian who unfortunately was blown up while performing his duties at the school. By the grace of God, it was one unfortunate victim and not a whole school of children. But even one is too many. Not one recommendation was made from this meeting to the House-Senate Labor Committee to amend the law to cover all boilers, increase the Labor Department staff or provide adequate funds for the department.

Each of these points discussed with you today are but part of the overall picture. Management and labor should join hands with pride and humility to work side by side towards a common goal, which is greater than all of us.

Nothing great was ever achieved without enthusiasm. This is 1961 with all its automated machinery, new hazards from chemicals and radiation. The old problems still have to be whipped before we can lick the new ones. We have a long way to go and a short time in which to do it.

Return home determined to work enthusiastically towards wiping out the misery and heartbreak caused by these needless deaths and injuries.

OFFICERS OF THE

LABOR CONFERENCE NATIONAL SAFETY COUNCIL 1961-62

Vice President for Labor—LLOYD D. UTTER, Director, Industrial Health & Safety Division, United Automobile, Aircraft and Agricultural Implement Workers of America, AFL-CIO, Detroit, Mich.

Labor Conference Chairman—GEORGE T. BROWN, Deputy Director, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.

Labor Conference Vice Chairman—HUNTER P. WHARTON, General Secretary-Treasurer, International Union of Operating Engineers, AFL-CIO, Washington, D. C.

Labor Conference Secretary—ROBERT M. WILKINS, Manager, Labor Department, National Safety Council, Chicago, Ill.

Labor Conference Representatives to N.S.C. Board of Directors—HARRY SEE, National Legislative Representative, Brotherhood of Railroad Trainmen, AFL-CIO, Washington, D. C.; E. D. SWISHER, Vice President, Oil, Chemical and Atomic Workers International Union, AFL-CIO, Denver, Colo.; GEORGE T. BROWN, Deputy Director, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.; CHARLES FERGUSON, Safety Director, United Mine Workers of America, Washington, D. C.; HUNTER P. WHARTON, General Secretary-Treasurer, International Union of Operating Engineers, AFL-CIO, Washington, D. C.; FINLAY C. ALLAN, Assistant to President, United Brotherhood of Carpenters and Joiners of America, AFL-CIO, Washington, D. C.

Representing State Labor Departments on Labor Conference Executive Committee—CLARENCE R. THORNTON, Commissioner, Arkansas Department of Labor, Little Rock, Ark.

Chairmen of Labor Conference Standing Committees—RODGER COYNE, Director, Occupational Safety and Health, International Union of Electrical, Radio and Machine Workers, AFL-CIO, Washington, D. C.; *Congress Program*—DAN SAIN, Safety Chairman, United Auto Workers Local No. 399, Flint, Mich.; *Executive*—GEORGE T. BROWN, Deputy Director, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.; *Fire Safety*—EDWARD B. HANCOCK, International Representative, International Association of Fire Fighters, AFL-CIO, Cincinnati, Ohio; *Membership*—Co-chairmen: JOHN D. CONNERS, Executive Secretary, AFL-CIO Committee on Safety and Occupational Health, AFL-CIO, Washington, D. C.; R. J. LAMOREUX, Director, Safety and Health Division, United Steelworkers of America, AFL-CIO-CLC, National Office, Toronto, Ont., Canada; *Nominating*—P. L. SIEMILLER, General Vice President, International Association of Machinists, AFL-CIO, Chicago, Ill.; *Occupational Health*—DR. F. A. VAN ATTA, Industrial Hygienist, United Automobile, Aircraft and Agricultural Implement Workers of America, AFL-CIO, Detroit, Mich.; *Planning*—GEORGE T. BROWN, Deputy Director, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.; *Publications*—J. GEORGE EICHHORN, Grand Lodge Representative, International Association of Machinists, AFL-CIO, Chicago, Ill.; *Safety Training*—VICTOR E. WHITEHOUSE, Director of Safety, International Brotherhood of Electrical Workers, AFL-CIO, Washington, D. C.; *State Labor Departments*—JOHN R. KUMPEL, Special Representative, Safety and Compensation, United Rubber, Cork, Linoleum and Plastic Workers of America, AFL-CIO, Akron, Ohio.

SAFETY, BUILT-IN

By JAMES P. McALLISTER III
General Mgr., McAllister Towing Ltd., Montreal, Que.

The docking of large ships with relatively small tugs is, at best, a very hazardous business. A few years ago the *John Pratt* of Montreal was heeled over so far by the hawser from a ship she was undocking, that she capsized and sank with the loss of four members of her crew.

During another undocking operation a tug, because it was unable to manoeuvre into a better position, released the towing hawser prematurely. The line became entangled in the propeller of the ship, leaving it helpless and at the mercy of the five-knot current in the harbor. The ship was carried down the river and under the Jacques-Cartier Bridge. But, in this case a catastrophe was averted when the bow anchor was released which held the ship in midstream.

Each of these situations could have been avoided if the tugs were more manoeuvrable and had greater stability.

So, to those connected with tugboats engaged in ship handling, safety is almost synonymous with performance. A tug which can perform exceptionally well is one which, per se, has a high degree of "safety built-in."

With this in mind, then, I would like to review the characteristics of the new twin-screw hydroconic tugs recently added to our Montreal and West Coast tug fleets. These characteristics, such as reserve power and manoeuvrability make possible the hydroconic tugs' excellent performance capabilities. At the same time, therefore, they are the most important safety features built into these tugs.

I will cover them more or less in their relative order of importance.

1. Manoeuvrability.

Manoeuvrability in the hydroconic tug *Helen M. McAllister* is very high. It is obtained by the use of twin screws and large rudders and by so arranging the stern and the deadwood area that flow across the vessel to rudders and wheels is virtually unimpeded when the former are hard over. This allows the vessel to be turned with

great facility and rather rapidly within her own length, so that she may be placed exactly where she is needed at any given moment.

The location of the towing hook is of great importance. If it is too far aft, the pull on the hook by the ship's hawser will tend to offset the turning effect of the rudder. With little power to steer itself, the tug would then be unable to "stay in shape" (that is, exert its pull in the desired direction from the ship) and the Captain might have to release the towline prematurely. The towing hook on the twin-screw hydroconic tug *Helen M. McAllister*, however, is located approximately at the center of lateral resistance, just aft of amidships, much closer to the axis about which the tug turns. The hawser in this case therefore, does not affect the ability of the tug to turn and move in the desired direction. The above point is very well illustrated when operating in a current.

The tug with the hook at the stern will be unable to turn itself into the current to get to the desired position upstream. Instead it will be swept broadside by the current toward a point downstream from the ship. When this happens, the tug, unable to pull in the desired direction, would have to release the tow line. This would leave the pilot on the ship without the assistance he might have needed to manoeuvre the ship without damage or injury to the crew and passengers.

The tug with its hook just aft of amidships, on the other hand, would not be hindered by the towline from turning directly into the current and running to the desired position to exert its pull.

Another factor which affects manoeuvrability is the speed with which the propeller(s) and rudder(s) respond to engine controls and helm in the pilot house. On the *Helen M. McAllister* the engine control lever in the pilot house is connected mechanically by a torsion bar system to the engine throttle and the control cock on the reverse reduction gear. The clutch it-

self is hydraulically operated and is capable of reversing very quickly.

This system is so effective that the direction of rotation of the propellers can be reversed within two seconds of the movement of the engine control lever in the pilot house. To complete the picture the propellers when started in the ahead or astern direction "bite" the water almost immediately, and because they are relatively large (98 inches in diameter) they create ample thrust to start the tug moving quickly either ahead or astern.

To summarize, then, the *Helen M. McAllister* attains maximum maneuverability on the end of a towline, primarily because:

1. The position of the hook is almost midship, and

2. The twin propellers and rudders can create a very high torque to turn the vessel in any direction.

So, when the *Helen M. McAllister* is in a dangerous position, due to the current or an unexpected movement of the ship, she is able to maneuver quickly to safety.

II. Visibility.

Lack of visibility in a tug can be one of the greatest dangers to its safe operation. A heavily obstructed view in any direction almost inevitably produces dangerous situations, at times, as the Master is unable to take the necessary action until the situation has developed. In order for the Captain to take advantage of the quick maneuverability of a vessel like the *Helen M. McAllister*, he must be able to see all that is going on around him.

Excellent visibility is attained on this vessel by large windows all around, not only forward, aft and on the sides, but also in the four corners of the pilot house. Since there is no captain's cabin behind the pilot house, the deep windows looking aft provide a view of part of the main deck at the stern. In addition, the slight obstruction caused by the stack is offset by controls being installed on both the port and starboard side so that the Captain can work, during a job, from the side giving him the most advantageous view.

Standing at the controls and with his head out of the window, he can see up and down the full length of the tug. This feature is particularly important in mak-

ing a soft landing against a moving ship, thus reducing the possibility of knocking an engineer or cook off his feet with an unexpected jolt. In addition, by being able to see the water immediately adjacent to the tug, from bow to stern, the possibility of running over debris or logs, which may cause damage to the propellers, is lessened.

For the safety of the deckhands the Captain should be able to see the entire working area on dock, from the fantail up to the towing hook. Such a view enables him to maneuver the stern of the tug in the direction which would best assist the deckhands to manhandle the heavy towline up to the hook. Also it would be unlikely for the Captain to release the towline if he could see that one of the deckhands was in the way.

Probably most important of all, though, the Captain must be able to see the ship and his towline leading from the hook up to the deck of the ship. Then, if the ship speeds up, slows down or begins to turn, the Captain will be aware of it immediately and can maneuver the tug accordingly. Although the deck over the *Helen M. McAllister's* pilot house is not transparent, the windows are high enough for the Captain to see the towline and the ship in all situations.

III. Stability.

It is essential that a harbor tug be very stable so that it is capable of being pulled sideways by a tow rope without rolling over. The unfortunate experience of the Montreal Harbour tug *John Pratt* illustrates only too clearly how quickly and suddenly a tug can be pulled broadside by the towline and then capsized. A high degree of stability, more than any other feature of a harbor tug, is necessary to the safety and, therefore, the peace of mind of the crew.

Stability may be defined either by curves of statistical stability, by dynamical stability or by the metacentric height, better known as GM. As most modern harbor tugs are essentially of similar type and the main dimensions for a given tug can only be varied without certain limits, it is natural to choose the metacentric height as the most convenient criterion when discussing stability.

The GM of the *Helen M. McAllister* at 15 inches, is considerably more than her

conventional counterpart. In addition, her large tow hook is so designed that when at right angles to the center line of the vessel, a moment is produced opposing the heeling moment caused by the tug being dragged sideways through the water. These two factors, the high amount of stability, and the specially designed towhook, make it virtually impossible for the *Helen M. McAllister* to be capsized.

At the same time the increase in breadth required to produce these metacentric heights is not a worry to the hydroconic form as the water flow is such that the resistance of the hull is relatively insensitive to breadth and it is therefore possible to build-in this safety without detriment to the propulsive qualities of the vessel.

IV. Protection for Propellers.

A traditional problem with twin-screw tugs has been propeller damage due to the propeller extending out beyond the sides of the tug. The twin-screw hydroconic tug, however, is so arranged at the stern, that the wide, flat sections completely cover the propeller. This cover extends sufficiently far to protect the propeller from contact with, say, a ship alongside, under any reasonable conditions of heel.

Coverage by the flat section is under water and this underwater coverage extends beyond the projection of the propellers, thus preventing air drawing, and hence giving a good solid flow of water to and from the propellers. This feature minimizes the possibility of ropes being drawn into the propeller.

In addition, flow to the propellers is along the buttock lines at the stern, and has little or no water line component. This has definite safety aspects because it not only prevents debris from being sucked into the propellers and causing damage, but also minimizes the possibility of a man, who might have fallen overboard, from being sucked into the propellers.

V. Single Engine Capability and Reserve Power.

Should there be mechanical trouble in a tug or should one propeller become entangled in a line when working, a very unfortunate situation may arise which would endanger the tug and the vessel she is

hauling. In the twin-screw hydroconic tug the vessel can continue to work with one propeller only, since the steering and general propeller capabilities are such that she can still maintain a straight course with quite a small angle of helm. In addition, the *Helen M. McAllister* can exert a tow rope pull in excess of nine tons with a single engine and propeller, which would be sufficient to continue the operation to safety.

VI. Seaworthiness.

Seaworthiness is a necessary feature for tugs that are operating in coastal waters. Last year, a twin-screw hydroconic tug, the *Island Mariner*, was sailed from England to Victoria, British Columbia, for duty on the West Coast. En route, it was caught in a hurricane off Bermuda, but the Captain reported that the vessel was never in danger at any time. During the height of the storm, he was forced to run with it and he mentioned that she maintained her heading with little tendency to brash.

Basically, the hydroconic tug is arranged so that with the wide, flat stern, the center of pitch is far aft, and the bow is of such a full form that it heavily dampens the motion. As a result, the bow does not acquire high pitching amplitudes, while the stern tends to follow the wave slope, i.e., slides up and down. This produces very satisfactory propulsive conditions as the propeller is never kicked out of the water, and hence there is no undue power loss or danger of mechanical or personnel trouble in the engine room.

Sizeable rolling chocks were fitted to the *Island Mariner* with the result that the rolling is dampened considerably. Although the *Island Mariner* has logged many days towing in the open ocean off the British Columbia coast, she rarely rolls the crockery off the galley table.

A more important result of this dampened motion than the saving of dishes, however, is the good physical condition of the crew. Fatigue and/or seasickness are at a minimum on the *Island Mariner*, and the men are therefore less prone to accidents.

VII. Structural Integrity and Continuity.

Great attention is paid to structural integrity and continuity because it is the opin-

tion of the designers of the hydroconic tug that vibration and loss of alignment of the main propulsion machinery is highly undesirable both from the efficiency and safety points of view in a small ship. Generally large powers are installed in towboats relative to the size of the ship and it is very easy to get bad vibration and machinery suffering from lack of alignment. All engine girders are taken right through to the stern and form the rudder trunks and seatings for the steering gear. The comparative lack of vibration undoubtedly produces a more satisfactory working condition and enables the crew to concentrate better upon the safe and efficient working of the ship.

The scantlings of the *Helen M. McAlister* are especially heavy with frame spacing cut in half forward of amidships to provide the strength to operate in ice. This additional strength is an added safety factor in case of collision or other damage.

The subject of marine safety in Montreal Harbor as well as throughout Canada, is a major concern of the Canadian Steamship Inspection Service. The numerous inspectors of this Service do a first class job in ensuring that ships are built, repaired and maintained in a safe operating condition and in accordance with a myriad set of regulations. These regulations cover sub-

jects all the way from safety valves and shafting to life boats.

But, as detailed as these time tested safety regulations are, I do not believe that they can possibly cover all the important safety features of an inherently hazardous business like the operation of harbor tugs. The harbor tug is a highly specialized vessel. It is for this reason that I chose to dwell on those items which make a tug an efficient vessel and, therefore, a safe vessel.

In the twin-screw hydroconic design we have a tug which scores high in maneuverability, visibility, stability, protection of propellers, power reserve, seaworthiness, strength of hull, thus providing a safe and efficient working implement for captain and crew. These qualities greatly enhance established safety regulations and the effectiveness of a properly trained "safety-conscious" crew.

It must be emphasized that a Master with boat handling ability and an awareness of safety must ultimately be relied upon to properly and safely operate a tug with these high performance capabilities; however, it is those safety factors which can be built in we believe the performance of the twin-screw hydroconic tug illustrates their effectiveness to such a degree that they become the worthy subject of this address.

SAFETY, BUILT-IN

By WILLIAM C. McNEAL

Vice Pres., Oil Transport Co., Inc., New Orleans, La.

I hope to pass along some safety ideas and also to inform you of the progress made in marine safety on our rivers. Most important, though, I am anxious to learn from you about safety—I am no expert. This is the principal reason I have been at these meetings for the past several years.

Built-in safety has been slow to arrive in the river business. But I am proud to say it is as much a fact today on the rivers as it is at sea. This has been rapid progress. I can recall six years ago we installed fixed carbon dioxide engine room fire fighting systems in two modern tow-

boats. Both boats had been built about 1949 with no such system. And there's a lot more to this story of adding safety features to existing towboats. However we got the job done with help from the Coast Guard, underwriters, deep sea operators, shipyard and some plaintiffs' attorneys.

Let's take a look at a conventional river towboat—our motor vessel *Bayou Larose*. This boat regularly works the river system with a tow of about 11,000 tons capacity, some one thousand feet long, in the petroleum trade. Certain conventional operational and safety features are apparent

at a glance—radar and radio antennae, two large searchlights, railings, ring buoys, a large whistle and navigation lights.

If we could get aboard more would be visible. These would include a rate of swing indicator, public address system and depth recorder in the wheelhouse, as well as excellent firefighting equipment with both carbon dioxide and water fog systems. You also get an indication here of good housekeeping, that oldest, good safety practice. I am proud to say this is true. Of course housekeeping for good housekeeping is a basic custom item. Also this boat is twin screw with wheelhouse engine control as are most river towboats. These two facts are taken for granted but they are big plus factors in a safety built-in program.

Towboats provide the glamour in our business. Like most glamorous items they are expensive, attract attention and require financial support. So we need the rather pedestrian barges as a tow for the boats. It's the barge that carries the cargo to earn the money—there would seem to be a word here somewhere. But I won't pursue it.

There is, though, this very real fact. We have concentrated our safety engineering on the towboats to a far greater degree than we have on our barges. And the ever widening scope of unusual cargoes demands we pay more attention to barge safety.

Here are some of our petroleum barges at a loading dock in Louisiana. They are all equipped with the Coast Guard required safety devices including a remote pump engine shutdown so ably advocated here a few years ago by Mr. Spellacy of Humble Oil & Refining Co. But let's take a look at some other features. Cargo hose hoists on barges are excellent devices. Note the dark green deck paint to prevent searchlight reflection at night. And perhaps you can detect the wide strip of non-skid paint around the edges of the barges. Also the edge has a white strip all around, to aid the pilot as well as the deckhand. Other deck obstructions are painted to contrast with dark green. Here again good housekeeping is vital. These barges are in the asphalt trade but you don't see any asphalt on deck. Also rope and cable are properly stowed.

Take a closer look with me at this new type cylindrical tank barge designed for

the asphalt trade. This barge has just completed its maiden loading of 250 degree asphalt. You can see the catwalk with hand-rail on top of each tank. And the side hand-rail is visible at the lower left corner of the picture. The steam line and cargo pipeline is in between the two tanks where crewmembers don't walk, thus helping to eliminate burns. We are looking at the bow of the barge. Usually the pumping unit is on the stern. But we felt the much larger bow area was the best location. This allows plenty of space on the stern deck for the crew to make barge couplings with less danger of falling overboard. Special purpose barges require special thought if we are to build in safety.

We've spent some time here looking at the built-in features on river equipment. These are all important along with many other items that are or can be built into the many vessels on our rivers. There is a staggering variety of vessels in use today. There will be more tomorrow as we find new and better ways of handling cargoes and barges. Planning for safety in equipment must start at the beginning of the construction program. And I believe today it generally does.

We have not yet touched on the most vital area where safety must be built in. Take a look at this picture. The man in the middle is master of the *Bayou Larose* and with him is the cook and one of his deck crew. All are human beings, all have brains. And it is in this brain that we have our vital area for building in safety. In New York last April, Mr. Mansell of Bethlehem Steel's Shipbuilding Div. made a summary of the President's safety conference that bears repeating.

He said, "In March of 1960, at the President's conference on occupational safety at Washington, D. C., the need was stressed for more employee and supervisory training, plus an awareness of the mental lapses of people. It was pointed out that, biologically, human beings have not changed in reaction time since the beginning of man, and that this has always been a problem in the increasingly complex industrial environment. The claim was made also that we have reached the point of diminishing return from purely physical safeguards, and that we must work on the physical characteristics of the individual, with the first line

supervisor understanding himself and the men working for him as to attitudes and emotions, which may seriously affect his conduct on the job."

Our company safety program has undergone a basic change since its inception in 1954. Simply put, it is this: we primarily worked at that time in safety engineering. Today we primarily work at safety psychology. I think Mr. Mansell has summed up the reasons for this change.

Practicing psychology is done by all of us each day in simply living. We need to pinpoint this in our safety programs. By way of suggestion I recommend a review of your safety program, quietly, in your head. You are out to sell an idea and this is one sales campaign where no holds should be barred. I remember the safety engineer who used to present an artificial eye to any man he spotted not wearing goggles where necessary in his plant. No words were necessary.

Specifically, on towboats, I would devote the most time to the captain, chief engineer, deckmate and cook. Why the first two should be sold is obvious since they lead the boat. But the deckmate is most important to me. He is on the spot with the men. Not only can he give a fast warning or an on-the-spot safety lesson, but he can see the hazards at close range. Many a valuable safety idea in our fleet has come from a deckmate. My reason for including the cook is a bit more subtle. Generally the cook is an older, more mature person. Also the cook sees everybody frequently in galley hull sections. So tell the cook on

talking about safety instead of pinup pictures. The mere mention of the word "safety" helps remind crew members.

Because towboat crews generally are not scholars of English, I prefer limited amount of written safety material. But it can be used. Keep it short, to the point and in words of less than four syllables. Posters are always excellent. A source of inland posters of first rate quality is available either through the American Waterways Operators or the Safety and Health Committee, or both.

The basic way to sell anything is to talk with the customer. So you must see your crews, talk with them, know them and just plain work hard for built-in safety in the head.

One final observation—few of us working at safety with inland companies are professional safety men. In fact, few of us work at safety full time in our companies. Most of us were assigned the job of safety. So now comes the question, are you sold on safety?

Three months ago I was attending a safety meeting with another interested person working part time in safety. As we left his plant in his car he failed to observe a stop sign and failed to observe the speed limit. I doubt that he is a successful safety salesman because he had not yet sold himself. I find it a bit uncomfortable to reflect on my own shortcomings in this field. We have a big job ahead of us. Let's start by making certain safety is built into our own heads.

SAFETY, BUILT-IN, ON RIVER TOWBOATS

By V. KEHRES

Asst. Chief Eng., St. Louis Shipbuilding & Steel Co., St. Louis, Mo.

The shipbuilder is the proverbial jack of all trades, and, if he is going to stay in business, he had better be the master of them all.

He is the contractor building a propulsion power plant, an electrical power plant, hotel accommodations and restaurant facilities. He is the insulation contractor, the sheetmetal worker, the plumber, electrician,

carpenter and painter. Besides all this, he must build a hull that will float and is stable and seaworthy to incorporate the results of the above labor.

Therefore, to the designer and shipbuilder, whether of ocean craft or of river craft, safety has many facets. Many safety features are common with other industries; many are unique with the marine field.

The naval architect's first responsibility is to design a hull that is stable and seaworthy to protect men and cargo. To insure that this safety is built in, naval architects have an intensive training period, and several agencies have established standards of safe design and construction. The American Bureau of Shipping and the United States Coast Guard, to name only two agencies, will approve design drawings and follow through with inspection during construction.

However, while stability and seaworthiness are the most important safety features that are built into a hull, we wish to discuss today some of the less obvious safety features which are included in river towboats and barges.

Many items, although they are vitally important, are common with all industries and are included by all reputable towboat builders.

We will list them here:

1. Non-skid deck surfaces and stairreads.
2. Handrails, grab rails and safety lines.
3. Adequate lighting on stairs and ladders.
4. Adequate floodlighting of deck work areas.
5. Guards over moving machinery parts.
6. Elimination of sharp plate edges.
7. Contrasting colors on deck fittings and other deck obstructions.
8. Insulation of engine exhaust lines.
9. Rubber floor mats and wood handrail switchboards.

The modern safe towboat has many unique features, however.

Standby equipment is very important. To prevent loss of the entire power plant, standby electrical generators are provided that can be thrown on the line on short notice. Loss of electrical power would kill all the motor driven equipment and could leave the boat and tow at the mercy of the river current, and hazards such as bridge piers, locks, dams and bars. Likewise standby air compressors and steering gear pumps are provided for the safety not only of the towboat and tow but for that of the crew. We have to admit, however, that in the opinion of the crew, the most important standby unit is the standby refrigeration compressor we install on most of our towboats. Most everything else is secondary to keeping the food on the mess table.

Continuing the theme that properly operating mechanical equipment contributes to the safety of personnel and tow, the use of audible and visual alarms is an important safety feature. In addition to the standard general alarm system to warn of fire and pending danger, there are alarms to indicate low lubricating oil pressure, high cooling water temperature, failure of a steering gear pump, fuel oil day tank low level, etc.

While escape hatches are common on ocean craft, it is only in recent years that they have been standard equipment on river towboats. This now common usage, like so many other safety improvements, was the result of a near catastrophe. A few years ago on a large towboat, a high pressure fuel line on a main propulsion engine developed a leak and filled the engine room with atomized oil. The engineer, working in the forward auxiliary machinery room, was unaware of the leak until the fuel was ignited, probably by the oil burner on the heating boiler. The engine room was immediately a holocaust, trapping the engineer in the below decks compartment. Thanks to some far thinking designer, this was one of the boats having an escape hatch from this compartment to the quarters above and the man's life was saved.

The firefighting equipment on towboats is improving all the time. Fire pumps of 300 GPM at 100 psi are not now uncommon. The fire pumps, usually located in the lower engine room, now have remote start-stop switches mounted on the outside of the deckhouse.

The problem of engine high-pressure fuel line failures is not uncommon. Several boats are fitted with fog nozzles mounted directly over the main engines. Upon detection of a fuel oil leak a fog spray is released, filling the engine room and thus avoiding ignition of the atomized oil. The source of water for these fog nozzles is a separate diesel-driven fire pump mounted on deck. Thus, the engineer, from a remote location, can eliminate the danger of fire and safely enter the space to cut off fuel pressure.

As an added precaution, to combat the same hazard, these boats have a cut off in the fuel oil line at the fuel pump which operates automatically when the fuel oil is cut off at the rack by the pilot house

control or manual engine controls. This in effect removes the pressure from the entire fuel line by remote control.

To get at the root of these fuel oil line leaks, however, we have instigated recent metallurgical research to improve the wearing qualities of the fuel line material. We believe that this problem will be resolved very soon.

Many towboats have banks of CO₂ cylinders that are piped to the engine room bilges for combating fires. From a remote control station outside of the deckhouse the CO₂ is released to any part of the bilges. The cylinders are sized so that the engine room can be completely flooded to smother out any fire. Since there is the inherent danger that a man could be trapped below and be suffocated by the CO₂, an alarm sounds when the CO₂ is released. Also, to cut off the air supply to a fire, a pressure switch, when the CO₂ is released, automatically cuts off all engine room supply and exhaust fans.

This principal of automatic shutdown is used in other applications.

A few years ago the engine crew of a 2400 H.P. towboat had a harrowing experience. The Chief was unaware that a lube oil leak had developed in the manifold of the turbocharger of the port engine. The Captain, seeing the smoke from the exhaust caused by the burning oil threw the clutch out—an unfortunate natural instinct. Away went the engine—running on lube oil since the overspeed trip had long since shut off the fuel oil. No one knows what fantastic RPM's were attained by the runaway engine when the flywheel started disintegrating. Pieces of cast iron, torn off the flywheel by centrifugal force, started flying through the engine room and through the roof. One piece sheared off the governor of the starboard engine and away went the second engine. Fortunately, the Chief was able to stop the engines without even an injury to any personnel.

To prevent such a recurrence of main engine "runaway," many boats now have an air and oil operated automatic shutdown on the air intake manifold energized by the overspeed governor. Several have manual air shutoffs, operable from outside the engine room.

In addition to lubricating oil low pres-

sure alarm, several boats have an automatic shutoff in the fuel line actuated by low lubricating oil pressure, thus preventing engine damage.

While on the subject of engines, it is good to note that several diesel engine manufacturers are designing their crankcase covers to withstand a crankcase explosion. Thus, not only are flames contained within the engine but the hazard of flying covers is eliminated.

When built by reputable shipyards there is a vast amount of hidden built-in safety in the electrical systems of river towboats. Proper grounding, insulation and installation of electrical equipment and wiring by trained competent electricians can be the most important asset to the boat owner and the most important safety feature to the crew.

Today's excellent electronic navigational equipment has added greatly to the safety of marine personnel. The almost universal use of radar on the larger boats has lessened the chance of collision with other boats, bridge piers, etc. The radio telephone is a great assist in anticipating an oncoming tow when navigating around a blind bend.

So from stem to stern and from the pilot house to the bilges, the shipbuilder is constantly safety conscious. Whether he is wearing the hat of the designer, the steel erector, the machinist, the pipefitter or the electrician, he is concerned with the safety of personnel.

The great improvements in recent years in the built-in safety features of the better river towboats is a credit not only to the enterprising shipyards but also to the many safety minded towboat operators. After all, many of the above features can be costly. It is the owner who pays the bill without the anticipation of a quick return on his money.

While all of these built-in safety features—the automatic shutdowns, the remote controls, etc.—are all commendable, they can breed a new danger. I am convinced that this trend to automation in the safety field can promote over-dependence on mechanical equipment and create safety laziness in personnel. It is incumbent upon the towboat owner constantly to instruct the crew that these built-in safety features are to aid and assist him, and are not a substitute for his constant concern for safety.

SAFETY, BUILT-IN

By WM. A. McCORMICK, JR.
Safety Supr., Union Barge Line Corp., Pittsburgh, Pa.

I certainly feel honored to have been asked to help out in this session, and yet I feel like a youngster to marine work. Although I have been partially associated with marine work for six years in lock, dam and bridge construction on the rivers, I have only been in full time marine operations since January 1 of this year. Throughout my presentation, I want you to keep in mind that "I just came on watch" for this job the first of the year.

My duties as safety supervisor with Union Barge Line Corp. are to help administer the corporation hazard control program in towboat operations. In addition to Union Barge, I have the same responsibilities in the Keystone Div. of Dravo Corp., a sand and gravel producer with a fleet of towboats, barges and dredges, with some towing in the coal trade operating on the Monongahela and Ohio Rivers in the Pittsburgh, Pa., area. Also, Keystone Div. operates nine land plants and three large mixer truck fleets.

My third area of responsibility is the Potomac Sand and Gravel Co. located in Washington, D. C., recently acquired by our corporation. This is a sand and gravel producing company operating in the Potomac River with five dredges, five tugboats, one towboat, two stiff leg derrick boats and a large fleet of sand barges feeding two large processing distribution land plants.

In more detail, my work consists of making inspections of all plant and marine equipment, making recommendations at all levels of management, developing and conducting safety education meetings for supervisors and working out problems in design with maintenance and engineering department people. In short, much time is spent on planning ahead, keeping up to date on new technological developments and selling the service—safety.

To do this job properly, you must like the work. You must be analytical minded, and like to work with all kinds and types of people from top management down

through the craftsman. The first essential of this work is to be able to work with and get along with all these people. The job can only be done by mixing with the people who do these jobs, observing their operations, asking them questions to learn all the details possible about the operation. You must convince these workmen that you need their help.

The quickest way to learn the routine and hazards of a job is to ask the man who is performing the operation. The many years of experience of all these workmen must not be ignored. To this end, much of my time is spent aboard our marine equipment under actual operation.

Employment with Union Barge Line enables one to enjoy a situation not common to many people in marine safety in that our parent company Dravo Corp., is a builder of marine equipment, as well as an operator of marine facilities. I learned early that the best time to get safety devices on a piece of marine equipment is when it is being built. This covers part of the area of the subject of our discussion here today, which, as you know, is "safety built in." It is much easier and less expensive to get such items as proper sloped stairways, shaft coupling guards, proper fire protection systems, hand rails, deck toe rails, etc. on the boat when it is being built, rather than after it is in service with full fuel bunkers. This is something our entire marine industry should strive for in the future, by taking advantage of the experience over the past years.

The Inland Waterways Safety and Health Association has formed a subcommittee for this purpose. Our aim is to develop minimum standards on various safety items that can be built into marine equipment. Eventually we hope to have a manual that can be placed in the hands of boat building companies and operating companies to help them build and maintain their boats and plant equipment as hazard free as possible. Of course this same information can be used to make existing equipment much safer.

Now, through the medium of some colored slides, I want to take you with me on a trip over several pieces of marine equipment and show you some of the situations I have noted and photographed in my travels. Whose equipment, or where it is, is not important. We will cover dredges, towboats and barges. We will see old equipment as well as new. We will see hazardous situations as well as good situations. Many of the ideas you will see for safer operation are old. Many may be new to you. If we do nothing more than to get you to thinking, we will have well spent our time here.

When looking for a good picture to take for an introductory slide, I could not pass up this scene.

Slide No. 1—Boys' Future. Two young boys, cub scout age, looking at the marine activities along the Ohio River. I am sure this takes us all back a few years. To me, this picture means a lot of things. It projects into the future—here are two young minds being developed. The things they see and hear in the next ten years, that is in the 1980's, will surely be instrumental in helping them make their choice of an occupation or profession for their life's work.

And, as I saw these two lads, the thought occurred to me—What if they choose the marine transportation industry? What would they be getting into safety-wise? Well, if our industry does not better itself, they will come into an industry that ranks 38th out of 41 major industries in this country. Just about on the bottom. And for every million manhours they and their buddies would work, 21 of their fellow workers will have disabling injuries, losing a total of 2296 mandays. Now I, for one, do not want to wish that on any of our future workers. I particularly do not wish it upon these three.

Landing Work

Slide No. 2—Stairs to Landing. When workmen and crew members get aboard towboats, they usually cross over a landing, a dock or a wharf. Due to the physical terrain and the nature of a river to cut a channel, most river landings require long stairways and gangways for access from top of bank to the river level.

Thought should be given here to angle

of stairs, width, type of tread, etc. Most of the people using these stairs and gangways are carrying a suitcase, tools, store parts, etc. At least one hand is always full. Thus good railings should exist here on both sides of the stairways.

Many of the women wear high heel shoes, thus tread type should be considered, so as to not catch high heels and trip the ladies. Also, width should be such that two people can pass easily. Remember all the traffic to and from the landing, regardless of reason, uses these access ways. Make it as efficient and safe as possible. In many instances a well sloped ramp can be used in place of a stairway. Consideration should also be given to the accumulation of snow and ice during the winter months, if in a northern area.

Slide No. 3—Life Ring Stand. For the protection of the workmen around landings, "life rings" should be placed at locations near the outer edge of the fleet. They should be visible and easy to get to and always ready for immediate casting.

Slide No. 4—Life Jackets—Kapok Type. When working near or over water, men should wear life jackets. There are many types on the market. All have advantages and disadvantages. This is one of the standard kapok types. Bulkiness is its greatest drawback.

Slide No. 5—Life Vest—Vinyl-Foam Type. Another type of vest used in marine work is this "vinyl foam" model. These vests are light and not bulky. The buoyant material is a series of independent air cells, thus the material will not absorb water. Tearing the material or punching it full of holes does not affect the buoyancy. The material will not support combustion. A disadvantage is that the pad is hot on the wearer's back in summer months, and in sub-zero temperatures the material becomes stiff.

Slide No. 6—Workmen Without Vests. When men work near or over water, they should wear vests. A severe bump or mistep or stumble can put them into the drink, and when the current is swift and the water is muddy, as it is during open river conditions, it is imperative that they be seen in the water.

Slide No. 7—Rowboat Scene. A common scene on the river. This is a yawl play

at a crew change on a dredge. One of these men is the Mate. We keep hearing that men are good swimmers. It is well to point out that it's usually a good swimmer who drowns, the non-swimmer most always has on his vest. If a piece of ragging flies and hits a man in the head, knocking him unconscious and into the water, being a good swimmer won't help at all. The real purpose of a vest is to that a man so he can be seen to be hauled in, not a competitive device for good swimmers. I have been tempted many times to put up signs saying—"Good swimmers never drown, they just float away and sink." I often see yawls so fully loaded that they look more like a "tramp ship" than for what they are intended.

Walkways and Railings

Now let's go aboard some equipment and see some stairs, walkways and applications of hand rail guards. People move all over the equipment, and for just plain walking, several things have been done to prevent falls. Also several hazards exist which can cause falls.

Slide No. 8—Tugboat Underway. Here we see material on the guard. This guard is not too wide and such obstructions increase the chance for a man overboard. Note that there are no life lines or rope railing on this boat.

Slide No. 9—Life Lines. These lines serve as a good railing. When stern lines are used, the snaps are loosed, then re-snapped after the stern lines have been dragged back and tightened in place.

Slide No. 10—Rope Railings. Here the guard is much wider than the top of the deck house, so rope railings are used. Notice, however, that there is no toe rail on this guard. If one slipped on ice and slid down under this particular rope face down, he would not have anything to catch onto.

Slide No. 11—Toe Rail. Here we see a toe rail to act as a catching point, should one begin to slide overboard.

Slide No. 12—Mariner Stairs. Continuing with stairs, here is a nice application. These stairs are well sloped, they aren't too steep, or too flat; they are equipped with good hand rails; the treads are open to prevent snow and ice from accumulating, and there is plenty of head room at the stair entrance.

Slide No. 13—Control Treads. These stair treads are painted with a non-skid mix and at night they reflect light. At night these stairs stand out like piano keys in a dark room.

Slide No. 14—Tow Knees Hand Rails. Hand rails on tow knees are very helpful to deckmen, especially when the decks are wet and the men are carrying ratchets, lines, tools, etc. This is a stairway and any stair way should have a hand rail.

Slide No. 15—Cover Barge Hand Rail. Here is a rail on a covered barge. Note the non-skid walking surface on the gumed.

Slide No. 16—Dredge Hoist Railing. Hoist landings should be well guarded. Here a section can be removed while landing the material. Then this section can be replaced, giving continued protection against falls overboard.

Slide No. 17—Searchlight Without a Railing. A hazard exists here in that there is no railing around this searchlight. Searchlights require considerable maintenance and should be protected as this next light shows.

Slide No. 18—Searchlight with Guard. Railings such as these prevent falls.

Slide No. 19—Engine Room. In this engine room, note the good railings, also note the toe rail on the deck to keep tools, bolts, pipe, rounds, etc. from falling below when working on engines.

Slide No. 20—Roofing Paper Walkway. Here is a good application for a non skid walkway. This is regular roofing paper anchored to the top of this tar pitch roof, above the engine room of a towboat.

Slide No. 21—Sand Well. No guard near the walkway here. One could slip into this well—it is an out of the way place, but men do go in this area to check the equipment and work if need be.

Slide No. 22—Spilled Gravel on Walkway. Here is a nice walkway, with a good handrail, but look at the mess here on this deck. This gravel is tough stuff to walk over. One could fall easily and strike his head on some steel object, causing a serious injury. This gravel was spilling over the edge of the walkway to the next deck 20 feet below where deck hands were working loading barges.

Slide No. 23—Sagging Belt. The cause of this gravel situation which you have just

seen, is the sag in this belt. An extra set of rollers here would prevent this situation.

Slide No. 24—Conveyor Belt. Another belt here with spilled gravel. This can also fall below and strike a worker. A longer skirt would help eliminate this condition.

Slide No. 25—Dirty Gnnel. The best deckhand in the industry could not walk over this obstacle course. Gnnels must be kept clean at all times, and believe me this is a constant battle. This particular barge situation was created at a landing where this barge was unloaded. However, it did come in a tow back to a dredge in this condition.

Slide No. 26—Cluttered Walkways. Here is a real accident trap. Tools on the walkway and a hose across the walkway, a real tripping hazard. No railing on the left side. As you can see, this is high in the air, about 60 feet to the water level.

Slide No. 27—Cluttered Rake on Barge. Such items make it rough on deck crews if not cleaned up.

Slide No. 28—Hand Winch. Here is something that can be a real accident maker. This is a hand winch used for lifting yaws on yawl booms and raising conveyors around dredges. You will note that this has a friction-type band brake. Many times this handle is not removed as it should be. The clutch is released and the handle unwinds and hits the workmen right smack across the head, or breaks a wrist or arm.

Slide No. 29—Electric Hoist. Of course the more modern method is to use electrically driven hoists and winches with push button control.

Slide No. 30—Electric Driven Winch. Here is an electrically driven winch, note how the gears are not guarded. It would be very easy for one to get caught between these gears. Note the crowded condition the operator would be in while operating this winch. Better design would have eliminated this situation.

Slide No. 31—Unguarded Belt Drive. Here is another accident trap—if one would slip and fall into this with his hand or arm, serious injury could result.

Slide No. 32—Guarded Drive. Here is a drive that is 100 per cent protected. This could not cause injury if anyone would come in contact with it.

Slide No. 33—Partially Protected Drive. Here is just about a 100 per cent guarding job, however one shaft end has been left unprotected. Note that one shaft end is covered with a metal cup and one left exposed. You can't see it, but there's a real sharp key sticking out of the groove which could cause injury to someone's knee or wind up clothing if someone came against it.

Slide No. 34—Shaft Cover. Here a walkway passes under a shaft. However the shaft is well protected with proper guarding.

Slide No. 35—Shaft Coupling Guard. Note the well-formed and well-insulated shaft coupling guard. This is the coupling between an engine and a light plant on a towboat. This same drive operates the pressure pump for the hydraulic steering system.

Slide No. 36—Belt Drive Shaft Protector. This is the scene in the engine room of a small construction job towboat. A four belt sheave drive was installed to run an air compressor in a changeover from manual to air steering. This is a very good application of scrap parts built into a very nice guard.

Slide No. 37—Main Drive Shaft Coupling Guard. Another well constructed and well anchored shaft coupling guard. This is on the main drive shaft of a large towboat. On many boats this area is used for storage. This is fine if done properly. However if any combustible material got against this exposed shaft it would be ignited by friction, the oldest fire starting principle in the world.

Slide No. 38—Flanking Rudder Bumper Plate Hazard. This is a real accident hazard built into a new boat. This is the end of the connecting arm on the flanking rudder control. When thrown to the extreme port position, this bearing point strikes against this bumper plate on the bulkhead. Just to the right of this area is a doorway. Anyone who would enter this area and try to take a shortcut, would certainly be killed if caught between the wall and the end of the control rod—thus a chain has been installed to prevent anyone from entering this area.

Slide No. 39—Resistor Bank Protection Screen. This resistor bank area carries 440 volts. However, this very nice guard made

from scrap pieces of dredge screens eliminates any hazard of electrocution, should some one fall into it or poke an iron rod or tool into the bank.

Slide No. 40—Grinder Protection. This is probably one of the most abused items in our industry. However, note here that the grinder tool post is well in toward the wheel, face shield is in place and goggles are supplied for the operator's use. Also wheels of the proper speed range and type should be used.

Slide No. 41—Kitchen Stove Guard. Most towboats vibrate a great deal, especially when flanking. Note here the weld rods that have been welded onto the stove top to prevent pans with scalding water from falling to the floor and possibly scalding the feet and legs of the kitchen personnel.

Slide No. 42—Pilot House Stairs Hazard. Note here that the stairways to the pilot house comes up at an angle where you enter them directly behind the pilot. Should one stumble and fall or mis-step especially at night when it is totally dark, one could fall directly down the stairway backward. Also a small dim night light would be helpful on all such stairways at night.

Slide No. 43—Mariner Pilot House Stairways—Good. Note that these stairs run parallel to the side of the pilot house. Here it is not so easy to back down the stairs by mistake. It might be well if a small lugged rod would be placed at the top of all pilot house stairs where they could only open from the "coming up" direction. From the pilot house side of the stairs, this rod would act as a railing.

Slide No. 44—Mariner Pilot House Controls. Note how all the controls in this pilot house can be reached by the pilot while sitting in the chair at the controls. In many pilot houses, the pilot must leave his chair and walk eight to ten feet to a radio, leaving the controls unattended. This particular boat is a very late design, where all controls are handy and the pilot does not have to leave the controls except very rarely. This is very important, especially when entering or leaving locks.

Special Hazards and Corrected Conditions Aboard Marine Equipment

Now, returning to the lower level of the towboat and out on the fleet, we will look

at some of the hazardous situations and what has been done to eliminate such conditions.

Slide No. 45—Cable Reel. This is a real accident maker aboard marine equipment. Here we have a wire reel which is not blocked. On marine equipment which yaws and rolls this reel would roll. All reels should be well blocked and preferably laid on the side, if possible. This is especially true on derrick boats when the deck goes out of level when heavy loads are picked up.

Slide No. 46—Yellow Line on Cover Barge. This is something with which we are all familiar. I'm sure. It is a bright yellow line painted continuously down the top of a covered barge. Anyone walking here, day or night, and sees a break in this white line, knows that a hatch cover is open, preventing a long fall into the barge.

Slide No. 47—Covered Barge Latch Cover Handle. Here is something that has caused fatalities. When the hatch cover rolls and strikes the end of the barge, a handle would fly over and strike a man standing in line with it. To eliminate this, these lugs were welded onto the latch cover handle. It can only rise to a vertical position.

Slide No. 48—Covered Barge Latch Handle—Critical Position. Here we see the latch cover in vertical position, the lugs preventing it from coming down over the end of the barge where it could strike anyone who may be standing in line with it.

Slide No. 49—Covered Barge Latch Handle and Employee. Here we see how an employee is protected by these lugs on the latch handle. We can see that the man is at the right height to be really "dlobbered" if this would be allowed to come on over striking his head.

Slide No. 50—Ladder Shoes. Here is something that all ladders should have when used aboard deck or any hard smooth surface. Note the ladder shoes prevent the ladder from slipping on the steel deck. Another feature here is the portable ladder step tread. This tread can be placed at any rung, allowing a 6 inch surface for the man to stand on. I sure would have appreciated this when I was a kid picking cherries back on the farm when I spent all day on a ladder rung or tree limb in my bare feet.

Slide No. 31—Permanent Rigging. Here is a ratchet, attached permanently to the side end of a barge. This metal plate is welded to the end of the eye bolt. It keeps the end of the ratchet above the deck and will not allow it to fall on deckhands' fingers. The piece of metal also acts as a permanent toothpick. Also note the non-skid surface aboard this barge.

Slide No. 32—Color Coated Ratchet. You will note that one end of this ratchet is painted green and the other end white. This is something a blacksmith did to make it easy to determine the right and left side of the ratchet. This is not a safety item, it is more an efficiency item. Anyone ordering a broken ratchet bolt, will know immediately which is left or right hand side when ordering the bolt.

Slide No. 33—Door Hooks. All doors on marine equipment should be arranged so they can be hooked in the open position. Many fingers have been damaged severely during windy days or when making up tow when doors have slammed shut on the workmen's hands.

Slide No. 34—Stove Hood. On many of the older boats when they used large stoves and then replaced them with more modern smaller stoves, the hood sticks out beyond the edge of the stove. Many of these hoods are low and are in the walking area of the kitchen crew, and become severe head bumpers. Note the hook in the upper left corner that can be used to hook the door in the open position.

Slide No. 35—Steering Gear Room. Here is a shut of the tiller room. Note the lubricating lines coming down to the various bushings in this equipment. These hoses tie into a central-point lubricating system which is a fine example of safety and efficiency tied together.

Slide No. 36—Central Lube System. These lines lead over to a central lubricating location as shown in this slide. This allows a man to do all lubricating from a clear unobstructed area and prevents him from climbing in and about the steering gear equipment.

Slide No. 37—Dredge Central Lube System. Here is the same thing applied to old equipment. Note how these caps and lines keep a man out of the hazard of climbing in on the digging ladder.

Fire Protection on Marine Equipment

Slide No. 38—Flammable Liquid Containers. Here is a common sight aboard marine equipment. Gasoline and flammable liquids are handled in just about every type of conceivable container that is made. Here we have two approved cans and sitting right along side of them is an unapproved five-gallon can. All containers should be a safety type can with the gauze flame arrestor in the spout.

Slide No. 39—Fuel Vent and Light Cover. Another precaution against fire on older boats is having the light bulb covered with a glass shield and a steel cage protector to keep it from breaking in the area of a fuel vent where fumes might be ignited.

Slide No. 40—Deck Fuel Vent. On newer boats, we have this arrangement where the fuel tank vent is located down on the guard deck level.

Slide No. 41—Hazardous Fire Ax. Here we see a fire ax stored away on the front end of a towboat. In this position, should someone slip and fall against this sharp point, it could cause a very severe injury. This hazard can be eliminated very easily by putting a cap over the point of the ax as shown here.

Slide No. 42—Fire Ax Covered Point. Here the sharp point of the ax is covered with a small piece of copper tubing. It is very simple to make. Take a small piece of copper tubing and hammer it flat on one side, then place it over the point of the fire ax. It can be removed very easily in case the ax is needed in a hurry.

Slide No. 43—Water Fire Hose. Most all marine equipment has water fire fighting equipment aboard. Here we see a very well stacked hose connected to the water line with the nozzle in place. It is very important that the line be connected to the water valve and to the hose to save time in case it is needed in a hurry for a fire. Fog nozzles are also used.

Slide No. 44—Fire Extinguishers. Most all marine equipment carries portable extinguishers. Here we see a very well equipped, well maintained extinguisher, well placed on the rig. However, it is noted that it is out in the open exposed to the atmosphere. All extinguishers, when placed outdoors where they can come in contact with the weather, should be covered, either with

a plastic bag or a box cover built over the extinguisher.

Slide No. 45—Heat Actuator.

Slide No. 46—Cylinders, Delay bottle and Trigger Head.

Slide No. 47—Main Valve.

Slide No. 48—Siren.

Slide No. 49—Pressure Operated Electric Switches.

Slide No. 50—Nozzle.

Slide No. 51—Manual Controls.

Conclusion

Slide No. 52—Boys' Future—(Slide No. 1). In closing, I want to ask each of you this question: What have you done to promote safety in our industry? Regardless of

your position, whether it be vice president, operations manager, safety director, marine architect, captain, chief mate—what have you done? This is the group that has to get things done.

We are part of an industry with great tradition. Tradition is a hard thing to cope with sometimes, because from it comes resistance to change. Nevertheless, it must give way to more efficient and safer ways. Progress must not be stopped in our economy. If you don't keep up with it, you will be passed by.

If we all keep driving, keeping our minds creative with a "don't give up" attitude, I feel certain that by the end of the next decade, our little friends here will be proud of the industry that we—then "old timers" will lay in their hands.

MANAGEMENT, LABOR, AND GOVERNMENT IN AN AGGRESSIVE ACCIDENT PREVENTION PROGRAM

By ARTHUR W. MOTLEY

Dir., Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.

In discussing my topic with you this afternoon, let me say at the outset that I consider the whole problem of accident prevention in the maritime industries—particularly longshoring and ship repairing, with which the Bureau of Labor Standards is most directly concerned—primarily a matter of three-way cooperation between management, labor, and government. It can be likened to a triple-pronged effort on the part of these groups to bring about something desired by each: improved safety performance. It is an instance where no single group acting alone can attain success, but all three, acting in concert, can achieve highly beneficial results.

As members of the Marine Section of the National Safety Council, this audience is well aware of past and current activities in the field of maritime safety, but perhaps a brief review of the background against which the U. S. Department of Labor's safety work in the maritime industries has been projected will be helpful.

Back in 1958, when Congress enacted

Public Law 85-742 it closed up a long-standing gap in safeguarding workers in longshoring, ship repair, and related maritime operations. This law, which directed the Secretary of Labor to establish and enforce regulations "reasonably necessary to protect the life, health, and safety of such employees, and to render safe such employment and places of employment," amended section 41 of the Longshoremen's and Harbor Workers' Compensation Act (Public Law 69-803).

Passed by Congress in 1927, this latter Act represents the first attempt to eliminate in the field of safety and compensation, the "no-man's land" in which waterfront employers and workers had been operating. Based on the federal maritime authority, it applied to longshoremen and harbor workers the already-established principle of statutory remedies, regardless of fault—as opposed to negligence suits brought under common admiralty law—in cases of job-incurred injuries.

This basic law provided workmen's compensation coverage for harbor workers and

for its administration by the U. S. Employees' Compensation Commission, an independent agency. However, under subsequent reorganization acts, Congress abolished the Commission and transferred its functions first to the Federal Security Agency and, in May, 1950, administration of the Act was vested in the Department of Labor, where it is carried out by the Bureau of Employees' Compensation. Related safety and health functions were delegated by the Secretary of Labor Standards.

In addition to the usual provisions concerning compensation coverage and benefits, it is Section 41 of the Act that is of particular interest from the safety standpoint. As originally passed, Section 41 provided: "The commission shall make studies and investigations with respect to safety provisions and the causes of injuries in employments covered by this act and shall from time to time make to Congress and to employers and carriers such recommendations as it may deem proper as to the best means of preventing such injuries."

The only real authority given the Commission was the authorization to enter places of employment covered by the act, and to examine equipment and conditions found. The original act did not confer authority to compel action looking toward accident prevention. Thus, in a sense, workers in these maritime industries were still in a "no-man's land" as compared with workers on dry land who were covered by State compensation laws as well as State safety laws conferring rule-making and enforcement authority upon an appropriate State agency.

Nevertheless, by providing a system of workmen's compensation for maritime workers, Congress provided a definite incentive, and the Commission offered encouragement, for employers in the covered industries—including stevedoring and ship repairing—to develop and extend accident prevention programs in their operations. Although under no compulsion to do so insofar as the Act's provisions were concerned, many employers initiated safety programs, while others expanded or breathed new life into their pre-existing safety efforts.

Various maritime interests in a number of our major ports, including those on the Pacific coast, recognized during the 1930's

a need for correcting unsafe working conditions in their operations and for instituting safe working practices among their employees. They recognized, too, that safe methods are, generally speaking, efficient methods as well. In some instances, the maritime industries adopted safety codes and applied them on a strictly voluntary basis—there were no mandatory safety requirements at this time.

Besides the safety standards in the several voluntary maritime codes, certain voluntary promotional activities were carried on. As early as 1946, the U. S. Employees' Compensation Commission and the Department of Labor launched a broad safety training program for waterfront employees under which monthly safety meetings were to be held by employers at which insurance company safety material was to be discussed. At the same time, the Department of Labor undertook to provide educational material in the form of visual aids and other safety suggestions. This work was carried out with the cooperation of the managements of numerous progressive companies in the maritime industries. The Department also worked closely with a number of unions, holding safety meetings and conducting other safety promotional work among union members. These activities were purely voluntary on the part of management and labor—there was no compulsion, other than a sincere desire to "do something" about accidents and their resultant injuries. Then, too, the Department's work in this area was necessarily limited to the part-time activities of a handful of federal safety consultants.

This work was extremely significant, however, as it helped to establish a climate of understanding and cooperation between the three key groups—management, labor, and the government.

Yet it soon became evident that this exclusively voluntary approach, with limited personnel and funds, was not effective in bringing about much improvement in the overall accident experience of maritime operations covered by the Compensation Act. Already known as a high-hazard activity, the maritime industries during the decade 1948-1957 compiled the unenviable record of 189,097 longshoremen and ship repairmen disabled by accidental injuries—at an average rate of 18,000 a year. In addition,

1,345 workers were killed on the job. Frequency and severity rates remained high. Clearly the voluntary efforts that had been undertaken had not produced the desired results by way of reducing the accident experience in these high-hazard operations. Meanwhile, Congress was not aware of this situation—various maritime safety bills were introduced after 1941, but none was reported out of committee.

In 1958, after extensive hearings at which individual employers, employer associations, labor unions, shipping interests and governmental agencies testified, Congress enacted Public Law 85-742, approved by the President August 23, 1958, to which I referred a few moments ago.

In brief, the law authorizes the Secretary of Labor to: (1) establish and enforce safety and health regulations applicable to employments covered by the Act; (2) study and investigate safety provisions and the causes and prevention of injuries, and from time to time to recommend to Congress the best means of preventing such injuries; (3) provide for the establishment and supervision of safety education and training programs for employers and employees; (4) consult with and advise employers on the best means of preventing injuries.

Let us briefly consider these four basic points, one-by-one.

First, "establish and enforce safety regulations." Under the authority granted the Secretary of Labor by the 1958 Law, we proceeded to draft a set of proposed minimum standards covering longshoring and ship repair operations. All available codes and standards applicable to these industries were analyzed and evaluated in preparing the draft regulations. These were then circulated widely among employers, unions, trade associations, the Coast Guard, the Navy Department, and the Maritime Administration for informal criticism and comment. After study and consideration of all criticisms and suggestions, a second draft was prepared for use at the public hearings. Four such hearings were held during the latter part of 1959—Chicago, New Orleans, San Francisco, and New York—in order to afford interested parties in all parts of the country opportunity to express their views. The hearings were well attended, and

many individuals and groups submitted written, rather than oral, comments either before or during the public sessions. Again, comments and suggestions were carefully weighed, and the regulations became effective March 21, 1960.

This audience is acquainted with these regulations. I have outlined the procedure by which they were brought into being because it illustrates a cooperative—not an authoritarian approach. Based on previously established voluntary standards, arrived at through the cooperation and collaboration of management, labor, and government, the Safety Regulations for Longshoring and Ship Repairing constitute a sound and reasonable guide to accident prevention in the affected operations.

As for enforcement, we have resorted to our authority to compel action only in those few instances where our consultative, educational approach has failed to produce compliance. However, there are a few employers, I regret to say, that have not fully responded to our consultative efforts and have given only lip service to the safety and health regulations. I have also been somewhat disappointed that while most employers are cooperating with our program, they have not given us more of the benefit of their advice, opinion,—yes, even criticism—for our use in improving our efforts to be of service. We welcome such advice and constructive criticism, and are hopeful it will be forthcoming in greater amount. I assure you it will be accepted in the same spirit as that in which it is offered—one of mutual respect and confidence, reinforced by a sincere desire for bettering the industries' safety record.

Second, "study and investigate safety provisions, the causes and prevention of injuries; recommend the best means of preventing them." Our safety staff, both in Washington and in the field are continually carrying out this directive of the law. When they visit or inspect a facility, they are constantly on the alert, not only for hazards, but also for methods of controlling them. Where applicable, this information is passed on to other employers and employees in the daily contacts our field safety men make. It is relayed to Washington, where it is used in a variety of ways; to assist in improving the performance of other field men, for consideration in connection with

any proposed amendments to the regulations, published as part of safety articles in various periodicals, and used in connection with the many technical safety publications and bulletins of the Bureau of Labor Standards. This becomes a matter of "spreading the word," and is an important phase of increasing the scope of safety knowledge. Again, it illustrates the cooperative approach we have followed.

Third, "provide for safety education of employers and employees." Heavy emphasis has been placed on this activity, not only because of the mandate handed us by Congress, but because we in the Bureau have long stressed the importance of safety training and education as one of the most potent forces in developing safe working conditions and safe work practices, not only in maritime operations, but in all other safety areas in which the Bureau has responsibility. Once more, it is a matter of a joint, cooperative approach. We have continually sought and received the wholehearted support and cooperation of employers and their associations, workers and their unions, educational institutions, other government agencies, and many others, in order to provide needed safety training and education. We shall continue to seek—and, hopefully, to obtain—such cooperation from management, labor, and government, as the occasion warrants. Unfortunately, some of our efforts to encourage safety training have not borne fruit, due to problems relating to pay for workers undergoing training. Certainly, cost is a factor here, but the cost of training, as compared with the cost of accidents, can leave little doubt as to which is the greater economy.

Fourth, "consult with and advise employers." This is the core of much of our safety work. In keeping with its long-range policy of promoting safety, rendering consulting, technical safety services, and providing educational and training opportunities, the Bureau of Labor Standards relies heavily on voluntary compliance of affected parties. While we intend to enforce the law conscientiously and impartially, we expect to continue spending the bulk of our time, as we have in the past, in technical consultation and advisory service.

I think it is significant that three of the above-mentioned four points in our mandate

from Congress call for activities that seek to bring about conformity to, and compliance with, accepted safety standards, as distinguished from compulsion and enforcement. We have stressed—and will continue to stress—the techniques of consultative, advisory, and informative services throughout our program of safety in the maritime industries. The most valuable role that the Bureau of Labor Standards can play in preventing maritime work injuries is to buttress and extend its technical advisory, consulting, and training services in this area.

You who are complying fully with the regulations and who are cooperating with us in our efforts to bring about a greater degree of safety are just as interested as we in government in seeing to it that the few firms repeatedly found in violation are brought into compliance. Therefore, we shall not hesitate to use our legal authority to effect compliance with the law and the regulations in those relatively rare instances where the "consultative approach" fails to bring it about.

While we have noted a high degree of compliance with the regulations on the part of the great majority of employers, further action has had to be taken in the case of a few firms. During the last fiscal year, court action was begun seeking to restrain two ship repair yards from continuing operations that were in violation of the regulations. In one case a restraining order was issued, in the other it was denied. No cases have been prosecuted, as yet, under the criminal procedures contained in the Act. Short of instituting legal action, we now send letters from our Area offices to the managements of those firms which have been repeatedly found in violation of the regulations and which have not responded to violation notices we have served. These letters summarize the code violations found and serve as a warning—a danger signal—prior to more drastic action. In some instances, we plan to schedule conferences with such managements, and anticipate some success in bringing about full compliance in this manner.

A few figures concerning our safety activities in ship repairing during the fiscal year ended June 30, 1961, give some insight into our work in this area. Bear in mind, these relate only to ship repairing; our longshoring activities are not included

Summary of Ship Repairing Safety Program Activities

Consultations	2,806
Evaluation Surveys	353
Accident Investigations	154
Complaint Investigations	84
Ships Inspected	4,968
Violations Cited	1,910
Violations Immediately Corrected	1,032
Recommendations Made	853
Recommendations Immediately Corrected	567
Training: Number of Sessions Held	167
Training: Number in Attendance	2,153
Safety Meetings: Number Held	201
Safety Meetings: Number in Attendance	1,527
Number of Publications Distributed	17,279

So much for past activity. What about problems and prospects in the foreseeable future?

1. In anticipation of extending coverage of the safety regulations to shipbreaking, we conducted a detailed study of these operations, drafted preliminary regulatory proposals and submitted them to the industry. Comments and suggestions received were used in preparing a second draft for consideration at a contemplated formal hearing. At this point, issuance of effective shipbreaking regulations has been delayed pending clarification of a jurisdictional question. We hope for an early solution of this problem, as the hazards of shipbreaking are great.

2. A number of proposed amendments to the ship repair regulations have been drafted and submitted to the industry for comment. These are specifically designed to deal with the problems of toxic, fire, and explosion hazards aboard vessels undergoing repair. From our studies of accident investigations it is abundantly clear that this is an area where regulations are necessary and where considerable research must be carried out. It is proposed to require medical examinations for employees exposed to metallic fumes to permit early recognition of metal fume poisoning so corrective action may be taken promptly. Further definition of the term "competent person" in connection with the certification as to maintenance of gas-free and non-toxic atmospheres aboard and around vessels has become necessary. We are now engaged in developing specific standards to assure the technical competency of persons in this work.

3. In the issuance of amendments—except those that are purely administrative in nature—the Bureau has followed its

original concept of seeking the widest possible notice and comment before promulgation. The only procedural change we have made is to hold a single public hearing in Washington instead of several hearings in different parts of the country. Since the bulk of the testimony is received in writing rather than orally, the opportunity afforded interested parties to comment and criticize is not impaired.

4. Ever since the Ship Repair Safety Regulations became effective, there has been a "feeling" in some quarters that they do not apply to the small boatyard operator. While we recognize that often the small yard cannot be held accountable for safety and health measures on exactly the same basis as the large operation, and that the degree of hazard frequently differs as between large and small yards, there is no arguing the fact that a worker in a small yard can be killed just as dead if, for example, he is hit on the head by a ten-pound block falling from a height of, say, fifteen feet, as he can in a large yard. Size of the operation is not the controlling factor. The small yard is definitely covered by our safety regulations, and we have followed the "rule of reason" in applying their requirements to such yards. There is need for further study in this area, especially with regard to operations that may be unique to small boatyards, and special study of the associated hazards is indicated.

5. The regulations require that employers keep records and report data on injuries and man-hours of exposure in employments under the Act. The Bureau of Labor Statistics receives these reports, and compiles injury frequency and severity data for individual companies, ports, districts, areas, and national totals. For the first time, comprehensive figures on accidents in the maritime industries are being received.

There has been some misunderstanding of the reporting requirements and consequent difficulty in obtaining data as to the extent of disability in individual cases. Much time has been spent by the field staffs of BLS and our own Bureau in obtaining complete and consistent reporting. Although the figures obtained for the calendar year 1960 are subject to some error, we expect to attain a satisfactory degree of uniformity in reporting during the current year.

6. Training sessions and safety meetings have increased in number and attendance as fast as we have been able to meet the demand for them. This important phase of our safety program is developing in intensity, as the initial need for concentrating on inspections and enforcement becomes less pressing.

7. We have maintained a close cooperative relationship with the U. S. Coast Guard. Thus, we have almost entirely avoided duplication of effort or conflict of jurisdiction in a situation where the lines of demarcation are narrow and in some cases ill-defined. The Bureau of Labor Standards has also maintained—and will continue to maintain—cordial working relations with the states and with other federal agencies such as the Army, the Navy, the Maritime Administration, and the State Department, all of which have interests closely touching on the field of maritime safety.

In conclusion, it can be said that throughout all our activities in the field of maritime safety over the years, we in the Bureau of Labor Standards have consistently followed the philosophy of the "team" ap-

proach. We have not tried to "go it alone." We have continually sought—and obtained—advice and counsel of affected parties, including management, labor and government agencies having an interest in this field. In the reverse direction, we have emphasized the concept of voluntary compliance with reasonable standards, and we have minimized the "police" aspects of our work. In short, we have relied—and shall continue to rely—upon educational, informative, consultative means, backed by enlightened self-interest, rather than formal authority, to make significant progress in the task that confronts all of us: safeguarding the lives, the limbs, and the health of those human beings who make their livelihood in maritime occupations.

This, I believe, typifies the joint task faced by your industries; by management, and labor, with government participating as adviser, as counselor, as stimulator and promoter in this cooperative endeavor. It should act as policeman and judge only in those few cases where cooperation fails to produce the desired result: making the industries safe for those who man them.

MANAGEMENT AND SAFETY

By HENRY Z. CARTER

President, Avondale Shipyards, Inc., New Orleans, La.

There is a general agreement that the prevention of occupational injuries is achieved, first, by control of the working conditions, and secondly, by control of the actions of people. Certainly management can accomplish such controls and that is why it is generally agreed that safety is a management function.

In discussing this, we should take a look at the history of occupational safety. We have engaged in all forms of productive activity for years. During that time, no doubt we have tried to protect workmen against the hazards of these activities, but it has only been in the last half century that there have been well organized efforts to prevent occupational injuries. These activities have taken many forms—the so-called "safety program" seemed something separate from the "production program."

Regardless of how much was said about the responsibility of management and supervision in regard to accident prevention, many times the "safety program" activities tended to take away such responsibility from line supervision. When safety inspections were made by safety personnel or inspection committees, it tended to relieve those who should really see that working conditions and practices were as safe as possible.

At times management responsibility was referred to in terms of "supporting the safety program." This often led to the impression that accident prevention was separate from the rest of the activities of the organization and only needed support from management rather than active direction by management by specific delegation of responsibility and holding them accountable.

No wonder after this half century of

organized accident prevention effort, we still talk about it as something that develops below management level and for which somebody has to go to management for approval and support. We should consider it as something that will be successful when management initiates and directs such activity through its line organization and necessary staff help. Also, accident prevention should be integrated into production as completely as possible.

If we will observe those companies whose management has recognized this, we will see that they have been successful in keeping their occupational injuries at a minimum. On the other hand where results of safety efforts are less consistent, it is often when too much of the total responsibility has rested upon the safety department and when the safety program is least integrated in the production effort.

We should consider some of the activities which are important to the prevention of occupational injuries and how they can best be integrated in the production effort.

1. *Selection and Placement of Employees.* This requires close co-ordination between a number of people. If pre-employment medical examinations are used, there must be adequate information on the physical, experience, and other requirements for each job to get the greatest value. This is achieved by job analysis carried out by personnel and physical requirements should be made available to the examining doctor so that he may interpret the results of examination of the prospective employees in terms of these job requirements.

2. *Training.* Training is carried out in various ways in different organizations depending upon their needs. Sometimes safety training is carried out separately from job training, that is, safety training being done by safety personnel and job training by the immediate supervisor. In most cases, both job and safety training on the job seems most effective.

3. *Accident Investigations and Records.* Most companies require foremen or supervisors to investigate all disabling injuries of the employees under their supervision and to submit a written report. This is not to place the blame, but to take corrective action for the future prevention of this type of accident. When supervision is

required to submit such reports to his superior with indication of corrective action or recommendations on what is necessary, he is reminded of his responsibility for accident prevention each time he makes an investigation and report.

4. *Maintenance of Safe Working Conditions.* All no doubt agree that a workman's immediate supervisor has the most direct responsibility for his safety, therefore, that supervisor should also have responsibility for seeing that the man's working area and conditions are safe. The supervisor should periodically check all tools and equipment used by his men to see that they are in a safe and workable condition.

5. *Supervision.* It is considered sound management principle that an individual should be responsible to one person rather than several persons for various parts of his job responsibilities. On this basis, an employee should be responsible to his immediate supervisor for the safe performance of his job, and the supervisor should be responsible (for safe performance of the people under his supervision) only to his immediate supervisor. Why should there be different categories of rules covering different aspects of the same man's job? Is it better to have "safety rules" as such, or is it better to have operating rules and procedures which are such that the man will perform this job's safety?

6. *Safety Education.* This phase of accident prevention is one where results are most difficult to determine. It is hard to say how much of this needs to be done. Safety education should be effective as possible and should be directed at specific recognized needs for such education. Mere use of films, posters, etc., without supporting action by supervision is relatively ineffective.

These are just a few illustrations of how safety effectiveness can be maximized by integration of safety controls with production controls. We can see this is a sound approach and will agree that much of the real control will be in the hands of those in the various levels of production management.

I have long recognized that successful accident prevention can be achieved through good management which effectively uses good technical knowledge within the organization.

DISCUSSION OF PAPER ENTITLED "MANAGEMENT AND SAFETY" BY HENRY Z. CARTER

By R. D. DAUTERICH

Industrial Relations Mgr., Maryland Shipbuilding & Drydock Co., Baltimore, Md.

A. We agree with Mr. Carter: To be most effective, the responsibility for safety must start with the chief executive and flow down through the line organization.

Three ways in which the chief executive can implement this responsibility are:

1. To personally visit the scene of a major accident and stay long enough to fully understand all that happened.
2. While making a plant tour, make safety suggestions or corrections on the spot. (This activity will be a mild irritant to full time safety people for various reasons, but the overall effect is very worthwhile.)
3. Read disabling injury reports and make written comments or queries on them.

B. We have stopped having production supervisors investigate and make written reports of accidents except where they are eyewitnesses.

Our reasoning is as follows:

1. Most line supervisors are not adept at carefully gathering and accurately reporting all pertinent facts.

2. To avoid the possibility of blame on himself or those under him, a supervisor usually is unable to consider an accident with sufficient objectivity.

Of course, if any member of supervision is at fault in connection with an accident, the fault must be pointed out and any additional steps taken that are deemed appropriate.

C. We suggest that more graphic words be sought to replace "accident" and "accident prevention" in industrial safety work. Many workmen, as well as people of all walks of life, seem to have become hardened to the word. An "accident" seems to have become something that is almost inescapable rather than a harmful, hurtful experience that could have been avoided. At this time, the best substitute we can think of is "disabling injury" but we feel that someone can do better than that.

20-20 HINDSIGHT

By DAVID R. LAVALLETTE

Health Physics Engineer, Bethlehem Steel Company (Shipbuilding Division) Quincy, Mass.

The application of nuclear power to ships as a means of propulsion has effected dramatic changes in the shipbuilding industry. Included among these changes are: advanced welding techniques, improved quality control procedures, lead shield fabrication methods, clean room applications, and health physics programs for the purpose of radiation protection. The latter of these innovations is the topic of this discussion.

A radiation protection program is by no means the only line of defense against radioactive hazards associated with reactors. Prior to operation, each reactor component and the reactor plant as a whole is subjected to an extensive test program to insure safety by ascertaining that all machinery and protection devices are in proper operating order. The design of the reactor plant together with the probability and con-

sequences of any conceivable accident are thoroughly reviewed by the AEC's Advisory Committee on Reactor Safeguards to assure adequate control of all possible sources of ionizing radiation.

The nuclear industry in this country is enjoying a fine safety record. This fine record is not accidental. Historically, even during the hectic Manhattan Project days of World War II, the realization of radiological hazards was concurrent with development of nuclear technology. Responsible agencies and industry have persisted in keeping countermeasures well ahead of the possible hazards.

As elsewhere, our Quincy Yard radiation safety program preceded initial reactor operation by a considerable margin. We embarked on an extensive radiation protection program more than three years prior to our first controlled reactor operation. The establishment and appraisal of such a program will be the subject of this paper.

The basic objective of our program is to minimize personnel radiation exposures and to insure that permissible exposure limits prescribed by law are not exceeded. The protection of the general public and company liability, and the fulfillment of moral obligations are other paramount objectives.

Permissible levels are established by the U.S. Atomic Energy Commission, and documented in the Code of Federal Regulations, Title 10, Part 20. Many states including Massachusetts also have regulations relating to ionizing radiation exposures. Compliance with the requirements of certain other agencies such as the Interstate Commerce Commission and the Coast Guard is sometimes required under special circumstances. Additionally, when Naval nuclear powered ships are involved, the regulations of the U.S. Navy must be observed.

Although some requirements are common to all codes, there are inconsistencies in certain details. It is therefore necessary, when formulating a set of regulations, to incorporate the most restrictive features of all applicable codes.

Our regulations and procedures are documented in a comprehensive volume entitled the "Health Physics Manual." The manual prescribes appropriate procedures to be followed under a wide variety of circumstances. Also included are descriptions of facilities

and equipment, responsibilities of various groups, and tables of permissible exposure criteria. This manual was submitted to the U.S. Atomic Energy Commission, the Navy, and other interested agencies prior to becoming effective.

The authority of the Health Physics Department is advisory in nature except in cases when emergency corrective actions are required to avert the creation of unsafe conditions. Health physics personnel routinely survey for potential hazards using appropriate instruments, and advise line supervision relative to necessary protection measures.

The health physics group is organized on a three shift basis, with each shift comprised of a supervisor and two technicians in the field. An instrument calibration and repair technician, and a laboratory technician are also employed on the day shift. Three film badge clerks are required for the personnel monitoring program. The size of the group has been tailored to cover routine operations. When operations require additional coverage, double shifting and overtime are utilized. The possibility of extended periods of heavy work loads does exist however, and we are currently considering the feasibility of training auxiliary forces which could be called upon in times of need. Such auxiliary forces would presumably be selected from other trades in the Yard.

EDUCATION

Unfortunately the nuclear age was ushered in under a mushroom cloud. In the minds of many the term nuclear reactor is synonymous with atomic bomb. (Actually a nuclear reactor cannot perform like a bomb.) Conversely, there are many who feel that because radiation can be neither felt, seen, or heard, it can produce no bodily harm. It is readily apparent, therefore, that an extensive educational campaign is essential to any successful radiation protection program.

Our educational program has included special presentations for: management and supervision, health physics personnel, production employees, plant protection personnel, industrial radiographers, and the public.

One of the earliest endeavors undertaken was the preparation and distribution of a booklet presenting a simplified, pictorially illustrated explanation of ionizing radiation, its hazards, and its safeguards. The booklet

was originally mailed to every employee, and is given to all new hires. This presentation has proven effective in furthering the understanding of those employees who are sincerely interested in the subject. For those who are less interested, but have a need to know, a more direct means of communication is necessary. Because the booklet was originally distributed more than a year prior to initial reactor operation, additional copies were issued to those personnel who were assigned to activities directly associated with potential radiation hazards. This second issue was made a few weeks before such assignments.

Management and supervisory personnel were given lecture presentations early in the program prior to training of other personnel. In this manner all supervisory employees had an opportunity for orientation prior to their men, and could play a more active role in subsequent educational activities.

Union officers and shop stewards were also invited to an indoctrination session prior to other personnel. This presented an opportunity for open discussion of the program and hence promoted good labor-management relations.

Since trained health physics personnel are not readily obtainable, it was necessary to train men to serve as shift supervisors and monitors. Engineers with some background in nuclear work were selected as shift supervisors. Men with some technical education or experience beyond the high school level were selected as monitors. Personality was carefully considered in the selection of candidates, because each man must double as a technician and a health physics ambassador.

All health physics personnel were given a comprehensive forty (40) hour course in radiation protection principles; were required to pass a rigid examination on the subject matter, and then spent two (2) or three (3) months gaining practical experience before being considered qualified. A yellow hard hat stenciled with the term Health Physics was issued to each man upon qualification. The yellow hats serve a two-fold purpose: (1) to render health physics personnel readily identifiable, and (2) to serve as a badge of proficiency.

Periodic open discussion periods and

quizzes have aided in maintaining a high degree of proficiency in the health physics group. The problems encountered in health physics change rapidly. A situation existing today may not arise again for several months. Reviews aid in maintaining a state of readiness to cope with any situation. In general this program has proven highly successful.

Education of production employees was conducted on two scales. Those employees who were to work in radiation areas requiring film badges, but not become involved with high radiation exposures or loose radioactive material, were given a brief talk regarding the significance and proper use of film badges. Employees who were expected to become more involved were given at least two hours of lectures and demonstrations regarding the nature of the potential hazard, proper use of protective equipment, and the respective responsibilities of all involved. On the job follow-up sessions have been necessary.

A group of sixty (60) maintenance personnel were selected for a special sixteen (16) hour course in decontamination techniques. During these sessions, emphasis was placed on the proper procedures to be followed in decontaminating various types of surfaces. Very few of the men trained were actually needed, but the availability of a sizable trained force is deemed highly desirable.

All firemen and members of the guard force have received several hours of lectures and demonstrations. Particular emphasis was placed on emergency situations involving radiation hazards. Each of these groups has been supplied with a radiation measuring instrument which may be used to assess a hazard under emergency circumstances.

A somewhat different type of training program has been developed for radiographers. These men work with radiation continuously, whereas other employees may be concerned with it for only a few weeks in the year. As with others of life's hazards, familiarity with radiation can breed contempt. For this reason reviews for radiographers are conducted on a routine basis. Formal courses are given to all new men. These courses are also required by the Code of Federal Regulations, Title 10, Part 31, and hence must be documented with the Atomic Energy Commission.

Education of the community has been effected largely through lecture-discussion periods for numerous civic organizations. This program was initiated three years prior to reactor operations and has been conducted on a continuing basis. Press releases based upon conferences with various governmental agencies have also served to inform the community of our operations. The attitude of the community toward nuclear operations in Quincy seems to indicate that the public relations program has been successful.

Our experience has demonstrated that two basic principles are essential to the success of any educational program relative to radiological safety: (1) The sometimes mystical sounding nuclear terminology must be reduced to simple everyday language, (2) Repetition is essential to the satisfactory understanding of all concerned.

FACILITIES

Health physics operations entail the utilization of a few special facilities not normally available in a conventional shipyard. For our operations, four such establishments appeared necessary: central facility, environmental sampling station, decontamination barge, and film badge issue station.

The central facility houses a small chemistry laboratory for sample preparation, a counting room for radioassay of samples, spaces for calibration and repair of field survey instruments, conference space, and an office. The grouping of these particular spaces within one area presented a slight design problem arising from the presence of instrument calibration sources in relatively close proximity to a counting room. The use of a collimated beam gamma source, and proper arrangement of rooms has permitted concurrent calibration and counting operations without interference.

An environmental survey sampling station was constructed on the waterfront. The site of this station was based upon a study of tidal currents and the location of fresh water runoffs to the river. Apparatus for the sampling of river water, airborne particulates, and precipitation are located at this station.

A decontamination facility was provided largely as an insurance measure. The construction and testing of nuclear powered ships does not necessarily require such a facility. An ever present potential need does

exist however, and it seemed prudent to be adequately prepared for any realistic eventualities.

Several alternatives were considered in planning for possible decontamination tasks. These included various combinations of trailers, trucks, stationary buildings, and barges. A barge was ultimately selected for its versatility, convenience, and economy of operation. The most obvious advantage is that a floating facility can be placed in close proximity to a ship, thus promoting the efficiency of service operations.

For our purposes a used cargo lighter was purchased, and appropriately outfitted. The main deck was divided in two general areas: one for decontamination of materials, and one for decontamination of personnel. The hold was equipped with tanks and piping necessary for liquid waste disposal operations. A control area and issue area on the main deck have also served as a convenient base of field operations for health physics personnel assigned to ship coverage.

To date the barge has been used for minor jobs which might well have been accomplished safely with less overall convenience using less adequate means. To assess the facility's value solely on this basis would be unfair. However, should a major decontamination effort become necessary the barge would prove invaluable. The prospect of engaging in nuclear shipbuilding activities without an equivalent decontamination facility would certainly appear indefensible.

A film badge issue station with a potential capacity of 4,000 badges was established in the form of a portable building. This building can be placed at any necessary location.

The handling of thousands of film badges together with the necessary paperwork involves a major clerical operation. Space for those clerical activities was provided within a partitioned subdivision of the station. This design has enabled the film badge clerks to perform routine film handling duties and render assistance to film badge users concurrently.

PERSONNEL MONITORING

As previously noted, physically qualified personnel whose work involves the possibility of exposure to radiation are permitted to receive small doses in accordance with prescribed standards. When such exposures

occur, employers must determine and record the dose which each employee receives. Although there are many commercial film badge services available for personnel monitoring purposes, we have found it more satisfactory to conduct our own film badge program at the Industrial Health Engineering Laboratory in our home office at Bethlehem, Pa.

A large scale personnel monitoring program is a potential bottleneck. Supervisors of personnel who may need film badges must anticipate their needs for Medical Department approvals and submit requests for film badge service well in advance. Their failure to do so results in a deluge of last minute requests, which jam the system, thus resulting in costly delays and inconvenience. Our experience indicates that such delays can be avoided only by the issuance of timely reminders by way of memoranda or telephone.

INDUSTRIAL RADIOGRAPHY

During the past four years the Quincy Yard Radiography Department has tripled in size, and the number of sources used has grown eight (8) to seventeen (17). Furthermore, the inspection of lead shielding and heavier piping components has required the use of larger sources than were required prior to the advent of nuclear ship construction.

Health physics responsibilities relative to this operation consist mainly of developing safe procedures, equipment, and facilities, administering the personnel monitoring program, educating radiographers, surveying radiographic exposures, and insuring compliance with AEC license procedures and regulations.

Three separate radiographic areas have been established. These are shielded facilities which permit unrestricted radiographic operations with insignificant exposures to the radiographers or other personnel. Such areas are equipped with alarm systems to warn the operators in the event of accidental intrusions by unauthorized personnel. Field operations on board ships must be conducted using appropriate barriers, ropes, warning signs, and surveillance.

The use of remotely controlled sources utilizing crank out cables has also contributed significantly to the reduction of exposures. Such devices have presented some troublesome problems. Sources have become de-

tached from cables, either through mechanical failure of a coupling device, or failure of the operators to properly attach the source.

Mechanical failure of couplings has apparently been eliminated by instituting a requirement for routine inspection, and requiring the vendor to supply couplings made of an improved metal. Personnel errors have apparently been eliminated by requiring every source coupling operation to be checked by two men. Overexposures resulting from decoupled sources are additionally guarded against by requiring that a survey meter be used after every exposure to insure that sources are properly restored to their shielded containers.

One excessive, although not biologically significant, exposure has occurred as a result of a decoupled source. Human error was the apparent cause. The aforementioned precautions were instituted after the incident.

Several other source decoupling incidents have occurred without any resulting overexposure. In all cases the source has been restored to a shielded container with minimum delay utilizing special techniques. Apart from the potential exposures involved, the cost of limiting access to a space where fifty or one hundred men are scheduled to work further accentuates the importance of eliminating the accidental decoupling of sources.

One of the most important functions of health physics is leak testing isotope sources. Sealed radiography sources should not present any contamination problems. If not properly encased, however, these sources can leak. In the past four years we have discovered two leaking sources. If not detected, such leakage could have serious consequences.

The degree of success of our radiation protection program for radiography is difficult to evaluate. One possible measure of success might be the personnel exposure records. During the three years prior to the establishment of a formal program the average annual per capita exposure for radiographers was 780 mrem. During the first three full years since its inception the corresponding average has been 293 mrem. (The average annual per capita exposure limit is 5000 mrem.) Our experience illustrates a definite advantage in maintaining a radiation control program which is administratively divorced from the group which

is primarily concerned with the production of radiographic exposures.

NUCLEAR POWER PROGRAM

The exceptionally high quality of naval nuclear propulsion units has thus far limited the necessity for any drastic health physics measures at the Quincy Yard. The operation, testing, and maintenance of reactor systems, however, require constant vigilance on the part of radiation protection personnel.

A nuclear reactor normally will not contribute significantly to radiation levels in the environment. To prove this, one of the first steps in establishing a radiation safety program for reactors is to make a survey of natural levels of radioactivity in the area surrounding the site of prospective reactor operation.

Natural levels of activity are characterized by seasonal variations, and are occasionally augmented by contributions from nuclear weapons fallout. It is, therefore, desirable to commence an environmental survey at least one year prior to reactor operation in order to develop a representative baseline.

Our survey was initiated in October of 1958, more than two and a half years prior to initial reactor operation and has continued to the present time. The survey has been a cooperative effort with the Massachusetts Department of Public Health participating in a routine exchange of samples and comparison of results. This arrangement has provided a routine check on accuracy, and introduced an impartial set of observations which are available to the public.

Included in the survey are analyses of: river water, bottom silt, clams, algae, airborne particles, and precipitation.

It is difficult to assess the value of such a program, or determine the optimum scope. To date, we have found no levels of radiation in excess of the normal background, and have had no cause to refer to the data to prove that the background has not been affected. Certainly the negative results will prove useful should any question arise at a future date.

Once reactor operations have commenced a prescribed pattern of routine coverage is required. Radiation areas are kept under surveillance by health physics personnel equipped with instrumentation and equipment for the measurement of external radia-

tion levels, and the detection of loose radioactive contamination.

Personnel not wearing film badges, are not allowed to enter radiation areas. Posting of such areas with warning drapes that must be moved aside to gain access, and maintaining a roving patrol have proved virtually 100 per cent effective in enforcing this restriction. The placing of guards at all accesses was once considered, but has proven unnecessary.

When operations require the opening of internally contaminated systems, a polyethylene tent is usually erected at the site of action to restrict the spread of contamination. Access to such areas is strictly controlled by health physics personnel. Potentially contaminated equipment passing the access point is sealed in plastic bags. Strict accountability for this equipment is maintained by the use of a system utilizing duplicate tags. Contaminated materials are taken to the decontamination barge for storage, decontamination, or waste disposal.

Instrument failures have provided the only major problem encountered in this program. Most commercially available radiation monitoring equipment has proven to be delicate, and unreliable. This is especially true of neutron measuring instruments. The problem is further compounded by the extreme environmental conditions experienced in machinery spaces. The inaccessibility of certain shipboard spaces leads to rough treatment of equipment which further complicates the problem. The only effective remedy for this situation has been a routine maintenance and repair program conducted by a well qualified electronics technician.

CONCLUSION

The program outlined above may appear elaborate and expensive. It is. The size of the control program, however, is not so much commensurate with the degree of hazard involved as it is with the nature of the hazard.

With some degree of oversimplification, it might be stated that the control of ionizing radiation requires extraordinary measures, because special equipment and capabilities are necessary to detect radiation, even at levels which could prove fatal.

The establishment of an effective radiation protection program requires extensive advance preparations including the acquisition

of facilities and equipment, the development of procedures, and the training of personnel. Overall success is largely dependent upon thoroughness of forethought.

As with any type of safety program, the human element plays an important role. In dealing with this problem, it is necessary to strike a happy medium between stern admonition regarding potential dangers, and confident reassurance that when properly handled, radiation presents no more of a threat to man's welfare than other hazards

which we all encounter daily. It is generally possible to minimize reliance upon human acts by the proper engineering and maintenance of equipment, and the use of protective devices.

In conclusion, the nuclear age has presented a new challenge to the art and science of personnel protection. That challenge can be met by the application of common sense safety engineering principles together with specialized techniques pertaining to the field of Health Physics.

DISCUSSION

By R. B. CHAPPELL, JR.

Industrial Relations Mgr., Electric Boat Div., General Dynamics Corp., Groton, Conn.

My colleagues and I have studied with considerable interest the paper authored and presented by Mr. David R. Lavalette. He has done a most commendable job in presenting the cause for radiation protection programs. His analysis and treatment of this field is timely and of interest to any shipbuilding industry.

The author presents two basic points in his paper, the establishment of a radiation protection program and its subsequent appraisal.

With regard to the establishment of the program, the author does not make it clear whether the Quincy Yard Program in part or in total is novel in concept, or whether it was patterned in part or in total after other shipyards. If it was modified from other shipyards, what were these modifications and the reasons for them.

With regard to the appraisal of the program, the following points require clarification. These points and their associated comments are not intended to be critical, but are offered for the purpose of broadening the scope of the presentation.

A. What is meant by a "fine" safety program? Are there any comparative or correlative statistics? It would be appreciated if the author would qualify this term.

B. The author points out that one of their earliest endeavors was the preparation and distribution of a booklet being mailed to every employee. He further suggests that

this method proved to be effective in furthering the understanding of its employees who were generally interested in the subject. It is not clear to us what the author means by "effectiveness" in understanding. Was there any attempt to determine whether this understanding exists? Was there any criterion used to evaluate this understanding, or does he suggest that merely sending a booklet to interested readers will be an effective method of acquiring understanding? Furthermore, it would have been most interesting to see the contents of the training program given to the radiation worker.

C. Our own experience of appraising novel programs includes the concept of "feedback criteria" as a result of experience. The author's efforts to provide this program in compliance with A.E.C. licensing regulations, etc. does not give specifics as to what their formalized retraining effort is, and how often the changing state of the art necessitates continual revision of the basic, initial program.

The author touches lightly on the relationship of the health physics department and other departments in the Quincy Yard. The essential relationship is largely advisory in nature. It would be interesting to us to know whether this organizational relationship has proven satisfactory for production purposes, whether nuclear production activities can proceed with or without an advisory health physics group, and to what

extent an advisory group such as this can hold up production.

It would also be very interesting to learn more of the specifics on which the public relations program was evaluated as successful, and the content of the attitude training that was given to the community.

Finally, the author mentions the prospect of setting up auxiliary forces for standby purposes. We concur wholeheartedly with

this concept. In fact, we have not only trained two groups for auxiliary radiation monitors for the past year, but have had our training program recognized by the A.E.C.

In conclusion, we are indebted to Mr. Lavalette for the opportunity to discuss his paper and in a general way, the stimulus his paper has given to our own investigations.

DISCUSSION

By K. R. HOLTZINGER

Chief Health Physicist, Todd Shipyards Corp.

Mr. Lavalette, in the paper just presented, has properly emphasized the salient features concerning the establishment and day-to-day operations of a program to provide protection from the radiological hazards so recently introduced into the shipyards.

As he mentioned in his introduction, such a program basically is not the only line of defense against these hazards. Yet, when nuclear operations in a yard have progressed to the stage of initial criticality for a ship's reactor, or when a nuclear powered ship arrives for the first time to have radioactive wastes removed or to have work performed on her radioactive systems, the reviews, the recommendations, and perhaps the responsibilities of most other groups are well behind. At that time, direct responsibility for the protection of personnel and property is turned over to the shipyard's Health Physics group.

Let us summarize, from the paper just presented, the requirements which must be met to assure adequate readiness for this group to discharge its responsibilities:

1. Early establishment of a program ahead of operations.

2. Proper staffing of a new organizational component, which will be short-handed one week and over-supplied the next, with technically trained, competent personnel.

3. Orientation and training of management, supervision, employees, and probably, at least a portion of the general public in a vital field.

4. Provision of properly designed facilities,

and adequate types and quantities of instruments and equipment, most of which have no other use in the yard.

5. The preparation and approval of procedures which not only indicate how a new group will perform its own operations, but which also present new controls with required compliance by the operating group and its personnel.

6. The granting of authority over operations, under certain conditions, to other than the operating group.

There are several comments regarding the above list that are worthy of mention:

A. The cost to management to initiate and maintain such a program is expensive, as Mr. Lavalette concluded. Also, it is elaborate, as it must be to provide its service under various and varying radiological and operating conditions;

B. Not only management, but also supervision and operating employees share some of the responsibilities for radiation protection with the health physics group; the former is responsible because it must delegate the necessary authority and provide funds for the necessary staff, facilities, equipment and training. Supervision and employees are responsible because they must become familiar with these new hazards, and must cooperate with the program by following the procedures established for the safe completion of their tasks;

C. The "ambassador" role of health physics personnel, as Mr. Lavalette termed it, is enormous—not only to "sell" the pro-

gram initially, but to maintain the complete cooperation of management, supervision and employees, and

D. Outside of the technical field with which we are concerned, the requirements (and the problem areas) in establishing and maintaining an effective radiological safety program are essentially the same as those encountered in establishing and maintaining an effective general safety program in a shipyard.

Before closing, I would like to qualify the author's statement that most commercially available radiation monitoring instrumentation is unreliable. Out of context, this impression could result in a compounded mass of problems. These instruments are reliable and because of the environment in which they are used and the punishment

they must take, often an instrument may go erratic or dead on the job, or it may be found in this condition when it should be ready for use on a job. In this manner such instruments can be considered to be unreliable.

On the other hand, I am certain that the author did not mean to imply that generally speaking, properly maintained and calibrated commercial instrumentation, checked for proper operation prior to use, will not give a valid indication of the existing radiological conditions when operated by qualified monitoring personnel.

In conclusion, I might add that from the success of the author's company in the field of radiation protection, his paper could just as well have been entitled "20-20 Foresight."

STEVEDORING AND SAFETY BEFORE AND AFTER THE OPENING OF THE ST. LAWRENCE SEAWAY

By W. STANLEY HUGGETT

Vice Pres., Marine Div., North Pier Terminal Co., Chicago

This is a terrible hour for a stevedore to make a speech. He might be hung over from the night before, and 9:45 or 10:00 is too early to get well again. I prefer speaking after lunch where a few "bombs" would give me courage and additional thoughts (however, the added thoughts might not be on the subject, but most likely on matters such as girls, etc.)

I'm reminded of the story of the stevedore who was making his first speech before a group—it's on page 47 of the *Speaker's Notebook*—it's a very old story but very good. You've all heard it, I'm sure, so I'll not repeat it—just think of it and have a good laugh, because it will be the last one you'll have for the next few minutes.

Stevedoring in the Great Lakes above the St. Lawrence Seaway has been referred to as high-altitude stevedoring, or what one Master referred to as high-altitude sailing, contending that vessels were made to operate at sea-level and not to fly or operate 600 feet above sea-level.

We up here in the hills began stevedoring operations on saltwater vessels prior to 1935. The ships at that time were no longer than 258 feet, the controlling factor being the length in the locks in the old seaway. They were generally built with two hatches forward and two hatches aft; three compartments, two for cargo, one for the engine room. The holds were not deep, many of the ships did not have 'tween decks, and the gear was simple to rig because it was small.

Supervision of labor was relatively simple because four gangs was the maximum that could be used on any ship. The cargo consisted of canned goods, tagged goods and other types of general cargo, but there were no heavy lifts and relatively little steel.

When the St. Lawrence Seaway opened, allowing the larger general cargo vessels, ranging from 8,000 to 12,000 tons, to enter the Great Lakes, there were few people who had ever seen one of these vessels except in movies or on television. These few people who had seen them were in

the supervisory capacity. I would say that almost none of the laborers had seen the larger vessels. When the first ones arrived, there was a tremendous amount of confusion and almost a fear of these "monsters."

When asking men to climb down ladders into the lower hold of a C-2 the first time, they thought they were climbing down a mine shaft and they weren't happy about it. The deck forces were appalled at the height of the gear and had no idea of what to do first or second.

This was not necessarily confined to labor alone. There were many persons in the supervisory positions who were of the same opinion. I recall one of our supervisors on the first C-2 we were to handle had six gangs on board. When asked why the delay in rigging, he said he wanted a vessel's officer at each hatch while the rigging was being performed. We have no trouble of this nature anymore, but it was embarrassing for the first time to have one of our own personnel make an admission of this type.

Before the Seaway opened, there were normally two foremen on each vessel watching two gangs each. With one man to watch only 22 men, it was relatively easy to look for unsafe acts. At that time, we had safety meetings only occasionally, usually after we had had a bad accident.

With the coming of the larger ships, which can employ up to nine gangs, we have hired additional foremen and we try to have one foreman handle not more than two gangs, or at the outside three gangs. When there are more than three gangs working the ship, we place a head foreman on each vessel to work between the gang foremen and the ship's officers. This man's first duty is to fill out a form we have developed, which is a check list of the condition of the gear.

Prior to the war, most cargo was handled by hand; there were no lift trucks or pallets used, and the plumb height in the shed was no factor, so overhead guards were not used even after lift trucks were finally employed. Since the opening of the Seaway and the larger ships, safety meetings with supervisory personnel and labor officials have proven beneficial, we feel. Overhead guards on fork lifts have become a requirement, as well as safety nets be-

tween the vessel's railing and the dock, and in certain places in the vessel's hold.

I might say here that the regulations set down by the U. S. Department of Labor have a definite effect on labor management, and most important on the vessels themselves. Prior to the opening of the St. Lawrence Seaway, many vessels that plied the Great Lakes from foreign ports were not safe to work on. In our standard contract with all vessels we handle, it is required that the vessels be maintained in such a fashion as to meet all requirements set forth by the U. S. Department of Labor.

It is standard procedure that the foremen in charge of the handling of the vessel contact the chief officer, requesting permission to inspect the certificate of safety for the gear. If the vessel does not have one, then we are not required to commence work. I might say we have had no occasion to stop work for the reason so far.

We people in Chicago have been fortunate in having a supervisor from the Department of Labor who has been most helpful and cooperative. The Department has set up schools on safety and has periodic meetings, which to the best of my knowledge have been well attended. We, ourselves, are having more safety meetings than we had prior to the arrival of the larger vessels. We feel that this will eventually prove to be beneficial.

With a seven-month season here in the lakes, safety is quite a problem, particularly in that the first several weeks of the season are more or less a training period for many laborers and a rehabilitation period, or I should say, a refresher course for the men who have worked in previous years.

The largest percentage of accidents by far occur with the new men. Out of 100 accident cases which occurred under my company's supervision last year, 41 of them involved inexperienced men, and 13 were uncontrollable, these two types making up over 50 per cent of the total accidents.

During the first several weeks, we are normally working long hours, seven days a week, with no let-up, in order to alleviate the normal spring jam-up. Generally, there are not enough regular laborers to fill all the positions during this period. This means that fresh crews cannot be employed for

sense that meeting after meeting and conference after conference we should talk at such length about gear and equipment and so little about human failures. I suspect it is because it seems so difficult to do anything about the human equation.

A not uncommon stevedoring accident is one where the gear is rigged to permit the landing of beams or pontoons on the offshore deck during uncovering operations. After the hatch is uncovered the gear is not re-rigged to handle the discharge of long logs or lumber from the hold. With the booms wing and wing the long loads make for a tightline situation. The midship guy carries away under the added stress as the load crosses the onshore deck. Technically, this is a gear failure; but the cause is human failure. It is a human failure on the part of the deckmen who failed to rig properly and on the part of supervision who failed to see that the gear was re-rigged before starting the operation. Both would no doubt blame the accident on the "rotten guy" and we would discuss the failure of guys at great length at our next safety meeting. Actually, the problem is with the two legged guys called men.

Why do we keep getting more and more rules and regulations regarding gear and equipment? I think there are three reasons.

First: An accident experience in an industry is bad and the union and the employer demand that something be done to make tools and equipment safer. They pressure (or correct) what they honestly (but mistakenly) believe to be the real accident causes.

Second: Government officials respond to these demands and commission their safety people to do something about them.

Third: Since it is always easy to deal with the tangible and difficult to deal with the intangible, safety people go to town on rules and regulations concerning gear and equipment. This is only natural because here they have something they can really sink their teeth into. But is all this time and effort productive of any appreciable reduction in accident experience? Not so long as we neglect 90 per cent or better of the real accident causes.

It just seems sensible to me to find out what really causes accidents and to devote

our time and efforts to elimination of these causes that would be more commensurate with the frequencies with which they occur. I agree that gear and equipment can become lethal weapons; but why? Statistics prove conclusively that between 75 and 90 per cent of all accidents involve "human failures." Our problem seems pretty clearly defined. It seems to boil down to unsafe work practices.

Let me cite you another example of what is meant by this expression. In preparing for the safety conference we reviewed last year's accident reports. We noted that we had two reports for the same man, on the same ship, on the same day. The descriptions of the accidents were almost identical. Both reports indicated that the man was working with his back to the rail and fell overboard when his picaroon suddenly pulled free. One report said he fell between the ship and the dock and the other said he fell off the offshore side into the water.

At first we were sure that these were duplicate reports of the same accident, but the discrepancy caused us to check further. We learned that this man had been working in the morning with his back to the offshore rail and went overboard when his picaroon pulled free. He was uninjured; and after changing into dry clothes, was right back on the job. Later that day he was engaged in the same operation on the onshore side of the vessel and again had his back to the rail when the picaroon pulled free and, again, he went overboard. This time he struck a fender log and received minor injuries. They could easily have been fatal!

Although this man was a regular longshoreman, he had never received a minute's training in how to use a picaroon or how to stand while using it. He had learned bad habits in the school of experience, and these bad habits had finally caught up with him—twice in the same day!

The foreman claimed that following the first accident he told the man to pull fore and aft—not athwartship—and never to stand atop a deckload with his back to the rail. It would appear that habit had prevailed over these belated instructions.

In discussing this accident at the Governor's Safety Conference someone pointed out that habits play a large part in safety

We can either develop good or bad habits in doing any task.

By now we knew that the tools and machines used daily in our industry were also being mis-used daily. This equipment is just like atomic energy in that it can be used for our benefit or for our destruction. And just like atomic energy, how it is used rests pretty much in the hands of the man using it. The big question is how do we get men to use these things safely? Someone suggested we plaster the waterfront with posters urging the men to "Work Safely!"

The consensus was that this alone would be about as effective as a sign in a cocktail lounge admonishing the customers, "Don't sin by drinking!"

It was soon apparent to one and all that men would continue to use unsafe work methods unless trained to do otherwise. With the advent of this realization in the minds of both labor and management, our training program was born.

The union said it would provide the men to be trained if management and the government agencies would provide the training. The safety people from the industry, the state, and the U. S. Department of Labor took the ball from there. They burned the midnight oil developing an 18-hour course for longshoremen in injury avoidance. They studied accident reports in detail to determine the areas in which training was most needed. They developed charts and other visual aids to assist in making the lecture portions of the course more interesting.

They secured many good films which helped provide both motivation and instruction in safe work practices, and they developed many practical demonstrations in the safe use of tools and equipment. In short, they tailor-made a course based on the local needs as indicated by analysis of local accident statistics. They then went to the union locals and said they were ready to train longshoremen. The response was most gratifying.

On January 30th, 31st, and February 1st, the first course was held in Port Gamble, Wash. This is a small local on the Puget Sound with 36 members. All of the men turned out to take the training. Not only did they attend the 3-day, 6-hour sessions on their own time and without pay, but they also arranged for their ladies auxiliary to

provide lunch each day for the hungry staff and students. At the conclusion of the course these men were most generous in their praise and encouraged the other locals to avail themselves of the training.

Next, the instructors went to Anacortes, Washington and again experienced the enthusiastic support of that local's entire membership. From there the training team went to the port of Everett with the same result.

By now word of the course had spread throughout the state and into neighboring states on the Pacific Coast. The men began asking for training and, in some instances, even demanding it.

In May and June, classes were set up to accommodate the men in the Grays Harbor area. The Aberdeen local of Grays Harbor has a large membership. It was decided to handle no more than 30 at a time as to do so would be to reduce the effectiveness of the session. Therefore, the classes were limited to that number and a series of classes set up so everyone would have the opportunity to attend. Each series of courses was 18 hours. The men asked for 3-hour sessions at night, two nights a week, for three weeks. The set quota of 30 for each class was filled.

Training was discontinued during the summer months because of vacations. Classes are to start again this month and the remainder of the Washington ports will be trained.

As yet it is too early to measure the effectiveness of this training. We do know that it has received a tremendously favorable response from the men. We are still a little amazed to find that longshoremen, after working all day, will sit three hours at night and listen to instruction on injury avoidance. We feel that the key to this success lies in the fact that the men were convinced at the outset that this was something for their benefit. Several have stated that they would have been less likely to attend if they were offered pay because then they would have expected a management "brain-washing session." We believe that the reason we continue to get such a wonderful response is due to the word-of-mouth advertising of those who have taken the course.

We believe that by making this a joint

craft antenna-reeling motors as cargo winches. These were DC motors, and we had a rectifier converter built so as to be able to operate on 110 volts AC.

This gear model has found considerable use by stevedores wishing to work out certain hoisting problems in connection with prospective ship jobs.

Paper drinking cups were a source of needless, wasteful loss. Investigation showed that another, and better, cup, packed in a manner more advantageous to our needs, could be purchased at far less cost. In addition, each individual cup bears one of an assortment of safety slogans. Paper cup costs were drastically reduced, and a means of bringing a safety message to the men was achieved.

We had a similar experience with work gloves, which employers had traditionally provided for certain types of work. A plastic-coated glove did not stand up well under normal work use, nor did it afford a secure gripping surface. Attempts were made to launder these gloves between times of use. They usually came back from the laundry in a semi-solid ball. We found a rough, neoprene-coated glove, which offered not only a safer, better grip, but also laundered well. Cost per dozen pair of gloves was about equal, but we obtained much longer life—thus effecting a reduction in cost, while increasing the safety factor.

Without doubt, much of the successful reception of this safety training course by foremen was due to their increasing awareness that the atmosphere for accident prevention was improving as a result of top management's awakened interest and activity. All about him, a foreman was able to see real evidence of this, for perhaps the first time.

More important, committee members regained confidence in the strength of their own unified accomplishments, and this gave them courage to proceed towards larger and more important projects.

At meetings, in talks with individual members, at every opportunity, the seed of the safety training program idea was planted. All were in favor, but all were concerned with the problem of turning it into a reality. A subcommittee appointed to study this problem reported in August, 1958, that there were two alternatives: (1) by mailing a

monthly accident prevention training letter to foremen, or (2) by giving foremen personal training in Accident Prevention and First Aid. An outline of a program in support of the latter alternative was distributed to the committee, which approved the program after thorough study and discussion.

Correlated Area Accident Prevention Program

- A. Area Accident Prevention Committee
 1. Establishes basic program
 - a. Subcommittee works out details.
 2. Promotes training for foremen
 - a. Accident prevention
- B. Individual companies
 1. Integrate program into own operations
 2. Promote and support
 - a. Constant instruction of men in Foremen in Accident Prevention
 - b. Safety training for foremen
 3. Instruct job-level safety committee representatives
- C. Accident Prevention Bureau
 1. Advises area accident prevention committee
 2. Advises individual companies
 3. Provides training instruction
 4. Provides statistical data
 - a. To area accident prevention committee
 - b. To individual members

In December, 1958, the committee was given a detailed outline of a proposed training course, along with the statement that "The course content must not be at variance with the safety attitudes of management; training given to supervisory employees, which conflicts with his experience with management will defeat itself." For this basic reason, training must actually begin at top levels, so that management has the necessary knowledge, the primary interest and understanding of the importance of safety in operations and its close relationship to production. Also stated at this time, was the importance of teaching a few, simple facts, rather than attempting to cover a wide range of subject matter.

In January, 1959, it was agreed to hold a full committee meeting to review the entire course, excepting the first aid portion, which was to be the basic American National Red

Cross course. This meeting accomplished a number of things: by editing the course content, we avoided future conflicts of ideas, we added to the curriculum and aided in setting up schedules for attendance and the actual instruction of foremen.

Our first course began in March, 1959, but not without misgivings. Many times we had discussed the problem of pay for time spent. After several head-splutting meetings, the committee adopted the point of view that our supervisory personnel (foremen and superintendents) should be voluntarily interested in such a course. Management would provide the opportunity for them to take advantage of the training, which would benefit not only their job progress, but their home and family lives as well.

Quite a number of top management persons attended our first course, along with several superintendents. However, the total number of foremen in attendance was somewhat disappointing. We finished the course out, issuing first aid certificate and letters of commendation from the Area Accident Prevention Committee to each successful student.

By word of mouth, during and after our first Course, word got around among foremen that the course was not only worthwhile, but actually interesting and enjoyable! Such response was evident that the second course was started in June, 1959, in the middle of the vacation period, when you might think it would be impossible to organize anything of this kind.

The second class added to the impetus of the first, and from this time on we have found it necessary to keep a waiting list of foremen who call and ask to have their names included for the next course. Now that more than two years have passed, we often experience individual foremen approaching to ask how the training program is progressing. Then they pull out their certificate from their wallets, check the date and remark, "It'll soon be three years since I went through the course. I'm ready to take it again, whenever you let me know." It is obvious that the course filled a need for closer contact between top management and foremen.

Our Foremen's Labor Relations Committee had recognized, in the interim, that to effect a completed training program required

some plan to indoctrinate newly appointed foremen. This has resulted in a plan, accepted by the Foremen's Union and management, that all probationary foremen must attend the next regularly scheduled supervisory safety training program to complete their probation.

Part II: The Supervisory Safety Training Program

Our Course is carried on at one location, a light and well-ventilated room of good size, made available to us by one of our member companies. Except for short periods when the ship's cargo gear model is shipped to another port for instruction purposes, it is kept available in this room.

Our course consists of eight, two-hour classes, conducted one day each week. We arrange to hold classes both afternoon and evening on the same day, so that both night and day men have equal opportunity to attend. Foremen are advised that they may transfer from class to class at will, so long as they do not miss any classes.

The beginning class is the most difficult of all. At this time, many of the men are strange to each other and to us. This has eased very noticeably as word of the course became widely known. It completely disappears by the second or third session.

Informality is the keynote. Questions and answers flow freely, but the course is steered so as not to deviate too far.

We begin our course with a brief outline of the history of waterfront accident prevention on the Pacific Coast, filling in the part played, the function and the purpose of the Accident Prevention Bureau.

Next, we trace the beginning of the "Pacific Coast Marine Safety Code," a major contribution to safety in the maritime industry, which had its beginnings in 1928. Tied into this is the much more recent "Safety and Health Regulations for Longshoring," which the entire industry assisted in promulgating. This latter fact is unknown to many foremen, and the explanation makes the regulations more readily acceptable.

We discuss safety programs in general, and specifically outline their purposes and objectives.

Many persons, foremen included, confused accidents with injuries. In discussing this, we are able to illuminate the necessity for

immediate and proper investigation of the factors which lead to accidents, and their need to be recorded, so that an accurate pattern of accident sources and causes may be disclosed. This is followed by a discussion on environmental accident causes as compared with behavioristic causes, and the relative importance of each.

Since poor housekeeping contributes to a substantial number of accidents, much emphasis is placed on the need for its correction.

Fire prevention problems, mainly from personnel smoking in unauthorized places, are outlined.

Personal protective equipment is discussed in sufficient detail so as to inform foremen when the various types of respirators should be issued to the men, along with proper directions to wear them.

Using a basic approach, we spend considerable time at several intervals during our course discussing ship's gear trimming practices, both safe and unsafe, demonstrating them on our gear model. The causes and the results of excessive strains are visible to all.

So that our course remains vital, we consistently ask for class comment on each subject. This often results in good exchanges which tend to clear up misunderstandings and open the way for fresh ideas. Also, such class participation makes the course doubly interesting to each of the participants. It also improves the quality of our course.

Portions of a standard first aid course are given during each session. We require active physical participation by each class member, so that we may be certain he grasps the information clearly. We stress what *not* to do in this phase of the Course more, perhaps, than what *to* do for injured persons. We concentrate on the three life endangering conditions: stoppage of breathing, excessive bleeding and treatment to prevent or control traumatic shock.

Stress is laid upon the key position held by foremen within the management framework. He is the catalyst who converts the plans of management into actual production. Production with safety results from his ability to properly coordinate people with equipment, materials and methods. Close relations

between foremen and management are an absolute necessity, since foremen are the final link in the management chain and, as such, must be motivated and instructed to carry out the plans and policies of management.

Foremen are management's safety representatives on the job. Given the right training and the proper stimulus, foremen are a major factor in reducing the accident frequency.

As of this date, we have been able to train a large number of foremen, superintendents, port captains and others. The total approximates seventy-five per cent of the total supervisory force in our area.

With this broad and firm foundation under us, we have begun a somewhat different training approach which will continue during the next two years. This is to be based on an instructional program geared directly to each individual stevedore member company's needs and desires. I anticipate that management within these firms must participate directly in all phases of the instruction to obtain real effectiveness.

We, in the southern California area, believe in the management approach. We have already proven that management can assume leadership in accident prevention by accepting and energizing their inalienable prerogatives.

Addenda

When this paper was composed, during the first quarter of 1961, it was a fairly accurate description of the degree of progress of our area safety program.

Beginning in April, this year, two stevedore member companies initiated *operational safety meetings* with their foremen. The meetings were so-called because one of our most difficult obstacles is a tendency for operations personnel to think of safety as separate and distinct, a thing apart, and this coupling of operations with safety draws them together again, as they should be.

In May, the first two were joined by a third stevedore member company, each of which conducted excellent, business-like meetings, closely related to the normal staff meetings customarily conducted by top management to acquaint its key personnel with the company's policies, plans, decisions and purposes. Such meetings form an excellent

opportunity for management to seek the cooperation and help of its key men in problem solving. Similarly, operational problems encountered by key people can be brought to top management for guidance or solution. There is, also, the chance to air any grievances which may occur. Some of these stem from misinformation, or misunderstanding, which can be rapidly cleared away.

In June, the trend of companies towards holding their own operational safety meetings continued, with the two largest stevedore companies in the area making plans to follow suit.

This development is altering the type of safety program, followed for so long in our area where low effort level programs, without real depth or integration into operational control, has given way to a vigorous,

new program, developing out of, and directly benefiting operations.

Key to this change is the belated recognition that foremen, walking bosses and ship bosses are actually the keys to accident-free operations, which management controlled but seldom used, with the inevitable result that foremen, as a group, lacked interest in accident prevention efforts, not having been seriously charged with this responsibility in conjunction with their jobs.

Credit for a large part of the new-found recognition and regard for foremen must go to the supervisory safety training program and to the foremen themselves, who very humanly responded to the attention shown them during the course and to the knowledge that they had a responsibility to discharge.

THE LOST TIME INJURY

By CAPT. LEIF M. JONASSEN
President, Cleveland Tankers, Inc., Cleveland, Ohio

I have chosen this topic, "The Lost Time Injury," for presentation here today, not only because this is a safety conference, but because the lost time injury is a major problem confronting industry, and my company, more so today than ever before.

This is not necessarily because the lost time injury frequency is on the increase, but first, because of the humane and moral factor, and second, because of the increasing financial burden resulting therefrom. Because of this problem, we have just recently inaugurated a formal safety program in our fleet in an effort to curb the lost time injury.

The lost time injury is costly, not only because of the expense and the problems that it creates in obtaining a suitable and experienced replacement, but also the increase in expenses such as maintenance and repair, transportation, cost of defending suits, and the spiraling awards allowed by the courts over the past few years. Most of these costs have increased substantially, and because of these increases, sizable amounts are necessary to even endeavor to settle

a claim amply. More importantly, however, as already mentioned, is the humane and moral obligation that we have. None of us wants to see loss of life or limb and of course the subsequent pain and loss of earnings to the individual.

I would like to tell you what we have undertaken and are doing with the lost time injury problem. I would like to say that although we have always been safety-minded, we have never before had a formal participating safety program.

Late last year, however, we decided that something more should be done about this problem. To find a solution, we had first to determine, if possible, the type of accident causing the most injuries. We took a good look at our past experience record and found that it was not necessarily the type of accident for which we were really looking, but rather that in most cases accidents reported were those caused by carelessness on the part of the injured party. In other words, these injuries were those which probably would not have occurred if

the man had given any thought to safety or to consequences.

Men have violated a safety practice at the risk of personal injury to save time, because it was easier, or for many other reasons, including the fact that they just didn't think. We believe that the latter is predominant, although we have found that a new man in that industry unfamiliar with the operation is more apt to have an accident.

Thus, it was determined, in addition to what we could do physically to curb the lost time injury, that above all, these men needed to become safety conscious. So, how do you get a seaman to become safety conscious? We tossed this question around our organization, and although we possibly didn't find all the answers, it prompted our instituting a formal safety program and, in addition, joining the National Safety Council.

We formed a safety committee to administer the safety program with myself as an active member. It is my conviction that top management must play an active role in any safety program. It was the consensus of the members of this committee, also made up of our top operating people, that the job of making these men safety conscious was of prime importance.

I don't want to infer that we are blaming all personal injury accidents on carelessness. However, this we found was the basic fault. We are cognizant of the fact that we are in a hazardous business and that some injuries just cannot be prevented, due to the make up of the vessels and the trade in which they are engaged, and of course, the circumstances at the time. We are aware also that as management, we can eliminate to some extent, or possibly even lessen, some hazardous conditions which may have been a part of the cause of an injury in the past, or which conceivably may be a cause for an injury in the future. If we are also thoroughly convinced that a clean and tidy ship makes for a safer ship. In passing, I might add that this principle applies to any type of operation, whether it be on ship, shore or in the home.

In summary then, the purpose of our safety program was:

1. Endeavor to get the crew to become safety conscious.

2. Promote good housekeeping.
3. Promote good safety practices and habits.
4. Eliminate or possibly lessen hazardous conditions.
5. Eliminate injuries.

Secondly then, our next step was putting the safety program into effect. It was apparent that quite a selling job was required to put number one into effect—getting the crew to become safety conscious. Contests have always been popular in promoting sales, so why not in promoting safety? We were told that it works, so we decided on the contest idea. Much thought was given to the kind, how to administer it, etc., and the more ideas we got the more complicated it became. We are in the tanker business on the lakes, where most of our vessels for part of the year are laid up because of ice conditions. Further, general business conditions change so that even in the navigation season we may have vessels in lay-up.

These reasons, plus the fact that the crew, especially the officers, are rotated on vessels throughout our fleet, made it difficult to find a contest which fitted all circumstances, which was fair to all personnel, and which accomplished all of our objectives. We wanted something, too, which would continue to keep the interest of the crews throughout the year.

We finally decided to try two contests. The first was a contest for each individual vessel and was based only on the number of days without a lost-time injury. The second was a fleetwide contest and, in addition to being based on days without a lost-time injury, was based on good housekeeping and compliance with good safety practices.

To keep the interest of the crew, we had to create some incentive. So the first contest was designed so that the awards were gradually increased the longer the vessel operated without a lost-time injury. It is probably a contest which is familiar to many of you and, in essence, it worked as follows.

When a vessel, from the beginning of the season (or whenever the vessel goes into operation), has 30 continuous days without a lost-time injury, a drawing is held among the unlicensed crew and the winner

is given a \$5 gift certificate. Then twice a month thereafter, as long as the vessel operates without a lost-time injury, a drawing is held and the award increased to a total of four when the vessel has operated as such for 120 days. The drawing of four \$5 awards then continues thereafter twice a month until a lost-time injury does occur.

If an injury resulting in lost time does occur the program must start anew with 30 consecutive days without a lost-time injury being required before another drawing of one name is begun.

The licensed officers have a similar program except that the master and the chief engineer are included only in the fleet contest and the number of awards on each drawing is limited to one. The number of eligible officers (six) on board the vessel does not warrant more than one award.

Although not too much money has been involved in this contest, the comments from our crews have been very encouraging, and we think it has definitely developed safety consciousness. The results have been very gratifying. Not only have our lost-time injuries been reduced in comparison with past years, but the total reportable accidents have also been reduced.

You wouldn't think that the \$5 award would create much interest, but believe me, members of the crew are now afraid of having an injury. This, we think is good, except that it may possibly encourage a man not to report an injury. For that reason, we did not include in the contest as a element the injury which did not result in lost time. I am sure, should a man have an injury severe enough to warrant medical attention, he would not refrain from reporting and seeking the proper medical help.

The master of the vessel and the chief engineer, who could either make or break the safety program, depending on their attitude, belief and practice in safety, have a stake, too, for in the second contest, these officers are competing with officers of all other vessels in the fleet for awards which will be given toward end of the navigation season for the safest ship.

This second contest is a little different, but the purpose is the same—safety, with the intent of reducing the lost time injury. The other four objectives of our safety program come into play in this second con-

test, because we consider having no lost-time injuries as being important; but of equal importance is the elimination, as much as possible, of the physical causes of accidents. Each month each vessel is scored, first by being given points if it had no lost-time injuries, or fewer points if an injury did occur, and second, by being given points based on an inspection of the vessel.

The inspection is one that is made each month by a team made up of our marine superintendent and fleet engineer. An inspection check list has been prepared where safety practices, good housekeeping practices, Coast Guard regulations, etc., are listed. This check list has been given to all vessels where the men can be constantly reminded of what should be done on their ship. The items on the lists are not new to the officers by any means.

However, the knowledge that the check list will be used for grading purposes in the contest seems to magnify the importance of many things that at one time the men were apt to overlook as unimportant. The master, chief engineer and all other officers have been encouraged to use this list, have their own inspection and grade themselves. Although this grading by the officers is not part of the safety contest, nevertheless it emphasizes certain items which are apt to cause accidents and subsequent low scoring when inspection is made by the inspection team.

Six items from this list are checked by the inspection team and points given accordingly. The score received is added to the points received based on the number of lost-time injuries and a formula is then used giving the vessel a rating based on operating days. The formula is necessary in view of the difference in operating days by each ship at the end of the season. It is felt the vessel with the most operating days should have a slight edge over the others since it has the additional days of exposure. The vessels are given a rating sheet monthly, which is posted on all bulletin boards showing where the vessels stand in the contest. We believe this serves as an incentive for the top vessel to retain its position and the stragglers to fight for the top spot.

The awards presented to the men on the winning ship are not large. Nevertheless, these awards plus the natural desire of any man to be a part of the winning team are

incentives. Awards are given to the entire crew from the master on down. The individual awards are based on the number of days that each man served aboard the vessel. A pennant will be given to the winning ship and will be flown during the following season.

We are not giving all of the credit for our good record this year to our safety contests, but feel definitely they have played a part. We are operators of a fleet of tankers that are old in years, as such, were not equipped with the built-in safety features set by the standards of 1960-61. However, over the years we have made structural changes in these vessels in order to make them safer.

We are, as part of our safety program, doing something more at this time toward the elimination or lessening of hazards which we, as management, can do without major structural changes. We have placed more emphasis on the painting of tripping and striking hazards with Day Glo paint; installing more abrasives on slippery spots including steward, engine and deck compartments, with much emphasis put on areas around hose connections where the slightest spillage, even a few drops, could cause a slipping accident; installing additional guards and railings; having more frequent inspections and renewing, where necessary, boarding ladders, working gear, hand tools, etc.; completing the installation of a complete chemical foam and dry powder fire extinguishing system on all of our light product vessels, even though very costly and not required by any governmental regulation for vessels the age of ours; and installing improved and more adequate lighting systems.

We are also constantly bringing the subject of safety to the attention of the crews by the use of National Safety Council literature and posters. At our annual meeting, where all officers are brought into Cleveland for a mutual discussion of problems, etc., we are placing more emphasis on safety talks and safety movies to emphasize to our officers what can be done in fighting oil fires and preventing accidents. We are constantly stressing the need for prompt and complete personal injury reports and we are then following through with prompt investigation of cause, and how the injury could have been prevented. This by no means covers the entire scope of our program but does hit the high spots.

Has this safety program worked? Also, from a business standpoint, have the results achieved been worth the cost of administering it?

Well, first, there is no doubt in our mind that the safety program has resulted in making every one of our men more safety-conscious, which makes for a good start. This year with more operating days of exposure, the number of lost time injuries has decreased 22 per cent under the average for the last few years.

As to the cost of administering it, we have estimated that the total cost for this year is just a fraction of some of the awards which have been allowed by the courts for injuries we have had in the past. As to the actual dollars and cents saved, this is of course impossible to determine, however, you can't measure in dollars and cents the feeling I have personally, knowing that we are doing everything within our power to prevent an injury.

BUILDING SAFETY INTO OIL TANKERS

By ROYDEN H. ROGERS
Manager, Construction & Development Department
Esso Tankers, Inc., New York, N. Y.

I have been asked to speak about the safety factors we take into consideration during the design stages of tanker construction in order to eliminate or reduce the possibility of accidents to deck or en-

gine department crew members.

Therefore, let us separate into categories the basic features of tanker design that need to be properly engineered from the beginning if hazards are to be eliminated:

A. Hull Design—1. Structure; 2. Deck Equipment; 3. Quarters; 4. Navigation Lay-out.

B. Machinery—1. Location and Access Thereto; 2. Fire Fighting.

C. Cargo System—1. Design; 2. Venting.

We should keep in mind, however, when discussing the details that although such considerations are extremely important, they are relatively insignificant if any inherent weakness is designed into the hull of the vessel, or its main machinery plant, that could possibly result in loss of the vessel and all hands. Now, let us review the design of the vessel in detail on the basis of the outline just mentioned.

The governmental regulatory bodies and ship classification societies set the standards for hull design on the basis of many years' experience with many types and sizes of vessels operating under all conditions. Using such regulatory body regulations as a basis, we in Esso then take great care to ensure continuity of structure at termination of girders and webs, insist on use of arcs or curves in plates at transition points, use brackets constructed as arcs to eliminate so-called hard spots at their toes, and allow no brackets of any consequence to terminate in the center of plate panels.

We require more X-rays of what we consider crucial welds than do the regulatory bodies to satisfy ourselves that we have no incipient spots that might start cracks. We are strict regarding weld/riveting sequences, and take particular pains to see that no welding is done on riveted gunwale bars after riveting, or during the life of the vessel.

The classification societies require a certain number of riveted seams in the shell and deck of oil tankers but do not state their exact location, except in general terms, such as "near longitudinal bulkhead," etc. We have gone one step farther and located the required seams at carefully calculated positions on the shell and deck envelope so that any crack starting within a panel and completely severing it, but terminating at the two rivet seams bounding the panel, would leave a residual sectional modulus of such value that the remaining hull girder would not be stressed beyond the yield point in the damaged condition. We allow no shipyard to deviate

from these panel locations to facilitate erection procedures.

Now that we have done all that we can to insure the integrity of the hull structure, let us talk about auxiliary deck machinery, such as anchor windlasses, winches, steering gears, etc. We are great believers in the value of a stern anchor and I mention it here because, although it does not affect the safety of the crew directly, it does indirectly, in that it helps to prevent groundings, swinging in narrow channels, and reduces possibilities of collisions.

We also use mooring winches on all vessels from 27,000 DWT upwards to control these large vessels when moored in high winds, heavy currents, under surge conditions, etc. Lines from mooring winches are easier to handle and adjustments can be made in length of mooring lines much more safely than by manhandling lines on bits. In view of the high loading rates, often in the neighborhood of 40,000/50,000 barrels per hour, the draft of the ship varies considerably in a short period of time, and we consider a quick means of compensating for change in length of mooring line very desirable.

We consider a fast acting rudder very necessary to give maneuverability in narrow channels. We are designing our newer vessels with a rudder area 15 to 20% larger than normal, for 40° helm angles, in lieu of 35°, and for hard-over to hard-over time somewhat less than required by the classification societies. As the result of this, we have built extreme maneuverability into our vessels from 48,000 DWT and larger.

I should next like to discuss the subject of safety requirements as they pertain to layout and construction of crew's quarters. Danger from fire is one factor we always have uppermost in our minds when laying out quarters arrangements. Therefore, we keep combustible materials to a minimum and do everything possible to contain a fire once it starts. We never use combustible material for quarters' sheathing or sheathing grounds and always have at least one or more air ports in every room of an opening type for emergency access, even though not necessary from a ventilation standpoint in this day of air conditioning.

We build so-called steel fire towers in our quarters' space for vertical access. Such towers have steel boundary bulkheads and vertically they extend from the lowest deck to the boat deck. Access to the fire tower is through steel doors at each deck level. Once in the tower, a man can bypass a fire on a deck between the one he is on and the boat deck.

We never permit open stairways on our vessels, unless there is a metal door at the top or bottom of the ladder to act as a fire barrier. All semi and permanent awnings are constructed of fireproof or self-extinguishing materials and insulation used has to have such characteristics also.

Painting is kept to a minimum on newer vessels by use of self-colored bulkhead and ceiling panels. We are presently considering the use of a fire-resistant paint, where painting is required, now that such paint is available for application directly over previously painted surfaces to render them fire resistant.

We do not allow any opening-type air ports on the poop front at the upper deck level and those installed are of the fixed light type. In rooms so situated, breakout panels are installed in room doors in case a jammed door does not permit ready egress. We are presently looking into the possibility of installing room doors that overlap the jamb so that there can be no question of their jamming. No doors are permitted in the poop front bulkhead at any level. All access to the aft quarters is from doors located in recessed areas in house sides.

We firmly believe such construction reduces the chance for fire on deck or galleys from gaining entrance to what might be considered the heart of the tanker. No access is permitted to bridge 'tween-deck space from inside midship quarters. Such access is from outside only.

On our more recent construction, we have reduced the inclination of our ladders so that they more nearly approximate that of the normal house step. This has proved to be very worthwhile and has received much favorable comment. We also carefully check headroom clearances associated with ladders at angles of various degrees of slope, and use a standard diagram of clearances for such purposes, which has proved very useful. Vertical ladders are always installed continuous to a definite

step-off platform. None are ever allowed to terminate more than one step height above a suitable landing.

We are very insistent that all tripping hazards be eliminated insofar as it is physically possible to do so. We always cut down coamings in way of ladders and walkways unless required by regulatory bodies and will not allow grating runners to project above gratings transverse to line of travel. Generally, this means terminating grating runs at corners on non-skid floor plate platforms where right angle turns are necessary. Obstructions that have to be installed in line with normal passageways are painted white for quick visibility at night. All walking lines are covered with non-skid type paints whenever possible.

We are very careful to see that the scuppers do not discharge into lower decks in such a manner that water has to run across deck passageways in order to reach nearest scupper opening. In the winter, such scupper drainage water frequently freezes and presents a sheet of ice for the crew to walk across. We insist on carrying scuppers through deck and thence transversely across under overhead into nearest vertical scupper at outboard side of ship.

On our newer vessels, we have recessed all machinery casing doors that the heavy doors cannot be opened into the face of a person using the fore and aft passageways.

On practically all post-war construction, stores are handled by an electric crane, either through side ports aft opening up into a passageway providing ready access to adjacent storerooms, or by means of an electric monorail lift suspended from a structural support at fidley top level. This monorail extends from side to side of the vessel over the poop, and is so designed that stores and spares can be dropped through a hatch directly into storage spaces. With such equipment, no "make-do" skids or jury rigs are required to handle stores or equipment.

Due to the size of our 77,000 and 86,000 DWT class vessels, 835' in overall length, and 112'6" and 125' in beam, respectively, we have decided to increase wheelhouse visibility to the greatest possible extent. Under day operating conditions, a half-height folding door separating the wheelhouse from a chartroom can be folded back.

When this is done, a watch officer standing on the centerline has 310° visibility and as he moves six feet off the centerline he can look directly aft. We are also adopting the U. S. rivers system of sloping wheelhouse windows forward to reduce glare.

The various navigational and communication instruments are being installed in a console at the forward end of the wheelhouse. Under this arrangement, the watch officer has everything he needs to control his vessel in one spot, plus a practically unlimited field of vision. Over the wheelhouse doors, port and starboard, facing outboard toward the bridge wings are located a rudder angle indicator and an R.P.M. counter. These instruments are readily visible from the extreme bridge wings and enable the pilot or watch officer to confirm that his orders are being carried out. The rudder angle indicator mounted on the overhead in the wheelhouse has three faces so that it is readily visible from any position in the wheelhouse. Dial R.P.M. indicators are angle mounted overhead in the wheelhouse for quick reference from any location therein.

Having these navigation instruments readily visible from many locations on the navigating bridge deck is very important when one considers the time involved in moving 125 feet across the full width of the bridge.

For ready accessibility in an emergency, we are arranging to store the emergency lifeboat radio in the poop rather than in the midship house as formerly, so that any severe damage amidship will not result in complete loss of radio facilities aboard ship. For the same reason, we are providing for a supplemental supply of medicines to be stored aft under the control of the chief engineer.

In the case of the power plant, we do our utmost to see that safety is designed into it from the very beginning by using suitable materials, equipment of robust construction, and providing easy access to the various components thereof. Suitable ladders and gratings, floor plates, steps, platforms and properly located lifting devices are provided for as required. Headroom on ladders and over gratings is carefully reviewed to make sure clearances are adequate. For this purpose, our design group for several years has been using a diagram giving

body clearances for different slopes that has proven very satisfactory. Handrails are in at least two tiers and single handrails are seldom used, and never on any grating from which a man could fall from any height.

Rotating equipment is provided with adequate guards and hot pipes are located away from normal access, or if this is not possible, are adequately insulated so that no member of the crew can inadvertently come into contact with such pipes and suffer burns.

We take great care to see that ventilation openings and water pipes are not installed over switchboards, control equipment and generators, in order to prevent any water dripping on such vital equipment. Motor starters are arranged with door interlocks so that the power and control circuits are completely de-energized when the door is open and, also, the internal arrangement is such as to prevent personnel contacting the hot leads when working on the starter. Suitable block valves and interlocks are provided as necessary to protect engineers working on equipment from being injured accidentally by coming in contact with live steam or electric current when starting up equipment.

We are using open type chemical feed tanks with pump injection, rather than feed through a pressure tank, so that accidental blow back of chemical is not possible with boiler water treatment.

The fire fighting system is carefully designed to cover every possible contingency. On our newer vessels, we are replacing the steam smothering system for the cargo tanks with an on-deck foam system having monitors mounted at strategic locations at the after end of the forecabin, midship house, poop front and on the fore and aft walkways. On the 77,000-86,000 DWT vessels, we are installing a diesel-driven fire pump under the forecabin. With such an arrangement, any of the crew isolated forward would be able to fight fire if an explosion amidship should cut them off from the fire fighting pumps aft. To ensure that every crew member in the deck department knows how to use it, we are insisting that this equipment be used every time wash-down water is required forward.

The on-deck firemain is constructed on a loop basis with suitable cross-connection

and block valves located so they can be utilized to make the firemain intact again if they are severed by an explosion or collision. Such a system of firemain enables water, or water fog and foam, to be used on deck at one and the same time if required.

The storage room for the CO₂ bottles used in fighting fire in the pumproom and machinery spaces is ventilated by a separate natural or mechanical system and all bulkheads and doors are of gas-tight construction so that there is no possibility of gas entering the quarters in case of accidental discharge of the bottles. On our newer vessels, we are installing water fog in fight pumproom fires. This has certain advantages; for when CO₂ is used for fire protection it is necessary to provide some built-in time delay to allow all personnel to be evacuated from the space before releasing the gas.

In the case of water spray protection, this can be put into use immediately without harmful effect to anyone in the space. On our newer vessels, we are installing a series of spray nozzles to protect the poop house front with a water curtain to prevent spread of fire aft which might destroy a major portion of vessel's fire fighting capacity. At the same time, such curtain protects members of the crew assigned to use foam monitors at poop front.

On our newer constructions, we are placing the cargo discharge lines in the cargo tanks with cargo discharge riser penetrating the deck directly under the crossovers. As the size of vessels increased, we have finally reached lines 20" in diameter. With the high cargo loading rates in use today, and the need for the crew to constantly cross the lines, even on suitably designed walkway crossovers in the most inclement weather, it was decided that, from a safety point of view, a hazard could be eliminated by clearing the decks of the cargo discharge lines, on crude carriers where product contamination from any leaky joints would not be any real problem.

On our two new U. S. flag tankers, *Esso Boston* and *Esso Baltimore*, the discharge lines in the cargo tanks were not fitted with couplings but were fitted with expansion loops to eliminate the possibility of leaking joints that might contaminate cargo if the vessels were placed in clean service. The

installation of large diameter lines in the system also meant that the valves were increased in size and we have had to consider power as a means of actuating them. Such valves are too large to be operated manually, except by a major effort on the part of the deck crew which often results in wrenched backs, muscular injury, etc.

Consequently, the valves of the main cargo system in tanks and in the pump room of our latest 47,000 DWT tanker, *Esso Norway*, and of the six 77,000 DWT and six 86,000 DWT vessels under construction, are, or will be fitted with, hydraulically operated cargo valves arranged for local operation.

In our cargo pumping system we have emergency pump shut-offs located at the pumproom entrance aft, amidship on the bridge deck aft (with shut-off buttons both inside and outside house) and on the midship house front bulkhead. The stop inside the house was installed so that if access to the outside stop was impossible because of fire, or because of blowing of product from a burst loading connection, the cargo pumps could be shut off from inside the midship house, with protection given the crew member by the steel house bulkhead.

On new construction, we are interlocking the mechanical ventilation system of the midship house with the emergency cargo pump shut-offs, to further limit any possible chance of drawing oil or vapors into the midship house, in case of a broken discharge connection amidship that would spew oil and vapors over the house.

Generally, the Esso family design their vessels to operate under a closed system of loading and discharging. This means all ullage covers are closed, vapor is discharged through risers at mast heads and all ullages are taken from tapes on sealed float gauge recording devices.

There are literally hundreds of ways of promoting safety by incorporating safety features into tanker design from the beginning. I have mentioned only a few because of time limitations. All this attention to safety detail will be of no avail, however, unless crew members are made safety-minded by constant drilling on the subject. No design can overcome a lackadaisical attitude about this subject on the part of either employer or employee.

CAUSES OF CLAIMS AND THEIR EFFECT ON CLAIM COST IN VESSEL OPERATION

By EARLE SMITH

Safety Dir., Waterman Steamship Corp., Mobile, Ala.

Before we have a look at some of the causes of claims and increased claim cost in vessel operation, let us have a look at the claim consciousness of the American public today as represented by the two following incidents, which involve a relative and a friend.

One of my aunts had occasion to visit one of Mobile's modern super markets, and while shopping, she stepped on a green bean which had apparently been dropped by one of her fellow shoppers. She slipped and fell, injuring her right wrist. On visiting one of our outstanding orthopedic physicians, he was very quick to inform her of the claim possibilities of her injury, even to the point of suggesting a capable attorney.

The second incident which indicates the trend of the times involves a young man whom I had coached in football. He was driving to work early one morning and as he approached a traffic light, it changed from green to amber. When he suddenly stopped, a city bus ran into the back of his car. There was no damage to either vehicle, but he probably suffered a mild back strain. He was able to secure competent medical evidence that the injury was of such severity as to justify a sizable settlement from the city bus lines insurance carrier.

On the surface, this would seem a legitimate claim, but early in his college career, and long before this happened he suffered a very severe back injury resulting in his being placed in a plaster cast and rendering him unable to play any more football. While he had been able to lead a fairly active life, his back continued on occasions to give him trouble. However, he maintained that for sometime prior to the bus accident, his back had not bothered him at all and that the sole cause of his present condition was the bus striking the back of his car.

These two incidents, I am sure, are very

similar to experiences all of you have occasion to deal with everyday. For this reason, I should like to talk to you about causes of claims and their effect on claim costs. In other words, factors which motivate claims and thereby result in increased cost of personal injuries in connection with vessel operation.

We have found that one of the most important factors in the motivation of claims is the lack of ability on the part of a Master and/or his officers to get along with ships' personnel. Master's or department head's ability to run an efficient ship or department and to treat men under their supervision as human beings can greatly reduce claims as opposed to accidents and consequently reduce operating expenses.

Last year, one vessel in our fleet cost us only \$600.00 in claims. We attributed this almost entirely to the ability of this vessel's Master to get along with his men. He always took time to give a man a draw if he had one coming. He always saw to it that a man got proper treatment if he was injured. He also gave time off to men in their home port and granted extra shore leave in foreign ports.

Actually, his lost time record has never been good because he is very quick to knock a man off if he gets hurt. However, his claim cost record has been fantastically good. By contrast, another ship had \$13,000.00 in claims against it in the same year. The Master on this vessel always seemed to have bad luck in that he was never able to pick up a good crew (according to him).

Late one afternoon while I was sitting in his office, one of the crew came in for a draw. Although he was allowed to make the draw against his earned wages, he had to take a lot of verbal abuse from the Master because he was late in making his request. At the vessel's next port of call, the man requested a Master's certificate—received a "not fit for duty" status report from Public Health on some trumped-up

illness and was able to take some time off at our expense.

If the Master had given the man the draw and told him to have a good time, he probably would have finished the trip and we would have heard nothing from him but because he did not stop to consider the man's feelings or treat him as he would have wished to be treated himself, the company had to pay out \$720.00 it might otherwise have saved.

It seems more than a coincidence that those vessels on which the Master is concerned with the welfare of his men always wind up in the group that has the lowest claim cost.

Failure of the Master to report an accident or illness promptly to the claim department often results in increased claim cost. Many times the man is put off until a report is received from the vessel. He feels he is being deprived of something that is his due and will seek legal advice which almost invariably results in higher settlement than if the claim is settled directly with the seaman.

Failure to report *factually* has also proven to be an important factor in increased claim cost. Distortion or omission of facts which are favorable to the injured employee can only result in failure to offer proper compensation in which case he secures legal advice with invariably a resulting higher claim cost.

Of even more importance is the failure to give the claim department the facts it needs to equitably dispose of the claim. Often the question of the injury report as to whether the man was sober is filled in with a question mark. A report which says the man slipped and fell on a ladder, or was hit by a 4 x 4 which dropped into the hold, does not tell the claim department anything. Was the ladder clean and dry? Was the location adequately illuminated and were the treads and handrails in good condition? Was the 4 x 4 left in a precarious position by someone for whose actions the ship would be responsible—or was it knocked into the hold by a longshoreman, or dropped on the man by another seaman? These are the things that the claim department needs to know—and the failure of the Master to report these facts costs the company money.

Misrepresentation of facts, for example, saying that the ladder was clean and dry when it was dripping with freshly applied fish oil, also costs the company money. It does no good for the claim department to deny liability in a case like this and at the time of trial have the seaman show up with two or three witnesses and a pair of oil soaked pants to prove his point. The claim department needs to know the truth, the whole truth and nothing but the truth if it is to operate efficiently.

Poor investigation and reporting of all conditions causing the accident has contributed more to increased claim cost than any other cause. For example, an able seaman was pulling the slack out of a tent gantline prior to raising gear when the tent gantline slipped off of cleat causing him to lose his balance and fall backwards, striking the back of his head and right shoulder on a winch cylinder.

This accident was reported promptly and the report apparently was a good one, but the condition of the deck was not noted in the report nor were there any photographs taken of the accident scene. Consequently, we were unable to refute the claim of an unseaworthy condition, "Grease and oil on deck." The result was a \$30,000.00 claim loss, where a complete and proper investigation would have resulted in about a \$5,000.00 claim.

Another example, late one afternoon after securing for sea, a day man came to the chief officer and requested some liniment, saying that while driving wedges, he had struck his knee and that it was not bad, but as a precautionary measure, to keep it from getting sore, he wanted to use some liniment. Sometime later, after the voyage payoff, he requested a Master's certificate again saying the knee was O.K., but since he was getting off the vessel, he had better get the knee checked at Public Health. Our next contact with this seaman was through his attorney stating his client had a knee operation for an injury caused by his slipping in grease and oil on deck.

We were unable to refute his claims because the Mate had not examined the accident site or looked at the injured knee or tied down the cause of the accident by getting a statement signed by the seaman set-

ting forth facts as to how the accident happened.

These are only a few examples of the many such instances where the failure to establish all of the facts relative to an accident scene has resulted in increased claim costs.

A very important cause of claims and increased claim cost can be a feeling among a vessel's personnel that the company's interest in them is only for its own personal gain. This is, indeed, one of the causes we have spent a great deal of time on.

First, a great effort has been made on the part of our claim department to treat an injured or ill employee fairly—thus establishing a reputation of fair play. They try to make an employee "whole" again, i.e., where the injury is an established fact and due to the vessel's fault, the employee receives lost wages and overtime.

If there is a permanent disability and/or if an unseaworthy condition was the cause, the employee is paid an additional amount. We feel this policy has paid off since we are getting fewer and fewer claims where the claimant is represented by an attorney. One of the important reasons we have been able to follow this policy has been the insistence on the part of our operating and claim departments that all incidents be reported *promptly and factually*.

During 1959 and 1960, the vessel in our fleet that had the highest claim cost as well as the highest accident frequency was proving to be a real accident prevention problem, in that the answer was not apparent as to just what we could do to help them attain a better record.

One week-end late in 1960 an emergency arose and it was my duty to sail a vessel. Shortly before sailing, the bos'n and the ship's delegate came to me and reported the cat walk over the after deck load was not properly secured. Inspection verified their report and the Master, as well as the traffic department, were informed the ship would not sail until the cat walk was properly secured.

When the vessel next called in Mobile, the bos'n and ship delegate met me and took me to the crew's mess where they showed me a bulletin board they had made indicating the number of days by department, since the last lost time case. They

also informed me that in the future, they would do everything possible to promote safety among the unlicensed personnel and that they were going to strive to make their ship the safest in the fleet.

To date, there have been no lost time cases and less than \$2,000.00 in claims on the vessel.

This is an example of how claims can be reduced and accidents prevented when seamen feel you are not only interested in their welfare, but are willing to do something about it.

Failure to join a vessel by a seaman quite frequently results in a claim. Since one of the few acceptable excuses to avoid a fine by the Union is a "Not Fit For Duty" slip because of an injury or illness, the seaman will make sure he has such an excuse. On one such occasion, a seaman was injured while wrestling in a local bar. This, plus an over-consumption of alcoholic beverages, caused him to miss the vessel at sailing time. The next morning he promptly reported to Public Health and secured a "Not Fit For Duty" slip for a back injury which he had reported on the vessel some two weeks prior to his failing to join, but which had not caused him any disability up to this time.

Another example of failure to join, which increases claim cost even more is when the seaman is on foreign articles. Recently, one of our vessels sailed from New Orleans and an A.B. failed to join. Some several months later, he appeared in our claim department with information showing that his reason for failing to join was an automobile wreck in which he had been quite severely injured and was hospitalized for an extended period of time.

Our investigation revealed that he had been on a frog gizzing expedition near his home in Mississippi and on the way back to the vessel, the car in which he was riding became involved in a wreck—thus we were responsible for his wages to the end of the voyage as well as his maintenance and care until he received a "Fit For Duty" status.

Lack of transportation rights as a claim cause is a constant problem since an injured or ill seaman always has transportation rights back to the port he joined. Recently, we had a vessel pay off in a gulf

port where the voyage began. Several of the seamen on this vessel had joined on the West Coast, so that when the vessel paid off they had no transportation rights back to the port they joined.

Consequently, these seamen all asked for Master's certificates since they wanted not to return to the West Coast but to collect the transportation in cash due them under the contract. Five of them were successful in getting "Not Fit For Duty" status from Public Health on such vague representation that they had coughed up blood or had black-out spells.

If the Master had not been alert to the situation and reported to the claim department, these men would have collected transportation. As it was, transportation was denied until we got a definite diagnosis from public health, and only one ever received any subsequent treatment.

In summation, the controllable factors which are causing claims and increased claim costs are:

- (1) Failure of the Master or department head to get along with vessel personnel.
- (2) Failure to promptly, correctly and completely report an accident or illness.

- (3) Failure to create a feeling among personnel that the company is interested in their welfare.

- (4) Failure to promptly and properly investigate accidents.

The final analysis of these controllable factors causing claims and increased claim costs clearly indicates that *better personnel relations* is of paramount importance in the prevention and control of claims. There is a further indication that better personnel relations will be of aid in controlling "Failure to join," and "Lack of Transportation" types of claims.

Finally, the cost of personal injuries in connection with vessel operation may be more adequately controlled with:

- (1) A well rounded joint labor management accident prevention effort.
- (2) Good employee relations.
- (3) Prompt and factual reporting of accidents.
- (4) Prompt and proper investigation of accidents.
- (5) Prompt and fair handling of legitimate claims.

THIS IS A SAFE SHIP

By H. C. ELLIS

Manager, West Coast Division, Marine Transportation Department
Socony Mobil Oil Company, Inc.

One of the reasons I am talking with you today, I feel quite sure, is because someone aboard our ships in our small West Coast tanker fleet took us seriously.

Many years ago we instituted a formal safety program aboard our ships, and part of the culmination of this program is the fact that last year we placed first in the National Safety Council Tanker Section Safety Contest with a record of no lost time accidents. This fact, I feel, helped contribute to the request that I present a paper here today.

This accomplishment has given me a great deal of personal pride and satisfaction, not so much because our ships took first place,

but because I know that through the hard work of everyone concerned—no one aboard our ships was seriously hurt last year. Of course, we had the usual run of minor burns, something in the eye, and slips and falls. No one, however, was hurt seriously enough to lose time from the job. We thereby avoided a lot of pain and suffering, as well as cost, that goes along with lost-time accidents.

Needless to say, a lot of effort has been made to try and keep the slogan, "This Is a Safe Ship," a true statement of fact. This message, in various ways, is imparted to every crew member who comes aboard our ships. It also serves as a reminder to the

regular crew. This is accomplished in many ways, and I'd like to tell you about some of the things we do and some of the things that have happened to us.

As on many other ships, a regular monthly safety meeting is held by the officers to discuss and argue out any safety problems that have arisen and to keep continuously in front of all concerned the fact that we have an official safety program and are vitally interested to see that its purpose is accomplished.

One of the most successful aspects of our program is that from time to time informal safety meetings are held by the unlicensed crew, usually supervised by an officer, in which again our safety program is brought to the fore. Occasionally attention is called to infractions of our safety rules. When this happens the infraction is discussed, and we always make sure that the correct way of doing the job is explained and demonstrated.

You might think that these meetings of the unlicensed people would turn into "bull sessions," but we have found this not to be the case. We are of the opinion that the men actually doing the physical work can make or break our safety records, and this is where we endeavor to concentrate our efforts.

We have found that this generates a considerable amount of "esprit de corps" when it comes to safety aboard our ships. For example, several years ago one of our stewards came aboard his ship in Seattle, and, in proceeding along the deck to his room amidships, ducked underneath the loading/discharge hoses at the manifold, lost his balance, fell overboard and landed on the dock. He was seriously injured and lost a leg as a result of it.

While this was not a matter for levity, the captain nevertheless later said to me, "You can't charge us with a lost-time accident when the steward fell off the ship. He was all right when he left the ship. He wasn't hurt until he hit the dock." Needless to say, his ship was charged with a lost-time accident. We have since prohibited this practice and installed an access ladder from the deck to the catwalk amidships.

There is another area of management that we think can be used with success to help improve or keep your safety record. We try

our best to see that men returning from leave or vacation are re-assigned to their old ship. This contributes to morale and helps the men keep an interest in their work and accomplishments they have achieved aboard their ship. We have also found that this pays off in helping to keep a tight, well-run ship. With a tight, well-run ship you have not only economy in operations, but you have economy in maintenance as well.

Why should a first assistant overhaul a valve he has just removed from a pipeline just so some new first can use it when he comes aboard and doesn't have to do the work? Why should a chief mate paint over the side just so his successor can take the credit for it later when the port captain from the home office comes aboard?

We feel that as a result of their lack of interest, which is understandable, the company suffers and in the pocketbook, too! Shipyard bills go up and the feeling of the men is that "What the hell, why should I knock myself out, I'm not coming back here after vacation!" This attitude also generates carelessness and the first thing you know the accident record takes an upward spiral.

Coming back to your old ship is like coming home. You know where everything is, how to take this corner slow, and how to duck here. You can even find your way around in the dark sometimes if necessary.

Picture what could happen when you go aboard a strange or unfamiliar ship. A wiper could fall down a ladder because "they didn't have one in the same place aboard my last ship." A cook gets his fingers mashed in the galley door because "there was a door closer on the last ship I was on."

We are all strained and ill at ease in strange or unfamiliar places, and being so, we think, helps make for accidents. So we try to make every effort to see that each member of the crew when he returns to work is put into familiar and safe working places and living quarters—his old ship.

One of the unions on the West Coast has made it a practice, in order to spread the work and jobs, to rotate their men on the ships every seven months. This means that at the end of a seven-month period, a man has to get off and make room for another union member. You can imagine how this affects a safety program. There just isn't

any! We are not placing any blame on the union; they have their problems, just like we in management, but it's too bad that such a thing has to be.

This is an area where management could and should try and work something out to make sure employees are kept aboard for longer periods of time, say at least two years, so that the men would have the opportunity of developing safe work methods and habits the way the company feels they should. This is for the men's protection and could certainly save some grief and misery.

As you all know, no matter how hard you preach and hammer away on safety, sometimes a bad accident happens and is difficult to explain. We had one in 1959. One of our ships left her moorings at a submarine line up the coast from Los Angeles at 7:45 one night, headed for San Pedro. The ship was about 2 miles off at full speed when the third mate reported he heard a faint cry for help. The ship immediately was turned around and steered on a reciprocal course.

It was then discovered the Bos'n was missing and was presumed lost overboard. The mooring launch at the submarine line terminal was asked by telephone to help in the search and the Coast Guard was notified by radio. The launch and a plane from the Coast Guard immediately set out. However, over two hours later the body was sighted floating face down in the water by the ship's lookout. The body was recovered, and, although artificial respiration and oxygen were applied for over an hour, the ship's crew was unable to revive the Bos'n. A doctor later attributed his death to drowning.

Our investigation of what happened could only determine that upon securing all the mooring lines and gear after sailing, the Bos'n dismissed his gang and was last seen going aft toward the fantail. Earlier in the day he had a couple of sailors move a large, full trash can from under the fo'c'sle head to the fantail to be emptied after leaving the moorings. His cap and bits of trash were found next to the railing on the port side and laying on some of the lines that had been used at the submarine moorings. The large trash can was missing. We can only presume that he fell overboard in attempting to empty the can. Fortunately, he had no wife or children.

Now, here is one of those unexplainable accidents that we mentioned. We don't mean the accident itself, but why and how did it come about. We can't explain it. Here was a very capable and experienced seaman. He had gone to sea for us for 15 years and had been Bos'n for 13 years. He had never had a really serious accident before, yet he violated two basic safety rules that we know of, maybe more. The first one is "Don't rely on Do It Yourself, get help if you need it." It goes without saying that if it took two men to move the trash can, it certainly would take two men to empty it.

The other rule or regulation violated was that it was apparent he had tried to empty the can over the railing, possibly standing on a bit while doing it (his cap was found next to the bit) instead of using the trash chute provided on the railing on the stern. Another rule he might have violated is "One hand for yourself—one for the ship" in doing any precarious job. We feel that if he had followed this rule he might have saved himself when he lost his balance.

Why did this experienced seaman fail to follow these rules after all the safety meetings he had been in and all the demonstrations and instructions in safety he had given to new men under him? This is why we say that sometimes accidents are unexplainable. Maybe we all can learn a lesson from this that no matter how experienced you are and how much you know, no one should take safe working habits and practices for granted.

And then, there are the thoughtless people who know better, but just didn't think. We recall the case awhile back of a cook telling another cook that when grinding meat in the meat grinder to always use the wooden tamper to press the meat into the grinder and not to use fingers "like this." He then proceeded to push the meat into the grinder with his fingers and promptly got the tip of them cut off! What can you do about a person like this? We think he learned his lesson the hard way!

Another and very pertinent part of our safety program can be likened to one of the slogans by the National Safety Council, under whose auspices we are meeting here today, in connection with their drive on automobile accidents and deaths—"Drive Defensively." Our men are urged to "Work Defensively." Don't rely on an accident not

happening because all the mechanical safeguards are provided for a given job or because your fellow worker is experienced and trained to work safely. Our men are urged to discover potentially dangerous conditions and work methods and correct them *before* we have to analyze an accident to see what went wrong. Yet, despite all this, a serious accident occurred that is a good example of not "Working Defensively."

A fireman was instructed by the second assistant engineer to renew the packing on the steam valve on the soot blower line in back of the port boiler, a job he had done before and with which he was familiar. He apparently had difficulty in removing the packing after removing the packing gland and decided to remove the bonnet in order to complete the job. He claimed he opened and closed the valve two or three times to see if there was any pressure on the line and decided it was safe to remove the bonnet. He then slacked off the four bolts of the valve bonnet and turned the valve wheel to break the joint. The bonnet blew off, and the man was scalded by steam about the chest, arms, neck and face. This caused him to fall from the grating where he was working to the floor plates, a distance of about ten feet, breaking his left leg.

Why didn't he check to make sure steam was off the line and that the drains were open before doing the job? We feel that he didn't "Work Defensively"! All the safeguards were there, and he was well trained. Somewhere in his safety education the "Work Defensively" attitude was missed. Somewhere we missed!

I'd now like to quote to you an excerpt from a talk given by our port captain in 1959 before the annual Western Oil & Gas Association Regional Safety Conference in Long Beach, California, which we believe pretty well hits the nail on the head in summing up our attitude toward a good and efficient safety program:

"I believe we should all be reminded that safety aboard ship is the day-to-day constant supervision to correct, educate, to show, and to explain. Chip away at carelessness, negligence and foolhardiness, little by little, until you have a reasonable amount of safety."

"The problem is to find some way to remind the men of the established safety procedures. These procedures are not the whim of the people who suggest them, but the result of a detailed analysis of accidents that have occurred and the best way to prevent them in the future."

"The methods of reminding men of safe practices are many and varied. You can literally kick a man when he violates a rule of safety, but this obviously is not good motivation. The most practical way is repetition. You remind the men at every occasion, by sign, by word of mouth, commendation, and by every means of communication known to man. And then you Repeat, Repeat, Repeat and Repeat. Time is not a factor when it comes to promoting safety."

"When you have done all this and continue to do it, we believe you can then go aboard one of your ships and say with a great deal of satisfaction and pride—"This is a safe ship."

SAFETY CONTROL — NS SAVANNAH

By CAPT. GASTON R. DeGROOTE
Master, NS Savannah, States Marine Lines, Inc., Camden, N. J.

I have great respect for the accomplishments of the National Safety Council—particularly in the maritime field. As a ship's master, I know first hand the importance of what the Council is doing to encourage safe practices and prevent accidents. Your sponsorship of this panel to-

day is an outstanding example of your desire to probe deeply into this vital subject.

The papers committee has asked me to speak on the nuclear ship *Savannah*, of which I have the privilege to serve as master. States Marine Lines considers it a great honor to have been appointed as general

agent for the government in operation of this vessel, the world's first nuclear powered merchant ship. As you may know, she is now undergoing final tests and systems checkout in Camden, N. J., and will shortly receive her first loading of nuclear fuel.

By way of introduction may I point out that this paper must—of necessity—take a somewhat different approach to the subject of safety than that followed by your past speakers.

For example, it would be superfluous to discuss here the conventional safety features of the *NS Savannah*, which are similar to those found in any modern vessel built in the United States. I will also limit references to radiation safety measures—designed to protect the health and well being of personnel. Although this would be a logical topic to include in any discussion of the *Savannah*, there is a more detailed paper covering that field already on your agenda.

Instead, my discussion will deal with safety as demonstrated—first, in the construction of the *Savannah's* nuclear system, and second, in the controls which assure safe operation of the reactor plant. My remarks will be of a semi-technical nature rather than a presentation of safety ideas or results.

It should be noted at this point that the systems I shall describe were determined to be necessary, not just for this type of reactor, but for this specific reactor, installed in the *Savannah*. Different reactor types that may be used in future ships may or may not require these particular safeguards. Similarly, advanced concepts of the pressurized water reactor itself could call for completely different methods.

It should also be noted that in this project the Government has an active upgrading program in continuous operation, whereby we hope to simplify equipment and controls as much as possible. I should probably emphasize at this point that in addition to safety instrumentation, the *Savannah* is equipped with a number of control systems that serve other purposes, such as automatic operation.

The *NS Savannah* is a single screw passenger cargo vessel of advanced design. Her length overall is 595 feet 6 inches; her beam, 78 feet. She will draw 29 feet 6 inches, loaded. Her displacement is 22,000

tons, and her cruising speed is 20 knots. Maximum shaft horsepower is 22,000. There are accommodations for sixty passengers, who will also have the use of attractive dining and recreation facilities including a swimming pool. The *Savannah* will require a crew of about 110. Some 9400 tons of cargo can be carried in her seven cargo holds.

Approximately amidships, abaft of No. 4 hold, is the reactor compartment. The nuclear reactor is the heart of the *Savannah's* propulsion system—it can take her 14 times around the world without refueling. The world's fossil fuels—oil, coal and gas—are ample for years to come, but are not inexhaustible. So we look to the atom for a new kind of fuel to meet future needs. In merchant shipping the prospect of nuclear power is extremely attractive because cargo capacity can be increased by eliminating the need for storing a large fuel supply.

It is important to point out that the *Savannah* is not expected to be economical at this time as compared to conventional ships. Instead, its purpose is to demonstrate to the world that the force of the atom can be harnessed and put to peaceful use for the benefit of all mankind. Also, to allow American steamship companies to observe the possibilities of nuclear power for future vessels, and thus to foster the growth of our American Merchant Marine.

Now let us look at the *Savannah's* nuclear plant. As you are already aware, I am sure, the reactor generates heat—which raises steam to run the turbine. Fuel is placed in the core of the reactor in a unit consisting of pellets of enriched uranium oxide encased in stainless steel tubes. A controlled nuclear reaction takes place, causing tremendous heat. Water is circulated around the hot fuel, carrying heat to a secondary water system in a heat exchanger. This secondary water supply, converted into steam, drives the turbine.

The reaction is controlled by twenty-one boron stainless steel control rods. When the reactor is shut down, all the rods are fully in place within the core, and neutrons released by the fuel are absorbed by these rods. When the plant is started up these control rods are withdrawn, singly or in groups, and the number of neutrons available to split the atoms in the uranium is increased.

The *Savannah's* reactor system was designed and constructed with safety as a paramount consideration. Under no circumstances will passengers or operating personnel be exposed to dangerous, uncontrolled radiation. Operation of the ship will not adversely affect any environment in which it is located. The nuclear plant will be completely protected from any possible damage due to ship movements, at sea or in port. With this in mind, we first observe that the reactor core—where nuclear fission takes place—is sealed within a carbon steel pressure vessel with a wall 6½ inches thick, clad internally with stainless steel. This vessel is approximately 27 feet long and 8.2 feet in diameter.

The pressure vessel, in turn, is enclosed by primary shielding which consists of a steel and lead tank filled with water.

Next, there is a steel containment vessel which surrounds not only the core, the pressure vessel and its primary shield tank, but also most of the associated reactor systems, such as heat exchangers, pressurizer, pumps and related valves. This containment vessel is a structure 50 feet long and 35 feet in diameter.

In addition, the ship's hull is specifically designed to protect the containment vessel against damage from collision.

An egg crate structure of steel on the bottom protects the *Savannah* from being pierced through grounding.

A concrete wall four feet thick holds the containment vessel firmly in place, and also serves as the secondary shield. As a further cushion against any possible damage, there is a special resilient collision mat which lines the sides of the compartment in which the containment vessel is located. It consists of alternate layers of redwood and steel, and is two feet thick.

There are sway brackets, designed to support the containment vessel in the event that the ship is rolling or pitching. This possibility has been further dealt with by installing the latest type stabilizers which function to reduce the "roll" of the ship.

The upper portion of the containment vessel is provided with extra protection by an envelope of lead and polyethylene. Finally, the base of the compartment has an insulating water shield.

This adds up to approximately 2400 tons of steel, lead, concrete and polyethylene which shield the containment vessel—and the reactor plant—from any possible damage.

Needless to say, the designers rightly feel that more than adequate safeguards have been built into the *Savannah*. Indeed, it will be one of the safest vessels afloat.

A complex system of instruments constantly monitors reactor performance, as well as operation of the pressurizer, pumps and other parts of the plant. These instruments transmit signals to a main control panel, and also to the automatic safety and control systems.

The safety system is designed so that, if conditions develop which could be hazardous to the reactor or to personnel, the reactor will immediately and automatically shut down. To do this, all control rods which have been withdrawn are returned to their original position in the core, instantly stopping the fission process. At the same time there also are visible and audible alarms.

This automatic shut down is accomplished by either of two methods, depending upon the type of emergency—one called scramming and the other called fast insertion.

In a scram action, it takes only 8/10 of a second for hydraulic actuators to insert all withdrawn rods into the core.

In the case of fast insertion, electric drives are used, taking a maximum of about 4 minutes.

Either a fast insertion or a scram signal over-rides all control signals, manual or automatic. Once a scram is initiated it cannot be stopped by the operator. Fast insertion can be stopped by the operator by means of an over-ride switch on the control console. A manually operated switch also permits the operator to cause a scram at any time.

There are two alarm panels and two amplifiers. All scram signals enter these panels. From there they are applied to safety amplifiers which trip and release the scram action in the control rod system.

Now what are the conditions in the reactor plant which will activate the safety system for automatic shut down? One condition would be an abnormal nuclear level

—another condition could be non-nuclear, such as abnormal temperatures, pressures, and flow rates—items familiar to us in conventional marine power plants.

Nuclear conditions in the reactor are measured continuously by 10 measuring channels which cover the entire neutron flux range of the reactor. These channels receive their signals from 10 neutron detectors located in vertical wells around the shield tank of the reactor. There are at least three detectors for each of three power ranges—start up, intermediate, and operating power. Therefore, situations which would lead to an unsafe condition in the reactor at any power range are always monitored by at least three detectors and at times by seven detectors.

During plant start up, an unsafe condition—measured by any one of four detectors—will scram the reactor. In the intermediate and power ranges, at least two detectors must signal an unsafe condition before a scram is initiated. This guards against shut down caused by instrument failures, but still provides for maximum reliability and safety.

In addition to nuclear protection, the power plant is also instrumented to prevent unsafe conditions of a non-nuclear nature. This non-nuclear instrumentation is a network of standard reliable indicators, controllers, and equipment to provide information and to control the primary, secondary, auxiliary, propulsion, and ship services systems. The basis for design of the non-nuclear instrumentation is two fold: a) simplicity, and b) fail safe—that is, to fail to the more favorable non-operating condition upon failure. Also, alarms are provided to indicate equipment or instrument conditions which would place the plant in an undesired operating condition.

Of course, the containment which encloses the nuclear portion of the plant must contain penetrations of piping and instrumentation cables. To keep these penetrations at a minimum we have converted many of our pneumatic controls to electrical, using multi-conductor cables for penetration, then reconverting to pneumatic control at the main control console. Thus, it is possible to have the more rapid response of a pneumatic system, and still maintain integrity of the containment design.

Both the nuclear and non-nuclear characteristics of the *NS Savannah*, therefore, take into account all the possible consequences of nuclear power plant operation and operator error. This design and the built-in safety features have been reviewed by at least six independent organizations, including government agencies and independent nuclear engineering consulting firms, during the construction and testing phases. Therefore, the *NS Savannah* incorporates the latest and most reliable safety features known to the nuclear and conventional power industries today.

I have just described for you the safety system and related instruments of the nuclear ship *Savannah*. Because a nuclear reactor, like a conventional plant, requires skillful operation by well trained personnel, I would like to mention in conclusion the training participated in by her deck and engineering officers.

The 21 engineering officers, all hand picked by States Marine Lines, began their training in September, 1958. This group successfully completed a fifteen month course at Lynchburg College and in the field at such sites as Hanford, Washington; San Jose, California; and Idaho Falls, Idaho. Simulator training at Lynchburg in the summer of 1960 completed the field training. Following this training these officers joined the vessel at Camden where they are participating in equipment testing as the machinery is installed. In addition to being licensed by the United States Coast Guard as marine engineers, these men also successfully passed the reactor operators' two day written test required by the Atomic Energy Commission.

Six deck officers, all holding masters licenses, were selected to participate in training for the *Savannah*. Although this course was in less detail than that undertaken by the engineers, it was designed to provide a good appreciation and understanding of the limitations of the reactor.

It included schooling at Lynchburg and training at Argonne National Laboratory, Chicago; Taft Engineering Center, Cincinnati, Ohio; and the Damage Control School at Philadelphia, conducted by the United States Navy. After completing this twelve month course, the master, chief officer and second officer were selected.

The *Savannah*, in addition to being equipped with the latest safety control devices, will be manned by the best trained personnel to be found on any merchant vessel in the world.

Speaking in their behalf, and in behalf of States Marine Lines, I wish to ask for your continued interest in the *NS Savannah* as she takes her place in the American merchant marine.

A P. & I. UNDERWRITER'S PART IN MARITIME SAFETY

By JOSEPH E. DOTI
Vice President, Marine Office of America

For the benefit of any who may not be familiar with marine insurance terminology, I would like to explain that "P. & I." in the subject of this talk, stands for "protection and indemnity." P. & I. insurance is a form of marine insurance which shipowners carry to protect themselves against various legal liabilities arising out of the operation of their vessels including claims for loss of life, injury and illness of seamen, passengers, longshoremen and other third parties; loss of and damage to cargo and damage to docks, bridges or other property. However, the Marine Office of America has expanded the traditional "protection" concept to bring it up to date by providing extensive services to our assureds on behalf of Maritime Safety, through its Division, the United States P. & I. Agency.

Our Company became a leading pioneer in the cause of Maritime Safety more than thirty years ago, at a time when the movement was still in its infancy. Although a substantial proportion of American industry already had committed itself at that time to the doctrine of safer operation, the movement had made little progress among the seafaring community.

There were various reasons for this—first and foremost, was the fact that sailors generally are conservative men by nature. That is, they are conservative in their opinions and ideas but not always in their conduct. They are inclined to view innovation with skepticism and change with caution. Generally, they take pride in their profession, particularly in its virility and the capacity it generates to endure hardship and danger. Consequently, there was re-

sistance to a movement which preached care and caution, as being too "sissified" for hard-boiled seamen.

Shipowners, in general, reflected these views of their men. In addition, they were confronted with the inevitable obstacle of costs. Setting up a Safety program and providing trained personnel to operate it cost a considerable sum—even in the Thirties. While it was urged that the expense would be small in comparison with the benefits derived, the fact remained that costs would be immediate and specific but benefits slow in appearing. Many of them, though real and important, necessarily fall into the category of intangibles.

Still another difficulty was an apprehension that the Safety program might breed legal difficulties. Some of the more conservative legal advisers of shipowners were worried that any record of a ship's deficiencies—actual or suggested—might provide a damaging background in the event of litigation over personal injuries or property damage, claimed to have resulted from such shortcomings.

Another concern was that some shipowners felt that Safety Meetings, even those limited to officers—might encourage criticism of working practices and working conditions and develop influences which would tend to undermine discipline on board ship. Some shipowners saw this as a very real hazard.

In spite of great resistance, our Agency as then represented by its recent former President, Edward C. Holden, Jr. (whom most of you know well) persevered in persuading our Assureds to embark on

such new course. Progress was slow but steady. By the end of that decade, many companies had established safety departments and programs in their organizations.

Then came World War II which dealt a severe blow to marine safety. With men dying all over the Seven Seas, there was little opportunity to strive for safe working practices and conditions but at the end of the War, interest was not long in reviving. For one thing, shoreside industry had made great strides in safer operations. The safety movement there had not been impaired seriously by the War. The effect of this shoreside safety progress now carried over into the maritime industry and the ground lost during the War was regained quite quickly.

Within a comparatively short time, no large company operating ocean-going ships could afford to operate without a safety department. Smaller companies soon were following suit. Our own Safety Department increased in activity and size. I might mention here that this renewed interest in maritime safety was pretty well confined to ocean-going tonnage for some years. In the past few years, however, the inland operators have been making impressive strides in catching up.

Results of the revival in marine safety interest have been impressive, as shown by the Safety records of the leading shipping companies, and there can be no question but that the maritime industry has accomplished significant safety progress during the period since the end of World War II.

We like to think that the part played by our Company in this advance has been constructive and significant. A glance at the activities of our Safety Department gives an idea of what an underwriter can contribute to the cause.

SAFETY INSPECTIONS

For one thing, at the invitation of our Assureds, our Safety Inspectors try to visit their vessels and conduct Safety Inspections at reasonable intervals. Ocean-going vessels are usually inspected at New York, New Orleans or San Francisco and inland craft at these and various other ports including Houston and Chicago. On each such visit, the vessel is inspected for Safety hazards in company with ships' departmental heads,

when available—and often with Safety representatives of the shore establishment.

What do our Safety Inspectors look for on their ship inspections? Certain basic conditions are familiar to all ship inspectors—defects on ships which, like original sin, have been with us since time immemorial. I refer to things like unsafe gangways, rickety ladders, missing handrails, bad lighting, cluttered decks, home-made benches, jumbled storerooms and similar items of bad housekeeping. However, as Underwriter's representatives, our Safety Inspectors are in a position to compare ships of many different lines and thereby gain a range of experience considerably greater than that available to the average owner's representative.

Thus, when a new product is being widely accepted in the industry and suddenly reflects a new hazard, our men are able to look for trouble on all ships equipped with the product without waiting for each shipowner to learn the hard way by suffering similar casualties separately. If old equipment that is common to many ships of about the same age suddenly starts giving way in unexpected places, our people get the word quickly and not only pass it along but are alerted as to what to look for on their inspections.

Synthetic mooring lines and stoppers are examples of new products with new hazards, where our experience has been of value to some of our Assureds. As another instance some of our Companies began using a new soogey compound which they did not know had an acid base. It worked fine, as it was an excellent cleanser, until on one ship a new manila gantline was made up and the forward face of the bridge was soogied down. Some of the soogey inadvertently got on the gantline, as it usually does. When the soogeying was finished, the gantline was coiled up and hung in the forepeak. Two months later, still looking brand new, it was broken out and rigged with a bosn's chair to paint the stack. A seaman was hauled up and had just made himself fast when the line parted, dropping him to the deck 40 feet below. Investigation revealed that the inside of the line was completely rotted. The result—a permanently injured seaman and a claim that cost the shipowner in excess of \$60,000.00.

On another ship, the booms were soogied, the guylines triced up against them, and when the booms were raised and a strain taken on the guylines, they all parted promptly. On a third vessel, a manila mooring line was coiled near a bulkhead that had been soogied. When the line was used next time, it gave way as soon as a strain came on it.

Speaking of chemicals commonly used on board ship, a not infrequent cause of bad race and eye burns has been the partially open can of lye or other bowl cleanser left on a shelf and ready to fall or to "spit" into the face and eyes and even to blind the next luckless user because of built-up pressure.

Old equipment is even more guilty than new in presenting hazards. Wastage of material and objects in the less accessible places—inside of objects and underneath painted or protected places—is something that our Safety Inspectors are particularly alert to detect.

A few years ago we had a rash of injuries to longshoremen when runners whipped out of runner guides because the guides were rusting loose or were excessively worn on one side or had been knocked out of alignment. Minute, careful inspection was required to detect these faults but it was found that the condition was quite general and that many guides were being held in place by only a fraction of the original metal.

Many stewards and galley personnel cover sebox gratings with plastic-sprayed cardboard runners. These are dangerous as tripping hazards and also, as slipping hazards. Sometimes they conceal a further hazard arising from a broken or missing section of the grating. We had two nasty ankle fracture claims as a result of such missing grating boards where the space was covered by cardboard. In new construction, lightweight aluminum gratings, which give better traction than the old wooden ones, are being introduced.

Other items for which our Safety Inspectors have learned to keep wary eyes, include square cornered stack hooks which have carried away at the corners in the past because of metal fatigue—rounded stack hooks are much safer; welded hold ladder rungs which crystallize when struck

repeatedly by cargo drails and may drop a seaman or longshoreman into the hold; inoperable fire dampers, frozen by rust or paint; lack of identification plates on valves, lines, etc.; missing warning signs around switchboards, overhead obstructions, "No Smoking" areas, etc.; and the absence of Safety color code painting on deck obstructions and other tripping hazards.

Reports of inspections, listing deficiencies with recommendations for correction, are promptly submitted to the Assureds who usually forward copies to the Master of the ship concerned. Should the shipowner so prefer, written reports are omitted and our Safety Inspectors report directly to Assureds' representatives. In any event, it is understood by all that our recommendations are merely suggestions. We have neither desire nor authority to force our attention on any assured who does not wish to avail himself of our Safety services.

Sometimes for one reason or another, the recommendations of our Safety men are not carried out—at least, not carried out promptly. For example, when one of our Inspectors noticed that only a single line was rigged around the top accommodation ladder platform, leaving an open gap of about three feet between the line and the platform, he recommended that a double line be installed. Somebody "did not get the word" and nothing was done. On the very next voyage, when the vessel returned to the same port, a seaman coming back at night fell from the top gangway platform to the pier below and was crippled for life. No one knew exactly what had caused the man to fall but from the start his lawsuit alleged "failure to provide double hand lines"—the inevitable result: \$75,000.00 payment.

More recently, one of our Safety Inspectors recommended that open manholes in the resistor houses be kept covered in port, that signs to this effect be stenciled inside the covers, and that the covers be painted white. A few weeks later, an electrician stepped into an open manhole in the resistor house. Again, an accident that could have been prevented and a claim that could have been avoided.

SAFETY MINUTES

Next, at the request of certain of our Assureds, we review all Safety Minutes submitted by their vessels and comment upon

them by letters to the Assureds. Copies of our letters or transcripts of their contents are then forwarded to the ships concerned, with covering letters by the shipping companies.

In our review, we consider and offer suggestions on specific Safety problems raised in the meetings but basically, we look for compliance with Assureds' directives, genuine Safety interest and regular and reasonably frequent meetings with sufficient membership participation to show that all hands are interested and thinking about Safety.

DIRECT CONSULTATION

Another service is conducted by way of direct consultation with appropriate personnel in the marine departments of our Assureds. Their own particular problems are analyzed and discussed with them. Very often we are in a position to offer suggestions as a result of similar experiences sustained by other of our Assureds, which have not yet become general knowledge.

For example, a ship sustained a casualty when a winch drum collapsed, revealing that the shell of the drum had been badly worn down. Quick drill testing of the winch drums on other ships of the fleet showed that a number were in similar condition. Because of our position as a clearing house for such information, we were in a position to warn other Assureds before they found out for themselves—the hard way.

On another occasion, we warned our Assureds of a series of accidents involving aluminum stepladders. They are popular on board ship because of their light weight but have a tendency to collapse without warning once they are bent and then straightened out. Magnesium ladders have proved to be even more treacherous and both can be dangerous around electrical equipment.

An example of new hazards reaching our attention promptly through reported injuries concerns a piece of equipment which has made its debut on new ship construction as a replacement for the time-honored Lyle gun. A rocket is now used, presenting the great advantage of mobility and adaptability for use in the most favorable location on the ship. The apparatus is equipped with a circular shield to protect the operator from blast. The illustration in the accompanying instructions shows it held at arm's length,

shoulder high when firing, but in practice, it has been found that it is so heavy (about 20 lbs.) that when held in this position men do not have strength enough to cope with the recoil and the shield is apt to fly back and strike the operator in the face.

As a precaution against such mishaps, a line may be rigged between two stanchions, on which to rest the appliance—or it can be tied down to a pipe rail with the shield outboard. When tripods are provided on which to mount the apparatus, they take care of the recoil problem. I might add one final precaution to take in practice firing and that is to make sure that enough line is attached to the rocket to provide a "tail", otherwise, the rocket may fly aimlessly and even boomerang back on the ship.

SAFETY LETTERS

A major method of distributing centralized information to our Assureds for their ships is by means of Safety Letters published by our Safety Department twice a month under the authorship of Arthur E. Willis, a member of our Staff. These are of various types: a supervisory series, a series of oil tankers, a special for dry cargo ships, another for inland marine and a series of general Safety Letters more or less suitable for all mariners. Since 1955, when these letters were initiated, the circulation has increased from 150 to around 1500. The increase has been accomplished solely by individual request. I might add that we have not restricted distribution of these letters to our Assureds. The members of our Executive Committee felt that any responsible shipping company, so desiring, should have the benefit of these Safety Letters, and we have put many applicants on our mailing lists from all over the world.

Inspiration for our Safety Letters comes from many sources such as, the frequency and character of injury claims reported to us; reports by our shipboard Safety Inspectors; suggestions by our Assureds; material in Safety literature, etc. As an example of a Safety Letter's causation and function, one of our Safety Inspectors was aboard a tanker one day when he noticed a corroded strongback bolt from a tank top, which had just been removed for replacement. This formed the theme of one of our earliest Safety Letters and proved of much interest. I brought this bolt with me and you may wish to pass it around. You

can imagine what might have happened if that bolt had carried away while a man was looking down into the tank—there would have been a decapitation job which every guillotine would have envied.

When we issued a special Safety Letter dealing with Radar some five years ago, world-wide requests for copies were received including many from foreign ships. This was shortly after the collision between the STOCKHOLM and the ANDREA DORIA and among the applicants for copies of our Radar Safety Letter were half a dozen officers from the DORIA who walked into our office one morning. Several thousand copies of this letter were issued, three editions having been printed.

Another special Letter dealt with the characteristics of modern tanker cargoes and was in such demand that the American Petroleum Institute requested several hundred copies for distribution among its membership. Still another on Weather Routing resulted in a request from the United States Weather Bureau for several thousand copies.

Many of the Safety Letters have been reprinted by various agencies; such as, the Marine Section of the National Safety Council; the "Proceedings of the Merchant Marine Council of the U. S. Coast Guard"; the M.S.T.S. Magazine and various publications issued by individual shipping companies.

Proof that our letters are "getting through" to the seamen came as a suggestion from an unlicensed man on one of the ships. He was much impressed by a particular letter and suggested to his Company that it be reproduced and mounted for distribution and permanent display on all the ships of that fleet. The idea was well received and was carried out by having the substance of the letter printed and mounted on a card between sheets of plastic. I brought a sample with me in order that you might pass it around among you.

SAFETY MANUALS

In another effort to reach the personnel on the ships, our Safety Department prepared two separate manuals as "Guides to Accident Prevention"—one for Tankers and the other for Cargo and Passenger Ships. These manuals contain specific instructions for setting up a Safety program aboard

ship, advice on safe practices for most shipboard operations, procedures for conducting Safety meetings together with an abundance of material for discussion. After approval by each Assured, copies are distributed to the Master and department heads on all of their vessels. These manuals are highly prized and have been in great demand. They have even been made a part of the curriculum of one of the major maritime academies.

DISCUSSION GROUPS

To help in the creation of a forum for shore personnel actively concerned with Safety, Captain Robert H. Smith, Manager of our Safety Department, took an active part in bringing about the formation of a "Tanker Safety Discussion Group" in New York City in 1952. This was followed shortly by the organization of the "Dry Cargo Discussion Group." Since their formation, we have actively participated in the monthly meetings of both groups.

The training film devoted to modern methods of fire fighting on oil tankers recently completed by the U. S. Coast Guard in conjunction with other industry groups was first conceived at a meeting of the Tanker Discussion Group and several of its members took initial steps towards its preparation. We are hopeful that this film will constitute a major contribution toward dealing with a terrible and much-too-frequent form of ship casualty.

ADVISORY COMMITTEE

Another Safety forum has developed in the Advisory Committee of our Agency. This Committee, which meets monthly, includes top Management Executives of several of our Assureds and our own Company.

In order to widen the Agency's usefulness to shipowners and operators, the Committee includes in its discussions major Safety problems and matters of industry-wide importance, such as, proposed international Conventions, new or proposed legislation or regulations, etc. The recommendations of the Committee are followed through by appropriate action on the part of the Agency's Safety Department or by our Assureds.

I mentioned some time back the obstacles encountered during the early days of Mari-

time Safety pioneering. It is interesting to note how time has dealt with some of them. The fear that Safety Meetings on board ship might undermine discipline has been well dissipated. True, some such meetings occasionally degenerate into "gripe sessions" where some individuals seek "to rebuild the ship." However, this only occurs when the individual in charge does not preside with a firm hand. That is a fault of that individual, rather than the system, and emphasizes a point which shoreside industry learned long ago; that is, the need for Safety training of supervisors.

On the other hand, when their officers have interested themselves in the Safety program sincerely and have put genuine effort into helping it to succeed, the men have been quick to recognize it and have responded appreciatively. Under such conditions, discipline and morale have definitely benefited.

As I have mentioned, industry generally has long realized the need for special training in Safety for its supervisory personnel and ships' officers are, of course, supervisors in the fullest sense. It is not news that the effectiveness of a ship's Safety program depends on the attitude and interest of Management toward it, but it is important that such interest be demonstrated.

We had a case not long ago of an Assured whose fleet had a very poor loss record. This fact was not surprising since it had no Safety program whatever. A new President took office with this Assured and soon became "sold" on the value of a good Safety program. After broad consultation with several Safety activities, including our Company, a program was drawn up carefully for the ships of the fleet. Suitable directives were prepared to launch the program—but they were not put in the mail. Instead, this busy executive got up early and met every ship of the fleet as it came

back to the home port. As soon as he got aboard each ship, he went to the Captain's cabin and handed the new Safety directives to the Master, sitting down with him to explain in detail just what was wanted and how to go about producing it. It is hardly surprising that this crash program achieved remarkable effects in record time.

The cost bogie has retreated from the foreground in the Safety picture. True, today's Safety costs are higher than ever, but much more so are the costs of accidents. Direct costs including jury awards, settlement and expenses of litigation have reached startling proportions and indirect costs still are conservatively estimated as more than four times greater than direct costs.

The consideration of public relations is, perhaps, the most intangible of all, yet also, perhaps, the most cogent. Public goodwill is as vital to the owner of cargo-carrying ships as it is to the owner of passenger ships. Unfortunately, many maritime casualties are very spectacular in their nature and as such, attract the attention of the newspapers and fire reportorial imaginations until the public image of the shipowners involved is very badly damaged. In fact, more than one shipping company has been seriously affected or put out of business by one or more such casualties—not by the actual direct costs of the claims settlements (most of which are insured) but by the force of public opinion causing a boycott of their ships or products carried. And more than one shipowner who survived such an experience has been converted from scepticism into strong advocacy of an aggressive Safety program.

To conclude briefly, our Company is proud of its efforts in the cause of Maritime Safety and of the results which the industry has achieved. It has been a most pleasant and rewarding experience.

ELECTRICAL SAFETY IN SHIPS

By CAPTAIN O. T. ESTES

Chief, Electrical Engineering Branch, Merchant Marine Technical Div.
United States Coast Guard, Washington, D. C.

Electrical safety in ships includes the prevention of shock, fire and even panic; I propose to take these one at a time and tie them into everyday experiences.

Much has been said and done to protect the unsuspecting person from electrical shock. Suppose you wish to install a washer or electric dryer in your basement. Or possibly you are remodeling your bathroom. Whether you do this job yourself or have a contractor do it, the work should be examined by the local city or county electrical inspector. Following the National Electrical Code (210-22 and 410-93) this inspector will require grounding type receptacle outlets in kitchens, workshops, garages, etc., where the outlet may supply equipment used by persons standing on the ground or on grounded conductive materials. Metal enclosures for lighting fixtures, faceplates etc. in these areas must be grounded. The purpose of all this is to eliminate the possibility of a person bridging across a source of voltage.

For example, a person in a bathtub shouldn't be reaching over to touch the faceplate on an electrical outlet or a mirror light. However if he does he will not be shocked if the bathtub, radiator, faucets, faceplate and lighting fixture enclosure are all properly connected together to ground. The same is true of your electric dryer or washer and set tub or pipes in the basement.

The same is true aboard ship and this principle is applied to large vessels inspected by the U. S. Coast Guard under the "Electrical Engineering Regulations" CG 259 (46 CFR 111.05 and 46 CFR 111.60). In a steel hulled vessel everyone is walking on or touching ground wherever they go. You might say that aboard a steel vessel one foot is always in the bathtub. And the hands and other parts of the body are nearly always within reach of power cables or electrical equipment containing lethal voltages. Aboard ship the cable armor, the enclosures of lighting fixtures and other electrical equipment should all be grounded to the hull of the vessel, thereby bringing all exposed

metal to a common potential and eliminating shock hazard from this source.

The portable tools used aboard ship are good examples. The metal enclosure of the tool, that part carried in the hands of the operator, is connected directly to ground (vessel-hull) through a third conductor in the supply cable. This requires grounding type plugs and receptacles. With this grounded enclosure arrangement the operator is safeguarded against holding a "hot" (faulted) tool in his hands while touching ground with other parts of his body.

This rule of connecting all exposed metal to ground potential is simple and direct. Unfortunately it is sometimes not followed. During the last year our record of marine casualties listed three deaths by electrocution.

While working on a barge in Florida a young shore worker was stripped to the waist. When he reached over to pull on a portable fan his bare sweating chest touched a hatch coaming as his hands contacted the faulted electric fan. Death resulted. This would not have happened if the exposed parts of the fan had been held to the potential of the barge by a grounding connection.

Similarly a death occurred during repair work on the Dutch yacht *Frieda* in a U. S. port when a worker's body was in contact with the metal hull while his hands held a "hot" electric sander. Here a jury rig extension cord had been employed which did not contain a grounding conductor to ground the tool housing.

A real booby trap was set up on a T2 tanker. The ground strap to one propulsion cable armor was defeated by someone who insulated it with tape. This permitted 2300 volts on this cable armor when a ground fault occurred and an unsuspecting engineer was electrocuted.

I could go on and on giving examples such as shock to welders or shock by tools and resulting falls off ladders. The latest published figures indicate that 12 deaths were

caused in 1957 by electric shock on U. S. Navy ships.

What is the answer to this electrical shock problem? Whether in your small boat or in an ocean liner, it boils down to not bridging parts of the body across a voltage source. If the electrical device is completely disconnected by a disconnect switch then it can be touched in safety. Disconnect switches which open all supply conductors are needed in order to service equipment without exposure to shock. The servicing personnel sometimes fail to use the disconnect and work "hot."

Preventing this is a matter of indoctrination and education. But for electrical equipment that is energized and running, reducing shock hazard is a matter of connecting all exposed metal to ground potential. In a metal hulled vessel the ground is the hull. In a plastic or wooden hulled small vessel ground it is the bonding system which connects all metal enclosures together.

One caution to you who may be doing it yourself. The grounding conductor that connects the tool frame to ground should be of good size and with tight connections so it will be of minimum resistance. This is to insure that on tool fault this grounding conductor will carry sufficient current to interrupt the fuse or breaker and keep the tool housing at ground potential. The same size for grounding conductor as for supply conductors is a good rule.

The best scheme is to have a multi conductor supply cable for all tools with the green colored wire used for grounding. Frequent maintenance checks to see that the grounding connections are properly connected and of low resistance is a good precaution. An ohmmeter check between tool housing and ground should read less than 3 ohms.

Fire is the greatest dread of seamen, and rightfully so. In the last three years our casualty report files indicate 163 fires attributed to electrical origin. One half of the vessels were a total loss, and 15 deaths resulted. So as not to alarm you who operate large ships, let me quickly point out that these fires, loss of vessels and deaths were primarily attributed to small pleasure vessels and fishing vessels. On large Coast Guard inspected vessels of over 500 gross tons, during this period there were 25 fires reported but no loss of vessels and no deaths.

Being an electrician I feel that electricity is blamed for many casualties without justification. When the investigator doesn't know what caused the fire he "presumes" it to be of electrical origin. However there is one statistic I cannot deny—the reports for year 1960 show 14 small boat fires started at the instant the engine starter button was pushed.

Oh yes, it could be argued that this doesn't mean that there was any faulty electrical equipment. The starting battery, contactors and starting motor were probably operating in a perfectly normal fashion and if the explosive vapors had not been in the engine compartment these fires or explosions would not have occurred. It could be argued that the presence of gasoline vapors, propane gas or other combustibles was the proximate cause of the fire. But this is a fine point because the normal sparking of contacts or motor commutators can ignite explosive vapors.

The problem is solved equally well by removing either the electrical equipment or the hazardous vapors so that the two are not present together. The vessels involved in these reports were generally small in size and gasoline was the principal source of explosive vapor. In small boats we rely on the use of a blower system to clear out any explosive vapors prior to energizing the electrical equipment in the engine compartment. A good sniff with the nose before starting is also highly recommended!

In large ships the accumulation of combustible gases in the engine room is less likely since this is a manned and well ventilated space. However to be safe from fires of electrical origin large and small vessels must be designed, built and maintained with precautions in mind. Fire hazard can exist wherever electrical potential is present and the electrical installation covers a far greater area on a vessel than any other type of installation. We must guard against over fusing circuits, locating electrical equipment in spaces where flammable vapors or gases may normally accumulate, using equipment with less than minimal electrical clearances, and overheating, particularly of lighting fixtures, in proximity to combustibles. Much of electrical safety is just common sense.

Finally, consider panic. When in 1904 the *General Slocum* burned in New York Har-

bor with 957 victims mostly women and children there was panic. In 1912 when the *Titanic* sank with loss of 1,517 lives, and in 1932 when the *Morro Castle* burned with a loss of 124 lives, there was panic aboard.

One of my jobs today is to "sell" you on the idea that electricity can add safety to a ship by reducing panic. The human being is by nature afraid of the dark. Place him in the dark, in a strange place, with other people, in threatening circumstances, and the stage is set for panic. Part of the answer to panic aboard ship, even in the time of great danger, is to keep the lights on and to tell the person how to help himself, all of which can be done with proper electrical arrangements.

The SOLAS conventions have brought about international recognition of this fact but it is sometimes hard to "sell" to the man who pays the bill for an emergency lighting system. SOLAS 1929 first required emergency lighting systems in passenger ships and SOLAS 1960 has extended this requirement to cover international cargo vessels.

The idea of protecting the unsuspecting passenger by furnishing him with sufficient lights to find his way to the lifeboats as required by the SOLAS Conventions is sound. Having emergency lights to assist the crew in restoring normal services or to better employ fire fighting and damage control methods is also sound.

For example, recently on a cargo vessel an electrical failure to the only electrical system, left the ship in total darkness below decks. The chief engineer in his one man panic and haste to restore service tripped over a deck plate, fell, struck his head near the switchboard, and died. If his ship had been built under the present requirements he would have had sufficient emergency lighting to effect repairs.

None of us will quarrel with the need of emergency lights in the operating rooms of hospitals. How would you like to be performing a delicate operation on a person or on machinery in the dark? You are seven

decks down in the bowels of the ship, how do you get to safety?

Probably the best argument I can give for keeping the lights on in an emergency is the case of the *Andrea Doria*. True there were 43 lives lost in this collision, but about 1700 were saved. I make the statement: All the while lifeboats were being lowered and even as the ship was over at 45° and sinking the emergency lights were burning.

Now I ask the question: How many deaths might we have had that night on the *Andrea Doria* if the ship had been in total darkness, with no guiding lights or announcing system to lead the passengers and crew from the underdecks to the boats?

With this "panic argument" I hope to have "sold" all of you on the need for an emergency lighting system, that lights are needed to restore services after casualty and lights are needed to guide passengers to the open decks and lifeboats or liferafts.

To summarize, we have discussed shock, fire and panic hazards aboard ship. The remedy to the shock and fire hazards lies in well designed robust electrical equipment with the exposed metal parts grounded, proper protection against overcurrents, good connections, isolating high temperature items from combustibles, etc., and proper maintenance. Fortunately the electrical industry has generally supplied equipment which has been designed to combat shock and fire. Unfortunately the human doesn't always install or use this equipment properly.

The remedy to panic is in not letting a panic situation arise. A partial answer to the casualty and panic situations lies in providing an emergency lighting system. Lights under emergency conditions give those on board a better chance.

In the marine electrical safety field as in any safety field the continuing efforts of the National Safety Council, ship owners, ship operators, the Coast Guard and others is needed to educate those who haven't yet learned.

REVIEW OF MARINE CASUALTIES

By COMMANDER JOHN H. HAWLEY
Chief, Casualty Review Branch, U. S. Coast Guard, Washington, D. C.

At the entrance to the Archives in Washington is inscribed "What is Past is Prologue." One story has it that a visitor to the Capital asked his taxi driver what it meant. The cabbie replied "It means we ain't seen nothin' yet."

From a marine casualty point of view, at least, we've seen plenty. In many areas we've profited by past mistakes. In others more effort is indicated. A brief review of some of the significant aspects of more recent casualties may light the way.

You no doubt will recall the *Amoco Virginia* disaster on November 8, 1959, in the Houston Ship Channel. The vessel was loading automotive gasoline and number 2 heating oil at the Hess Terminal.

The evidence developed by the Marine Board of Investigation was largely circumstantial but it appears that there was accidental discharge of gasoline into the water from the tanker which was ignited by open flame oil lanterns used as running lights on a loaded sand barge being pushed or towed past the area.

Incredible as it may seem, the evidence indicated that the night mate in charge of loading aboard the *Amoco Virginia* and the master of the tug *Pan Six* who was the tancer in charge of the pumping operations on two tank barges alongside had both been put on notice an hour or more before the fire that there was gasoline on the water around the vessel but pumping operations were continued. Six crew members from the *Amoco Virginia* and one fireman lost their lives as a result of that casualty.

Aside from the more obvious lesson, this casualty pointed up the problem created by accidental spillages of any commodity which might create a hazard to safety. In the *Amoco Virginia* case, the Board also found that at some time prior to the casualty a tank barge had been holed while being shifted and as a result gasoline flowed into the channel. While not contributing since it preceded the fire by 12 hours, it unquestionably created a dangerous situation at that time.

Largely as a result of this casualty, the entire problem of spillages, leakages or discharge of hazardous or dangerous material into navigable waters of the United States has been made the subject of a special Coast Guard study. That study is still going on. The problem is vast and goes beyond the basic responsibility of the Coast Guard for safety of life at sea.

While petroleum products in the water are primarily a hazard to ships and water front facilities, the spillage of other dangerous materials such as poisonous chemicals into rivers which provide water for drinking and industrial purposes could conceivably imperil the lives and livelihood of thousands of people. The solution is basically simple. Prevent spillages and discharges to the extent possible.

This is nothing new. Normally, no vessel will purposely dump cargo into the rivers. On the other hand, accidents do happen. Recognizing the potential danger if some commodities are accidentally spilled, extra care is indicated when they are being handled. Greater attention to navigation and the placement of barges strategically within a tow are two of the more obvious considerations.

When accidental spillages occur, immediate reporting by the master, operator, owner or person in charge is essential so that precautions may be taken to close off water intakes and protect water front facilities as well as other shipping. For the present time at least, such reports should be made to the nearest office of the Coast Guard.

Undoubtedly when the Coast Guard study is completed, there will be recommendations for specific regulations in this regard.

A 14 year record for U. S. ocean-going certificated passenger ships was broken on October 22, 1960, when the combination freight and passenger vessel *Alcoa Corsair* collided with the Italian freight vessel *Lorenzo Marcello* in the lower Mississippi River. Five passengers and five crew members lost their lives and six passengers and four crew members were injured in this casualty—all from the *Alcoa Corsair*. Not since 1946 has

a passenger been killed aboard an inspected U. S. ocean-going passenger vessel as a result of a vessel casualty. It was in that year that the passenger vessel *Yukon* stranded on the shores of Cape Fairfield, Alaska, with the subsequent loss of nine passengers and two crew members and the total loss of the vessel.

The *Alcoa Corsair*/*Lorenzo Marcello* collision, typical of most other collisions, was due to personnel fault. The *Alcoa Corsair* was downbound and rounding Sixty Mile Point which entails about a 90° right turn over a 2-mile course. The *Lorenzo Marcello*, upbound, was heading for the Point as is the custom and the *Alcoa Corsair* was keeping to the bend. It was a clear, dark night. The vessels were in sight of each other when over two miles apart and when within one and one-half miles, two-blast signals were exchanged. There were conflicting versions as to what subsequently occurred but two facts were indisputable. The *Alcoa Corsair* was permitted to swing about 16° further right than the axis of the channel below Sixty Mile Point and the *Lorenzo Marcello* turned right at the last minute in the face of the *Alcoa Corsair*.

It was the opinion of the Coast Guard that this casualty was caused by the failure of both vessels to navigate with caution. The *Alcoa Corsair* failed to make a timely and sufficient alteration of course to port to insure a safe starboard-to-starboard passing and the *Lorenzo Marcello* failed to recognize the increasing danger of the situation which should have been apparent.

The case was unique in one respect. In the face of the traditional master/pilot relationship, it is seldom that the vessel's officers do not share the blame for an accident. In this instance the situation was more than just a case of meeting vessels, but one of vessels meeting in a river where a knowledge of local conditions and customs dictated the special qualifications of a pilot.

In addition, it was considered that under the circumstances, the officers on the bridges of the two vessels who were not pilots would not realize that their vessels were standing into danger prior to the time collision was imminent. Hence, it was concluded that the responsibility for this collision rested solely with the pilots of the two vessels.

No review of past casualties would be complete without comment about radar. In the past two fiscal years there have been two particularly significant radar cases. One was the collision between the SS *Mormacpine* and the fishing vessel *Jane* off Cape Flattery, Washington, on September 27, 1959, and the other was between the British freighter *South African Pioneer* and the fishing vessel *Ponchaton* off Cape May, New Jersey, on April 10, 1961.

In the first case, the *Mormacpine* was proceeding full ahead at 11.5 knots on a northerly heading off the Washington coast early on the morning of September 27, 1959. Upon sighting a fog bank ahead, the lookout was posted on the bow and fog signals were commenced. The engine was placed on standby but no reduction in speed was made. The radar was on and appeared to be operating satisfactorily showing a good presentation of land mass but no vessel targets were observed.

The vessel had entered the fog bank and visibility was between 500 and 1,000 yards. At 0746 the master ordered right rudder to enter the Strait of Juan de Fuca. At this time, the lookout reported by phone to the master that he heard a whistle ahead. Immediately the engine was stopped and the master checked the radar which was on the eight-mile scale but observed no vessel targets.

Approximately one and one-half minutes later the lookout reported sighting a vessel 1,000 feet ahead fine on the starboard bow. This later proved to be the *FV Jane*. The *Jane* appeared to be underway with little or no way on and was heading across the bow of the *Mormacpine* from starboard to port. Upon receiving the report from the lookout, the master ordered full astern on the engines. The rudder was already hard right. The response to the engine order was immediate but these maneuvers did not succeed in evading the *Jane* and at about 0755, with the *Mormacpine* making an estimated three to four knots through the water, her bow struck and holed the *Jane* on her port side.

The *Jane*, a 49 foot, wood hull fishing vessel, was en route Neah Bay, Washington, to Destruction Island. After clearing the harbor, she headed west at half speed—approximately five knots—into a nine foot

westerly swell. At 0720 fog was encountered. Fog signals were commenced and speed was reduced to four knots. The *Mormacpine* was first observed bearing down on the port side of the *Jane* about 50 to 60 feet away. The *Mormacpine* was undamaged but the *Jane* was severely holed and sank three minutes after the collision. Three of the five crew members aboard the *Jane* were rescued but the master and the fifth crew member were lost.

In the second case, the *South African Pioneer* was en route to New York from Charleston, S. C., heading on a course of 015°T at 14 knots. At about 0542 on the morning of April 10, 1961, visibility decreased to one and one-half miles. Fog signals were commenced and the engine was placed on standby which would result in a reduction of speed to 10.2 knots as the vessel reached maneuvering rpm. The radar was on the eight-mile scale. Sea return extended three miles from the center of the cone and rain areas appeared beyond this range. No contacts were observed on the scope.

At 0545 the lookout was sent below to call the stewards' department. Between 0549 and 0550 a red light was observed close ahead 10 degrees on the starboard bow. Hard right rudder was ordered and moments later was shifted to hard left, then amidships and full astern. At 0551 the stern of the *Pioneer* struck the *Powhatan* amidships on the port side at a 60 degree angle. The *Pioneer's* speed was estimated to be slightly under 10 knots.

The *Powhatan*, a 78 ft. wood hull fishing vessel was proceeding south-southwest at a speed of seven knots toward Hampton, Va., through rough seas and heavy swells. There was no lookout on the bow. There was a helmsman at the wheel and the master was making a loran fix from the receiver located in his room immediately abaft the wheelhouse. The *Pioneer* was first observed by the helmsman who shouted the warning. When the master came out of his room the *Pioneer* was so close he could not see her navigation lights.

Almost immediately thereafter the *Powhatan* was struck and cut in two. The speed of the *Powhatan* at the time of impact was estimated somewhat less than seven knots. There was no damage to the *Pioneer*. Out

of five crew members aboard the *Powhatan*, four lost their lives.

In both of these cases personnel fault was considered to be the principal cause. Both the *Mormacpine* and the *South African Pioneer* were going at an immoderate speed. On both fishing vessels there was evidence of improper lookout. In both of these cases sea conditions were such that the fishing vessels could reasonably be expected to be obscured as radar targets. Both of these fishing vessels were constructed of wood and could further be expected to produce poor radar returns and on both the *Mormacpine* and the *Pioneer* the navigation personnel was undoubtedly influenced by the absence of any radar targets on the scope.

You are all familiar with the recommendations annexed to the International Rules of the Road adopted at the 1960 SOLAS Convention concerning the use of radar. The following is quoted from recommendation 2:

"... Information obtained from the use of radar is one of the circumstances to be taken into account when determining moderate speed. In this regard it must be recognized that small vessels, small icebergs, and similar floating objects may not be detected by radar..."

If heeded this recommendation should go far in preventing the type of casualty suffered by the *Jane* and the *Powhatan*. These two casualties also indicate the need for increasing the radar reflectivity of wooden vessels. Radar reflectors are available and prudence dictates that small seagoing vessels install such devices. But as pointed out by the Commandant of the Coast Guard in action on the *Mormacpine/Jane* case, "The increase in radar detectability presently offered by this equipment is definitely limited and offers no assurance that vessels so equipped will be observed by radar." In heavy seas the odds are even further reduced.

From the safety point of view another particularly significant casualty was the breaking up of the T2 tanker *Pine Ridge* off Hatteras on December 21, 1960. The résumé and Commandant's action in this case appears in the November issue of the Proceedings of the Merchant Marine Council. Briefly, the vessel, in ballast, was heading into heavy weather. Speed had been reduced to about nine knots. She was roll-

ing and pitching heavily and possibly taking green seas over the bow, but none of the witnesses had the impression that she was pounding or slamming hard. At 1145, December 21, without any warning, there was a loud crack and the vessel forward of number six tank was observed to raise up out of the water. On a subsequent sea the vessel tore across the deck and the bow cleared around to the right, then broke completely off.

At the time of the casualty the master, chief mate, second mate, third mate, radio officer, chief steward and quartermaster were in the midship house which was on the forward section. As the forward section separated the bow was observed to be high out of the water and the after end awash up to the boat deck. No lifeboats were launched from the forward section, and sometime during the late afternoon or early evening of December 21, the forward section sank. There were no survivors from the forward section, nor were any bodies recovered.

The Marine Board convened to investigate this casualty found that the failure was primarily of the ductile type indicating a high stress condition. In this connection, the Board found that the loading distribution of the vessel resulted in a sag numeral of almost plus 150 and a hog numeral of almost minus 20, calculated in accordance with the American Bureau of Shipping publication "Guidance Manual for Loading T-2 Tankers." The maximum sag numeral recommended in the manual is 100 and the figure of plus 150 reflects a dangerous condition of stress.

In addition to improper ballasting, the Board concluded that the weakened structural condition of the vessel was also a contributing factor. Audio gauge readings of the main hull structure after the casualty indicated a generally borderline condition, and some areas where wastage was actually excessive. The vessel had been drydocked two months before the casualty and was attended by a Coast Guard inspector, as well as a classification surveyor and the owner's representative. There is no doubt that they did what they thought should have been done, and their requirements for repairs and renewals were made in good faith.

The problem they faced is the most difficult one in the field of vessel inspection;

that is, the determining of the condition of an aged vessel and deciding what must be done to permit the vessel to continue operating with safety. It seems logical that as a vessel advances in years, examinations and inspections must necessarily be increasingly detailed and critical. Beyond that there must be a satisfactory resolution of the differences of opinion which are bound to arise. In his action on the *Pine Ridge* case, the Commandant commented as follows in this regard:

"Obviously the proper balance between economy of operation and safety can only be achieved with full cooperation, mutual assistance and a frank exchange of information between those directly concerned."

During fiscal 1961, there were 2,015 casualties to commercial vessels reported to the Coast Guard. This compares with 1,988 the year before. In fiscal '61, 156 persons lost their lives in vessel casualties aboard commercial vessels of all sizes as opposed to 133 in fiscal '60.

Forty of these deaths occurred on inspected vessels and 116 on uninspected vessels. Among the uninspected vessels, those engaged in commercial fishing once again accounted for the most deaths, with a total of 58. Uninspected tugs ran second with a total of 21. The classification of vessel casualty which accounted for the greatest percentage of these deaths on uninspected vessels was flooding, sinking and capsizing. In the case of commercial fishing vessels, 29 lost their lives in casualties of this type, and on uninspected tugs, 16 lost their lives.

In our tabulation of personal accidents aboard commercial inspected vessels the category which accounted for the greatest number of deaths in fiscal 1961 was death from natural causes. The total was 165. In this category 80 of the deaths to crew members resulted from one of the cardiovascular diseases.

The second largest number of deaths from personal accidents on board inspected vessels occurred as a result of falling overboard. Sixteen persons were killed from this cause, of which nine were crew members.

Aboard uninspected commercial vessels the situation was reversed. Natural causes was second, having accounted for 26 deaths

of which 21 resulted from cardio-vascular disease to crew members.

The major cause of death from personal accidents aboard uninspected commercial vessels was falling overboard. A total of 70 lives were accounted for in this category of which 28 were crew members off fishing vessels and 27 were crew members off tugs and tows. These figures on deaths from falling overboard are the most disturbing of the year. On uninspected vessels this was the greatest single cause of death.

In June 1959, when the Coast Guard issued its first approval on the work-vest type life preserver it was hoped that deaths due to falling overboard would be materially reduced. They haven't been. The reports of investigations received on these cases indicate that in most instances on tugs, tows and dredges, life vests were available. How can we get people to wear them? Stating it more broadly, how can we get people to take safety precautions of any kind?

Scare statistics obviously have little effect, and certainly our seamen if not our entire population are safety educated. The problem seems to lie in the same basic human weakness that keeps us from taking our doctor's advice. If this is true, it would appear that more forceful leadership on the part of ships' officers, and other designated supervisors among the unlicensed persons, can go a long way towards correcting the unsafe conditions and preventing unsafe practices which cause these casualties.

Our records appear to indicate that in the lower echelons particularly there is a marked reluctance on the part of supervisors to insist on safe work methods. This is especially true if the subordinate himself is known to be an experienced man. Going back for a moment to the figures on deaths resulting from falls over the side, if the masters or supervisors required that life jackets or life vests be worn, and accepted no deviation, it is reasonable to assume that many of those who died would still be with us.

The third largest number of deaths from personal accidents on inspected commercial vessels occurred as a result of suicide. Twelve persons died in this manner, of which nine were crew members and three were passengers. In addition, 11 crew members disappeared from inspected vessels

under circumstances which suggested the possibility of suicide.

The third largest number of deaths from personal accidents on uninspected commercial vessels resulted from disappearances of which there were nine cases, eight of which involved crew members. While some of these cases might have been suicides, six cases were on fishing vessels, which tends to increase the probability of accidental falls.

On commercial uninspected vessels, positive suicides were almost inconsequential, with only two cases tabulated.

Among categories which account for the greatest number of non-fatal personal accidents, resulting in incapacitation for a period in excess of 72 hours—slips and falls on deck and other ships and falls—the same level accounted for most of them with a combined total of 202 injury cases on all commercial vessels, both inspected and uninspected. In these categories no one was killed aboard inspected vessels, but two were killed on uninspected vessels. The principal causes of these accidents were unsafe practices and poor maintenance or housekeeping, which accounted for 57 cases; human error not otherwise classified, which means a misstep on the part of the individual, accounted for 46 cases; and weather conditions were given as the cause in 53 cases.

The second largest group of injuries occurred as a result of slips and falls on ladders and stairs. There were 116 injury cases in this group covering all commercial vessels, plus two deaths on inspected vessels but none on uninspected vessels. Principal causes were unsafe practices or conditions and missteps in that order.

Our casualty reports in recent years are beginning to reflect a greater number of personal accidents being attributed directly to intoxication. During fiscal 1961, 11 deaths and 41 injuries were considered to have been caused primarily by intoxication. Fights aboard ship are also accounting for more casualties. There was one death and 92 injuries recorded in this category. It is doubtful that this reflects a true increase in casualties of these types, but rather that reporting superiors and even witnesses are becoming less reluctant to call a spade a shovel.

From an analysis of the death and injury

statistics it is apparent that continued efforts to make vessels safe have paid off and this is particularly true of inspected vessels. Of course, there is still plenty of room for improvement as evidenced by some of the individual cases we have discussed here.

On the other hand the sum of our casualty

experience for fiscal 1961, supported by figures for previous years, indicates that greater effort must be exerted to get individuals to work safely. It is in the area of personnel fault, both from the standpoint of vessel casualties and personal accidents, that the greatest strides towards maximum safety remain to be made.

MARINE SECTION BUSINESS SESSION AND COMMITTEE REPORTS

ANNUAL BUSINESS MEETING OF THE MARINE SECTION

By W. M. GAGE

Secretary, Marine Section, National Safety Council, Chicago

The annual business meeting of the Marine Section, National Safety Council was opened by general chairman, Richard W. Berry at 10:00 a.m., October 18, 1961 in the Lincoln-Douglas Room of the La Salle Hotel, Chicago, Illinois.

After a brief word of greeting to the members present, Chairman Berry introduced Mr. Merrill W. Pollard of the National Safety Council staff, who spoke on the reorganization of the industrial services activities of the Council in order to best serve the needs of the membership. Mr. Pollard emphasized the need for interesting top management in industries in safety promotional work. He pointed out the need for wide dissemination of information on safety practices and for safety men to assist in this by writing up such material for publication. Member companies were urged to take an active part in Council activities.

Mr. L. W. Dutton, Marine Section staff representative spoke briefly on the National Safety Council's campaign to increase the use of automobile seat belts and solicited the cooperation of the Marine Section. He also referred to the recently issued brochure on industrial safety services and to the Council's publicity activities.

Reports of committees and groups were made as printed below.

Staff representative, Mr. L. W. Dutton, reported on a number of matters currently

under development by the National Safety Council of concern to the Marine Section. He noted the excellent work done by outgoing general chairman, Richard W. Berry during his term of office. The work of the industrial conference was described. While each section seems to feel it has problems and interests differing from the others, in the final analysis, there are much greater similarities than differences. Mr. Dutton spoke briefly on the proposed activities manual for the Marine Section. After noting the importance of the safety discussion groups now operating, he proposed that an additional group be formed on the West Coast. The section was advised that the Marine Section now has two representatives on the American Standards Association Committee responsible for 210 code matters. An attempt will be made to have the code modified to take into account that Marine accidents are counted on a 24-hour-a-day basis, while credit is given toward exposure for 8 hours only.

General chairman Richard W. Berry reported on the activities of the Marine Section during his term of office. At the conclusion of his report, he paid tribute to Mr. Harold M. Wick for his many years of untiring service to the Marine Section. He was directed by unanimous vote of the members present to write to the American Bureau of Shipping expressing the appreciation of the Marine Section for the bureau's

generosity in making it possible for Mr. Wick to devote much time and effort to the Sections' affairs.

The report of the nominating committee, Mr. Robert E. O'Brien, chairman, was received and the committee discharged with thanks. After minor amendments, the secretary was directed to cast one ballot for the revised slate.

The new general chairman, Mr. W. Lyle Bull, and vice general chairman, Capt. R. E. Mackey, were then introduced and expressed their appreciation to the membership for their confidence. Mr. Bull invited the members to a reception to be held in the Century Room of the La Salle Hotel at 6:00 p.m. that evening.

Presentation of Special Awards was made by Capt. Hewlett R. Bishop, Atlantic Coast Director, U. S. Maritime Administration. In preliminary remarks, Capt. Bishop endorsed the National Safety Council's campaign to encourage the use of automobile seat belts, noting that statistics showed that 73 per cent of all auto fatalities occurred within 30 miles of the victims' home, and at speeds of less than 30 miles per hour.

Special awards to authors of the best papers read during the past year in the different categories were made as follows:

Shipbuilding: Mr. Douglas Mansell (Award accepted by Mr. W. D. Brown)

Cargo and Passenger: Capt. Barrett (Award accepted by Mr. R. E. O'Brien).

Inland Waterways: Mr. John Kern (Award accepted by Mr. Bowden).

Stevedoring: Mr. Alex Chopin (Award accepted by Capt. Buxton).

Tankers: Capt. R. E. Mackey.

Special awards were made to the following for their work in preparation of the film "Fire Fighting Aboard Tankers": Mr. James Hughes, Mr. Charles A. Culver, Mr. Wallace M. Gage.

In connection with the latter awards and in recognition of the needs of the Marine Industry for safety training films, the following committee was appointed by the general chairman to study the matter: Mr. Charles A. Culver, Mr. James Hughes, Capt. Coe, Mr. Warren D. Lindsay.

Presentation of a testimonial in the form of a plaque and a set of book ends was made to retiring general chairman, R. W. Berry by Harold M. Wick on behalf of the Marine Section, in appreciation of the outstanding service rendered by Mr. Berry during his term of office.

Mr. Wick was presented with a testimonial certificate in recognition of his many years of service as a member of the Marine Section executive committee and for the excellent work he has done as program chairman.

REPORT OF MST'S SAFETY ACTIVITIES

By VICE ADM. ROY A. GANO

USN, Commander, Military Sea Transportation Service, Washington, D.C.

This past year has been one of increased world tension with a corresponding demand upon MST'S. At the same time, our activity in the field of special projects has increased. Both situations have created some different safety problems for us requiring much of our attention. Nevertheless, there are a few items from our overall operations which can be reported on as being of general interest to the Marine Section.

Some years ago, MST'S developed standard station bills for each of the types of ships operated. The advantage of this uniformity is obvious. An MST'S seaman

on transfer from one ship to another or from one command to another and find the same emergency procedures in effect.

This year we revised and updated our station bills. The primary change of interest here is the standardization of optional internal ship emergency signals. The Coast Guard has designated basic signals for fire, abandon ship, handling boats and dismissal from drills but authorizes masters to establish such other emergency signals as they may consider necessary. We found that these signals varied widely from ship to ship. Accordingly, we have standardized certain signals within MST'S.

a. For *Man Overboard*, we use three long rings, the letter "O", on the general alarm bells.

b. For *ABC Defense*, we follow the general alarm signal with short and long rings, the letter "A", on the alarm bells.

c. For directing the emergency boat, when there are no other ships in the vicinity, we use one blast to turn to starboard, two to turn to port, three for dead ahead, four to head towards the ship and five for stand off—we are maneuvering.

d. For *Steering Casualty*, we use a long and two short rings on the general alarm bells, the international signal for "keep clear of me—I am maneuvering with difficulty."

As you can see we have tied these in with existing signals where possible. We feel

these additional signals give all hands prompt notice of an existing emergency and that they have helped improve and standardize shipboard organization and readiness to cope with emergencies at sea.

2. At the present time we are in the process of training our officer personnel in external cardiac massage as a first aid technique to be used in combination with mouth-to-mouth respiration.

3. As a final item, I want to say that we were pleased that the National Safety Council's "Industrial Supervisor" reprinted an article entitled "Remember the Human Factor" written by one of our masters. This article first appeared in the Navy's *Safety Review* and was reprinted in the May issue of *Industrial Supervisor*.

REPORT OF MARITIME ADMINISTRATION SAFETY ACTIVITIES

By CAPT. M. I. GOODMAN

Acting Chief, Officer of Ship Operations, Maritime Administration, Washington, D.C.

As reported last year, throughout the past several years ship operations under General Agency Agreement have remained at a low level and the Maritime Administration has only four GAA ships in operation. There has been little activity, therefore, in our ship operating safety program. There are several other administration activities that are closely related to the safety of ships at sea and these will be the subject of this report—the improvement of ships' operational and navigational equipment through research and development, and the incorporation of improved design and equipment specifications in new ship construction.

Research and development relating to public safety in prevention of collisions at sea which have been completed, are in progress, or under negotiation under the Maritime Administration research and development program are as follows:

Human Factors in Ship Navigation—An investigation in man-machine relationship of ship control, to measure casualties of ship collisions, degrees of human problem awareness and reaction to danger, equipment layout and limitations in assisting or detracting

from human decision making and initiation of action.

Study of Collisions—A study of ship collisions for a sample period to determine the distance that first detection of the ship were made using radar, sighting, and sound related to the sizes of vessels.

Experimental Radar Data Computer—The design and development of an experimental prototype computer system utilizing radar information capable of automatically or manually detecting and tracking ten ships movements, projecting their half hour estimated future position, warning of cautionary and danger situations, and indicating safe turn or speed to avoid collisions.

Steering Control and Course Computer—A design and mathematical investigation of means of improving automatic steering of ships, development of ships route, and recording of present position.

Bridge Control Systems Console—The design, mathematical investigation, and prototype development of an integrated bridge console with the objectives of improving gyro steering in rough weather, continuously

1961 National Safety Congress

determining ships stability condition and best loading, improving communication and radar for collision avoidance and narrow channel operation, use of weather routing in optimum course determination, and improvement of ships navigational aids.

Controllable Pitch Propeller—(under negotiation) The development of a 20,000 shaft horsepower controllable pitch propeller capable of permitting more rapid reverse thrust in stopping a ship.

Study of Merchant Ship Automation—A study of feasible systems of ship automation particularly for routine monitoring and tasks where inattention and deviation could contribute to equipment casualties.

Ship Maneuvering and Control—Investigation and model tank tests to develop design data for improved maneuvering and control responses of ships.

Ship Seakeeping Tests—Instrumentation tests and analyses of ship responses in bad weather to improve design of ships operation under adverse conditions.

In addition to the improvements under

study and developments in the field of research, plans and specifications for new ship construction incorporate new and improved features which have been fully tested and accepted. These features not only provide more economical ship operations, but greater safety.

They include the use of self tapping metal screws in floor plates, gratings and flat plate with abrasive overlay for engineering spaces which has proven safer for personnel with less cost. This is in lieu of the old raised diamond plate that was used for floor plates.

Another example is the use of lightweight reinforced plastic foam filled rectifier doors which also has proved safer for personnel, and is just as economical.

Under consideration is the use of a non-acid electrolyte for batteries. Tests are being made of Blue Dye aqueous cobalt sulphate electrolyte; so far it has proven to be safer for personnel in that it is less toxic and it allows for greater life for the batteries.

REPORT OF PASSENGER AND CARGO SERVICES

By SYDNEY BLACKLEDGE

Vice Pres., American Export Lines, Inc., Hoboken, N. J.

During the year the members of the Passenger and Cargo Services continued to be represented at meetings called by the chairman of cargo discussion group. In addition to these meeting our members also attend joint meetings with the tanker group.

We continue to recommend that safety programs be maintained and strongly en-

dorsed by ship operators in order to control accident rates among passengers and crews aboard American vessels.

With a view to avoiding repetition I close my report at this time and submit that the particulars of the various meetings will be aptly covered in the individual reports given by the respective chairmen of the concerned discussion groups.

REPORT OF AWARDS COMMITTEE

By CAPT. R. E. MACKEY

Asst. Mgr., Operations Div., Marine Dept., Texaco, Inc., New York City

On Wednesday, August 23, 1961, the awards committee of the National Safety Council met in the New York Office of Texaco. The committee came to the meeting after having studied all of the presentations at the New York and Chicago safety conventions, and the following decisions were made as to which papers were to receive an

award:

Shipbuilding and Repairing, Douglas Mansell, Bethlehem Steel Co.: "A Practical Safety Program for a Shipyard".

Inland Waterways, John Kern, Southern Industries Corp.: "On Deck Safety".

Passenger and Cargo Ship, E. G. Barrett, Moore-McCormack Lines, Inc.: "Safety On

Board Cargo & Passenger Liners".

Tankers, R. E. Mackey, Texaco Inc.

Stevedoring, A. Chopin, New York Ship-ping Association.

Government, None.

Over my protests, the other two members of the awards committee voted that my paper be given an award, and when you

take into consideration all those in the marine department of Texaco who put work and effort into it, the award would be accepted by me for them and not for me personally.

I would like to extend my sincere thanks to Capt. Renahan and Mr. Dempsey for their hard work in the selection of these awards.

REPORT OF TANKER SAFETY DISCUSSION GROUP

By JOHN R. WOLFE

Safety Dir., Military Sea Transportation Service, Washington, D. C.

A comprehensive program was carried out by the tanker safety discussion group during the past year. Discussion subjects, topics and activities which occurred are as follows:

September 1960

Organization and program planning meeting.

Election of chairman.

October 1960

"Safety and Fire Training for Foreign Flag Vessels" was discussed by Frank Konchalski, Esso Tankers and J. F. Acker, Jr., MSTS.

November 1960

Review of tanker paper, "Who's Setting the Course?" which was presented in Chicago by Captain R. E. Mackey, Assistant Manager, Operations, Marine Department, Texaco, Inc. Captain Mackey discussed his paper with us and, with Messrs. R. A. White and B. K. Stephens, explained the Texaco safety program in greater detail.

14 persons attended.

December 1960

We received a "snow job" from the weather man. Our scheduled speaker and many of our regular members were unable to attend.

February 1961

Annual U. S. Coast Guard session for discussion of marine casualties, Captain J. D. Craik, USCG and Captain F. K. Arzt, USCG, discussion leaders.

13 persons attended.

March 1961

"In-port Organization for Shipboard Fires" was discussed by a panel consisting of Mr. Charles A. Culver, The Atlantic Refining Co.; Mr. Vernon B. Johnson, Bureau of Ships, Navy Dept.; and Mr. William B. Marx, International Assn. of Fire Chiefs.

22 persons attended.

April 1961

Meeting cancelled due to conflict with the spring meeting of the Marine Section.

May 1961

Mr. Charles L. Boyle, Mgr., Marine Dept., Sun Oil Co., discussed, "Handling of Kerosene-Type Products."

25 persons attended.

Joint meetings with the dry cargo group were held in January and June. These will be reported on by Captain Smith.

The movie "Firefighting on Tank Vessels" which was produced by the U. S. Coast Guard assisted by a liaison committee from the Tanker Group was made available to the industry this year.

On September 13, 1961 the program for the coming year was planned at an organizing meeting held in New York. Captain G. P. Hersom, Marine Dept., Sinclair Refining Co., was elected chairman. The group decided to have a vice chairman to concentrate on improving attendance at monthly meetings. Mr. R. B. Davidson, Sun Oil Co., was elected as the first vice chairman.

Last evening the tanker group held an informal get-together and dinner meeting at George Diamond's. We hope to make this an annual feature of the National Safety Congress for members of the tanker group.

REPORT OF CARGO SHIP SAFETY DISCUSSION GROUP

By RICHARD N. LEPAGEE
Safety Dir., Farrell Lines, New York City

The cargo ship safety discussion group met at the Maritime Exchange in New York once each month throughout the period from September, 1960, through June, 1961. Two of these meetings were held jointly with the tanker safety discussion group, as reported by Captain Smith.

At the commencement of the 1960/61 year, attendance by representatives of Marine Section member organizations was at a less than satisfactory level to obtain the greatest possible value from the meetings. Gradual improvement in meeting attendance has been realized throughout the year, as a result of providing adequate notification of meetings and interesting topics of discussion. Notices of scheduled meetings were mailed to the full address list following the organization meeting in September, 1960. Approximately one week prior to each scheduled meeting, a "notice of meeting" advising the principal topic and/or speakers was sent out; so that, in addition to the safety representative of the various member organizations, other operating personnel interested in the subject could arrange to attend. Further, regardless of whether or not an organization was represented at the meeting, a resume of each meeting was mailed to the full address list for their files.

Some improvement in regular attendance was realized, which resulted in lively and interesting discussions of the various topics covered during the year. Frequently, the group was addressed by persons eminently qualified to advise on specific topics under discussion. Some topics that highlighted the meetings of the past year were: comparison of qualities of synthetic lines to the basic manila; reflective materials and shipboard uses; duties of a master to sick or injured seamen; discussion of material, size and proper method of applying T/L chain stoppers. This latter subject was extremely

interesting as considerable research by several group members established that this information was not readily available to the marine industry.

Following the two-month summer recess, the cargo ship safety discussion group held its annual organization meeting on September 14, 1961. At this time, the undersigned was re-elected chairman for the 1961-62 year. The members present approved the suggestion that a Vice-Chairman be appointed to assist in the attendance drive and conduct the business of the group during an absence of the chairman due to business or other reasons. Mr. R. W. Snow was unanimously named vice-chairman for the coming year.

We were pleased to have Mr. L. Dutton present during our meeting of October 2, 1961, and look forward to his attendance any time his visits to New York coincide with a scheduled meeting.

The agenda for the coming year has been sent to all member organizations. We are sure that the topics for discussion will result in a very interesting series of meetings.

It has been noted that an organization situated in the Port of New York, which is very active in Marine Section activities has not been represented at any meeting of the cargo ship safety discussion group throughout the past year. It is well understood that full attendance enhances the value and scope of the discussions of this group. Accordingly, it is respectfully requested that the general chairmen of the Marine Section urge that principals of the member organizations assure regular attendance by a representative of their organization at the 1961-62 meetings of the cargo ship safety discussion group.

As a final note, I would like to express my appreciation for the opportunity to serve the Marine Section last year, and again during the forthcoming year.

REPORT OF JOINT CARGO AND TANKER SAFETY DISCUSSION GROUPS

By CAPT. ROBERT H. SMITH
Mgr., Safety Dept., United States P & I Agency, New York City

During the past season, regular monthly meetings of the cargo and tanker safety discussion groups were held and individual reports have been submitted by their respective chairmen.

Two joint meetings were held. On January 11, 1961, Mr. Henry Lamb of the American Standards Assn. discussed the Smith serious injury index before the group. On June 14, 1961, the tanker fire fighting film was previewed and the possibility of producing a similar film for specific cargo ship use was discussed. Every one of the cargo operator's representatives present was of the opinion that this should be done and

that a good part of the present tanker fire fighting film could be used.

For the coming year there will be two joint meetings, one on January 10, 1962, at which we are hoping to secure a speaker from the Maritime Safety Foundation and the meeting of June 13, 1962, which at the present time has been left open.

The success of these meetings depends upon the attendance and participation of the person within each company who is assigned the safety responsibilities and we again urge that every effort be made to attend these meetings.

REPORT OF GREAT LAKES SAFETY DISCUSSION GROUP

By ROBERT E. KRATZERT
Vessel Personnel Mgr., Columbia Transportation Div., Oglebay, Norton & Co.
Cleveland, Ohio

The Great Lakes safety discussion group consists of representatives of steamship companies, towing companies, admiralty law firms, marine insurance brokers, Lake Carriers' Association, and the United States Coast Guard. It is concerned with the safety of 10,000 seamen on three hundred Great Lakes ships. Most of the participating companies are members of the National Safety Council and participate in the marine safety contest.

Monthly luncheon meetings, held on the first Tuesday of each month, were very well attended this year. Attendance was between twenty and twenty-five persons at each meeting, and was not restricted to members of the National Safety Council. We have invited anybody in the marine industry who is interested in safety to attend the meetings.

A brief run-down of the agenda for each monthly meeting follows:

December—The program for the coming year was discussed. J. W. Manning of The

M. A. Hanna Company was elected Chairman for 1961.

January—Each company presented a report on the manner in which shipboard safety measures are used in their fleet.

February—A discussion on methods of communicating safety messages between company office and ship. This covered magazines, newsletters, bulletins, awards, etc.

March—A discussion on disciplinary action taken aboard ship as a measure of safety.

April—Coast Guard Day. Introduction of Captain James McIntosh, newly appointed chief, Merchant Marine safety division for the Ninth Coast Guard district. Discussion on cooperation between industry and Coast Guard.

May—Discussion of certain lost-time accidents—their cause, prevention and claims involved.

June—A new film, "That They May Live", describing in detail the mouth to mouth method of resuscitation, was shown. An excellent film. This group highly recommends its widespread distribution.

July—Discussion on lost-time accidents—a statistical review and classification on Interlake Steamship Co. ships presented by Dick Weckel.

August—A discussion on *Safe Sailing*, the revised edition of the Lake Carriers' Association manual for prevention of ship-

board accidents. A reminder that copies are available for distribution.

September—A number of dock superintendents were guests to discuss safety on and around the docks as pertains to seamen.

October—A film, "Firefighting Aboard Tankers", was shown through the courtesy of the Coast Guard. A discussion on firefighting followed.

No new members were recruited for the National Safety Council or the safety contest. However, all concerned felt the meeting this year accomplished a great deal.

REPORT OF SAFETY INFORMATION AND POSTER COMMITTEE

By CAPT. MILTON BREECE

Mgr., Port of New York Office, Esso Standard Div. of Humble Oil & Refining Co., New York City

The safety poster material developed by this committee at its meeting held in New York on August 3, 1960, was approved by the general chairman and submitted, during the early part of this year, to the Council with the request that every effort be made to make available to the Marine Section new safety posters geared to our particular industry. We are advised by Mr. L. W. Dutton that three new posters with a maritime theme are now being processed with three more scheduled for processing in the next few months. These posters will be reproduced in miniature as they become available and appear in the *National Safety News* and *Marine Section News Letter*.

No further business has been conducted by the poster committee this year to date because the back-log of suggested poster material, submitted by the committee during previous years, appears more than adequate to cover the section's existing quota.

The safety poster committee will meet in the near future to develop additional material and ideas for subsequent poster series. In this regard, the committee invites and would welcome any suggestions from the members. It is planned, also at this meeting, to review the poster ideas previously submitted, but not yet processed for production, and, if deemed necessary, to up-date and/or modify the material to meet new requirements.

The worth of having safety posters available that relate directly to living and working on board ships is surely recognized by members of the Marine Section. We, therefore, appeal not only to the members of this section, but to all of the marine industry to actively support this program and to evidence this support through purchase and display of all available safety posters developed by the Marine Sections Committee.

REPORT OF MARINE SECTION NEWSLETTER

By MR. WARREN D. LINDSAY

Dir. of Safety, United States Lines, New York City

The Marine Section published 10 monthly issues of the *Newsletter* and the eleventh issue is now at Council headquarters for printing. The December issue is edited by the National Safety Council for all sections.

The editor wishes to thank all of those companies who regularly submit their safety publications which furnish the bulk of the material for the *Newsletter* as well as the United States Coast Guard for their "Proceedings of the Merchant Marine Council" and M.S.T.S. for their magazine *Sealift*.

Any member company which publishes a safety periodical or house organ is requested to send a copy to the editor of the *Marine Section Newsletter* so that their safety experiences, problems and solutions may be passed on to other members thru this medium.

I wish to acknowledge the great help of Wally Gage, your assistant editor and a special acknowledgment to Harold Wick for his many contributions to the *Newsletter*.

REPORT OF INLAND WATERWAYS COMMITTEE

By F. A. MECHLING

Vice Pres., A. L. Mechling Barge Lines, Joliet, Ind.

Safety activities in the inland waterways industry during the past year centered about the continued activities of two working groups.

The American Waterways Operators, Inc., produced and distributed upwards of 1,500 safety posters to the industry each month, and in cooperation with the National Safety Council, once again sponsored the barge and towing vessel industry safety contest. Awards for the top winners in the safety contest were presented at a luncheon in New York last May. The association continues to cooperate with other groups engaged in promoting safety throughout the industry.

The Inland Waterways Safety and Health Association, composed of a group of inland water carriers, marine insurance underwriters, labor union executives and representatives from the U. S. Coast Guard and U. S. Army Corps of Engineers, expanded their very successful program of activities from the previous year. Through the efforts of this group, the U. S. Public Health Service established an out-patient clinic for the treatment of seamen at Joliet, Illinois. The group developed and distributed to the industry a directory of all U. S. Public Health Service hospitals, clinics and doctors.

Their very excellent safety poster program was continued and expanded during the past year, as was the publication *Towboat Tips* for distribution to boat personnel.

The association has several working committees, one of which is presently engaged in developing data on the handling of dangerous cargoes, principally chemicals and petrochemicals, the carriage of which is becoming so prevalent on the inland waterways.

Another committee of the association is developing a safety contest for boat personnel, while a recently-formed committee is working to develop standards of safety in towboat and barge construction.

In other activities, the group once again developed and published personnel injury statistics, and is now planning to produce its second film, this one devoted entirely to the *Handling of Rigging*.

Other committees of the association are working on developing a standardized Station Bill for use in towboats; specifications for life vests for use by deckhands and ship repairmen to be Coast Guard approved; and, improvement in the design of towboat ratchets.

In an effort to expand its sphere of

activities, the Inland Waterways Safety and Health Association, at its regular bi-monthly meeting earlier this week, appointed a committee to explore the possibility of forming a southern division of the association to bring together marine operators

along the Gulf Coast into a common safety activity.

An inland waterways session will be held as a part of the forthcoming Louisiana safety conference which will be held in New Orleans, December 11, 1961.

REPORT OF GULF AREA

By ROBERT RADER

Vice Pres., Lykes Bros. S. S. Co., New Orleans, La.

During the past year, the marine and stevedoring industry in the gulf area has displayed a far greater concern in the promotion of accident prevention than in prior years. This additional interest can be credited to many factors. Management and labor has learned that a safe operation is an efficient operation and the returns in reduced human suffering and increased productivity outweigh the time and effort expended to advance safety on all fronts.

Sponsorship of educational activities has progressed in the Gulf Region—

The U. S. Coast Guard Auxiliaries, Power Squadrons, private yachting associations, state and municipal commissions; in addition to the many private clubs in the area; have concentrated upon educating the boating public in the safe and proper manner of operating small pleasure craft. These educational functions become more important each year, due to the tremendous increase in recreational boating activities in the gulf states.

The U. S. Maritime Administration, and MSTSS has conducted the atomic, biological and chemical defense school. This facility, in addition to the radar observer's training school, continues to train Merchant Marine personnel in the area.

The Bureau of Labor Standards has presented safety courses in the principal gulf ports dealing with longshore work hazards. A large number of stevedoring supervisory personnel have completed these courses, thereby attaining a better understanding of the safety problems confronting the industry.

Technical schools, colleges and universities in the gulf states, continue to include accident prevention courses as part of their evening classes.

Several stevedoring companies throughout the area have adopted the policy of conducting safety lectures at shipside, during stand-by time or when work has stopped temporarily due to late arrivals, rain or breakdowns. This method of teaching the man on the job has gained popularity because of the obvious advantages in alerting the workers themselves to the hazards of their occupation.

These excellent educational media serve the public interest by emphasizing the dangers encountered on our waterfronts while extending specialized training to those persons who are responsible for protecting their employees from bodily harm.

There has been innumerable advancement of safety movements in the individual ports along the gulf coast. A few of the more noteworthy are—

Brownsville, Texas—Responsible parties at this port have intensified the promotion of safety activities to a fine degree. Shipping and stevedoring interests have responded with whole-hearted participation.

Corpus Christi, Texas—The Navigation District and various oil companies at this port have organized a special fire fighting unit to combat liquid fires around the harbor area.

The Sabine Area, Beaumont, Port Arthur and Orange, Texas—These ports, as always, have continued their very active participation in safety promotion. The enthusiastic support from the oil companies, marine interest and stevedores residing in the area, has gained national prominence by their improved records.

Lake Charles, La.—This port has concentrated on a local comprehensive educational program directed to the men on the job. The success of this campaign is reflected in

a steadily decreasing insurance rate and reduction of accidents in the stevedoring industry.

Houston, Texas—This port has made great strides in accident prevention, primarily due to the concerted efforts of various organizations devoted to marine safety. The port advisory committee, and the marine safety steering committee, composed of members from warehouse terminal, dock board, stevedore, steamship and towing companies, bring their combined efforts together to improve port conditions and safety factors for the betterment of all persons engaged in the marine industry.

Lubbock, Texas—The marine safety council of this port has made vast progress in the promotion of waterfront safety and has received area-wide attention during the stevedoring safety month of March, 1961. Regularly scheduled monthly meetings at this port, attended by union officials, Dept. of Labor consultants, stevedores and insurance company engineers have led to an impressive improvement in the safety record.

New Orleans, La.—This port has progressed greatly in safety promotion during the past year. The marine section of the delta safety society and the marine section, metropolitan New Orleans safety council, continued their furtherance of accident prevention into all phases of the marine industry. These organizations participate vigorously in the Louisiana safety conference, held in December of each year, which attracts important industrial leaders from all parts of the country.

Mobile, Alabama—The port authority of Mobile has become the first on the gulf coast to install a VHF-FM intraport radio-telephone system to facilitate the safe movement of ships in the harbor area. Pilots in this vicinity will be provided with portable units for direct communication with interested parties to insure better control of ship traffic.

Tampa, Florida—As the hub of a rapidly expanding section of the gulf coast, this port displays an increasing awareness of the need for safety in every phase of its waterfront activities. Shipyards, terminals, stevedores and other marine interests, in addition to city and county authorities, have separately and collectively adopted progressive programs of accident prevention which has checked the accident growth in the area. Because of the zeal exhibited by the civic and industrial leaders of the Tampa area, this port has taken an important place in the field of safety.

It is apparent that safety awareness has become an integral part of the everyday port activities in the gulf region. This trend is evidenced on the federal, state, municipal and port authority levels by the visual safety improvements in wharf areas and port facilities. The intensification of safety meetings and discussions, in an effort to introduce safety factors into every endeavor, where the possibility of accidents exist, is a credit to the industry. Considerable advancement was achieved during 1961 and even better results are expected in the coming year.

REPORT OF GREAT LAKES AREA

By DAVID L. BUCHANAN

Dir., Claims Div., Pittsburgh S. S. Div., U. S. Steel Corp., Cleveland, Ohio

Members of the Marine Section, National Safety Council have been active in promoting marine safety. The group has worked closely with the Lake Carriers' Association in the preparation of a new booklet entitled, *Safe Sailing*, which is a manual for the prevention of accidents aboard Great Lakes ships. This booklet is very attractive, with illustrations and cartoons, and it is believed

will be an excellent aid in promoting marine safety.

The monthly meetings of the Great Lakes discussion group have been informative, interesting, and well attended. In addition to discussing physical conditions, much attention has been devoted to personnel indoctrination and procedures in promoting safety consciousness among crew members.

The shipbuilding companies on the Great

Lakes have been active in marine safety activities and all of them have representatives at the 1961 Marine Section, National Safety Council.

There is keen interest in the Marine Sec-

tion safety contest by Great Lakes vessels, in which there are 13 fleets participating. Representatives of the U. S. Coast Guard have been active in the furtherance of marine safety in the Great Lakes area.

REPORT OF PROGRAM COMMITTEE

By HAROLD M. WICK
Asst. Vice Pres., American Bureau of Shipping, New York City

Your program committee is pleased to report that once again, as in the last three years, we have found it necessary to expand the number of sessions conducted at our annual meetings. This year we welcome the new session on shipbuilding and ship repairing which has been reactivated after a lapse of some ten years. However, this will not affect the similar session which has always been a very popular feature at our spring meetings in New York. We indeed hope it will be feasible to conduct a shipbuilding and ship repairing session at future annual meetings.

The addition of this new session has forced us into a situation whereby we had to conduct simultaneous sessions for two segments of the Marine Section, as no other time could be provided for us by the National Safety Council. Therefore, we had to schedule the inland waterways session and the shipbuilding session for the same time on Monday afternoon, October 16. This is a rather awkward situation for those of us who are interested in both of these sessions. Whether anything can be done about this for next year's session is a question.

The other new additions in the last four years have been the stevedoring session and an inland waterways session. Of course, a stevedoring session is also held at the spring meetings.

Before proceeding any further with this report, the program committee wishes to express its appreciation for the fine cooperation extended by our retiring general chairman, Richard W. Berry. Great assistance was also received from Mr. John G. Canerott, of the American Waterways Operators in lining up the inland waterways program. As usual, David L. Buchanan

provided the Great Lakes participation in our program once again, and Robert P. Robert was instrumental in reviving the shipbuilding session.

We would like to call to the attention of the members the list of organizations participating in our annual meeting as shown on the cover of our leaflet program. I think all will agree this is an impressive list. While talking about the printed pamphlet program, we would like to call your attention to the fact that 3,000 copies were printed for us by the Marine Office of America. More than 2,200 of these copies were mailed out by the participating organizations mentioned. Marsh and McLennan paid for printing 3,000 copies of the Spring Meeting program.

A total of 19 speakers and 15 presiding chairmen were secured by the program committee for the current annual meeting, divided into seven sessions. Individual written instructions were issued to each man. In addition, the annual business meeting was scheduled. A joint luncheon with the Propeller Club, Port of Chicago, was arranged as usual, and Vice Admiral Roy A. Gano, Commander, Military Sea Transportation Service secured as the principal speaker.

A business meeting and luncheon of the executive committee and the members was arranged by the program committee during the past year. This was held in New York at the Downtown Athletic Club on February 20, 1961. It was particularly well attended, with members coming in from the Great Lakes and the gulf region. Presiding over the meeting was general chairman Richard W. Berry. Interesting reports were received from various committee heads. Wally Gage of Soccony Mobil Oil Co. acted as secretary

The annual spring meeting was arranged by the program committee, this being a two-day session in New York and held, as usual, in conjunction with the Greater New York safety council annual convention and exposition. This was held at the Statler Hotel, April 12 and 13. The committee secured nine speakers and the services of three session arrangers and nine presiding chairmen. There were three sessions, these being the annual shipbuilding and repair yard session; a ship operator's session, and a stevedoring session. A joint luncheon was arranged with the Propeller Club, Port of New York, at the Waldorf-Astoria Hotel at which Vice Admiral James A. Hirschfeld, Assistant Commandant, U. S. Coast Guard, was the principal speaker.

The committee wishes to express appreciation to the staff of the National Safety Council at Chicago, in particular to Mr. L. W. Dutton for the considerable assistance rendered in arranging with the LaSalle Hotel for the details of our luncheon with the Propeller Club, Port of Chicago.

The committee also wishes to express appreciation to various maritime organizations for assistance rendered in distributing copies of the spring meeting program and the annual meeting program. These were the American Merchant Marine Institute, the Lake Carriers Association, the American Waterways Operators, The Shipbuilders Council of America, the New York Shipping Association, the Propeller Clubs, Port of Chicago and Port of New York, and the National Cargo Bureau.

I commend to . . . good graces the new chairman of the program committee, Mr. Robert P. Robert, of the Todd Shipyards Corp. He has had an excellent experience cooperating in the past in the work of the committee and I am most happy to turn over the reins to such a worthy successor. It has been my pleasure to serve the Marine Section for the past twenty years, the last fourteen as program chairman, and I extend to all my best wishes for continued success in the good work we have been accomplishing.

REPORT OF PUBLIC RELATIONS COMMITTEE

By FRANK BRAYNARD
Dir., Bureau of Information, American Merchant Marine Inst., New York City

With the cooperation of the ship safety achievement award committee and many others, the Marine Section's publicity efforts have continued to serve our industry by putting before the public the story of ship safety. Publicizing the various safety awards, frequently with top Coast Guard officers making the presentations, has kept a steady stream of news stories and pictures on the marine pages and in the marine journals, with an occasional breakthrough into the general news sections.

It is true that we are in a sense talking to ourselves with most of these events. When and if we as the marine section feel the need of reaching larger segments of the public, your committee will be happy to discuss a program and a budget.

We have continued to send out news releases to papers throughout the country about the March and October Marine Section meetings. We are also supplying individually written stories to the three New York newspapers about each day's events at the meetings.

Considerable publicity was won through the new Jones F. Devlin awards presented by the American Merchant Marine Institute entirely on its own and without the joint sponsorship of the Marine Section. Forty-three ships earned these citations for going two or four years without a lost-time accident. I am happy to be here this year under the houseflag of the White "M", having been asked by Admiral Moran to continue serving the Marine Section.

REPORT OF THE SHIP SAFETY ACHIEVEMENT AWARD COMMITTEE

By CAPT. JONES F. DEVLIN, JR.
Vice Pres., United States Lines, New York City

Only one ship safety achievement award proper was made this year for a safety achievement taking place during 1960. However, five citations of merit were presented. Our committee met several times and was distressed at the lack of entries submitted for consideration.

May 1 review by division the awards that were made:

Tanker Division. Winner . . . *Esso Belshiem*, Marine Division, Humble Oil & Refining Company, for rescuing five from a disabled craft under difficult circumstances May 10, 1960.

Award 3 citations of Merit. M. E. Lombardi, California Shipping Company, for saving the crew of the *Tiviana Maru*.

February 13, 1960; Sheldon Clark, Sinclair Refining Company, for rescuing two Air Force officers from ditched plane March 30, 1960.

Dry Cargo Division. Citations of merit awarded to: *President Van Buren*, American President Lines, for transferring ship's surgeon under difficult circumstances to aid ill passenger, June 5, 1960; *Pioneer Main*, American Pioneer Lines, for saving life on a swamped trawler under difficult circumstances, April 8, 1960; *American Clipper*, United States Lines, for searching under difficult circumstances for survivors of ditched plane December 22, 1960.

Passenger Division. No winner for 1960. No citations of merit.

REPORT OF STATISTICS AND CONTESTS COMMITTEE

By J. L. MORROW
Safety Dir., Grace Line, New York City

The method used to arrive at the published figures and a report made to the general chairman. He thereupon initiated a further investigation with the assistance of our staff representative, Les Dutton. The results were of general interest and will therefore be outlined.

It was noted first that the "marine transportation" accident rates are actually an average of several industries, namely: harbor equipment; river & other craft; stevedoring; and tanker and cargo vessels. The effect of this combining is shown in the published figures for 1960, which list Marine Transportation with a frequency of 20.61, fourth from the bottom in a listing of 42 major industries, and far above the all-industry average of 6.04. However, the detailed breakdown of marine transportation shows:

Harbor Equipment . . . 51.15
River & Other Craft . . . 10.91
Stevedoring . . . 14.50
Tanker and Cargo Vessels . . . 6.44

It is notable that the rate for tanker and cargo vessels, which in the public mind is synonymous with the category marine transportation, is only about 1/3 of that published as the industry figure, and in fact is almost exactly equal to the all-industry average. This pattern is the same for past years as for 1960, and both the general chairman and myself advised the Council through Mr. Dutton that we felt this to be open to misinterpretation and it should be changed.

While Mr. Dutton expressed agreement in principle with our request, as did Gene Miller of the Council's Statistics Division, they called our attention to difficulties that stand in the way of the revision we hope to obtain. They pointed out, first, that the lumping together of the four groups previously mentioned into a category labelled "marine transportation" was done largely because none of the four sub-groups was large enough to be representative, due to the small number of companies reporting, so that they could not be listed separately. In 1959, for example, the tanker and dry cargo sub-group consisted of nine companies, principally operators of cargo vessels on the Great Lakes, and including no ocean-going vessels.

It is our feeling that grouping together four admittedly unrepresentative figures and calling them "marine transportation" does not result in an accurate figure, since the four figures so grouped are practically unrelated. Further, as previously stated, the figure resulting is such as to misrepresent what is usually thought of as marine transportation; that is, ships.

Mr. Dutton felt that the situation could be resolved and ships listed separately in the published figures, if more ocean-going ship operators would report their figures to the Council. This, it developed, led to still another problem. The steamship figures for the Accident Rates and Accident Facts publications are calculated, not in the manner of our contest rules, but according to American Standards Association pamphlet Z16.1.

The big difference in the two methods is that under Z16.1, a steamship company is required to report all disabling injuries 24 hours a day, but manhours are limited to eight hours a day. For this reason, most companies have understandably declined to report data to the Council.

The Z16.1 rules are an all-industry standard, and are made up by a committee comprised of representatives from various industries. The marine industry has never been on this committee, but at Mr. Dutton's suggestion, Capt. Mackey and myself were recently appointed to represent the ASME on the committee. It will be our purpose to try to change the Z16.1 rule to eliminate the disadvantage mentioned previously. If this can be done to the satisfaction of our industry, it should be possible to get a greater number of steamship companies to report to the Council with the result that accurate accident rates can be published for our industry. If Capt. Mackey and I are not successful, then we shall probably have other recommendations to make to the Marine Section next year.

On the matter of the Marine Section contest, the general chairman and I have agreed that a change should be made in the definition of reportable injuries, in order that the question of delayed disabilities can be resolved. As presently written, the rules make an accident reportable only if the injured man is unable to stand his next watch or perform his next assigned duty. The proposed change would amend Rule 7(a) (2) approximately as follows:

"If it prevents a man from standing his next scheduled watch or assigned duty or if as a result of the accident and while still in the company's employ he is later unable to perform his duties."

This proposal was discussed at a joint meeting of the tanker and dry cargo discussion groups, and as a result of an objection made by a tanker company representative it was suggested that the words "while still in the company's employ" be changed to read "during the same voyage in which the injury occurred."

REPORT OF GENERAL CHAIRMAN

By RICHARD W. BERRY
Asst. Vice Pres., United Fruit Co., Boston, Mass.

I have the following to report at the close of my term as general chairman:

a. A program has been initiated under which a set of working rules is being prepared for the guidance of section officers in conducting the business of the section. It is hoped the plan will be ready for presentation at the winter, 1962, meeting.

b. The contest and awards committee has recommended a change in the definition of "lost-time accident" under the contest rules. This will be available for adoption at the winter, 1962, meeting. Favorable action is recommended.

c. Progress has been made toward resolving the problem of statistical distortion of marine industry figures in National Safety Council published records. The industry, through the American Merchant Marine Institute, has nominated two members to serve on the American Standards Association Z161 committee to help deal with the problem and full cooperation of the National Safety Council staff has been generously extended.

d. Increase in membership was pursued with somewhat disappointing results this year, although there was a net gain of one major company.

The year was generally successful insofar as section activities are concerned and the ever increasing response and enthusiasm at the spring and annual meetings as well

as at discussion group meetings is most gratifying.

The presentation of the National Safety Council award of merit to the U. S. Coast Guard for its publication "Proceedings of the Merchant Marine Council" is noted as being most highly deserved.

Most regrettably, the death of Mr. Carl Vander Clute is here recorded. Mr. Vander Clute, former General Chairman and a very active and valuable friend of the Marine Section for over twenty years passed away on June 1, 1961. His wisdom, wit and vitality will long be remembered by his host of friends.

At this session of the safety congress, Mr. Harold Wick has declined to stand for re-election as program chairman due to his intended retirement from the industry early next year. Mr. Robert P. Robert has been nominated in his stead. Mr. Wick has consented to continue as a member of the executive committee in the newly created post of administrative consultant, where his experience and advice will continue to be available to the section. On behalf of the membership here and now is recorded the heartfelt gratitude the section bears toward Mr. Wick for his selfless and unstinting efforts in its behalf for a period of over twenty years. His devotion is without doubt the greatest single factor in the successful conduct of the section affairs. The best wishes of each and every member go with him always.

REPORT OF THE SHIPBUILDING AND SHIP REPAIR COMMITTEE

By ROBERT P. ROBERT
Chief Safety Engr., Todd Shipyards Corp., New York City

Of principal interest to the industries concerned and to interested Marine Section members in allied fields is the reactivation of a session for shipbuilding and ship repair yards during the National Safety Congress in Chicago.

Initial plans for this session were discussed at a meeting of the executive committee members in October, 1960 and with continued interest on the part of these members an excellent program was completed.

The shipbuilding and ship repair committee arranged an interesting session for the spring meeting in New York and were gratified to see a large attendance as well as excellent advance publicity. Three fine, constructive papers were read and it should be noted that subsequent to this meeting extracts from these papers have appeared in quite a few trade publications.

With cooperation on the part of the Atlantic Shipyard Safety Exchange, short articles which had been written for the Marine Section's Newsletter were given to the editor for copy in the monthly newsletters.

During the year members from the executive committee assisted in redrafting the U. S. Department of Labor, Bureau of Labor Standards' preliminary draft on safety and health regulations for demolition.

The shipbuilding and ship repair committee has assumed an active role in fostering both interest and action to determine

procedures for dealing with the toxicity, flammability and explosive qualities of preservatives used in confined spaces. Included in this procedure is research on the development of a quick method for determining the three aforementioned qualities. It is hoped that this project will produce effective, definite conclusions.

The chairman wishes to extend thanks not only to members of the executive committee for their assistance, but also to other members of the Marine Section, for cooperation received during the year. We would be remiss if we did not extend our sincere thanks to Mr. Harold Wick for his many suggestions and the time he took to discuss matters with us.

In relinquishing the chairmanship, we would like to recommend to our successor, Mr. Dawson, that:

1. The shipbuilding and ship repair section be continued in Chicago.
2. The executive committee promote a drive for new members.
3. A procedure be developed to insure continuation of copy for the monthly Marine Section Newsletter.
4. Shipbuilding and ship repair yards on the West Coast be contacted and brought into the activities of the October Session.
5. Continued publicity be used to promote the sessions under the auspices of this committee.

OFFICERS OF THE

MARINE SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—W. LAYE BULL, Exec. Vice Pres., American Export Lines, New York, N. Y.

Executive General Chairman—CAPT. R. E. MACKEY, Asst. Mgr., Operations Marine Dept., Texaco Inc., New York, N. Y.

Vice General Chairmen (Atlantic Area)—JOHN H. HANER, Asst. to Pres., Todd Shipyards Corp., New York, N. Y.; H. G. HOPWOOD, Vice Pres. and Operating Mgr., Grace Line, New York, N. Y.; CHARLES L. BOYLE, Mgr., Marine Dept., Sun Oil Co., Marcus Hook, Pa.; W. N. DAMONTE, Vice Pres. and Mgr., Marine Dept., Sinclair Refining Co., New York, N. Y.; C. I. MELLENDRECK, Marine Mgr., Eastern Div., Tidewater Oil Co., New York, N. Y.; J. V. C. MALCOLMSON, Vice Pres., Marine Dept., Texaco Inc., New York, N. Y.; DOUGLAS MAXWELL, Mgr., Brooklyn Yards, Bethlehem Steel Co., Shipbuilding Div., New York, N. Y.; ROBERT J. TARR, Exec. Vice Pres., Luckenbach S. S. Co., New York, N. Y.; PARKER WISE, Mgr., U. S. Operations, Marine Transp. Dept., Socony Mobil Oil Co., New York, N. Y.

Vice General Chairman (Gulf Area)—ROBERT RADEN, Vice Pres., Lykes Bros. S. S. Co., New Orleans, La.

Vice General Chairmen (Pacific Area)—LAWRENCE C. FORD (Chairman), Pres., California Shipping Co., San Francisco, Calif.; RANDOLPH SEVIER, Pres., Matson Navigation Co., San Francisco, Calif.; CAPT. T. C. CONWELL, Vice Pres., Operations, American President Lines, San Francisco, Calif.

Vice General Chairmen (Great Lakes Area)—DAVID L. BUCHANAN, Dir., Claims Div., Pittsburgh S. S. Div., U. S. Steel Corp., Cleveland, Ohio; JOHN L. HORTON, Asst. Mgr., Marine Dept., Cleveland Cliffs Iron Co., Cleveland, Ohio.

Vice General Chairmen (Inland Waterways)—Operations—F. A. MECHLING, Vice Pres., A. L. Mechling Barge Lines, Joliet, Ill.; Membership—WM. C. McNEAL, Vice Pres., Oil Transport Co., New Orleans, La.

Vice General Chairman (Shipbuilding)—HENRY Z. CARTER, Pres., Avondale Shipyards, Inc., New Orleans, La.

Vice General Chairman (Passenger and Cargo Services)—SABNEY BLACKLEDGE, Vice Pres., American Export Lines, New York, N. Y.

Vice General Chairmen (Tankers)—CAPT. WM. B. CHATFIELD, Keystone Shipping Co., Philadelphia, Pa.; CHARLES A. CULVER, Marine Safety Engr., The Atlantic Refining Co., Philadelphia, Pa.

Vice General Chairman (Coastal Regions and International Safety Conventions)—ADM. ALFRED C. RICHMOND, U. S. C. G., Commandant, U. S. Coast Guard, Washington, D. C.

Chairman, Nominating Committee—RICHARD W. BERRY, Asst. Vice Pres., United Fruit Co., Boston, Mass.

Secretary—WALLACE M. GAGE, Supvr., Operations Sec., Marine Transp. Dept., Socony Mobil Oil Co., New York, N. Y.

Advisory Committee (Past General Chairmen)—ROBERT E. O'BRIEN (Chairman), Vice Pres., Operations Moore-McCormack Lines, New York, N. Y.; RICHARD W. BERRY,

Asst. Vice Pres. United Fruit Co., Boston, Mass.; L. H. QUACKENBUSH, Vice Pres., States Marine Lines, New York, N. Y.; CAPT. JONES F. DEVLIN, JR., Vice Pres., United States Lines, New York, N. Y.; JOHN D. ROGERS, Gen. Mgr., Marine Dept., Humble Oil & Refining Co., Houston, Texas; HARRY X. KELLY, Mississippi Shipping Co. (Delta Lines), New Orleans, La.; JOHN G. PEW, JR., Vice Pres., Sun Shipbuilding & Drydock Co., Chester, Pa.; REAR ADM. GEORGE WAUCHOP, Exec. Vice Pres., Farrell Lines, New York, N. Y.; LEIGH R. SANFORD, Shipbuilders' Council of America, Pelham Manor, N. Y.; LOUIS B. PATE, Consultant Nat'l Cargo Bureau, San Francisco, Calif.; REAR ADM. ROBERT C. LEE (Chairman), Moore-McCormack Lines, New York, N. Y.; VICE ADM. EDWARD C. HOLDEN, JR., USNR, Ret., Dir. of Safety, Maritime Safety Foundation, New York, N. Y.

Administrative Consultant—HAROLD M. WICK, Asst. Vice Pres., American Bureau of Shipping, New York, N. Y.

Assistant General Chairman (Programs, Conventions)—ROBERT P. ROBERT, Chief Safety Engr., Todd Shipyards Corp., New York, N. Y.

Assistant General Chairman (Membership)—SYDNEY WINE, Asst. Gen. Mgr., Marine Div., Humble Oil & Refining Co., Houston, Texas

Director, Safety Information and Posters—CAPT. MILTON INFECT, Marine Dept., Humble Oil & Refining Co., Houston, Texas

Vice General Chairmen (Stevedoring)—ANDREW D. WARMICK, Pres., T. Hogg & Sons, Inc., New York, N. Y.; ROBERT P. ALDEN, Safety & Wage Adm., Castle & Cooke, Inc., Honolulu, Hawaii

Director, Public Relations—FRANK BRAYNARD, Dir., Public Relations, Moran Towing & Transp. Co., New York, N. Y.

Director, Maritime Associations—CARL E. McDOWELL, Exec. Vice Pres., Am. Inst. of Marine Underwriters, New York, N. Y.

Editor, Marine Newsletter—WARREN D. LINDBAY, Dir. of Safety, United States Lines, New York, N. Y.

REGIONAL ACTIVITIES

Assistants to Vice General Chairmen (Coastal Regions and International Conventions)—REAR ADM. EDWIN J. ROLAND, Commander, 3rd Coast Guard Dist., Custom House, New York, N. Y.; CAPT. A. H. MCCOMB, JR., U. S. C. G., Chief, International Maritime Safety Coordinating Staff, U. S. Coast Guard, Washington, D. C.

ASSISTANT CHAIRMEN

Atlantic Region—Tanker Operations—CAPT. WILLIAM G. ANDERSON, Mgr. of Operations, Marine Div., The Atlantic Refining Co., Philadelphia, Pa.; CAPT. WALTER MATSON, Mgr., Gulf-East Coast Operations, Soccony Mobil Oil Co., New York, N. Y.; H. S. BREWSTER, Dir. of Operations, Marine Dept., Gulf Oil Corp., New York, N. Y.

Gulf Region—Ships, Stevedoring—CAPT. J. B. RUCKER, Mgr., Accident Prev. Div., Lykes Bros. S. S. Co., New Orleans, La.; EARLE SMITH, Safety Dir., Waterman S. S. Corp., Mobile, Ala.; O. P. VILAKURUJA, Claim Agent & Safety Mgr., T. Smith & Son, Sec. Orleans, La.; E. R. SEANEN, Safety Dir., Mississippi Shipping Co. (Delta Lines), New Orleans, La.

Pacific Region—Ships, Stevedoring—J. ROBERT SKYDER, Dir., Accident Prevention Bureau, Pacific Maritime Assn., San Francisco, Calif.; L. O. COFFMAN, Safety Engr., Matson Navigation Co., San Francisco, Calif.

Great Lakes Region—Bulk Carriers—WM. ECKERT, Mgr., Safety Dept., Interlake S. S. Co., Cleveland, Ohio; L. C. MATIA, Vice Pres., The Wilson Marine Transit Co., Cleveland, Ohio; CAPT. J. MCINTOSH, Marine Inspection Officer, Cleveland, Ohio

Director, Inland Waterways, Operating and Shipbuilding—BRANTON B. CARR, Pres., The American Waterways Operators, Inc., Washington, D. C.

Assistant Directors, Inland Waterways—ROBERT L. GRAY, Mgr., River Operations, Ashland Oil & Refining Co., Ashland, Ky.; G. A. PETERKIN, JR., Pres., Dixie Carriers, Houston, Texas

SPECIAL SERVICE COMMITTEES

Chairman, Ship Owners and Associations Committee—RALPH E. CASEY, Pres., American Merchant Marine Institute, New York, N. Y.

Chairman, Statistics and Contests Committee—J. L. MORROW, Safety Dir., Grace Line, New York, N. Y.

Shipbuilding and Ship Repair Committee—WAINWRIGHT DAWSON (Chairman), Safety Engr., Bethlehem Steel Co., Bethlehem, Pa.; R. B. CHAPPELL, JR., Ind. Relations Mgr., Electric Boat Div., General Dynamics Corp., Groton, Conn.; R. D. DAUTERICH, Indus. Relations Mgr., Maryland S. B. & D. D. Co., Baltimore, Md.; WM. D. FEEHAN, Safety Engr., Sun S. B. & D. D. Co., Chester, Pa.; HERMAN J. NORDSTROM, Asst. Plant Protection Engr., Newport News S. B. & D. D. Co., Newport News, Va.; JAMES O'DONNELL, Dir. of Safety, Avondale Shipyards, Inc., New Orleans, La.; A. M. PELHAM, Safety Dept., Ingalls Shipbuilding Corp., Pascagoula, Miss.; ROBERT P. ROBERT, Chief Safety Engr., Todd Shipyards Corp., New York, N. Y.; I. C. YATES, Dir. of Safety, Alabama Drydock & Shipbuilding Co., Mobile, Ala.

Chairman, Ships Safety Achievement Awards Committee—CAPT. JONES F. DEVLIN, JR., Vice Pres., United States Lines, New York, N. Y.

Chairman, Engineering and Minimum Standards Committee—CAPT. C. P. MURPHY, U.S.C.G., Asst. Chief, Office of Merchant Marine Safety, U. S. Coast Guard, Washington, D. C.

Chairman, Liaison Committee for Cargo Ship and Tanker Discussion Groups—CAPT. R. H. SMITH, Mgr., Safety Dept., United States P. & I. Agency, Inc., New York, N. Y.

Tanker Safety Discussion Group—CAPT. G. P. HENSON (Chairman), Marine Dept., Sinclair Refining Co., Marcus Hook, Pa.; ROBT. B. DAVIDSON (Vice Chairman), Sun Oil Co. Refinery, Marcus Hook, Pa.

Chairman, Cargo Ship Discussion Group—CAPT. R. N. LE PAGE, Safety Dir., Farrell Lines, New York, N. Y.

Chairman, Great Lakes Safety Discussion Group—JOHN MANNING, Asst. Mgr., M. A. Hanna Co. Agents, Cleveland, Ohio

Chairman, Gov't. Discussion Group—CAPT. J. B. OREN, U.S.C.G., Asst. Chief, Office of Engrg. and Safety Dir., U. S. Coast Guard, Washington, D. C.

Awards Committee—CAPT. R. E. MACKAY (Chairman), Asst. Mgr., Operations Div., Marine Dept., Texaco, Inc., New York, N. Y.; J. M. DEMPSEY, JR., Vice Pres., States-Marine Lines, New York, N. Y.; CAPT. L. A. RENEHAN, Farrell Lines, New York, N. Y.

GOVERNMENT COMMITTEES

Chairmen, Safety Policies for Regulations, Ship Inspections—REAR ADM. IRVIN J. STEPHENS, Chief, Office of Merchant Marine Safety, U. S. Coast Guard, Washington, D. C.; REAR ADM. HALEST C. SHEPHERD, U.S.C.G. (Retired), Westmoreland Hill, Washington, D. C.

Chairman, Committee for Safety—National Defense Transport—Vice Adm. Roy A. Gano, U.S.N., Commander, Military Sea Transport Service, Washington, D. C.

Transportation Committee, MSTC—Atlantic Area—Capt. D. A. Stuart; Pacific Area—Rear Adm. E. B. McKinney; Europe—Capt. J. R. Lenz; Far East Area—Capt. H. D. Sturr; Gulf Sub Area—Capt. I. W. White

Chairman, National Defense Transportation—Reading—Capt. M. I. Goodman, Maritime Administration, Washington, D. C.

Chairman, Safety Committee for Longshoremen, Harbor Workers—R. W. Nitterstrom, Chief Maritime Safety Services, Bureau of Labor Standards, U. S. Dept. of Labor, Washington, D. C.

Chairman, U. S. Naval Shipyard Safety Committee—Capt. J. T. Riordan, Dir. of Safety, Office of Indust. Relations, U. S. Navy Dept., Washington, D. C.

Staff Representative—L. W. Dutton, National Safety Council, Chicago, Ill.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

NON-DESTRUCTIVE TESTING OF METALS

By D. P. WALSH

Mgr., Distributor & Representative Sales, Marketing & Development Dept.
Magnaflux Corp., Chicago

The purpose of non-destructive testing is to provide decision-making facts. With these facts you make judgments and take appropriate action. In your case the decision is also based on considerations of safety and plant productivity.

In this discussion, we are concerned with minimizing injuries to personnel and loss of production by detecting fatigue cracks in parts or equipment—before a breakdown and/or accident occurs. Metal does not crystallize and break suddenly. This fact has been proven by the National Bureau of Standards. Actually, a fatigue crack initiates in a highly stressed area and grows gradually.

In a shaft that broke on the job, the fatigue crack started at the top and gradually grew in size. Flexing caused a second crack to initiate at the bottom of the shaft. Both grew in size until the remaining sound metal could not bear the load. Then the shaft broke suddenly. This condition could have been detected at any stage of the growth period. It should have been detected while servicing, repairing, or overhauling the equipment. The breakdown could have been averted.

Experience has taught us that "visual observation, even with magnification cannot readily locate all small, tight-lipped cracks. Various non-destructive methods of testing will reveal all such defects positively." (N.S.C. Data Sheet #448). This discussion will confine itself to magnetic particle inspection methods which are relatively simple in operation and are in extensive use.

A bar magnet attracts magnetic particles because of magnetic leakage from its north pole through the air to its south pole. Break it in three and there are three complete magnets, each with a north and a south pole. Reassemble it with north pole of one touching the south pole of the other, sprinkle on magnetic particles, and the particles are attracted and held by the magnetic leakage from a north pole to a south pole. In other words, the magnetic

field crosses the break and the particles are attracted. Similarly, in magnetic particle testing, a magnetic field is made to cross the crack. Particles are applied, and are attracted and held right on the crack itself.

A dense abrupt leakage field is caused by a crack. The particle buildup is dense, or closely packed, and has height. A less dense, flatter leakage pattern is caused by a sub-surface defect. The particle pattern will be less dense, relatively flat, and broader.

Crack detection involves the use of a small seven-pound yoke kit powered by 115-volt A.C. or a 12-volt battery. It is energized, the magnetic field crosses the crack, as particles are applied lightly. They instantly mark the crack, and its true extent right on the part itself, even though the crack be filled with contaminants. Because of the speed of inspection and low cost of expendables, this yoke and a companion coil are used fairly extensively in maintenance programs.

One of the important functions of inspection is to point up the true extent and direction of cracks. Another is to be sure that cracks are completely removed by salvage methods, or before repair, as by welding. A third is to determine that the salvage or repair method is in itself satisfactory.

Because there are two principal reasons for using non-destructive testing methods, namely personal safety and economy, their use has grown rapidly. The value of safe practices cannot be over-emphasized or indexed in dollars. The value of time wasted on defective raw material, time and material wasted by unsatisfactory processes, or lost production due to equipment breakdown are somewhat more tangible. The result is that non-destructive testing methods are used in practically all industries. A few examples of magnetic particle inspection in maintenance programs by various industries follow:

1. A fork lift was magnetized by high amperage current flowing through a coil formed by three or four turns of cable.

While the current flowed magnetic powder was applied. The powder formation marked the crack adjoining the radius. To demagnetize after inspection, the coil is energized and then drawn two or three feet away from the work before de-energizing.

2. A crack in a crane hook could be magnetized with cable as described, or with a small portable yoke or coil kit. Though magnetic powder can be used, fluorescent magnetic particles would be preferable.

3. A large crack in a cast valve resulted from a refinery flash fire. This crack occurred on the side opposite to that which was exposed to the fire.

4. A large dock unloading tower had been in service for several years. Its 315 welded clusters were magnetic particle inspected. 15 per cent of the welds had fatigue cracks. All cracks were chipped out, checked to be sure they were removed completely, re-welded, and the welds checked for reliability.

5. Inspection of welds on the bottom of a jacketed reaction tank was made during overhaul. Two things may be of interest: (1) contact is made with prods and the current flows, the powder is applied, and (2) the equipment used provides A.C. current or half wave D.C. The former will locate cracks and crack-like defects. The latter is used to reveal sub-surface conditions such as slag inclusions, open root, etc.

The preceding examples illustrate the "dry" method, where magnetic particles in the form of powder are sprinkled or blown on the section being inspected while the part is being magnetized. This method is recommended for castings, welds, and other relatively rough surfaces and also for the detection of sub-surface defects.

In the wet method, particles are suspended in a liquid. Fluorescent magnetic

particle inspection is recommended for practically all other applications. The reasons for this are (1) rapid coverage of the part with the inspection medium, (2) lowest cost in expendable materials, (3) most rapid inspection as cracks glow and attract attention under black light, (4) the tiniest cracks are made visible so that salvage as by grinding and polishing can be performed readily and at lowest cost.

Sometimes the question arises "how deep is that crack?" With a fatigue crack depth is important only if salvage or repair is possible. If so, the magnetic particle build-up can be indicative of the depth. Close observation will reveal that the build-up of particles mark a series of small cracks or one continuous large crack with a high, dense buildup. In the former, the small cracks will be relatively shallow. In the latter the large crack will be much deeper. In either case, a rule of thumb is that the depth of a fatigue crack will approximate 25 to 30 per cent of its total length. With small cracks actual depth can be determined accurately by alternately grinding and re-testing until the root is removed.

With large cracks a hole may be drilled to determine depth. Where salvage or repair is impractical and a replacement cannot be made, small holes drilled at the extreme ends of fatigue cracks will retard failure.

Practical men with practical problems involving the very important aspects of safety and adequate production are probably quite aware of the benefits which can derive from good inspection and good maintenance. Considerable savings and added safety result from a good planned maintenance program. They are also probably aware of the areas of interest of various responsible department heads, and their feelings with regard to the action of others as it concerns them.

THE FOUNDRY BUFFOON— AN INDUSTRIAL MENACE

By HERBERT J. WEBER

Director, Safety Hygiene & Air Pollution Control Program
American Foundrymen's Society, Des Plaines, Ill.

We know that, for safety's sake, horseplay cannot be tolerated in the foundry. Although the original joke could be embarrassing, or even slightly painful, it is the secondary reaction that is fraught with danger. The pranks played in the foundry are as old as the industry itself.

Some time ago a Detroit newspaper carried a story about a maintenance man who climbed inside the concrete mixer of a ready-mix truck to do some repairs.

The driver of the truck, having a reputation as a practical joker, then decided to throw the mixer in gear for laughs. The maintenance man was mangled to death.

When the police asked the unfunny joker why he did such a thing, he answered, "I just wanted to see what would happen." Yes, that story is true!

We have similar clowns in the foundry who insist on being the show-off or the life of the party. Like spoiled kids, they want to draw attention to themselves . . . they want to be noticed. Following are some true accounts of these menaces.

There is the "look-Ma-no-hands" type of lift truck driver. One of these show-offs was driving his truck at full speed with his hands placed behind his head to show his skill. The truck ran over a casting causing the truck to swerve into a pit mold. The driver smashed his leg and the mold, too. The mold damage is regrettable.

The yo-yo crane operator is particularly funny.

This type of clown takes a ladle of molten metal down the bay and by adroitly jerking the crane, gets the ladle to swing in pendulum-like fashion. One of them, while playing yo-yo, struck a pile of flasks and splashed metal on two men, causing severe burns.

The lunch box joke always draws a laugh but sometimes a broken toe or sprained back. In this comical scene, a molder's lunch

box was emptied and lead pigs put in. At noon time, the molder picked up his lunch box but was off balance and the unexpected weight caught him unprepared. The sudden twist sprained his back and he was off work for a week.

Another hilarious joke was pulled by a crane operator who was holding a ladle of metal on the hook while the man below was skimming it. The crane man threw the aluminum rod from a cigaret pack into the ladle . . . just for laughs. The sudden flash caused the skimmer to jerk the skimming bar and he got a splash of hot slag on his face.

Then there were the two buffoons who used to turn off the exhaust system over the degreasing tank just to watch the elderly degreaser operator get drunk from the vapor and stagger around. The humor in this lay in the fact that the old man was a teetotaler. It was fun to make him drunk. One day the jokers left the exhaust off too long.

Now let me tell you about the spit fire trick. As you know, phosphorus, when exposed to air, will ignite spontaneously. Hence it is kept in water.

In order to make phosphor copper, a stick of phosphorus is taken from a water container and rapidly plunged into molten copper. The man doing this job in a certain foundry used to show off in front of visitors by putting a small piece of phosphorus in his mouth and spitting it out just in time to ignite as it hit the floor. The scene is dramatic. The man spits fire.

One day, his timing was off and he burned a nice hole in his jaw.

I must tell you also about the hot-stream trick. In this display of daring, the show-off runs his finger rapidly through a stream of hot metal without getting burned. This can really be done if the finger is turned out and down.

However, one ham actor tried it with the finger turned out and up. He caught a pool of metal in the palm of his hand.

Any molder who has filled a flask from a sand heap knows the nerve shocking sensation of driving his shovel into a buried mild-weight or pig. Seldom is the weight buried at the end of the shovel stroke where it will only slightly affect the molder's arm.

The shock of a shovel hitting metal can be heard for a distance of six floors on either side of the victim. This allows the audience to howl with glee while the victim's hand and arm go numb and his shoulder feels as if it had been pulled from its socket. If the victim will utter a stream of profanity while he grasps his broken hand, the thrill of enjoyment will be even greater for the jokester's public.

The greased handle gimmick is as old as grease and handles. Only once have I seen this script develop into an unusual ending. A gangwayman on the shift had been the butt of this trite joke so often that he had lost all appreciation of the humor in it. He felt it was time he called someone's attention to the inhuman treatment he had been receiving. Setting his wirebarrow in the gangway where he knew the inevitable would happen, he retired to the restroom. Upon his return he stood beside the halted vehicle until the superintendent wandered up the gangway. When the superintendent drew alongside, the sand buggy jockey suggested that the superintendent test the weight and balance of the prehistoric device.

In the hierarchy of this foundry the superintendent was protected from the humor of the pranksters. No practical joker who had developed a habit of eating would satisfy his sense of humor by making the superintendent play straight-man. Without giving it a second thought, the superintendent stooped and grasped the handles. Gobs of grease oozed between the fingers of both hands.

The superintendent had perfect control of a violent temper. Rising slowly, he stood glaring at the gangwayman while a crimson wave of color rose from his throat to the roots of his closely cropped light blonde hair. He took the handful of waste proffered by the mute former gangwayman.

Slowly, he removed the greater part of the grease from his hands.

Softly and through clenched teeth he said, "You will get your check in the office."

Fraught with danger is the ferro-silicon gag. This is usually practiced on the greenhorn who is hired as a melter's assistant. His job is to charge the electric furnace with the materials comprising the heat, one of which is ferro-silicon which is very *phoney*.

The jest consists of soaking a small piece of ferro-silicon in water. When the greenhorn charges this material, the unexpected spatter and roar from the charging door will make him jump like a scared rabbit. Of course, the singeing of his clothing and skin is incidental.

Another gag that's good for an illiterate laugh or two—and a ruptured vertebral disc—is to fill a large coke wheelbarrow with pig covered and hidden by coke. More than one back has been permanently bent by this hilarious prank. A rod wired to the wheel in such manner that the wheel will make almost a complete turn before coming to an abrupt stop will result in a lot of fun for some people—and a broken rib or two.

I suggested in the beginning that the secondary reaction is often more dangerous than the prank.

The court jester usually selects his victim with great care. It is the person least able to defend himself who becomes the butt of his cowardly humor. He doesn't appreciate a joke that misfires. He will do his best to make up the loss and regain his public. Being stupid or ignorant of the danger involved, he will use fire, water, air or electricity to maim his uncooperative victim.

We once hired the quietest, best-built jolt-squeezer man in the business. In the same shop we had Bugs, the buffoon who had developed into a science the art of snapping cigarette butts into a pocket. It was just a matter of time before the two got together.

One day, Bugs slipped one butt too many into the big boy's pocket and the race was on. The big boy caught him by the belt and one leg; turned him upside down and drove his head into a soft sand heap.

This should have ended the incident but it didn't. The next day, Bugs was caught, unfortunately, wiring the big boy's squeaker handle to a 220-volt line. Had the molder grabbed that handle, I'm sure he would have been severely injured or even killed.

All these incidents that I have reported involved only one prankster but when you have two practical jokers in competition for top entertainer in a shop, the problem really becomes complicated. This is because there

can be only one star and the process of elimination becomes primitive.

The Haynes Stellite Co. of Kokomo, Indiana, holds the best all-time, no-injury safety record known in the foundry industry. This foundry has operated 7,407,010 continuous man-hours without a disabling injury. I don't think that record would be possible if the company had buffoons on the payroll.

WHEN MEN BEHAVE LIKE BUFFOONS

By LEON BRODY

Dir. of Research, Center for Safety Education, New York University, New York City

A buffoon is a clown. Etymologically, he is first cousin to a buffo, a male singer of comic opera roles. Of the latter there are two main types: tenor buffo and basso buffo. Tenor is the highest male voice next to the *falsetto*. So one is tempted to say that a foundry buffoon is likely to be a "phoney." Or, since basso is the *lowest* singing male voice, one could also say that the foundry buffoon is just a plain low character.

In any case the *kinds* of hazardous things such persons do in a foundry have been dramatically illustrated by the preceding speaker. So I should like to concentrate on the *reasons* for such actions, and on some remedial measures.

Safety directors or supervisors are naturally inclined to look for clues or suggestions couched in the language of their specific industry. This, however, is not all-essential for effective understanding and programming. Whether an organization is engaged in producing donuts or manufacturing wing nuts, the basic safety problems are the same. For there is a major common denominator to all production, to all services, and to all levels of production and service. That common denominator is *people* . . . the human element. It underlies efficiency . . . it is fundamental to safety.

Now back to buffoons. Nearly every one is a buffoon at one time or another because of temporary stresses or disturbances on and off the job. And then there are some

—a small minority, fortunately, who have more or less gotten into the habit. This is usually a matter of ancient history, with foundations in early childhood. It's like the iceberg with seven-ninths of its volume hidden below the surface of the water. To understand all this we need to know something about the basic motives or needs of man.

In general, people are moved to do things, or to resist doing them, because of three fundamental needs. These are: the need for security; the need for self-esteem; and the need for affection. When these needs are reasonably satisfied, a fellow is more or less at peace with his physical and social environment. Block the satisfaction of a basic need—for example, arbitrarily assign him a menial task, make him feel like a fool in front of his work group, or let a thoughtless wife belittle a reasonable effort—and down goes self-esteem, up goes tension, out comes an impulsive act, and high rises accident potential.

On the other hand, oversatisfying a need is dangerous too—like overeating or overdrinking. For if we let a fellow get away with things and shirk responsibilities, if we let him feel too big, he may also feel master of things of which he is not master; he may take risks; he may become aggressive and incontinent. And these are traits that we know don't mix with safety, on the job or off. The tough part about all this is that most often the motivation is in the

sub-conscious. The guy isn't aware of why he is doing what he is doing; he isn't aware of its significance for his safety and the safety of others.

Permit me, now, to cite an actual case history illustrating how this general theory of accident causation can be used to advantage. Potentially, steel mills are dangerous places in which to work. Yet the steel industry in Pennsylvania, for example, possesses a lower accident rate than do the state's 5-and-10 cent stores! How has this come about?

In part this accomplishment has been due to a steady hammering at accident reduction through insistence on the use of safety equipment; through such measures as posting colored flags in danger areas, marking building corners with yellow and black stripes, painting hand railings yellow, etc., etc. But primarily the accomplishment of greater safety stems from industry recognition that knowing is not enough—that things like attitudes are involved. Operations Attitude, as it came to be known, was born in a Chicago plant.

Company officials a few years ago came to the conclusion that the problem of safety ought also to be tackled in the light of psychological knowledge of the motivating forces that influence human behavior. Specifically, in drawing up safety rules, should not consideration be given to workers' views and feelings and intimate knowledge of the work? Would not the men be more willing to assume and accept responsibility for following safe procedures if they themselves had a chance to contribute to their formulation? Might not their attitudes then change from "I've got to do it" to "I want to do it"?

Well, the men were brought into conference, two or three at a time, to get their thoughts on safe procedures and to help formulate them with their supervisor and a safety coordinator. In this particular plant the accident rate had been the highest for any of the company's main plants—229 accidents for every million manhours. Some two years later the plant had achieved an all-time low. And in fact the accident rate at plants where Operations Attitude was subsequently tried out dropped to less than a third of the frequency rate of the steel industry as a whole. Moreover there is

reason to believe that the increased safety consciousness of the men carried over to their homes and communities. That's important, because you know how much industry is concerned, and properly so, with off-job safety of employees.

Why does worker participation in safety programs have such a favorable effect? Boiling it down, we are involving men in something important to their security; and by giving them an active voice in decisions pertaining to safety, we are helping them to satisfy their need for self-esteem. It is in the latter regard, perhaps, that the greatest opportunity resides for effective programming. Let's analyze this need for self-esteem a little further, in terms of what might be called a "worker's creed."

—We . . . as workers . . . like to give and get a word of encouragement, a friendly pat on the back, and recognition for work well done.

—We like to talk things over, to express ourselves, just as much as we believe it important to listen to others.

—We want to hear about our mistakes when we make them, but in a manner that we can learn from them.

—We believe that purely personal feelings should be kept out of the picture insofar as our jobs are concerned.

—We recognize that modern business and industry are pretty complicated, that many people have many different responsibilities for its success.

—We like to be kept informed of matters affecting our jobs, like changes in policies or procedures—and if possible, we like to have a voice in their development.

—We believe that "Will you . . ." gets a thing done better than "Go and . . ." and that "Thank you" is something to say as well as to hear.

—We know that a smile is an important aid to good human relations. (And by the way, they say it takes 72 muscles to frown, only 16 to smile.)

—And finally, we believe it most important to be genuinely interested in people—that is, cordial, considerate, and helpful.

Now this may sound like a sermon, but I can't emphasize enough that accidents—like absenteeism, poor production, and labor friction—are essentially symptoms of conditions that are not right, and more often than not they are not right because of undesirable human relations.

Needless to say, there is a variety of programs that management can provide to help meet the worker's needs and thereby make him a safer worker. But obviously, in terms of our worker's creed and organizational structure, nothing is more im-

portant than the man-to-man relationship of supervisor and worker. It has properly been emphasized that direct responsibility for safety should be placed as near as possible to where the action takes place—at the level of the first-line supervisor.

To help him carry out this responsibility most effectively it is essential that the supervisor understand (1) himself; (2) his men. If this means anything, it means training in human relations. Emphasized here should be the realization that there is a reason for unusual behavior; and that such habits or attitudes may be pretty deeply entrenched, therefore not easy to change. When a supervisor has mastered this understanding (and the support of top management is essential to help make this possible), then he has mastered half of the job of getting along with people.

Of course there are other, more specific training requirements if maximum safety is to be achieved. Not too widely recognized are these:

(1) Supervisors should be trained to spot indicators of potential accidents, such as unusual errors in work performance, changes in everyday manners, exceptional absence, changes in simple habits, and near-accident occurrences.

(2) Supervisors should be trained in the ability to talk with a worker (true communication)—and in the knack of listening, an indispensable tool in the relief of mental or emotional tension and in the revelation of facts important to management and the worker.

Now I had previously indicated the possible deep-seatedness of the problem of buffoonery and related questionable behavior. Supervision, naturally, cannot be expected to resolve this situation. So permit

me to say a few words about certain aspects of the long-run approach to the problem.

A world-famous psychiatrist once observed, "Among all my patients in the second half of life there has not been one whose problem in the last resort was not that of finding a religious outlook on life. It is safe to say that everyone of them fell ill because he had lost that which the living religions . . . have given to their followers and none of them has really been healed who did not regain his religious outlook on life."

This dramatic statement is something to ponder. As true as it may be, it is still lacking in one respect. The inadequacy is to be found in the words, "lost" and "did not regain." Countless persons who are mentally ill never had a religious outlook to lose. Their childhood and youth were weakened for want of religious education.

In an infinite universe which the finite human mind can never fully penetrate, faith and spiritual values are the greatest human asset, the greatest aid to a sense of security. Such faith and values cannot be acquired by a smattering of indoctrination. Religious education, formally and informally, and in the broad sense of the term, must begin early and persist if it is to have any profound effect on mental health—if it is to produce the calm of mind and emotion that go hand in hand with a basic feeling of belonging to a meaningful, eternal order.

Finally, it goes without saying that the full elimination of buffoonery and other undesirable traits is a matter of character development that can be accomplished only with the aid of wholesome home influences and competent, dedicated effort in our schools.

THINGS MONEY WON'T BUY

By J. S. HARRISON

Vice Pres. in Charge, Personnel & Industrial Relations, Aluminum Co. of America, Pittsburgh, Pa.

Terrific strides have been made since the first Safety Congress was held in Milwaukee in 1912. As you know, out of that conference—which was attended by 300 men from 40 organizations—came the idea of a national organization to promote accident prevention efforts in industry. Today, through its nearly 13,000 members, working in 250 state councils and local chapters, the National Safety Council continues to give force and direction to the solution of one of America's most persistent and destructive social problems.

Since the year of the Council's birth, a steadily reduced death rate has brought a saving of nearly a million lives.

And yet, because it is concerned with *prevention*—as is any important institution—the National Safety Council will never find its work all done. For example, today—October 18, 1961—during the brief time I will be talking with you, at least four lives will be lost in accidents, 350 more people will be injured, and accident costs will mount to the tune of half a million dollars.

Little wonder that your company and mine are concerned about accident prevention and how to minimize the loss of life, resources, and efficiency.

Alcoa is proud of its continuous affiliation with the National Safety Council since 1917, when the Foundry Section and the Iron and Steel Section merged to form the Metals Section. We are pleased that Will Gilliland, our Assistant Manager of Safety, is serving as general chairman of the Metals Section this year, and that Byron Kent, of our Davenport, Iowa Works, heads the section's non-ferrous industry committee.

It is good to see, too, that a number of our other safety managers, from as far away as North Carolina and the West Coast, are present for these sessions of the 49th National Safety Congress. Alcoa also heartily endorses the work of local council and is glad to have its personnel participate in the vital work carried on in our plant communities.

It is interesting to take a look at the scope of the accident prevention programs of 1961 against the background of history. This backward glance, I believe, helps us see more clearly not only where we are but also what our future course should be.

There has, of course, been concern about safety throughout man's history. For example, Cicero, the Roman orator and statesman, in the year 50 B. C. declared that "the safety of the people is the supreme law."

And the late Bishop Charles E. Woodcock, who held pastorates in some of our large industrial centers during the late 19th century, once said, "There is nothing under God's heaven that justifies your creation or your citizenship but this gospel—that the next greatest thing to creating a life is to save a life."

Nevertheless, there have been times when relatively little was done to conserve human resources.

History shows that the Industrial Revolution of the 18th century was not accomplished without its toll of human life. The new machines meant the end of much back-breaking work, but people became the "shock troops" in industrial progress. The Industrial Revolution yielded great benefits, but its harvest also included such things as crowded tenements, child labor, and a high accident rate among workers ill prepared to cope with the new tolls of production.

From our vantage point today, it is difficult to understand the spirit of fatalism with which most people regarded accidents a century ago. Accidents and loss of life were regrettable, but all too often they were accepted as part of the price of industrial progress.

Safety leadership among industrialists was woefully weak at first. You may recall, however, the significance of an event which took place not far from here in 1892. That was the organizing of a safety department in the Joliet works of the old Illinois Steel Co. As you know, because of this definite

start and because this program spread to many other mills, Joliet has been called "the birthplace of the American industrial accident-prevention movement."

About this time, companies began to show more interest in the behavior of their employees. The early minutes of Alcoa's Board of Directors bear this out in a way I thought you might enjoy.

The minutes of June 3, 1889—our company was less than a year old at the time—show that the following resolution was adopted by the Board of Directors:

"WHEREAS, Mr. Scott reported that he had visited the works several times and found the condition of affairs rotten to the core, as exemplified by his visiting the works on May 31st, and finding no one there after waiting about 15 minutes in the hot and engine rooms, but finally found Bouger asleep behind the engine and was only able to waken Bouger after striking him hard four times with his umbrella, when Bouger got up immediately and went into the office . . .

"RESOLVED, that we take immediate steps to disinfect the disgraceful state of affairs and to procure a manager to look after the plant and improve the morals of the employees."

We regard this as a bit of whimsy today, but it was a serious matter in 1889. Alcoa's early minutes also show that in 1892 the directors appointed a committee to investigate the circumstances surrounding an employee's eye injury. And, just a few months later, a committee was named to secure liability insurance.

So, here and there, as the 19th century came to a close, industry was becoming more aware of hazards and began to do something about them.

But at the beginning of the present century, there came about a dramatic change as the result of public opinion. People were no longer willing to accept conditions just because they had always been that way. Therefore Roosevelt in the White House was pointing a guilty finger at those who were failing in their duty to society. The clergy joined the press in shouting for industrial legislation. The old philosophy of "the public be damned" was giving way—and fast.

One of the dramatic events which hastened the spread of industrial safety-consciousness was the famous Triangle Shirt Waist Factory fire in New York in 1911, in which over 100 young girls lost their

lives. By 1917, at least 41 states had passed new or improved laws which more specifically defined safety regulations in factories and provided more severe punishment for violations.

But meanwhile, industry was getting its own house in order. It was in 1913 that a small group of far-seeing men, appalled by the human tragedy of accidents and abhorring waste in an otherwise efficient society, met in Milwaukee and laid the groundwork for what was destined to become the National Safety Council. In 1915, the slogan "Safety First" was coined. This little epigram was destined to become a household word—and the "granddaddy" of many another safety slogan.

There were skeptics, of course, who doubted that anything could be done about human carelessness. But the record soon began to speak for itself, as a virtual science of safety emerged to prove that accident prevention works.

Yes, accident prevention is possible, but no one need tell you men that it is an easy job. The diagnosis of the problem is easy; it's the cure that's difficult.

All of us would agree that some degree of accident prevention can be accomplished through the improvement of physical environment, tools, and equipment. We can make some progress by means of regulations and proper supervision, but I would like to say at this point that I am not at all sure that our supervisors have effectively instructed and then insisted that the safe way to do a job is as much a requirement of fulfilling the job classification as that of proper quality or quantity of production. Maybe the lack of grievance on this subject is evidence that we really are not enforcing this requirement. Maybe management at higher levels has not adequately educated our supervisors in this concept.

Because accident prevention is chiefly a problem of human motivation, however, the only truly effective way to meet it is to have the individual accept it as his own responsibility.

I believe that this matter is symptomatic of a much larger problem—one with which every individual must be personally and intimately concerned if we are to survive. Safety can mean survival in an immediate sense. Beyond this, however, the acceptance

or rejection of individual responsibility for the consequences of our own behavior can mean the difference in our collective survival.

Leaders in the safety movement have a tremendous challenge and responsibility in the life-or-death struggle in which we are now engaged for men's minds and hearts. And the measure of this success or failure will, in my opinion, go far beyond injury frequency and severity rates.

Let us take a look at our behavior in regard to some aspects of this problem as it stands today. How have we as individuals accepted our personal responsibility for our own and our brother's well-being? What, for example, is our present approach to the matters of individual and collective security?

We have, by and large, willingly helped to create billions in expenditures to realize "security." Consider for the moment the money which we as Americans spend each year for such security measures as national defense and insurance against every conceivable kind of risk from death to unemployment. Security has become so important that today millions of people look to the government for the answer to all their many needs.

Security itself has become a commodity instead of a matter of personal responsibility. A price tag has been attached to it. It is purchased much as one would purchase an automobile—on the installment plan.

It seems to be the prevalent American attitude that all one has to do to obtain what he wants is to spend money for it. Even our foreign policy is chained to this belief. We are now reaping the benefits of this policy in too many of the world's areas.

What really is the true basis of security? Isn't it this same individual sense of accountability for our own actions—a reflection of our maturity and common sense in our behavior?

Accountability is also the thing upon which safety must be built. Personal responsibility is the key to security, and it is also the key to safety. It is the basis of our survival as individuals and as a nation.

Safety is still free for the asking. It involves no payroll deductions, no billings

from the government. However, all too often the safety message has fallen on deaf ears. Why has safety received this brush-off from the public? Is it because it lacks a price tag? Must we make a commodity of safety to have it accepted? Is this the only way that it will assume any value in the minds of our people? If this is true, then I say we as a nation are in a bad way!

The individual must identify safety with the way he lives. He must make it his way of life—not just on the road over the Fourth of July, or boating on Labor Day weekend, or in the plant—but everywhere, all the time.

The real task ahead of us is to keep on showing the American public that safety must become an intrinsic part of their individual way of life. In a democracy, the only way to do this is to mobilize public opinion. This was demonstrated in World War II. The American people, after being told what had to be done and their part in the job, pulled together as a team and accomplished the goal against great odds.

In its war on accidents, industry has worked to do just this sort of mobilizing. In large part, this effort—this job of getting the individual to become personally involved with safety—has been extremely successful.

The most salient reason for a decreased death rate among workers is that industrial organizations have waged an unending campaign to mobilize employee opinion against accidents. Through you and your counterparts, workers have been made constantly aware of the dangers inherent in doing their jobs carelessly. They are subjected to safety through meetings, campaigns, equipment design, work procedures, slogans, posters, and word of mouth. As you men know, often one employee will remind another that he's doing right by safety. He'll do this because he knows that one slacker can endanger the lives of those around him.

You men are here today because much remains to be done in cutting down industrial accidents. We should not be satisfied until we have reached the point where we can devote all our time and effort to prevention instead of correcting the errors and repairing the damage after the accident.

One careless moment can stain many months of alert attention to safety precau-

tions. We must find ways and means of making people everywhere conscious of this urgent need to constantly "be where they are with all their minds."

We had a tragic reminder of this last May at one of our plants. An employee in the sand foundry was working on a sand mold that weighed nearly a ton. Dissatisfied with the position of the wooden members upon which the mold rested, he hoisted the mold a couple of feet above the floor with the crane in order to re-position the supports.

Standard procedure for this operation which had been discussed with this same man only two weeks before, requires that all four legs of the sling be used in hoisting a mold. Also, the mold is to be moved off to one side of the timbers so that at no time will it be high enough off the floor to be suspended above the worker.

In this case, the employee used only two legs of the sling and failed to move the mold off to the side. He had been warned of the possible tragic consequence of this practice on previous occasions but chose instead to take the obvious chance.

That moment in May was his moment of truth. The mold fell on him, as he crawled under it to move the timbers, and it crushed his skull. We were criticized by the union on grounds that the equipment was "unsafe."

In the majority of our accidents and probably the majority of yours as well, the basic cause is not unsafe equipment but unsafe use of the equipment. This is the point we must continue to emphasize to people everywhere. Any equipment will be unsafe when it is used unsafely. It is the individual's personal responsibility to insure his own safety by his own behavior.

Management itself must not only feel a great deal of responsibility for safety, but must also constantly back up the efforts of the safety department.

One of Alcoa's operating division managers and an outstanding supporter of our safety program, Ben Sloane, worked his

way up through the plant organization, became a works manager, was later operations manager at one of our largest operations, and is now manager of Alcoa's smelting division.

Ben has always been vitally interested in this subject of safety, and a few months ago, he directed the following remarks to his Works Managers:

The trouble with our safety record is that we have put too much confidence in the poster, the safe guard, the safety-toe shoes, and the mechanical device. At the same time, we've put too little confidence in the human equation—such as the foreman-to-man relationship, the foreman's attitude, and the general safety consciousness of our people. A marked improvement will not be a spontaneous reaction; it will of necessity await your personally pushing the starter switch and guiding the program.

Ben went on to say: "The safety record of your plant is a criterion of your ability as a manager, just as costs and quality continue to reflect efficiency in management."

We subscribe to Ben's theory. Safety must be the concern of all management at all levels. I'm sure that one of the most frustrating experiences some of you may have had comes from the feeling now and then that you are carrying on the safety battle all alone. Too often it appears that safety is assigned to the safety manager and then forgotten by the people whose interest and support are essential to success.

It's possible, of course, for the safety function to become merely another box on the organization chart, but the responsibility for making safety a state of mind rests with all of us.

If our management appears not to be as concerned with safety as we think it should be, it may be time for us to take stock of our approach in getting our story across. Conveying the safety message—up, down, and across—is an obligation.

I submit that the price of safety is identical with that of freedom. The two run parallel courses; they are inseparable. They are things money won't buy!

PSYCHOLOGICAL APPROACH IN JOB TRAINING

By JOHN NEUMANN

Senior Training Instructor, Timken Roller Bearing Co., Canton, Ohio

At the Timken Roller Bearing Co., when we list the duties of a foreman, topmost on this list would be the duty—"dealing with people."

Trump card when we deal with people is—"proper communications." We at Timken know that the ace in this game of dealing with people is a clear and thorough understanding of the foreman's responsibility to safety.

The Timken Roller Bearing Co., as producers of tapered roller bearings, high quality alloy steel and nick bits has the knowledge that it takes people to produce these products. It takes healthy, safe employees. The man who directs and supervises these employees, the man who is in immediate contact with the employee is the best means by which to arrive at a successfully-working safety program. Timken's program is aimed at the floor supervisor with the intent and purpose of keeping him mindful of safety and supplied with all pertinent safety information.

Safety in any industry must have a beginning, and the place for this is with the new employee; but safety must also have a continuation—it must become a vibrant, living part of every individual in an organization. To accomplish this aim, safety cannot be narrowed down to guards, protective equipment, housekeeping, etc., but must be looked at from every angle. At the Timken Roller Bearing Co., we have looked at safety from many angles and we know that there are many views that we have yet to see.

The mechanics of presentation of our safety program involve a safety meeting for supervisors once every two months. The material covered in these presentations looks seriously into all facets of safety. After the foreman's meeting there is a two-month period of time in which each foreman contacts the employees at their work stations, on an individual basis, and stresses safety. It is during these informal talks that safety knowledge and awareness takes place. Each of these contacts and the material discussed

are recorded by the foreman on an employee's safety contact sheet. Statistics tell us that lost time accidents have been reduced by approximately 80 per cent since the beginning of this safety program.

It is our intention to give you a sample of what our presentations to the supervisors are like. This is the sixth of fifteen that have been produced.

Instructor's Lesson Plan

Course No. 6

A Practical Approach to Safety Talks with Employees

Many people have the idea that a person's mind is like a tape recorder with the ears as two small microphones. They further believe that all information that goes through these two microphones is recorded on the tape. So it's an easy thing when we want to recall something to switch to rapid rewind, going back on the tape to when we heard that information and then switching to "listen" on the recorder so that the mouth can spout out this information.

Contrary to this belief, this is not the way that real learning takes place. In fact, a very small percentage of learning takes place under a strictly listening-type situation. In addition, we can say that under the situation just described, a "get through the course and please the teacher" attitude is usually in existence.

How then is real training accomplished? Let's mention some important points necessary to good instruction.

To accomplish good instruction, arrange for the learner to make discoveries. These should fall into:

- mental discoveries,
- physical discoveries.

The studio, field trip, laboratory, experience-type of training is far superior to a formal lecture.

As an example—reading a book may help you to build a house, but until you experience the actual work involved in building, you haven't accomplished the real job

nor can you say you are a builder. This same point holds true in safety—you can read about safety on posters, in pamphlets, etc.—you can attend safety meetings where you hear talks, see slides and movies—but none of these or other devices will give you a safe department until you campaign, instruct, or in other words, personally take safety to your employees.

Training should reorganize a person's life. Personal talks with employees must be so planned and so presented that they will reorganize the employee's thinking and action in respect to safety on the job.

A bright lad somewhere back in time once made an illuminating remark when he said, "I think the best thing for us to do is to begin at the beginning." This piece of logic is very applicable to safety—proper indoctrination of new employees in respect to departmental concentration on safety is one of the supervisor's prime responsibilities.

Let's back that last statement up with an example: "I, as a new employee of our department, I can't stress strongly enough the importance we put on safety on the job."

This kind of an introduction to the new employee with an explanation of the additional emphasis placed on safety will create a long-lasting impression.

What we have just covered is beginning at the beginning—but naturally, not all of your employees are new employees, and it is in the area of discussions and contacts with your older, more experienced employees that your tools of experience, tact, sincerity, and psychology must be used to do a good job. No, we don't mean a heart and flowers approach, but a sincere, man-to-man, adult exchange of facts and viewpoints.

Related to every area of advancement, be it technical, physical, chemical, medical—every area, spare none—is this unavoidable fact—progress comes from one source: the imagination, inspiration and thinking of people—progress toward safer and, in combination, more efficient work; progress toward more concern for the employee's well-being must also come from people—yes, the supervisor.

Who's responsible for safety?

The answer is obvious—everybody!

Personal contacts with employees to talk about safety should not be regarded as an additional job tacked onto existing work, but as a regular prime responsibility of supervision.

Two general areas, or we might say conditions, contribute to accidents and in-

Area 1—consists of material or physical objects such as equipment, machinery, tooling, materials, etc. Equipment, machinery, and tooling can be guarded or designed to incorporate safety. Material can be properly stacked or stored to make handling safe. The ability to take the danger out of the material things involved in work is usually an easy accomplishment.

Area 2—consists of human knowledge, remembrance, and movement. The ability to take the danger out of the human elements involved in work is an extremely difficult accomplishment. The best approach is the same as the approach used in looking at any job: it must be logical and systematic.

We said that the most prevalent human factors involved in work are knowledge, movement, and remembrance. Think seriously a moment on knowledge and movement. Knowledge a person gains from effective teaching and experience. Movement is a physical coordination which also comes from effective training and experience. So it is possible for a supervisor to remove the two human elements of danger (lack of knowledge, improper movement) by effective training and supervised experience.

The most difficult of the human elements of danger (not remembering) is the area in which we must direct all possible effort. It's true, of course, that effective training and supervised initial experience eliminate to a degree the danger of not remembering. However, it's a known fact that we, on occasions, forget—and this forgetting can only be eliminated by repetition of important facts that have been forgotten.

Repeating a message again and again is not an easy task. If you don't believe this, ask the advertising men who have to prepare T.V. commercials to sell soap, cigarettes, toothpaste, etc. The head shrinkers bring a word into this type of situation—motivation. They say that people must be motivated—and what they say is true.

But to say that people must be motivated, and to motivate people, are horses of differ-

out colors. There are a lot of channels through which people can be motivated. Let's list some to provide you some fuel for thought:

- individual and family security,
- individual and family health,
- personal recognition,
- economic reward,
- increased status,
- individual creativity.

These channels can apply to the person to be motivated, or to the person motivating toward the goal of safety awareness.

Over 80 per cent of the visitations that take place at our company hospitals because of injuries are due to minor cuts, lacerations, abrasions, contusions, and bruises. Of all the types of injuries to eliminate, this category is the most difficult. If we could give you a solution—a cure-all—humanity would probably put up a statue of us. We won't hold our breath for that statue, for we know that the cure lies with you—not with us.

The first step towards the solution of the problem of cuts, lacerations, abrasions, and contusions is the recognition that the problem exists. Your knowing that a problem exists and keeping yourself and your employees aware of this problem will provide the solution to it. This solution is not an over-night deal—but can be obtained by adding the magic element of perseverance.

Flag waving is a bunch of hog-wash! A great many people called the great strides of advancement in the technological fields hog-wash. One of these strides was the establishment of a preventive maintenance program for all machines. This has long since proven highly successful.

The first and most important tool necessary to a successful human preventative maintenance program is a good supervisor. A good supervisor, like any good man, does not live in that dismal swamp land called "indifference"; nor does he look at friends, employees, or problems with all the enthusiasm of a corpse.

Boil it all down and it condenses to a priceless, magical element (that we all possess, but which, through lack of use, has for most of us become rusty), common sense. If we were to tear down this tool of common sense, we would find that it's made up of these important parts:

1. Ability to think logically and systematically.
2. Control of emotions.
3. Just and high ideals.
4. A control of egotism.
5. Belief and practice of the golden rule.
6. Courage.

It's possible to shine these parts—lubricate them with usage—and apply them to the important job of protecting your employees from physical injury and pain.

OFFICERS OF THE

METALS SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—D. D. MATHER, Works Safety Administrator Safety & Welfare Dept., Jones & Laughlin Steel Corp., Pittsburgh Works Div., Pittsburgh, Pa.

First Vice Chairman—JAMES G. CULLEN, Supvr., Safety Section Employee Services Dept., Ford Motor Co., Dearborn, Mich.

Second Vice Chairman—J. W. TYSSE, Mgr. of Safety, Republic Steel Corp., Cleveland, Ohio

Third Vice Chairman—C. E. WILSON, Safety Engr., Bethlehem Steel Co., Bethlehem, Pa.

Secretary—W. D. WILLIAMS, Asst. Supvr. of Safety, The Youngstown Sheet & Tube Co., East Chicago, Ind.

Newsletter Editor—R. I. REICHEL, Supvr. of Safety, The Youngstown Sheet & Tube Co., Youngstown, Ohio

Co-Editor—D. L. JOHNSON, Supvr., Safety Engr., Pennsylvania Manufacturers Assn., Casualty Insurance Co., Pittsburgh, Pa.

Program Committee—G. LUNDIE (Chairman), Asst. Dir., Safety & Plant Protection, Inland Steel Co., East Chicago, Ind.; H. D. HICKEY, Supvr. of Safety, Bethlehem Steel Co., Buffalo, N. Y.; J. D. LARAU, Supvr., Industrial Safety Section, Steel Division, Ford Motor Co., Dearborn, Mich.; EDW. MANDRY, Supt., Ind. Relations, Cleveland Dist., Republic Steel Corp., Cleveland, Ohio; R. A. Accidents to employees involving material handling regardless of their severity if studied by methods personnel might indicate the need for a change. Manual labor today is expensive in any plant. A study of contributory causes of accidents might show that we can anticipate future incidents which would involve delay, or damage, and consequential increased cost of operation. A change to conveyors or use of portable power tools might be the economic solution.

If accidents occur because of congestion, the layout department can use the data to eliminate an unnecessary operating cost.

If certain motions in the feeding of a machine require an excessive amount of reaching, and because of this condition accidents are reported, the planning department has an opportunity to make the operation more efficient.

A simple case of an employee who was injured when he tripped over the curled edge of one of the steel plates that were used to protect a wood floor during hand trucking operations illustrates what can be done to reduce costs when accident data is properly utilized. In this case investigation disclosed that it was extremely difficult to see the floor directly ahead when pushing a loaded truck. Moreover, these curled edges had frequently hindered the operation when the wheels struck the plate and swung the truck around. Merchandise had been knocked off and damaged. Time was required to clean up such spills. Other trucks were held up and employees were developing an attitude that management was not interested.

A study of the job offered several solutions to the problem that not only reduced the probability of injury but improved the operating efficiency. Use of accident data in this manner provides the means of improving maintenance programs, storage facilities, job training, communications and employee morale.

The proper use of accident data will provide management with material that can be used effectively to improve the quality of supervision. Supervision fundamentally is the art of controlling the performance of workers. If they do something contrary to the right way, it is an indication that supervision is weak.

Some of the reasons for unsafe performances frequently found will bear repeating.

Individuals are unaware that what they did was wrong.

They misunderstood the instructions that were given.

They didn't consider the instructions important.

They weren't given specific instructions.

They found it awkward to follow the instructions that had been given.

They were handicapped by some physical impairment.

They were mentally upset because of financial worries and personal problems.

They were obviously prone to recklessness or day dreaming and easily distracted.

They deliberately disregarded instructions.

Economic advancement therefore, can be realized when management fully utilizes the potential gains that are possible from an effective accident prevention program. What constitutes an effective program and what does it cost should be considered.

Accident prevention does not differ from any other management function. Certain procedures are essential for achieving the objectives. The application of these procedures does require the time of various personnel but while this is being done primarily to prevent accidents, we are contributing in no small measure to the overall operating productivity of the company. For this reason, it is very difficult to separate the cost and profit of an effective program.

Perhaps if we had the answers to such questions as the following, it might be done with some degree of accuracy.

What does it cost to have a working force whose morale has been undetermined?

What does it cost to have supervisors who do not know how to detect evidences of inefficiency?

What does it cost to operate under the handicap of impending fear of breakdown, delay, insufficient manpower?

What does it cost to attempt spasmodically to inaugurate a safety campaign when an accident stirs up critical comment and puts the limelight on your company?

What does it cost to let employees learn from personal experience instead of taking advantage of the past experience, as the basis of training?

Management considers it profitable to improve its operating efficiency in every practical way. To accomplish this, they make job studies to eliminate loss motion. They study plant layout and material handling methods to reduce transportation costs. They spot check operations to determine the causes of down time of equipment.

A properly developed accident prevention program can be the vehicle for successfully accomplishing these studies. But it does not seem fair or reasonable to charge the time required to do this entirely to a safety program. In addition, management considers it profitable to provide development courses for their supervisory personnel.

Participation in accident prevention gives the supervisor the opportunity of exercising his ability to deal with people to a much greater degree than he finds possible in many of his other duties. He gets to know their attitudes better, he improves on the quality of giving instructions, he has experience in getting people to work cooperatively in solving a problem and he increases his power of observation. The benefits of course are not limited to the prevention of injuries.

A brief consideration of the procedures of a program will show that they are activities closely identified with similar procedures that are accepted as essential for the successful operation of any business.

1. The indoctrination of employees—

Employees should be instructed as respects their participation in the overall program. They should understand interest management has in their safety. They should be told what management has done to make their job and working environment safe.

2. Development of operating rules—

Each job should be studied and specific rules developed that reflect the experience of individuals plus the knowledge gained from past accidents.

3. The instruction of supervisors—

We cannot assume that supervisors will automatically shoulder a full share of responsibility for their part in an

accident prevention program. They should receive instructions that specifically explain the practical approach to each part of the program as it affects their daily activities.

4. Inspections and observations—

Standards of performance the same as quality control, can only be maintained by frequent checking. It is essential, therefore, that supervisory personnel initiate a regular program of observing workers performance and check for compliance with instructions.

5. The reporting and investigation of accidents—

Regardless of the severity of personal injury, all accidents should be investigated. Unless the cause can be determined and the reason for the cause established, we cannot assume that similar accidents will not occur.

It is the severity potential represented in the accident cause rather than the extent of injury that should influence our action.

6. The correlation and study of accident data—

Unfavorable trends or items deserving of preferred attention because of the serious potentials can only be determined from a careful study of the accumulated data on individual cases.

7. The management control unit—

Management should establish a procedure that will enable the safety administrator to make direct contact at a level where executive action can be taken when the need arises. This control could be an individual or a group but in any case, it should have the authority to make decisions and to act when facts are presented.

If these procedures are followed conscientiously, they will not only reduce the probability of injury but will aid materially in reducing operating costs. Management has said that costs can be reduced by—

The proper training of individuals to do the job assigned.

The standardization of work methods.

The development of supervisory personnel. The establishment and policing of procedures and controls.

knowledge of which would be of assistance to any supervisor in the event of a mine fire.

Lecture and demonstrations of sampling and analysis of mine atmospheres; causes of underground fires; methods of fighting underground fires—directly and indirectly; construction of all types of barricades; recovery of a sealed mine fire area—when and how; and supervisory duties at the time of an emergency.

In the event of a mine fire, a trained supervisor would be available to accompany a rescue team underground. We emphasize that he would not take the place of a regular team captain, but would take the position as number two man. The captain is still responsible for his team, including now the supervisor, but the latter might direct some special operation not a part of regular training, and would be in a position to make a full report on conditions to management on his return to surface. He would be an ideal person to act as a guide in the event it became necessary to use teams from other mines.

In 1957, the department received a request from a manager of one of our mines to provide a course designed to assist a mine manager and mine superintendent in making decisions in the event of a fire in his mine. This was done, and the management course in mine rescue has been well received throughout the industry. Two hundred and twenty managers, mine superintendents, chief engineers, safety directors, chief electricians and mechanical superintendents have attended.

The management course consists of a prepared paper dealing with such topics as: limitations of rescue teams and equipment; care of teams—health, meals, rotation, age limits, medical examinations; fires in mines—causes, stages, control of; gas sampling, analysis, interpretation of results; recovery following mine fires, and fire procedure, fire organization and control headquarters.

Originally this course was designed for approximately four hours, but generally the discussions and the relating of personal experiences on the part of those attending have extended it to a full day or even more. Printed copies of the paper are distributed before the class begins.

There is always a concern in the minds of us who are responsible for conducting mine rescue training that the subject may become boring to some of the older men, who have worked the same problems, used the same instruments, worn the same apparatus, sat through the same lectures and even listened to the same jokes, time after time. There is a limit to the type of work that can be done while wearing breathing apparatus, and there are just so many words to be memorized in the text book. We do re-word the problems in the hope the men won't recognize them as ones they had last year, but there's a limit to that, too.

The apparent solution to this vexing problem has been mine rescue competition. Now we may be "babes in the woods" in competitions, referring of course only to length of time, when compared to coal mining areas in other Canadian provinces, or in the United States, but we have developed a system of competitions that works, that suits our particular needs, and does create the necessary spark needed to maintain interest.

Ontario's first official mine rescue competition in 1950 was a purely local event between the mines in the Porcupine mining area of Northern Ontario. The site, by the way, of the Hollinger fire. Word of this competition spread to other districts and interest increased until three years later, four districts entered teams. Now, 11 years later, eight mining districts are taking part in Provincial mine rescue competitions. Each year some 45 teams enter into a round of competitions to produce eight district winners, and out of that, one team emerges as the provincial champions.

Originally the winning teams of the district competitions were brought to a central point and a "big day" was held. As teams began to be entered from distant points, as far as 1,200 miles apart, it became necessary from a cost standpoint to discontinue a central competition. In its place, and to keep the provincial competition operating, a team of three judges, consisting of the Inspector of Mine Rescue Training, the Assistant Chief Engineer of Mines, and a District Engi-

neer of Mines, the latter chosen by rotation, travel to each of the eight districts. An identical problem, oral examination and test of apparatus work is presented to each team that has already become district champions. Of course every precaution must be taken to guard against advance information getting ahead of the judges, so each of the provincial events must be held indoors, and admittance must be restricted. All problems are conducted in total darkness—illuminated only by miner's cap lamps, to add reality.

In 1958, following a suggestion by one of our mine rescue station superintendents, it was decided to make use of the trained supervisors as briefing officers in our mine rescue competitions. The plan has been very successful, and it does help to keep up the interest of this category of men.

Each mine entering a team in competition must provide a briefing officer from among its supervisors taking rescue training. He is given the narrative or story of events leading up to the moment at which he appears on the scene. The chief judge will answer any reasonable questions the briefing officer may ask, and will then leave him alone for 10 minutes to prepare his plan of action.

With as many as eight teams entered in a single district competition, there could be eight different plans of action, some good and some not so good. In order to not handicap the team, the chief judge will receive the briefing officer's plan, and then hand a standard problem or directive to him to study and pass on to his team. The briefing officer's plan will be marked but only nominal demerits are given. It is primarily the team that is in competition, and nothing must be done to jeopardize its chances.

The Mine Safety Appliances Co., has, since 1950, presented a fine trophy to the provincial champions, and cash prizes to each member of the first three teams.

The work-horse and the back-bone of mine rescue training in Ontario is the McCaa 2-hour, self-contained breathing apparatus. By far the greatest percentage of our training involves this piece of equipment. Where mines are deep and

large, even two hours is too short a time for some operations, without frequent trips back to fresh air for re-charging.

However, we do have a number of small metal mines, where fire hazard is at a minimum, labor turnover is high, and where it is not practical to try to maintain one or more full teams intensively trained with the McCaa apparatus.

In 1952 it was decided to experiment with the use of half-hour demand apparatus in the Cobalt district, where the mines are comparatively shallow and distances from the shaft are not too great. A system of re-charging demand apparatus while it is being worn in contaminated air was developed by the Ontario Department of Mines together with the Scott Aviation Co. This became an immediate success, and we now have some 60 half-hour air-demand apparatus in use in Ontario.

Improved methods have been developed for the transportation of large air cylinders underground, and all air-demand teams must be thoroughly familiar with re-charging techniques.

In conclusion, in case there are still some skeptics that don't believe a fire can occur in a metal mine, I would point out that we have had in our Ontario metal mines 186 underground fires in the period from 1947 to 1960. Of these, 109 were electrical, 27 were caused by burning or welding operations, 20 from smoking, 10 due to spontaneous combustion of sulphides, 2 from overheated air receivers, 3 resulting from blasting, 3 spread down the shaft from surface, 3 set for warmth, 6 by friction, 2 by diesel equipment, and one, believe it or not, by lightning.

We are happy and proud to say, however, that no lives were lost as a result of any of those 186 fires. Rescue teams were used in 33 of them, and it was only because many of the others were discovered in time that teams were not used more often. One of the extra dividends derived from mine rescue training is that the thousand or more individual trainees become automatically fire hazard conscious, and whether they realize it or not, are continually on the lookout for conditions that could lead to an outbreak.

PREVIEW OF SLIDE-SCRIPT ON UNDERGROUND HAULAGE SAFETY

By HERBERT A. WENDEL
Chairman, Bureau of Safety
The Anaconda Company
Butte, Mont.

The initial reception and response to the first Script-Slide production by the Visual Education Committee in 1959, "Safety in Open Pit Operations," indicated the need for additional similar Mining Section service projects. During 1961 the Visual Education Committee has been quite active and has accomplished the following objectives:

1. Produced a Script-Slide series of 101 colored 35 mm slides with a suggested script on Underground Haulage Safety.
2. Submitted a series of 12 posters to the National Safety Council for consideration in producing a series of posters for the Mining Section's Falls of Ground Campaign in 1962.
3. Recommended changes on the series of four Accident Preventers, used in the previous Falls of Ground Campaign, to produce a new series for the 1962 campaign.
4. Submitted pictures and posters to the Newsletter editor.
5. Sent a questionnaire to Mining Section member organizations to determine future visual education needs.

6. Developed and produced a Script-Slide program for the 1962 Falls of Ground campaign.

7. Cooperated with other Mining Section committees on committee projects.

Active members of the Visual Education Committee during 1961 were: H. A. Wendel—Chairman; A. W. Ness—American Smelting and Refining Company, Salt Lake City; Fred Pearson—Noranda Mines Ltd., Noranda, Quebec; Melvin Taylor—Compania Minera de Cananea, S.A., de C.V., Cananea, Sonora, Mexico; and Morgan Wadsworth—American Metals Climax, Climax, Colorado.

The Script-Slide program on Underground Haulage Safety consists of a total of 101 colored 35 mm slides. This type of visual education material allows a mine organization to use or delete any slides not appli-

cable and makes it convenient to separate the slides into a series of shorter presentations. The script may also be altered or changed as desired.

The National Safety Council plans again to have several sets of this program available for free use by member organizations on a request basis as a Council service. Duplicate sets of slides were available immediately following the preview at the 1961 National Safety Congress.

SUGGESTED SCRIPT FOR SOUND-SLIDE PROJECT ON UNDERGROUND HAULAGE SAFETY

1: Safety in underground haulage concerns everyone who works in an underground mine. Because heavy equipment—motors, cars and trucks—are operated in narrow tunnels, often at considerable speeds, there naturally are a number of hazards we must know about and guard against.

As in all places where safety is important we can avoid or eliminate the hazards if we know what they are and where danger exists.

This series of pictures we are presenting today show some of these dangers and how accidents and possible injuries can be prevented. Not only motor crews are involved in haulage safety but also everyone who works on the level, especially along or near haulage ways.

You will notice that the pictures show different types of haulage equipment, some with trolley locomotives and others with battery powered locomotives. Some of the men pictured are wearing safety glasses in addition to hard hats and safety shoes as some operations require all employees on surface and underground to wear safety glasses.

And, although some of the equipment may look strange to you the same hazards exist here at our operations and result in the same kind of accidents and injuries.

2: Probably more motor crew members are injured while performing the rather simple act of coupling cars together—the sensible safety conscious person always stands well back in the clear and waits for the train to stop before trying to couple. Here the cars have been stopped about two feet away from the car to be coupled on. Notice that this man has a whistle he uses for signaling his partner.

3: Now we see a swamper who has given the motorman a stop signal and in perfect safety steps in between the cars to align the couplers.

4: Then before signalling the motorman to push the cars together, the swamper has stepped back in the clear.

5: Then as the couplers come together properly they are securely coupled and the swamper has avoided possible injury.

6: Some operations require the use of safety chains on couplers to prevent cars from breaking away if they should become uncoupled. This is a good precaution where grades are steep.

7: But sometimes the couplers do not mesh properly. . . .

8: Then it is necessary for the swamper to have the cars pulled apart again so he can re-align the couplers. Ordinarily this is a safe procedure if all safety rules are followed, but this man is taking a short-cut—he is trying to line up the couplers with his hand while the train is in motion. He is so careless that he has his head and body in danger and does not have his whistle where it can be instantly used. This man is asking for it!

9: Men can get in even worse predicaments, this fellow could not get in the clear if he wanted to.

10: Another unsafe act is that of kicking the couplers in line while the train is moving. Even with the whistle in his mouth this man could suffer a serious foot injury. . . .

11: Which is exactly what did happen!

12: Of course you can buy feet and legs in a store but you probably won't be able to run or dance any more. Always think of the consequences before taking a chance or a short-cut.

13: Another very dangerous practice is trying to couple cars while standing in the

inside of a curve or other restricted place. . . .

14: Because you can get caught, and pinched or rolled between the cars and the timber or ground. This type of accident always involves very serious or fatal injuries. . . .

15: And such accidents can be so easily avoided if men remember to stand on the outside of a curve or in a place with proper clearance. You must also remember never to expose yourself or reach in between cars unless they are stopped.

16: Another dangerous practice often indulged in by motor crews is to leave cars or locomotives parked in very tight places. This not only endangers their safety when coupling or uncoupling cars, but also creates a hazard for pedestrians. . . .

17: This swamper is really in a tight and dangerous spot where he cannot get in the clear if the cars accidentally move. . . .

18: As happened here, and the result—a serious head injury.

19: And how easily this accident could have been prevented, simply by parking cars in places of proper clearance. . . .

20: In places with good clearance you can easily get in the clear if something goes wrong.

21: In order to provide safety for pedestrians along haulageways, safety zones are established. Men walking along haulageways must ever be on the alert for trains approaching from either direction. Watch out for lights and signals; listen for bells, whistles or sirens. Motorcrews have the responsibility to keep headlights on and sound warnings, especially at curves and when men are observed along the haulageway. Some safety zones are in untimbered areas.

22: Safety zones may also be in timbered areas, but in either case pedestrians must be sure to get well in the clear and wait until the train has passed. It is a good practice to look up and down the track before stepping out again, as a car may have become uncoupled and could strike you.

23: Here is a man who didn't quite reach a safety zone in time. Note how close he is to a possible accident, especially if a car should jump the track. Motorcrews should slow down or stop if pedestrians are not in the clear.

24: Locomotives, like all other types of running equipment, work better and safer if they are kept in good working order. Good motor men always check brakes, controller and clean out the cab at the start of every shift. . . .

25: They also check the sand boxes and fill them up before starting the shift's work.

26: A little sand on a slippery section of track will produce more work and may also prevent a serious or fatal injury.

27: It is very important for the motorman to always sound the bell before starting the motor after any stop. A railroad engineer always sounds a warning before moving the train. You never know who may not be in the clear.

28: Some underground locomotives have air whistles or sirens for warning devices. Whatever warning device you have, use it! It is better to make too much noise than not enough!—

29: Because when a locomotive is moving at full speed it may not be able to stop in time to prevent an accident.

30: Flesh and bone are no match for this monster, don't run too fast.

31: Motormen, like other men who use equipment, often get careless in their habits, especially while operating the locomotive. "Familiarity breeds contempt" and often bad habit as well. These could, and often do result in serious consequences. Standing up in the cab may be alright if the motor is stopped but should never be done when the train is in motion as low clearances may exist along the way. You could also be thrown out of the cab if the train suddenly stopped.

32: One of the worst of these careless habits is shown here—a motorman with his feet out of the cab and resting on the bumper. What if the bumper should strike something?

33: Suppose the motor coupler strikes a car coupler—this man could easily lose a foot. . . .

34: Or he could fall out of the cab and get caught between the motor and a car and lose his life.

35: However, the man who sits properly in a locomotive cab has little to fear, and can do more and better work.

36: Some very dangerous habits are devel-

oped by the men who operate trolley locomotives. One of the most hazardous of the common unsafe acts is the practice of "back-polling." This means that the motorman is too lazy or careless to turn the trolley pole when the locomotive is to move a short distance in the other direction!—

37: This unsafe practice can be done in either direction, whether the train is going forward or backward.

38: Sometimes they get away with it but at other times this short cut becomes a short-cut to the hospital or to eternity!

39: This is worth another look. Look and Remember! This could happen to you.

40: How easy it is to avoid accidents and injuries if every job is done the right way. Always turn the trolley pole, even for very short distances when backing up or changing direction.

41: Motormen are charged with the responsibility of protecting their own safety and also safeguarding others. Caution must be exercised when the locomotive approaches curves or intersections as men or other equipment may be in the way. Sound a warning at all curves! . . .

42: And when approaching any intersection, especially if other locomotives are operating on the level.

43: Don't forget to sound a warning. Slow down or stop when approaching ventilation control doors as men or equipment may be right behind or ahead of that door.

44: The swamper or switchman of a train crew also has a responsibility for his personal safety and for the safety of others. For this reason he often rides in the front car when a train is pushed; here he can watch out for rocks on the track and warn pedestrians. When riding in side dump or bottom dump cars the swamper must brace himself with his hands. It is very important that he keep his hands in the clear; the end of the car is best for this purpose.

45: Never place your hands on the sides of a car as they may get pinched or crushed by falling rocks or obstructions, especially in tight places where timbers may be squeezing.

46: Some mines require that the swamper or switchmen walk ahead of the train. When this is done be careful not to slip and also keep well ahead of the train at all times.

47: Swampers, like motorman, also engage in some very dangerous practices like this man who is riding with his feet on the car coupler.—Not a very secure position if the car runs over a rock, or if his boots, or the coupler is slippery.

48: Remember to wait until the car or locomotive stops before getting off. Jumping on or off moving cars is a very foolhardy stunt! . . .

49: Ending like this—not a very healthy position to suddenly find yourself in. . . .

50: If you were lucky enough to escape with your life. This type of accident almost always results in disability or death. Again, Don't Take Chances!

51: The same thing is true when you get into a car—never board a moving train, wait until it stops.

52: Probably one of the easiest ways for a motorman to get injured is through the use of unsafe practices when pulling or pushing cars or trucks loaded with timber or materials. This locomotive is pulling a loaded truck, if the motor stops suddenly the truck may not, some material may slide forward and strike the motorman.

53: How much safer a person feels when an empty car is placed between the locomotive and the loaded truck. How much better for the material to strike the car than you.

54: It is even more dangerous to push a loaded truck ahead of a locomotive. . . .

55: As timber or materials may strike against ground or timber. Not a very pleasant position for the motorman. Many men have been seriously injured or killed in this manner.

56: Again, this type accident can easily be prevented by placing an empty car between the motor and the loaded truck.

57: At times it is easier to put pipe, rails or timber on top of a car as a truck may not be handy.

58: In this case it is even more important to have an extra margin of safety—an empty car—between the locomotive and the loaded car. . . .

59: If I were the motorman I would feel better and safer with two cars between me and that load of pipe.

60: This is what can happen to you when you neglect to protect yourself. This one kind of accident is so unnecessary.

61: Here is an example of another equally dangerous and senseless practice often indulged in by careless motor crews—carrying tools and materials on top of the locomotive. These objects not only restrict the motorman's view, but may be pushed back against him, especially if an obstruction or low place is encountered. . . .

62: Keep the top of the locomotive clean and free of materials. Always use a car or truck to transport materials and equipment. . . .

63: So you will never be the victim of an accident like this.

64: This scene is worth another look. I hope it impresses you of the terrible consequences that may result from violation of safety rules and practices.

65: But above all, never try to commit suicide by being careless in transporting explosives such as placing a carton of dynamite on top of a trolley locomotive. Think what would happen if the trolley pole broke or there was a short-circuit in the armature.

66: There is only one safe place to carry explosives and that is in an explosives or powder car. . . .

67: Otherwise the locomotive may look like this. Imagine how the motorman looked. Life is too precious for us to take needless and foolish chances.

68: Sometimes an explosion may cause a fire that not only destroys a valuable piece of equipment but may endanger the life of every man in the mine.

69: Runaway cars can be a menace to anyone working or walking along a mine haulage way. The only way to be sure cars will not run away, especially where grades are steep, is to block them securely. This car is not blocked and could start moving quite easily if accidentally pushed or bumped. Men have been seriously injured or killed by runaway cars or trucks.

70: There are many ways of blocking cars such as with timbers, wedges, chains or blocks. Here is a simple effective way to block cars on steep grades, a block and a piece of lagging.

71: Specially constructed car blocks, held in place by chains to prevent slipping, provide a safe means for blocking cars. Notice that this type has a handle so you can keep

to their own actions, but the inexperienced men present a great hazard. First, they must be trained in doing their particular job and only their job. One of the biggest accident hazards is the man doing someone else's job. We find that an electrician rarely injures himself doing his regular work. The same goes for a carpenter or a mechanic.

Trouble always starts when one of the tradesmen start to do the other fellow's job with which he isn't familiar, such as burning or connecting up a live wire, or trying to take short cuts. Our usual procedure is to take men entirely unfamiliar with tunnel work and put them in the top gang on the surface, the track gang, or the bull gang, until they become familiar with the general procedure of drilling, blasting, and mucking out.

Shaft sinking is started by using a crane to excavate down to solid rock. Exterior forms and liner plates are then installed. The exterior of the shaft was 24 feet and the interior 14 feet. When the 100 foot mark was reached the temporary headframe was set up.

A crew of 12 men was used in sinking the shaft, composed of a walking boss, a shifter, six miners, a pumpman, a compressor operator and a bellman.

As soon as the temporary headframe was installed, a Joy grapple, air operated on a Chicago boom, was used to muck out. The grapple was equipped with a 3½ cubic yard bucket. The shaft, 800 feet deep took 129 working days, and then the shaft was belled out to allow room to bring in the track and other equipment. When the tunnel grade was reached a pilot tunnel of 50 feet was driven in each direction from the shaft. The sides of the pilot tunnel are then slabbled in to enlarge the tunnel to a 15 foot horseshoe shape. The mucking was done with a #630 Eimco mucker, air operated. Usually a 3-track transition took 17 working days with a 3-shift operation; this included a double track section to the face alternating both sides of the shaft to 200 feet. A sump 30 feet deep, 14 feet in diameter was sunk with conventional shaft methods.

The ventilation in the shaft was supplied by a Buffalo 5000 cubic foot capacity blower fed through the utility lines.

Upon completion of the sump and the transition the permanent shaft steel was

erected. This included the guides, fan line, landing chairs, mucklopper and gates. The shaft steel was placed at 80 feet per shift taking about four days to erect. The permanent headframe, cages, etc. took about two weeks to complete.

Permanent equipment was then taken into the tunnel consisting of two model 40 Eimco muckers, air operated, a drill jumbo with five Gardner Denver 93 liner drills, one Gardner Denver model 143 down the hole drill, all hydraulically controlled booms and positioners. Attached to the drill jumbo is a steel car with drill steel, roof bolts and other equipment.

Roof bolts were installed with an R.B. 94 Gardner Denver stoper drill. The roof bolts were Republic steel 1½ inch by 72 inch expansion shell with a one inch split wedge type.

The tunnel face was drilled with a crew of six miners, four chuck tenders, one shifter, one walking boss, two electricians, one mechanic. Drilling time for the operation was usually one hour. The drill pattern was 38 to 40 holes, 12 feet deep, a burn hole 12 feet by 8 inches. Usually the loading time was one-half hour. Two hundred forty to 260 pounds of Gelex #2 powder with 45 delays including double priming, no stemming was used. Smoke time was twenty minutes maximum.

Ventilation was supplied by a Ruth Conover 15,000 cubic foot blower, supplied through a 26-inch vent line of 14 gauge spiral Naylor pipe.

In the tunnel the roof is constantly watched by the entire heading crew because long experience has proved that falling rock usually means serious injury. After the tunnel face or heading has been blasted, the broken rock, or as it is known to tunnel stuffs, muck, must be removed from the tunnel and the drilling of another round starts all over again. Today, we have roof bolts that are driven into the roof in a pattern that covers the roof so that unless we strike very bad ground or roof bolts prove to be a wonderful protection. Lagging had been the sole roof support for all past tunnel operations.

The purpose of the roof bolts is to squeeze layers of rock together to form a beam. This beam supports the rock above, therefore, prevents roof falls. This is accom-

plished by anchoring one end of the bolt in a hole about 6 feet deep in the rock and screwing a nut and washer on the outer end of the bolt. The anchoring is done by expanding a corrugated shell until it tightens against the sides of the hole or by driving a wedge in the slotted ends of the bolt. Both methods do a very good job.

A stoper drill is used to drive the wedge into the slotted rod and an impact wrench is employed in tightening the nut on the bolt. Two bolts are connected by a flap strip of steel one quarter of an inch thick by five inches wide by about four feet, six inches long. This assembly is called one-roof bolting unit. The units are spread in a pattern across the arch of the roof generally parallel to the center line, and arranged so as to give maximum protection to the miners; such protection was unheard of in previous years. The roof bolts also serve to hold up loose sections of the rock to prevent sliding of one layer on another. They also act as supports for the ventilation pipe that furnishes free air directly to the heading and the electric cables.

The chief hazards encountered in roof bolting are the flaking off of small fragments of rock while a hole is being drilled and the breaking of the stoper drill steel. Roof bolts have proven to be an almost foolproof method of supporting the roof. They have given the miner a real feeling of safety.

The mucking operation usually took one hour and 20 minutes after which the track laying took 25 minutes, using a 60 pound rail or short 10 or 12-foot temporary sections. Temporary electric lights were strung in the heading and scaling down was done during the mucking operations. The face was always wet down during the mucking operations and carried on during the entire mucking operations. Side dump cars of 6 cubic yards capacity were used and 15 or 16 cars of muck usually were loaded after each shot. Muck trains were operated by 10-ton diesel locomotives equipped with scrubbers to eliminate carbon monoxide conditions. Car passers were shot every 90 feet to facilitate moving empty cars for loading.

Water supply lines were 4-inch, air lines were 8-inch and discharge lines were 6-inch. Electricity was supplied with 23,000 voltage reduced by transformers every 3000 feet to

44 and 250. Light and pump switches were placed every 1500 feet to 2000 feet with variations.

We find that inattention to the job details is the main cause of our accidents. Next comes inexperience, and then finally, the fellow who takes chances. A miner may get injured by falling rock, or from lifting. A chuck tender usually gets injured in moving the machine or setting a stoper drill or vertical drill for roof bolting. Pinched fingers and hand injuries are caused in the ratchets of the drills.

Our safety program is aimed at instilling the superintendents with the need of indoctrinating the walking bosses in safety procedures. The walkers, in turn, set them across to the shifter or foreman. The State laws governing working conditions are clear and understandable, and all real construction outfits live up to each code rule. Where they find that a rule causes a hardship, they petition the Board of Standards and Appeals for a variation. After an extensive investigation the petition is either granted or denied. All tunnel work is done under State Code No. 30.

There is no work in the world like driving tunnel as it comprises all the crafts and all types of work. The men on the job are never interfered with. If the safety engineer in his inspection sees a workman doing something in an unsafe manner he immediately finds the shifter and sees to it that the shifter corrects the man immediately. The safety engineer makes a thorough inspection of the entire job starting at the face and working along the entire job. He may see a man riding on the front end of a locomotive, or in between the motor and a chuck car. He immediately stops the motor-man and has the man get out of the danger zone. To sell safety to every man on the job, you must have some knowledge of the work. This is gained only from experience. In our 25 years of experience we have seen the results of all kinds of serious accidents. Therefore, we are able to explain to each man the reason why he should do things the right way.

Hazards are encountered by men who want to do things the lazy way, and the safety engineer must be alert to these hazards. On starting a job, each shifter must take a few minutes before each shift to hold a short safety meeting. The hazards to

be encountered by that particular crew are discussed, also the different phases of the work, and who is to do what is thoroughly gone over. When excavating the blasted rock the chuck tenders are usually the car passer crew.

Because of the small diameter of the tunnel it is necessary to have one car positioned off the main track. The device for doing this is called a car passer. The car passer crew sees to it that the empty cars are put into loading positions. Serious accidents have occurred in this phase of the work, and the men are cautioned continually on where to stand, how to move the cars, and how to position the cars on the car passer. This is one phase of the work that must be watched carefully. Railroadings is a great hazard, and some of our most serious injuries occur when a workman takes chances in this operation.

The State law demands periodic checking of all locomotives underground. Frequent inspections must be made with a carbon monoxide tester to check all exhausts on every motor. Motors are also checked daily for brakes, lights, and warning signals, and to see that they are operated properly as to speed, etc.

All of our key men are experienced tunnel men and have been in tunnel work more than 25 years. Many of us have worked side by side all these years. Each of us knows what to expect of the other, and what to do when the unexpected happens. Every one of our supervisory personnel is fully cognizant of the working conditions and would not care to be in any other work. For this reason, each old-timer knows that tunnel work can be just as safe as any other kind of work.

The safety engineer must check all equipment to see that it is in good working condition, must check to see that all hoisting cables have been greased properly. All elevators must be checked once a month to see if the safety catches or dogs work properly. This is a must, and a record is kept of the distance the cage drops, after engaging the safety dog, which is usually one to two inches. All hoisting cables carrying the elevator must be resocketed at least every six months, at which time several feet of cable is cut off. All bearing points are changed by this shortening of the cable and it is then resocketed by factory men of

the cable company. New York State has a very highly trained personnel in the Bureau of Mines, Division of Industrial Safety Service of the Labor Department. These men make periodic inspections to see that each safety device is in good working condition; check to see that all regulations pertaining to explosives are adhered to; make tests for gas; make sure that all ventilation is adequate and that the fans supplying the ventilation meet the State requirements. These men have been a great help in maintaining safety standards and cutting down on accidents. The B.V.S. and the State Insurance Fund have also contributed to accident control with their safety inspectors.

Some methane gas has been encountered in the excavation of our tunnels, so the shifters must make a test for gas at the heading on every shift. They use an explosive meter and a flame safety lamp for this purpose. The explosive meter will give him a fairly accurate reading on methane or natural gas. The flame safety lamp will also signal any gas conditions, as well as to give definite warnings of lack of oxygen. In the early part of our work at the Intake Tunnel, one of the miners stood on the muck pile and started to scale the roof of the tunnel at the face after blasting. He knocked one of the P.A.R. lights off the steel pin that was holding it overhead. The miner reached down to pick up the light, the filament of which gives off a small flame, and as he got it waist high there was an explosion; three men were severely burned about the face and hands. They were treated immediately by the registered nurse who prepared them for removal to the hospital.

Due to prompt attention and medication we use for such emergencies, the men escaped without even a facial disfigurement. This accident, like all such accidents, was reported by phone to the New York State Bureau of Mines and Tunnels, who in turn asked the Federal Bureau of Mines to make a thorough check on all our gas conditions. The finding of natural gas pockets led us into a strenuous training project which, while costly, definitely paid off in safety.

After our gas explosion, with the cooperation of the U.S. Bureau of Mines, its Wilkes Barre, Pa. office sent us three exceptionally qualified experts to conduct our training classes. The men were first trained in Mine Rescue work, which includes the

use of all types of gas masks, how to detect gas and what to do in the emergency. Secondly, they were trained in accident prevention. This training includes all the phases of our particular job, and finally each man was trained in first aid. The men were, and are, paid straight time for attending classes and a light lunch was served. Upon completion of our training program, a first aid contest was held in Roscoe, New York. This was the first hard rock mining contest ever held in New York State.

In October of 1956 one of our men was seriously injured by a rock fall and sustained a broken back. He was placed in a local hospital under the care of our attending surgeon who produced wonderful results, but the prognosis was that it would be a permanent total disability. During the treatments over a period of eight months, the injured man was seen by three top neurosurgeons, two from New York City and one from Binghamton, New York. All three of these men, who are tops in their profession, diagnosed the case as a hopeless total disability and that rehabilitation was out of the picture. With this staring us in the face, we felt that we had come to an impasse and had even made tentative arrangements to have the injured man flown by ambulance plane to North Carolina to be near his wife and children.

Even though we had the medical reports stating that there was little or no chance of further improvement we did not give up. The man himself has been a tower of strength as he has never once complained, but has steadfastly maintained that he was going to walk again. In talking to some insurance friends I heard of a similar case that had been handled by a Doctor Hoen in New York City. Our doctor immediately got in touch with Doctor Hoen who came up and made a thorough examination. Doctor Hoen stated in his report that he was very much impressed with the patient's attitude and that he felt he could have him up on his feet with braces and crutches in three months and eventually have him drive his own car to North Carolina instead of going by ambulance plane.

This was such wonderful news that we made immediate arrangements for his removal to the New York Rehabilitation where he is now and making good progress. We feel that our personal supervision of these

serious cases, paid off in this instance, as this man might have remained a bed patient for the forty-two months life expectancy in these cases, and that would be it.

We report every accident through the proper channels. When a man is injured he must report to the nurse. If additional medical care is needed, he is immediately taken to the doctor's office or to a hospital in our own ambulance, one of which is garaged at each construction location. Our medical service is watched very carefully and I am notified immediately of every accident requiring medical attention, regardless of the hour of the day or night. If it is a hospital case, I go immediately to the hospital to see that all necessary medical care is available, such as blood plasma, an eye specialist, or any other form of medical attention or medication. We have lists of public blood donors of all types available for any emergencies. This is very essential where there may be more than one injured man.

Should there be a shortage of any requirement, we immediately take the necessary steps to get it. In such instances, we call on local police or the state police. Through the years we have found that by looking after an injured man, he rarely forgets it, and, on future occasions he is more cooperative in following the instructions of the safety engineer.

Safety on any job is a matter of common sense, education, experience and most of all, active interest and cooperation of top management. This top interest is not something just to be talked about or sloganized, but top management must work at it continuously. We are fortunate in having our project manager and all our top management thoroughly active in our safety work. It is a proven fact that the rising costs in compensation have caused definite action to be taken by management in looking at safety programs that must meet the particular job requirements.

We firmly believe that compensation costs will demand that every large construction company will eventually have to maintain a safety department with a thorough knowledge of compensation matters as the injured man is a direct result of an unsafe practice and getting the man back to work will be a direct cost. It is going to be necessary to train each crew in safety procedures of their

particular job. General safety programs will not suffice as conditions on one project are foreign to conditions on the other.

While progress is the most important part of every project, progress without safety is foolhardy and safety without claim supervision is too costly. In many cases the humane element is lacking and the injured man becomes a compensation number.

We firmly believe that it is very essential that every man injured should know that management is interested in his getting better and back on the job. We make it our business to see every man who has a lost time accident to inform him of his compensation rights and our help. We consider this an important element in safety work.

Over the years we have found it necessary to attend compensation hearings on all serious and phony cases. We not only help to save thousands of dollars but do a great

deal to straighten out cases that could hang on indefinitely, because we feel that usually the injured man never gets enough to compensate him for a real serious injury and usually we can suggest to the carrier that certain procedures be waived and the man be given additional help. We also invite the compensation personnel to the job so that they may get a first-hand picture of the entire operation.

Each month we get out a bulletin in which we give our progress figures at each location and we discuss each lost time accident, also listing our frequency and severity records. This keeps every man on the job informed as to why they should work safely and to prove to them that they are personally the losers every time they get hurt, bringing home to them that they cannot afford to have an accident. It also makes them feel that they are an important part of the job.

SAFETY ASPECTS ON THE USE OF MECHANICAL RAISE CLIMBERS

By LEONARD P. COLVIN

Asst. Research Engineer, The Anaconda Company, Butte, Mont.

Mining companies are intensely interested in new equipment to help increase production, lower costs, and improve working conditions. The mechanical raise climber contributes to all three goals. Properly used, it will increase production, cut costs and has a number of important safety aspects which are the subject of this discussion.

The raise climber is an elevator that eliminates timbering while driving a raise. It facilitates the movement of men and materials safely to and from the working face and provides a platform to make work at the face easier and safer.

An extensive time study of Butte raise climbing operations showed that a greater percentage of the mining cycle is spent in effecting the direct advancement of the raise, with much work required in our conventional raises being eliminated. As a result, the raise climber has cut the mining cycle time required to less than half. Lifting large

timbers, installing bulkheads, drill stagings, lining chutes and climbing ladders are elements not present in climber-driven raises.

While the raise climber does away with many of the usual hazards of raising, others in connection with the climber operation have developed. Proper ventilation of climber raises; the correct design of storage room for the climber and equipment; and the type of mucking or raise chute lay-out are of prime consideration in the prevention of accidents.

The climber is considered an elevator and should be maintained as one. Miners and maintenance men must be trained to follow a daily and weekly lubrication and inspection schedule. Daily testing and inspection of the safety brakes is essential.

Through experience we have added and changed some mechanical features of our raise climbers. Raise climber manufacturers are also constantly trying to improve the

versatility and safety features of their climbers.

When the miners are unable to descend a raise on a climber due to mechanical failure or lack of air power, a definite mechanical procedure is followed. For unforeseen emergencies a long nylon rope and two safety belts are provided on all climbers in Butte.

Summarizing, the climber has cut the time of a complete raise cycle by half and lessened the preparation work and fatigue accordingly. Many of the hazards of driving timbered raises have been eliminated by the use of the climber; however, it is apparent that the first-line supervisor, maintenance

men, and the miners greatly influence the safety aspects of the climber.

To obtain optimum safety of the personnel operating the climber requires of all concerned, that lubrication, inspection, maintenance and correct handling be rigidly adhered to. Also, the training of personnel for correctly operating and maintaining the climber is necessary. The storage room design used in raising is of primary importance and certain mechanical changes in some climber models are desirable.

All of the foregoing elements should contribute to a reduction in the number of accidents in driving raises.

STOPPING METHODS IN THE LAKE AMBROSIA URANIUM MINES

By H. J. ABBISS

Safety Director, Homestake-Sapin Partners, Grants, N. M.

The Lake Ambrosia uranium mines are situated in an area some 30 miles northwest of the town of Grants in New Mexico. Underground mining started approximately four years ago and today there are more than 18 companies active in mineral extraction. The mining methods described in this paper are those being used by the majority of the operators in the area. Due to the different types of ore bodies it is not uncommon for a company to extract the ore in a mine by a combination of these methods.

Prior to describing the mining methods a brief description of the geology of the area is necessary.

The ore is found in two formations, the Todilto limestone and the Westwater sandstone. Most of the ore bodies in the Todilto are small and discontinuous. My paper will therefore deal with the Westwater ore bodies.

These ore bodies may be classed as trends, pods and stacks. The term "stack" arose from the early conception of the thick ore bodies wherein the geologists pictured them as being a point of intersection of numerous trends—or a "stacking" of trends. Most of the ore bodies in Ambrosia Lake are of the trend type, some being over 2000 feet long

and ranging from 50-200 feet in width. Pods or kidney shaped ore bodies may be as much as 1000 feet in their long dimension.

Delineation of the ore prior to stopping is done by extensive long hole drilling from development drifts. These holes quite often perform a dual function in that they provide good drainage for the water in addition to providing geological data.

The stopping methods used in the Lake Ambrosia mines fall under the following headings:

1. Trackless Room & Pillar
2. Slusher Room & Pillar
3. Long Hole Room & Pillar
4. Cut and Fill
5. Modified Shrinkage and Others

Trackless room and pillar mining is carried out in areas where the ore ranges from 5 to 15 feet in thickness. Drifting was done on a predetermined grid pattern, usually 50 foot centers. The basic development drifts are usually 7 by 10 feet or 7 by 14 feet in cross section, which leaves pillars of varying dimensions. In the majority of cases these pillars are 36 by 36 feet or 40 by 40 feet in area.

Pillar removal is accomplished by splitting pillars with a trackless or slusher drift

and removing subsequent pillar stumps by slabbing into adjacent pillar crosscuts. Trucking is done from the pillar crosscuts (or drifts) where remaining pillars provide protection. Occasionally stulls or clusters of three stulls are installed on the stopping line or cave line for temporary protection while drilling and mucking. If required then timber cribs are installed. Retreat mining is started from an ore fringe and an attempt is made to proceed with pillar removal in a uniform retreat line.

Where mucking cannot be done from a safe position near the cave line, scrapers are used to pull the broken ore back to a safe place for subsequent loading with diesel front end loaders or trucks.

Drilling for pillar removal is done with drills mounted on air legs, using 1½-inch hexagon drill steel with carbide bits. Rounds vary from 6 to 13 feet in length.

Blasting is done electrically using 1¼ by 16 inch semi-gelatin dynamite and milli-second blasting caps. Condenser discharge blasting machines are used to detonate the rounds.

In general, slusher room and pillar methods are used for mining thin horizons of ore (less than 5 feet thick) or areas inaccessible to trackless equipment. The basic development for slusher room and pillar stopping is done with drifts driven on 25 by 50 foot centers or 50 by 50 foot centers ranging from 6 to 8 feet wide. Broken ore is slushed to properly spaced raises and transferred to the haulage level through chutes into cars or trucks.

In most retreat work the pillars are slabbed along a retreating face perpendicular to the 50 foot grid dimension. The broken ore is cross slushed to the drifts and then to the extraction raises. Lines of stulls are carried behind the mining face.

In some cases where the back is weak the retreat mining is done by driving panels 8 feet wide through the pillar leaving an 8-foot pillar. A 40-foot pillar would be split with two panels 8 feet wide leaving three 8-foot pillars. After each panel is driven and supported the remaining 8-foot pillar is slabbed into the panel and slushed out. In some cases small stumps are left for support as well as slabs and cribs.

Drilling and blasting procedures are the

same as used in the room and pillar method of mining.

Slushing is done with two and three drum 15 and 25 H.P. electric hoists pulling 48 and 34-inch light weight welded scrapers.

In many instances ore pods will be thicker than 15 feet but not thick enough for cut and fill mining. Where this is the case pillars are removed by room and pillar methods using sectional drill steel for blast hole drilling. In most cases the basic development drifts are driven on a 50 by 50 foot grid pattern and the ore removed to full height before pillar removal starts. After the rooms are excavated to full height, the pillar is split with a drift approximately 8 feet high in the bottom section of the ore. From this drift one-half of the pillar (approximately 20 x 40 ft.) is ring drilled with sectional drill steel to reach the top and lateral extent of the ore. Burden on the rings is usually 3 feet. The holes are loaded with 1¼ by 16 inch sticks and primed with milli-second caps. Usually the broken ore can be blasted into an area next to the remaining pillars and away from the cave area.

Usually the stopes are too high to use stull or crib timber effectively and much removal must be done with slusher hoists and scrapers. Men are required to stay out of these open stopes and safe access must be provided to reach slusher tail blocks. In most cases muck removal after a blast can be completed before excessive cave from the back causes too much dilution of the ore.

Slushing equipment and techniques are similar to those used in other stopping methods. Ore is slushed to extraction raises or to points where it may be loaded with diesel powered loaders.

In one mine where the ore is approximately 500 by 180 feet in area the ore is mined by cut and fill stopping methods. Within the ore body stopes have been laid out approximately 25 feet wide and perpendicular to the long axis.

Initial development of the cut and fill area was done by driving raises from slusher rooms which were below the ore. From these raises, which were driven into the various stope panels, stope drifts were driven on the bottom of the ore to the ore limits in each panel. These drifts provide a start-

ing point for "slibbing out" each panel in the cut and fill stopes.

To date horizontal cuts have been taken in the cut and fill stopes which vary from 8 to 15 feet high. After the cut is mined, the back is bolted with studded roof bolts of the 1½-inch expansion shell type. Chain link fencing is installed on these bolts before the broken ore is removed.

Mucking is done with diesel powered front end loaders or scrapers and the broken ore dumped into a raise or chimney where it is dropped to the loading scum below.

Drilling is done with air leg mounted machines and similar drill steel and bits as those used in other stopping operations.

Blasting procedure is the same as in the other stopping areas.

After the broken ore is removed from a cut or lift, vertical "gob fences" are constructed along the stope boundaries and cabled together in order to confine the fill material in the stope. Gob fences are constructed of 2-inch lagging nailed on the inside of 8 by 8 inch posts spaced on 5-foot centers.

Waste back fill is dumped into the stope through fill raises and spread with scrapers or diesel powered, front end loaders. Fill is spread in the stope so that it will range from 3 to 8 feet from the back and ore extraction chutes are constructed or extended to the top of the fill.

As mining commences on the next lift or cut the chain link fencing is removed from the back before blasting. This fencing is rolled up and stored for re-use on the next cut.

Mining is continued to the top of the ore and the back supported with cribs which are placed on top of the fill after mining the last lift or cut.

Subsequent stopes or panels will be mined in sequence along side of the completed stopes or panels. Considerably more timber will be used in these subsequent panels to provide temporary support in the brow area adjacent to the mined out and filled stope. Mining will commence in the original stope panel drift and the ore will be slabbed out to the gob fence of the adjacent filled stope.

Fill material used for stope back filling is mine waste from early development work and is transferred into the mine through a 32-inch borehole and hauled by truck to the

stope fill raises on a level above the Cut and Fill stopes.

In one operation where the ore is relatively thick, that is 60 feet or more and long and narrow, a modified shrinkage stope method has been adopted. Scram drifts and cones are driven under the ore body with raises driven at 30-foot centers along the strike. After the under cut is completed the ore is blasted by drilling flat long hole mines from the raises. Since the raises are inaccessible after the first blast, the ore is shot from bottom to top in one blast, the rings being drilled on 5-foot centers.

In another mine where the ore is of high enough grade to require 100 per cent extraction, the ore body has been developed with three parallel sub-level rail headings on 200-foot centers with ore passes on 75-inch centers. Slusher slots are cut between draw points on adjacent rail headings perpendicular to the rail. These slots are cut through the full thickness of the ore and supported with square set timbers. The 75- by 200-foot blocks thus delineated are being mined by driving a series of drifts 6 feet wide and 9 feet high through at right angles between two adjacent slots and shrinking the ore over these drifts. The muck in the shrink slot is slushed out and replaced with sand containing Portland cement (1 sack per ton). The shrink slots are accessible from both ends for slushing the broken muck and filling.

Development drifts outlining the pillars are usually supported by the use of rock bolts with chain link fencing or steel mats. The New Mexico Safety Code states that any place over 10 feet in height or over 8 feet wide will have permanent support to within 10 feet from the face. In some cases drift sets are used for support. During pillar extraction the extensive use of stulls or cribs in conjunction with rock bolting is the general practice.

Due to the presence of radon and the daughter products, coupled with the use of diesel equipment, it is necessary that each mine has an effective ventilation system. In stopping this is accomplished by fresh air being constantly supplied to all working headings. Mechanical ventilation with the use of brattices, auxiliary fans and vent tubing is used.

In the past, all operations were faced with

problems during the stoppage cycle but with constant research, good planning and supervision plus the help from certain agencies

it has been proved that the mining of uranium ore in the Lake Ambrosia area can be done effectively and safely.

THE 1962 CAMPAIGN TO REDUCE INJURIES FROM FALLS OF GROUND

By AL KOLU

Chairman, Campaign Advisory Committee, Assistant Safety Supervisor
Pickands Mather & Co., Inc., Duluth, Minn.

Those who were active in the 1955 National Safety Council's international campaign for the prevention of injuries from falls of ground at metal and nonmetal mines (other than coal) will recall that it was the first major campaign conducted by the mining section; and, while participants lacked experience, they made up for it in enthusiasm. I would like to refresh your memories on what happened.

First, we had active participation in United States, Canada, South Africa, Cuba, Cyprus and the Philippine Islands; and second, we got results.

The 1955 frequency experience, compared to the base period of 1954, fell 29 per cent. Three out of every four of the 250 participating mines reported improvement; and this improvement ranged from 24 per cent in Canada, 30 per cent in the United States, to 43 per cent in the group including South Africa, Cuba, Cyprus, and the Philippine Islands.

Certain mining areas showed even more startling results. For example, participating mines in the southwest United States showed an average improvement of 36 per cent. Those in the eastern part of the United States showed an improvement averaging 46 per cent. British Columbia achieved the largest improvement, with 56 per cent. It was estimated that at least 245 lost-time and 15 permanent total disabilities and fatalities were prevented in the participating mines.

Unquestionably, that campaign was worth all the effort and enthusiasm that was poured into it.

Let's examine what has occurred in the years following that campaign. In 1955, the

frequency rate for fall-of-ground accidents in the metal and nonmetal mines in the United States averaged 6.6. Comparing this with the last complete figures available for this group in 1958, we find there has been an increase to 7.63. Preliminary 1959 figures indicate a rate still higher—8.4. The 1960 over-all Canadian experience shows similar high rates.

We all know that falls of ground lead as a cause of serious disability and death and that their prevention is one of the most rewarding objectives. An analysis of years prior to 1955 indicated that more than 3 per cent of all lost-time injuries from falls of ground are fatal, 80 per cent are serious, and less than 17 per cent are minor. 1959 figures indicate that the 3 per cent has now grown to more than 4 1/4 per cent.

You can well appreciate, therefore, why there is a great need for a concentrated attack on falls-of-ground accidents, and since we now have not only the enthusiasm but the experience, the campaign we plan for 1962 should deal a hard blow to this persistent hazard.

Now for 1962. Our goal is a reduction of 30 per cent or more in the frequency rate of injuries and fatalities from falls-of-ground accidents in our participating mines. The campaign will run from January 1, 1962, to December 31, 1962. We intend not only to intensify our effort, but to broaden the coverage by enrolling more mines in the campaign.

The campaign is sponsored by the mining section of the National Safety Council under the direction of an advisory committee composed of Al Kolu, Pickands Mather & Co., Inc. chairman; Edward C. Leonard,

Inland Steel Company; and John A. Cooke, Falconbridge Nickel Mines Ltd. Endorsing and cooperating in the campaign are federal, state, and provincial mining departments, mining associations, mining publications, insurance carriers, and others having an interest in the welfare of the mining industry.

All underground noncoal mines are urged to participate in the campaign, including mines in Canada and other countries outside the Continental United States. Membership in the Mining Section of the National Safety Council is not required.

The only requirements for participation are:

- 1) If the company operates two or more mines, each mine must enroll separately.
- 2) Each participant agrees to furnish a simple report of injuries resulting from falls of ground for 1961, a report at the end of the first six months of the campaign, and a report covering the last six months.

The Council will make awards to mines and supervisors achieving the campaign goal and meeting the other campaign requirements.

The National Safety Council has produced various materials to assist participants to achieve an effective campaign, which are as follows:

- 1) Announcement poster.
- 2) A scoreboard poster.
- 3) Twelve posters, one for each month of the year, emphasizing an important safe practice for avoiding injury from falls of ground.
- 4) A series of twelve information sheets, one for each month of the campaign.
- 5) A set of four illustrated booklets, each containing illustrations emphasizing safe practices pertaining to the prevention of falls of ground.
- 6) Reflecting safety signs for mounting at strategic points underground. (These come in sets of four, made up in two colors

and bearing various phrases pertaining to the prevention of falls-of-ground accidents.)

7) Reflecting Scotchlite stickers for hard hats which have the green cross for safety on an off-white background, with the phrase "Prevent Falls of Ground" imprinted. (These are to be distributed to all underground employees of all mines enrolled in the campaign.)

Other bulletins and promotional material will also be mailed. A new slide film has been prepared. All campaign materials are now ready and available for purchase from the Council.

Committees and their members have worked hard in developing the above aids for the Campaign. I want to express my appreciation for the cooperation of all committee members, and I wish to thank the many others who contributed statistics and material. Clint Hoch, staff representative, and the staff of the National Safety Council deserve special mention for their hard work in preparation of the campaign.

The campaign is on. Now it is up to each of us to see that as many mines as possible are entered, to see that campaign material is used, and to see that there is no letdown during the entire year of 1962. This is no small job. It's a big-scale operation that deserves and must have the all-out efforts of every safety man. You should get this program before your top management immediately and see to it that every supervisor is keyed up to top effort.

The material and program prepared by the National Safety Council will be a valuable aid, as will the various agencies and departments mentioned previously, but the final results will come from your supervisors' know-how and enthusiasm. This is your opportunity to make one of the biggest possible contributions towards saving life and limb. We want the campaign big, and we want it successful. Let's give it everything we've got.

LOW-COST BLASTING AGENTS

By GLENN H. DAMON

Chief, Branch of Explosives Research, U. S. Bureau of Mines
Washington, D. C.

The cost of blasting is important to the development of many mineral deposits. Since the introduction of explosives to the mining industry in 1627, when black powder first was used at the Royal Mines of Schenitz, Austria,¹ explosives have played an ever increasing role in the mining industry. In the United States alone, over one billion pounds of explosives are used each year and approximately 75 per cent of this total is used in mining. Thus, until recently, the American mining industry was spending approximately \$175 million per year on explosives, exclusive of detonators and blasting supplies.

While this cost is not large in comparison to the value of the products from the mineral industries, any saving in the cost of the explosives is reflected in lower mining costs, provided this change does not result in increased costs for drilling or for handling the broken ore. In addition, any decrease in the cost of blasting should be accomplished without a decrease in the safety of the mining operation.

Attempts to lower blasting costs by the use of cheaper or more efficient explosives are not new. The development of nitroglycerin-based high explosives resulted² from efforts to find an explosive more efficient than black powder. Even before this, chlorate explosives³ were investigated and were rejected because of their hazards. In 1871, Sprengel⁴ patented a series of explosives intended for mining which gave promise of reducing blasting costs. These explosives combined certain oxidizing and reducing substances which could be mixed just before the explosive was used.

The original "Sprengel explosives" used oxidizing materials, such as potassium chlorate, nitric acid, and nitrogen tetroxide, with combustible materials such as nitrobenzene, nitronaphthalene, carbon disulfide, and petroleum. Liquid oxygen explosives were introduced later and proved moderately successful in the United States, particularly in strip mining coal. Although Sprengel explosives are generally very powerful and moderate

in price, they have never seriously challenged the nitroglycerin dynamites. Some, such as nitrogen tetroxide mixed with a hydrocarbon, are too hazardous to be practical for general mining.

Explosives composed of mixtures of ammonium nitrate and a fuel were first suggested by Ohlsson and Norrbein⁵ in one of the earliest patents covering commercial high explosives. The first practical, commercial "blasting agent" using the ammonium nitrate-fuel system was introduced to mining about 1935. This type blasting agent, sometimes called "nitro-carbo-nitrate," was noncap sensitive, but could be readily and reliably detonated by a strong primer.

However, the full economic advantage of the ammonium nitrate-fuel system was not realized until the introduction of Akremite⁶ to coal stripping operations in 1955. This system employed a porous, fertilizer-grade, prilled ammonium nitrate sensitized by carbon black. The ammonium nitrate and the fuel were mixed at or near the site of the mining operation and the product was packaged in polyethylene bags. Under the confinement provided by the borehole, this oxidant-fuel system could be detonated with a dynamite primer; the primer comprising from 5 to 25 per cent of the weight of the final charge.

It was soon apparent, however, that a liquid fuel such as diesel oil could be applied more readily and would have many advantages over a solid fuel. The economic advantage of this blasting system is apparent since oil is very cheap and fertilizer-grade ammonium nitrate (FGAN) sells for approximately 31 cents per pound. Equivalent-strength dynamites sell for 15 cents to 22 cents per pound.

Prilled ammonium nitrate is relatively porous, but the carbon black in Akremite reached only the outer surface of the prill which was already covered with a diatomaceous earth, anti-caking agent. Now a large proportion of the blasting agents are prepared from uncoated prills and a liquid fuel.

Most of the ammonium nitrate produced and used in the United States is made by reacting ammonia with nitric acid. The bulk of the production is used by the fertilizer industry and most of the remainder (approximately 700 million pounds per year) is used in the explosives industry. To a considerable extent, the physical properties of the ammonium nitrate are controlled by the method of manufacture or production. Particle size and particle density are important for material used in the explosives industry, but are relatively unimportant in the fertilizer industry. Also, ammonium nitrate is extremely soluble in water and tends to harden into a solid mass when exposed to atmospheric moisture. To prevent this caking, it was formerly common practice to add one to three per cent of a petroleum wax coating to prevent setting. After the disastrous explosion in 1947 at Texas City, Tex., involving such organic-coated ammonium nitrate, the use of wax anti-caking agents was discontinued for fertilizer material and an equivalent effect was obtained by adding two to four per cent kieselsguhr.

Until about 1947 nearly all the ammonium nitrate produced in the United States was made by graining process. Here the water is evaporated from the ammonium nitrate solution at atmospheric pressure and the size and density of the product can be controlled by the rate of heating and the amount of stirring. This process still is followed for most ammonium nitrate used in dynamite. A moderately dense uniform-particle-size material can be made by this method.

The largest percentage of ammonium nitrate produced in the United States is made by the prilling process. In this method, a hot, 95 per cent solution of ammonium nitrate is sprayed down through a counter-current stream of hot air rising in a prilling tower. As the material solidifies, most of the water is removed and the resulting product becomes moderately porous and almost spherical. By carefully controlling the conditions in the prilling tower, it is possible to vary the particle density of the prills from approximately 0.76 to 0.95. This density is appreciably lower than that for grained ammonium nitrate, which averages approximately one.

Experience indicates that a relatively

porous, prilled ammonium nitrate produces the most satisfactory blasting agent when compounded with the proper proportion of fuel oil. The principal disadvantage is the relatively low density. It has also been found that uncoated prills produce better all-purpose blasting agents than similar prills containing three or four per cent kieselsguhr. To meet this demand, industry now is producing prilled ammonium nitrate with either no anti-caking agent or with only a very slight coating. In more recent developments, a surface active agent is added to the ammonium nitrate to insure a more intimate contact between the oil and the surface of the prills.

Number 2 diesel fuel has been found most satisfactory for producing these low-cost blasting agents. More volatile fuels, such as gasoline, should not be used because of the fire and gas-explosion hazards. The ready availability of diesel fuel and its low price make it particularly attractive as the combustible material in blasting agents, but almost any oxidizable material can supply the fuel requirement and, to varying degrees, the sensitization to initiation. Pulverized coal, chars, nitromethane, and even such improbable fuels as molasses have been employed, often in combination with some fuel oil.

Most prilled, fertilizer-grade ammonium nitrate will absorb up to 6 or 8 per cent oil. Excess oil tends to drain off and collect at the bottom of the container. Since approximately 6 per cent oil with the ammonium nitrate forms a stoichiometric mixture, the preparation of the blasting agent should be moderately simple. However, experience has shown that accurate compounding and careful mixing gives a decidedly superior product.

The most common practice for field mixing is to pour a measured quantity of fuel oil into each bag of ammonium nitrate. If the amount of oil added is carefully controlled, and if time is allowed for the prills to absorb the oil, a moderately satisfactory product is obtained. The mixed product then can be poured directly into the boreholes.

The most uniform product is obtained by stirring in any of a number of conventional mixers. Careful compounding and thorough mixing give a product of quite uniform characteristics which can then be loaded

or poured directly into dry boreholes or packaged in a plastic or other waterproof container for use in wet boreholes. The mixer should be so constructed as to minimize confinement, frictional heating, and crushing of the prilled material.

Most, if not all, the explosives companies in the United States produce and sell a blasting agent or agents similar to, and competitive with, the field-mixed ammonium nitrate-fuel oil. The product is either delivered in bags for use by pouring directly into dry holes or in waterproof containers for either dry or wet holes. In addition, the companies traditionally provide technical assistance for the blasting operations.

Most vertical holes are loaded by pouring the premixed product directly into the borehole. Pneumatic loading is generally used for horizontal boreholes. Where boreholes cannot be completely free of water, it is now rather common to employ a waterproof explosive such as Pelletol (TNT), slurry explosives, gelatin dynamite, or a blasting agent packaged in a waterproof container to fill the hole to the water level. If more explosive is required, the remainder of the charge consists of loose prills and oil.

Research, to be described later, has shown that adequate initiation is one of the most important factors in the successful performance of low-cost blasting agents. In the early work with ammonium nitrate-fuel oil (AN-FO) blasting agents, initiation was accomplished by using a high-strength dynamite for 3 to 25 per cent of the entire charge. The desire to lower the overall blasting costs has caused many mines and quarries to decrease the quantity of primer and substitute a cheap, low-strength dynamite for the high-strength gelatin dynamite. While the AN-FO mixtures now being prepared are generally more sensitive than those made several years ago, most explosives people agree that improper or poor initiation decreases safety and increases the overall cost of blasting.

Detonating cord has been used with moderate success to initiate AN-FO mixtures. While this may have some advantages from the standpoint of safety, it is doubtful whether maximum performance can be obtained by this method.

A more recent method of initiation involves the use of pentolite or composition B

primers. Although these primers are moderately expensive, they have proved very effective, even when used in sizes from $\frac{1}{8}$ to $\frac{1}{2}$ of a pound. Even smaller primers have been used successfully in relatively small boreholes. The use of this type initiator is increasing in popularity and may eventually replace many of the other forms.

The success of AN-FO blasting agents in open pit mining and quarrying has stimulated efforts to apply the same materials to underground mining. Experimenters have been able to produce ammonium nitrate with physical properties which, when fuel oil is added, makes it sufficiently sensitive to propagate (under borehole confinement) in columns down to approximately 1 1/4 inches in diameter.

The first extensive use of AN-FO blasting agents underground was at the Eagle-Picher lead and zinc mine near Picher, Okla. Mine operators found that uncoated ammonium nitrate prills were much more satisfactory in the small-diameter holes used. About the same time, the International Salt Co. began an investigation at its Detroit (Mich.) mine. This mine proved to be almost ideal for studying this type because it is relatively dry, ventilation is excellent, and all shooting is done off shift. Mine officials found also that uncoated prills were more satisfactory than the normal fertilizer-grade prills and that pneumatic loading of the holes was a necessity.

Efforts are being made to introduce AN-FO blasting agents to underground potash, gypsum, and limestone mines. These mines are generally quite dry and ventilation is generally not difficult. However, the practice is still not widespread and many problems are still unsolved.

Any discussion of blasting developments using AN-FO underground would be incomplete without mentioning the work being done in Sweden. In that country, a fine-grained ammonium nitrate is used instead of the prilled product employed in the United States. Pneumatic loading is used. Swedish users report successful blasting in borehole diameters as small as one inch.

The economic advantage from using blasting agents based on AN-FO has stimulated an unprecedented amount of research on explosives and blasting. Before 1955, most

research on commercial explosives was performed by explosives companies, a few mining schools, and governmental organizations, such as the Federal Bureau of Mines. Chemical concerns manufacturing fertilizer-grade ammonium nitrate suddenly became interested in the potential market for their product afforded by the shift in explosives technology.

Almost all ammonium nitrate used in dynamite is the grained type and usually it is prepared by the explosives companies. On the other hand, the physical characteristics of ammonium nitrate prills made them generally more suitable for compounding the simple, low-cost blasting agents. As a result, several chemical concerns have supported research leading towards the development of improved blasting agents. Some of this work has been by the concerns themselves, but much has been done by various mining schools, research institutes, and consulting firms.

To meet this new competition, explosives companies have increased their efforts to produce a product with performance equal to or superior to the field-mixed product, and competitive in price with that product. In addition to the previously named groups, several of the larger mining companies have performed experimental work on the application of this product to their specific problems. The Bureau of Mines has also been engaged in research on two of the most important safety aspects of this material. These are: the sensitivity of the blasting agents, and the relationship between the toxic fumes evolved by the detonation of the blasting agent and the physical and chemical factors associated with the compounding, mixing, and use of the materials.

Without doubt, the most comprehensive series of research reports on ammonium nitrate-fuel oil blasting agents was given at the Fifth Annual Symposium on Mining Research held at Rolla, Mo., in November, 1959, and at the International Mining Symposium at Rolla, in February, 1961. Papers from all segments of government and industry were presented. Another excellent review of the entire subject of modern blasting agents is given in a recent article by Cook¹. This summarizes much of the research at the University of Utah and provides some theoretical explanations for the behavior of this type explosive mixture.

The results of these research studies will form the basis for my discussion of performance variables.

No absolute standard of blasting performance has been developed. Therefore, performance cannot be judged solely on the number of tons of rock loosened per pound of explosive used. It must be judged on the basis of the overall cost of the mining operation, over a sufficiently long period to average out the effects of uncontrollable variables.

The most important variables in determining the performance of a blasting explosive are:

1. The strength or maximum available energy.
2. Detonation rate.
3. Detonation pressure.
4. Borehole pressure.
5. Density.
6. Sensitivity.

Some of these variables are more or less interrelated.

The true strength of an explosive should be measured in terms of the total energy released (per unit weight) by the explosive reaction. In practice, the strength of an explosive is determined by the ballistic mortar and is expressed in terms of its equivalence to a given strength of straight dynamite. Thus, a 60 per cent dynamite gives the same ballistic mortar reaction as a 60 per cent straight dynamite. While this method gives useful information, the results cannot be translated directly into performance.

Detonation velocity is usually taken as the basic criterion of the intensity of explosion or detonation. Explosives having a high detonation rate usually give high shattering effect or brisance. Such explosives normally are used for blasting extremely hard rock. Low-velocity explosives are more effective where a heaving or pushing action will loosen the rock or consolidated earth. In general, the detonation velocity varies linearly with the density of the explosive.

Detonation pressure and borehole pressure depend upon charge density; the amount of gas released by the chemical reaction; the total amount of energy evolved; and the rate at which that energy is released. If the explosive charge completely fills the

cross section of the borehole, the detonation pressure and the borehole pressure will be approximately the same. These parameters are evidently of importance in calculating the theoretical performance of an explosive, but it is difficult for the practical mining engineer to use this data. Therefore, the remaining discussion in this section will be confined to variables more directly under the control of the explosives engineer.

Composition of a blasting agent is a controllable variable that materially affects both safety and performance. Maximum explosive strength is obtained with a stoichiometrically balanced (fuel-oxygen) mixture consisting of 94.3 per cent ammonium nitrate and 5.7 per cent fuel oil. Such an oxygen-balanced composition is approximately equivalent to 60 per cent (weight strength) dynamite. Maximum detonation rate for such a mixture of 0.90 bulk density is about 13,000 feet per second.

However, detonation rates actually attained are usually lower than the theoretical, due to compositional variables and, often, to less-than-optimum initiation. Bruzewski, Clark, Yancik and Kohler report¹¹ that an excess of oil is less detrimental to the detonation velocity than a deficiency of oil.

Other factors being equal, oxygen-balanced mixtures give maximum strength and produce a minimum of toxic fumes. This is especially important if AN-FO blasting agents are to be used underground. Van Dolah, Hanna, Murphy, and Damon¹² found that the volume of toxic gases per pound of explosives used is at a minimum with an oxygen-balanced composition; the amount and nature of toxic fumes produced being very sensitive to the concentration of the fuel in the mixture.

Since the initiation of a high-rate detonation is essential to the safety and the performance of a blasting agent, the sensitivity of various AN-FO mixtures is of interest. Van Dolah and associates¹² found maximum sensitivity in somewhat over-oxygenized compositions containing about four per cent oil. However, Yancik, Bruzewski, and Clark¹¹ reported finding little difference in sensitivity among compositions that varied between one and seven per cent in oil content. In any case, it is better, safety wise, to adjust sensitivity to desired levels by means that do not involve fuel-oxygen imbalance.

While most AN-FO mixtures are insensitive to a No. 6 or a No. 8 blasting cap, it is possible to produce cap-sensitive mixtures. When a stoichiometric mixture of prills and oil is crushed, the sensitivity of the pulverized material is higher than the original mixture. Brinkley, Sykes, and Myers¹³ report on a method of particle size reduction which produced a uniformly cap-sensitive product. Hino and Yokogawa¹⁴ comment that it is possible to produce an ammonium nitrate-fuel mixture in which high-rate propagation is achieved in cartridges less than one inch in diameter, even when initiated by a No. 6 detonator. For these results, the mean particle diameter of the ammonium nitrate is reduced to less than 20 microns. Thus, particle size reduction is a means of eliminating or reducing the size of the primer.

It has been shown also that uncoated prills produce a more sensitive blasting agent than the same mixture composition using inert coated prills. Still greater sensitivity has been obtained by the incorporation of a surface active agent into the uncoated prills.

The appearance of brown oxides of nitrogen indicates an incomplete detonation reaction with resulting poor performance and increased fume hazard. Figure 1 shows the effect of primer strength on the production of toxic gases from AN-FO compositions. On the right side of this figure is shown, for comparison purposes, the results obtained with a typical dynamite when initiated by a No. 6 electric blasting cap. Data on the detonation rate of similar mixtures, using various strength initiation, confirms the conclusion that the better the initiation, the more complete the reaction.

The ready solubility of ammonium nitrate in water makes it uneconomical to use such a blasting agent in wet boreholes. However, it is interesting to note the effect of water on the detonation properties of AN-FO compositions. If the production of oxides of nitrogen can be taken as a criterion of the completeness of a reaction, Figure 2 shows that small amounts of water appreciably change the reaction, even when the AN-FO charge is initiated with a PETN (pentaerythritol tetramitate) primer.

Much has been written about the safety of AN-FO blasting agents. We must admit that the safety record of these new blasting

Figure 1

agents is excellent, but we would be naive to assume that accidents cannot and will not occur. Any tendency toward considering these materials as being perfectly safe creates a hazard which will eventually lead to serious mishaps.

If AN-FO blasting agents are treated as high explosives, the safety record of these materials should continue to be outstanding.

On the basis of present information, the Bureau of Mines has published¹⁵ what it believes to be the best general safety recommendations. A recent publication of the National Fire Protection Association¹⁶ gives much valuable information, but is not as detailed as the Bureau of Mines circular.

Most ammonium nitrate-fuel oil blasting agents are insensitive to the usual impact

Figure 2

and friction tests that are applied to high explosives. However, because of their low sensitivity, a relatively high-strength booster must be used. This in itself does not create a hazard, provided handling, loading, and firing are performed in the same manner as that employed when dynamite is used as the entire charge. However, ammonium nitrate-fuel oil mixtures have another disadvantage in that propagation through an air gap is poor. Therefore, it is essential that the column of blasting agent be continuous. For example, the detonation reaction with most dynamites will propagate across an air space varying from 3 to 25 inches. On the other hand, an air gap of from one to two inches in a column of AN-FO blasting agent will usually result in detonation failure.

Cap-sensitive AN-FO mixtures can be prepared. Evidently, these mixtures must be considered as high explosives. Some information indicates that repeated temperature cycling of ammonium nitrate prills through the 90°F phase-change region may result in a "cap-sensitive product" when treated with oil.

Fire is probably the greatest hazard connected with the handling and use of ammonium nitrate and blasting agents produced from ammonium nitrate. Without doubt, the addition of fuel oil to ammonium nitrate increases the fire hazard. However, small quantities of AN-FO mixtures are difficult to burn. For maximum safety, the Bureau believes that the blasting agents should be prepared, stored, and handled as an explosive. If these precautions are taken, the safety record for these new blasting agents should be equal or superior to that of dynamite.

Because of the low sensitivity of blasting agents, some users have suggested that these compositions need not be stored in bulletproof magazines. A recent study throws some doubt upon this general conclusion. The standard military rifle bullet test did not provide initiation, even under high confinement. However, it was found that certain high-velocity sporting loads can cause bullet initiation of some of the more sensitive blasting agents.

Many new hazards may be encountered when AN-FO blasting agents are used underground. Toxic fumes are of minor importance in open-pit operations, but they

are a serious hazard when produced underground where ventilation may be marginal. Properly prepared, well initiated charges of AN-FO produce fumes comparable with good dynamite, but slight variations in composition, confinement of charge, moisture or initiation may materially increase the hazard. Also, the generation, accumulation and discharge of static electricity, which may be produced in the pneumatic loading of small boreholes, is a matter of considerable concern. The information about these problems is still inconclusive.

Ammonium nitrate-fuel oil blasting agents have proven amazingly successful, but the search for lower cost blasting has not been confined solely to this system. Several fuel-oxidant systems of other characteristics have been, or are now being, investigated. Since American experience with these other types of blasting agents is generally not extensive, they will not be discussed in great detail in this presentation.

Ammonium nitrate-fuel oil blasting agents have many advantages for open-pit mining, but their solubility in water and their relatively low density are definite disadvantages. Through research performed in the United States and Canada², relatively low-cost slurry explosives have been developed, with densities comparable to gelatin dynamites. These slurry explosives consist principally of ammonium nitrate, TNT, and water. A typical composition will contain about 65 per cent ammonium nitrate, 20-25 per cent TNT, and the remainder water. In some cases, sodium nitrate is substituted for part of the ammonium nitrate and RDX or other explosives may be substituted for TNT.

The ammonium nitrate-TNT-water system cannot be used successfully in wet holes because of the added dilution effect and the gradual segregation of the solid particles from the solution. It has been found, however, that the addition of a small percentage of a guar gum and small amounts of stabilizing agents will give a product which is more nearly a gel than a slurry. These relatively cohesive slurries can be packaged in polyethylene bags or the slurry can be forced directly into the borehole. Since the density of the mixture is higher than that of water, no difficulty is encountered in placing the explosive at the bottom of a water-filled borehole.

Slurry explosives are more expensive than AN-FO blasting agents, but they appear suitable for hard-rock blasting operations and also where water is present. In general, these slurries are not cap-sensitive and are normally initiated with a small pentolite booster. These explosives now cost from 12 to 14 cents per pound at the mine.

Explosives employing sodium or potassium chlorate as the oxidizing agent were suggested before Nobel's discovery of dynamite. However, the practical use of chlorate explosives in mining operations is relatively new. Records indicate they have been used in Finland since the mid-1920's and they have been under extensive development in Sweden³ since 1937. These explosives are now being exploited in several countries under the names of "Imatrex" and "Snoratrex."

Imatrex consists of potassium chlorate so prepared that it will absorb a definite quantity of a mineral oil to form the final explosive mixture. Imatrex representatives propose that the impregnation with oil be made at or near the blasting site. Thus, the method of preparation and use is similar to AN-FO blasting agents.

The second product, Snoratrex, is prepared from sodium chlorate and is said to have characteristics more nearly like those of the slurry explosives mentioned earlier.

Chlorate explosives have not met with general favor in the United States. While pure potassium or sodium chlorate are not particularly hazardous to handle and use, they may become highly hazardous when contaminated with organic material. Additionally, the cost of the chlorate salts, in comparison to ammonium nitrate at approximately 3½ cents per pound, does not make the chlorates too interesting from an economic standpoint. However, American and Canadian interests are investigating the economic possibility of using sodium chlorate impregnated with a mineral oil.

One hazard with chlorates in explosive mixtures should be noted. Chlorates and ammonium salts must never be used in the same mixture because of the possible interchange of ions to produce the hazardous ammonium chlorate. The Interstate Commerce Commission classes any such mixtures as "forbidden" from all shipments involving interstate commerce⁴.

A discussion of low-cost blasting agents would be incomplete without mention of liquid oxygen explosives. Liquid oxygen explosives (LOX) were introduced in 1895⁵ and since have seen intermittent use in various countries. The extensive investigations on this type explosive make it unnecessary to describe the system in detail. Both safety and performance depend largely upon the character of the absorbing carbonaceous material. In the United States, certain carbon blacks have given the most satisfactory results. However, other types of carbonaceous materials have been used satisfactorily in France and India.

The most comprehensive review of the safety characteristics of LOX is given in a Bureau of Mines publication by Tournay, Bower, and Brown⁶.

The development of AN-FO blasting agents in the United States has resulted in the virtual elimination of LOX. However, LOX still has economic possibilities where a high-strength, high-rate, and moderately low-cost explosive is required.

An explosive system based on sensitized nitromethane is reported to be under development. Details are not available, but the relatively high cost of nitromethane may restrict its use to special applications.

A new explosive and blasting technique has been recently announced⁷. This system is reported to be under field development in the taconite deposits of northern Minnesota.

A stoichiometric mixture of ammonium nitrate and fuel oil has given the mining industry a low-cost blasting agent which has proven surprisingly efficient in a wide range of applications. This low-cost composition is particularly suited for open-pit operations where relatively large-diameter boreholes are in common use. The generally good results obtained are believed to be due partly to the close coupling (contact) between the charge and the material being blasted, yielding borehole charge densities essentially equal to product bulk density. Application of AN-FO blasting agents to underground operations is still limited. Many problems still must be solved before this material can be employed safely in small diameter holes. One of the principal concerns is providing adequate ventilation for the rapid removal of toxic gases that may be produced on detonation of such charges.

A brief description is given of several other promising systems that employ relatively low-cost fuel-oxidant materials. More complete investigation will be required to determine the relative merits of these systems.

The types and uses of low-cost blasting agents are many. Because of this diversity, they cannot be judged solely on the basis of physical and chemical tests. Furthermore, complex interrelationships must be considered. As a possible example: An AN-FO mixture which has been found ideal for certain surface blasting may be somewhat hazardous and too costly for ready adaptation to certain underground sites; on the other hand, there may be conditions in which the same AN-FO mixture might be used safely and economically in another underground mine. Because of these many complexities and the wide range of possible variations in the composition and use of low-cost blasting agents, the Bureau of Mines will diligently continue its long-range studies. When significant findings are made, these will be reported to the public through the Bureau's technical publications.

OBSERVATIONS ON UNDERGROUND BLASTING WITH AMMONIUM NITRATE-FUEL OIL EXPLOSIVES

By ROY G. STOTT

Mining Health and Safety Eng., Bureau of Mines
U. S. Dept. of the Interior, Washington, D. C.

The purpose of this paper is to present available factual data relative to health and safety in connection with the use of field-mixed ammonium nitrate-fuel oil (AN-FO) compositions used for underground blasting.

The information presented is intended to help the mining industry to use cheaper explosives safely rather than to oppose their use. Although the Bureau of Mines recognizes the inherently insensitive nature of AN-FO explosives, it is also aware of potential hazards introduced by the do-it-yourself features of mixing, handling, and using such ingredients on the job. The Bureau of Mines believes that control of these hazards is best accomplished through research, dissemination of vital information, education of supervisors and workmen, maintenance of close supervisory controls, and adherence to basic explosives safety practices. Any relaxation of care in handling materials used for blasting regardless of their insensitivity or other inherent safety features will inevitably lead to serious accidents and loss of life.

Following the introduction of Akremite for blasting overburden in strip mining of coal in 1955 and the ease with which acceptable cheap explosives could be made by mixing carbon black with fertilizer-grade ammonium nitrate on the job site, numerous mine operators were attracted by the cost advantages of utilizing such products for blasting. Many began experiments of their own and soon found that diesel oil was a suitable sensitizing agent that was easily mixed with ammonium nitrate. This product gained widespread use in open-pit blasting operations.

Ammonium nitrate-fuel oil blasting agents were introduced in underground mining on an experimental scale in a lead-zinc mine near Picher, Okla. in April 1958. There it was found that uncoated pills mixed with six per cent diesel oil would, under certain

conditions, pull satisfactory blast rounds in dry small-diameter holes in hard rock. About the same time similar successful tests were undertaken in an underground Michigan salt mine. Later that year a potash mine in New Mexico conducted an investigation in an underground mine situated on the public domain and operated under federal-lease provisions, with cooperation from the Bureau of Mines.

At present efforts are being made by some operators to extend the use of AN-FO blasting agents to other underground mines, most of which are generally quite dry and well ventilated; however, the practice is still not widespread and many problems concerning safety in their use are still unsolved. The mining industry on numerous occasions has expressed vital interest in safety considerations and problems concerning the application of AN-FO blasting agents. To understand these matter better from the safety point of view, a short synopsis of the basic properties of ammonium nitrate and review of certain disasters and accidents involving this substance is presented.

Basic Properties of Ammonium Nitrate

Authorities have not always agreed on the degree of hazard involved in the manufacture and handling of ammonium nitrate. For example, Munroe¹ quoted the following from Turner's *Chemistry*, published in 1835: "When this salt is exposed to fire, it liquefies, emits aqueous vapor, dries and detonates." And Aufschlager² in 1924 concluded:

To summarize . . . it appears that the observed velocity of detonation of about 2,500 meters per second removes all doubt as to the character of ammonium nitrate as a brisant explosive.

but Norman³ in 1924 stated:

I consider that ammonium nitrate is

not an explosive by itself because millions of pounds of it have been and are now being made every month in Europe and in this country. . . . Ammonium nitrate, in my opinion, does not constitute anything more than a fire hazard when handled by itself.

and Parisot¹⁰ in 1939, considered pure ammonium nitrate to be a feeble explosive and its explosive character to depend upon impurities present.

Ammonium nitrate is ordinarily a white crystalline solid with an oxygen balance of plus 20 per cent (20 per cent of its weight is comprised of oxygen available for combustion of other material in addition to complete combustion of the ammonium nitrate), a melting point of 337°F, a boiling point of 356° and reportedly begins to decompose slowly at about 392°F. It may exist in six different crystalline forms in the solid state depending upon temperature and pressure.

Ammonium nitrate is hygroscopic; that is, it may take up from or give off water to the atmosphere, depending upon temperature and relative humidity. This property causes caking of the salt and presence of water may cause marked increase in production of oxides of nitrogen when detonated.

Decomposition of ammonium nitrate may involve as many as eight different reactions; however, in general, all products are gaseous, being transformed into nitrogen, oxygen, water, and oxides of nitrogen. Generally, decomposition results in evolution of heat and is reported to be promoted by the presence of organic and carbonaceous matter and by metallic powders, such as aluminum, iron, and zinc. Various metals react with ammonium nitrate at elevated temperatures and some, such as zinc, at ordinary temperatures.

There is no recorded instance of spontaneous heating in pure ammonium nitrate; however, easily oxidizable metal powders in contact with wet ammonium nitrate may heat spontaneously.

When heated under confinement, or partial confinement it can explode. For pure ammonium nitrate the required temperatures for detonation have been reported from 572°F to 662°F. The required temperature

for detonation is lowered by the presence of certain impurities.

Ordinarily it is considered very difficult to detonate pure ammonium nitrate by ordinary impact or friction; however, crushed prills containing four per cent oil at a density of approximately 0.8 when confined have been detonated by impact of .30 caliber bullets.

Detonation velocity of ammonium nitrate increases with density but presence of an air gap in a train of the material may stop further propagation.

For mixtures of ammonium nitrate with sensitizing agents, such as fuel oil, sensitivity to detonation appears to increase with the age of mixture and decrease with greater density of compaction (28).

Major Disasters Involving Ammonium Nitrate

Appendix A lists nine major disasters involving ammonium nitrate together with a brief resume of what occurred.

These major disasters (single accidents that cause loss of five or more lives) point out the need for thorough understanding of the inherent hazards of ammonium nitrate by all persons who work with it and the dangers involved where large quantities are stored or handled. While it is true that certain conditions were necessary to cause detonation of this rather insensitive material, the fact remains that detonation did occur in these disasters, and caused the loss of more than 1,300 lives, injuries to more than 5,500 persons, and uncalculable property damage.

Explosives Accidents at Mines Using AN-FO for Blasting

The mining industry, by virtue of assuming responsibility in the do-it-yourself compounding and use of blasting agents, holds a vital trust in both public and private safety for the explosives it uses. A brief review of appendix B listing eight explosives accidents at mines using ammonium nitrate in their blasting operations will illustrate the extent to which this trust must be guarded to safeguard lives and health in future years.

Five of the eight accidents cited in appendix B may be considered typical run-of-the-mill blasting mishaps that could occur with any type of explosives. They are

characterized by human error and faulty judgment. One can only hope in these cases that carelessness among the injured workmen was not induced by "overselling" the safety features of ammonium nitrate blasting agents. Four of the mishaps recorded in appendix B illustrate the need for strict application of long-standing safety methods and procedures for initiating blasts after the explosives have been placed in blast holes.

The other three accidents indicate that special precautions should be adopted (1) when using air-placement methods and equipment for charging bore holes, (2) when transporting sensitized AN-FO, and (3) when disposing of bags used for mixing AN-FO and explosives containers, wrappers, and scrap lengths of detonating fuse. Suitable recommendations covering these problems have been published in Bureau of Mines Information Circulars 7968, Tentative Safety Recommendations for Field-Mixed Ammonium Nitrate Blasting Agents, and 7315, Destruction of Damaged, Deteriorated, or Unwanted Commercial Explosives.

The following observations have been extracted or evaluated from unpublished reports of investigations, safety inspections, and memoranda of field trip data submitted to the Bureau's Washington Office of Health and Safety Activities.

Fume Production from AN-FO Blasting Agents

Study of data concerning seven series of controlled tests involving 16 blasts in a potash mine and 15 blasts in an iron ore mine reveal that, under certain conditions and with well-regulated controls, the fume production of toxic gases from AN-FO blasting agents can be comparable to that from lime class one dynamites manufactured for underground use.¹¹ The necessary conditions include exact proportioning of ammonium nitrate prills and fuel oil, intimate mixing of the ingredients, avoiding contact of water with the blasting agent, maintaining a well-compacted uninterrupted train of explosives charge in the borehole, and strong initiation to insure complete detonation of the charge.

Erratic and excessive fume production in one series of test blasts was attributed to marginal initiation with a low-cost dynamite primer.

The most consistent and successful blasts were produced by air-placed AN-FO in dry holes and priming with high-strength dynamite initiated by No. 6 millisecond-delay electric detonators.

The most unsatisfactory blasts resulted from use of paper-wrapped AN-FO cartridges and low-strength dynamite primer cartridges. In the latter instances fume production was erratic, breakage was standard, occasional misfires occurred, and unexploded blasting material was found in "bootlegs" and in the muckpile. Separations of the "powder train" by cartridge wrappers and poor airgap sensitivity of AN-FO was, reportedly, one cause of detonation failure.

In conducting these tests, the toxic fume production was evaluated in terms of cubic feet of carbon monoxide (or oxides of nitrogen) generated per pound of explosive used. Fumes from AN-FO were compared to those produced from dynamite under standard test conditions. Generally the total weight of charge of air-placed AN-FO blasts exceeded that of standard dynamite blasts by as much as 75 per cent. Where paper wrapped cartridges of AN-FO were employed, the total weight of charges with AN-FO was somewhat less than that of the standard dynamite charges, because of the lower density of the cartridge materials.

Of psychological note regarding fumes from AN-FO underground blasting is a statement made to the author by a field engineer of the Bureau who said that some miners had no fear of fumes from AN-FO because their odor was not as objectionable as that from dynamite fumes. These miners have been observed returning to the work face too soon; that is, before such blasting fumes had been dissipated.

Static Electricity Hazards

The Bureau of Mines for many years has conducted demonstration lectures on hazards of static electricity for petroleum seismograph crews who use electric detonators in arid areas. These demonstrations illustrate how energy from static electricity can cause unexpected premature detonation of electric caps. Discharge energy of accumulated static electric charges under some conditions can detonate caps between the bridge wires of the cap and the shell of the cap or through energy flow through one unshunted leg wire across the bridge

heating element of the cap and through the other leg wire. The sources and means of generation of static electricity are many and varied and can include electrification of solids, liquids, gases, dusts, and vapors."

Generally, static electric charges result from the contact of separation of similar or dissimilar materials.¹⁰ However, static electricity sparks can be induced from thunderheads, dust storms, waterfalls, and charged bodies of air¹¹ several miles from apparent center of storms. Flowage of materials through nonconducting pipes or tubes and impingement of particles on insulated surfaces cause accumulations of electric charges. Roof falls, rock bursts, and gunniting operations in mines have been known to cause static sparks. Electrostatic charges expressed in volts alone are of little practical value in evaluating the hazards of detonating electric blasting caps by static electricity. The capacitance of the system must be considered and the evaluation expressed in terms of energy units.

Since the introduction of pneumatic equipment to air-place AN-FO compositions in last year, the Bureau of Mines has conducted certain tests to explore the degree of hazard of static electricity as a possible cause of premature detonations underground and to formulate safeguards against such possibilities. At present these tests, conducted on a limited scale underground, have been of exploratory nature and are not considered sufficient for reliable assessment of the magnitude of the hazard. The following summarizes known data:

1. Tests prove that relatively high voltages of static electricity can be generated when AN-FO is blown through pipes or tubing. Electrostatic charges ranging from 1,000 volts to over 8,000 volts have been measured. The magnitude of such charges depends on the velocity of the moving drill stream, the particle size, the temperature of the particles, the relative humidity and temperature of the surrounding atmosphere, and the conductivity of the wall surfaces.

2. Individual electric detonator caps of the same manufacturer showed wide variation in sensitivity to detonation by static electricity energy. Tests revealed that considerable special requirements are necessary to fire caps by static electricity. For example, corona current induced by a charge

of 42,000 volts through the detonator to its shell failed to fire the cap, yet 15 microamperes of current induced by 4,000 to 5,000 volts of static electricity fired a cap covered by soil in five seconds.

3. An insulated electric cap (not grounded to earth) is considerably more difficult to detonate by static electricity than a cap in contact with the ground.

4. Extensive tests involving several thousand readings under varied atmospheric and ground conditions would be required to assess the retentivity of electrostatic charges in boreholes due to impingement of AN-FO from pneumatic loading methods. Such tests are not conducive to reproducibility.

5. Use of conductive tubing, positive electric bonding of such tubing with the pneumatic loading equipment, the loading platform, accessory equipment (such as compressor), and ground will prevent accumulation of dangerous charges of static electricity. High resistant conductive clothing and footwear is considered advisable for operators of air-placement equipment.

6. From priming minimizes possibility of premature detonation from static electricity where air-placement of AN-FO is employed.

7. Aluminum or other metal inserts in plastic tubing are hazardous and not recommended because this metal can cause sparking hazards and galvanic battery effect action in presence of solutions. Use of aluminum tamping sticks has been known to cause premature detonations in geophysical blasting operations.

8. Atmospheres of low relative humidity favor generation and accumulation of high charges of static electricity.

Unsafe Practices Noted

Because widespread dissemination has been made of known safety features of AN-FO agents, Bureau of Mines safety personnel's comments on unsafe practices observed in mines where such blasting materials are used are worthy of consideration from the entire mining industry if maximum safety is to be achieved. Let us review just a few of these unsafe practices.

1. There are hundreds of tons of ammonium nitrate stored in barns, chicken coops, garages, or under tarpaulins throughout the area. It is being mixed with vari-

ous kinds of oils by all kinds of methods, such as in gasoline or electric motor concrete mixers, in steel wheelbarrows with steel shovels, and on concrete floors with steel tools.

2. No "Danger" warning signs or "No Smoking" signs were displayed at the AN-FO mixing station, the detonator magazine, or the explosives storage magazine underground.

3. A hand pump and nozzle were used to squirt oil into the ammonium nitrate bags. Generally, two strokes of the pump were made in adding two quarts of oil to each bag; however, the operator added more to some bags when he felt they needed more. The bags were left to soak for eight hours then emptied as needed into the air-placement machine. No other mixing provisions were performed at this underground operation.

4. Oil spills and spillage from ammonium nitrate bags were allowed to accumulate, both at the face and at the underground mixing station.

5. Two hundred sacks of untreated ammonium nitrate were stored under three unguarded electric light bulbs.

6. One bag of sensitized ammonium nitrate was touching the diesel engine of the explosives jeep. The detonator box was piled loosely on top of the explosive storage compartment and one case of the 70-per cent strength dynamite was lying next to the driver's seat.

7. Caked fuel-sensitized ammonium nitrate was found on the loading jeep.

8. Cuttings were not cleaned out of boreholes prior to charging with explosives.

9. Electric detonators were inserted in the ends of dynamite primer cartridges and the primed cartridges were laid loosely on the handrailing of the loading platform. No attempt was made to secure leg wires to the primer cartridge, and no attempt was made to insure that detonator caps remained inside the dynamite cartridge when inserted in the blasthole.

10. Primers are made by rolling one end of the dynamite cartridge to loosen the wrapping and then pulling out the crimped paper and inserting the detonator.

11. Electricity was not demerized from

the explosives loading jumbo during charging and priming of blastholes.

12. Open end plastic tubing used in air-placing AN-FO has been used to insert primers and for tamping them in place. Sharp thin-walled tubing is potentially capable of cutting through the wrapper and contacting the blasting cap. Mechanical damage to the cap could cause premature detonation.

The foregoing information presents case arguments that safety precautions are needed where field-mixed AN-FO compositions are used in mines, particularly in underground operations. By this means it is hoped that safety will be supplanted by real concern for corrective measures where indicated and needed. Fortunately many of the above-mentioned unsafe practices have been eliminated at some mines visited by Bureau of Mines safety or inspection personnel. In at least one instance, mine management has decided to eliminate uncertain mixing of ammonium nitrate and fuel oil underground—it has promoted the local establishment of a commercial mixing plant to insure uniform compounding and mixing of its blasting materials and elimination of fire and ignition hazards associated with mixing such ingredients underground.

Much effort and study have been expended in compiling Bureau of Mines Information Circular 7988, Tentative Safety Recommendations for Field-Mixed Ammonium Nitrate Blasting Agents, which is designed to help guide the mining industry in providing safeguards against hazards attendant to field-mixed explosives. Revisions of this circular will be forthcoming when significant findings warrant changes or additions to the recommendations previously published. On the basis of present information, the Bureau of Mines believes that I. C. 7988 presents in detailed form the best general safety recommendations covering field-mixed ammonium nitrate blasting agents.

In conclusion, we wish to emphasize once again that ammonium nitrate-fuel oil mixtures under some conditions can generate severe hazards from toxic fumes. To safeguard the health and well-being of underground workmen exposed to fumes from AN-FO, exact control of composition, moisture control, placement, and initiation in blasting are of utmost importance, and ade-

quate positive ventilation to reduce the fumes to acceptable limits is a necessity. Your attention is also directed to the fact that no blasting agent is currently approved by the Bureau of Mines as permissible for use in underground coal mines.

I sincerely hope this paper and its contents will help in accident prevention and industrial health improvement programs.

APPENDIX A
Major disasters involving ammonium nitrate

Date	Location and reference	No. killed	No. injured	Cause of disaster and remarks
Sept. 19, 1916	Aetna Company plant, Oakdale (near Pittsburgh), Pa.	6	5	3,000 lbs. of ammonium nitrate exploded while being concentrated in an evaporating pan. Shock was felt 7 miles away.
Oct. 4-6, 1915	Extruding plant of the T. A. Gillespie Loading Company, Morgan (near South Amboy), N. J.	70	—	Fire started in plant where ammonium nitrate was being loaded. Shells detonated causing bombardment for 2 days and a number of storage piles of ammonium nitrate caught fire and some exploded—explosion left a crater 150 feet long, 140 feet wide and 30 feet deep. Estimated damage \$15,000,000.
Aug. 26, 1921	Factory, Kriewald, Upper Silesia, Germany	19	—	Two cars of ammonium nitrate exploded during unloading operations. Explosive charges were being used to break up the cake. The factory was demolished leaving a crater approximately 90 feet wide and 20 feet deep.
Sept. 21, 1921	W. Silber plant, Oppau (near Weinheim), Germany	5/6	1,942	An estimated 10 per cent of a 1,300-ton storage pile of 56% mixture of ammonium nitrate and ammonium sulfate exploded during blasting with "coal-mine explosives" to break up the caked material. The town of 6,000 persons was virtually wiped out and a crater 260 feet across and 50 feet deep was made. It was stated that about 16,000 explosive charges had been fired previously without mishap and that blasting had been performed under expert supervision.
Mar. 1, 1924	Ammonite Company plant, Nixon, N. J.	17	15	Approximately 1,500 lbs. of ammonium nitrate exploded in a vacuum granulator during recovery processing of ammonium nitrate. It was believed to contain TNT or nitroaromatic impurities.
Apr. 29, 1942	S. A. des Produits Chimiques de Tessenderloo, Belgium	More than 100	—	Approximately 150 tons of ammonium nitrate exploded killing all witnesses. No evidence of fire preceding explosion was found and the cause was not definitely determined; however the report infers the cause could be from unauthorized blasting of caked material normally broken up by picks. One expert expressed an opinion that presence of free hydrochloric acid or other sensitive volatile compound may have rendered the storage pile sensitive enough to explode under impact shocks from picks or hammer mill. The disaster had been preceded by dry weather.
Apr. 16-17, 1947	Texas City, Tex.	562 (est.)	3,000 (est.)	Charge of between 1,000 and 2,000 tons of ammonium nitrate fertilizer exploded from fire in steamship Grandcamp and set off chain of fires and another explosion of 900 tons of ammonium nitrate fertilizer in nearby steamship High Flyer. Reportedly the initial fire was fought by sealing the hold containing the ammonium nitrate and flooding the hold with steam instead of water to avoid damaging the cargo.

Appendix A
Major disasters involving ammonium nitrate

Date	Location and reference	No. killed	No. injured	Cause of disaster and remarks
July 28, 1947	Harbor of Brest, France ^a	21	422	Fire in hold of steamship <i>Ocean Liberty</i> exploded cargo of 3,300 tons of ammonium nitrate fertilizer. Steam smothering was first attempted in fighting fire and then water was applied. The ship was abandoned and in process of being towed to sea when explosion occurred.
July 7, 1959	Roseburg, Oregon; truck explosion ^b	13	125	Heat from a fire in a building 3 feet from a parked truck carrying 4,000 lbs. of dynamite and 9,000 lbs. of AN-FO in 50-lb. paper bags caused explosion of the truck's contents. Damage estimated over \$10,000,000.

APPENDIX B
Explosives accidents at mines using ammonium nitrate field-mixed blasting agents^a

Date	Mine, company and location	No. killed	No. injured	Cause of accident and remarks
May 19, 1958	Muskingham (strip) mine, Central Ohio Coal Company, Cincinnati, O.	0	1	The bottom 3-foot deck charge of a drill hole failed to detonate in a blast. When the 30-cubic-yard shovel dipper dug into the mine, the charge detonated, damaging the dipper and injuring (slightly) the shovel operator by flying glass. The blast hole involved was 8 1/2 feet in depth and 8 inches in diameter. Because the bottom 3 feet was wet, this portion was charged with commercially prepared cans of AN blasting agent and primed with dynamite cartridges with detonator fuse strung from the primer charge to the collar of the hole. Four feet of clay stemming was placed over the bottom charge and the balance of the explosives column, consisting of bagged AN-FO with additional dynamite primers, was placed in the hole and stemmed. Failure of the bottom charge to detonate was attributed to damaging or cutting off of the detonating fuse during charging operations. The mine was not detected prior to the accident as the upper deck charge had detonated in the blast.
May 21, 1958	Cadiz No. 18 (strip) mine, Hanna Coal Company, Cadiz, O.	0	1	Premature detonation of blast occurred when the electric detonator cap wires were connected by error to an energized firing line. The blast holes, 8 1/2 inches in diameter and 70 feet deep, were charged with AN-FO in polyethylene-lined burlap bags prepared at the mine and were fired by dynamite primer charges initiated through detonating fuse and a No. 8 electric detonating cap.

APPENDIX B
Explosives accidents at mines using ammonium nitrate field-mixed blasting agents^a
(Cont'd.)

Date	Mine, company and location	No. killed	No. injured	Cause of accident and remarks
May 21, 1958				Prior to the accident the blasting machine had been repaired, tested, and returned to the blast site. Although the blasting machine featured four safety provisions (safety plug-in cord to power source, a short-circuit device, switch lock, and a blasting positioning switch) none of these devices was checked or in use at the time of the accident.
Sept. 23, 1958	Delta (strip) mine, Carmac Coal Company, Marion, Ill.	1	0	A drill helper was killed in a frame supply shed when struck on the head by a 100-lb. test load of earth expelled by blown-out shots. The shed was 22 feet from the nearest hole blasted and approximately 200 feet from two blown-out shots. Several other men had also taken shelter in the shed, but the roof failed to protect the deceased. A fire was used for blasting.
Apr. 2, 1959	Muskingham (strip) mine, Central Ohio Coal Company, Cincinnati, O.	0	0	A 3-ton truck loaded with 12,000 lbs. of AN-FO in bags, 150 lbs. of high-velocity gelatin dynamite in shipping cases, and about 2,000 feet of detonating fuse in containers caught fire and exploded. About 150 electric detonators were also carried in a wooden container in a steel compartment under the truck body near the front. Reportedly, the tarpaulin covering the load of AN-FO in bags loosened from its fastenings and caught fire from contact with the exhaust pipe of the truck. The fire was discovered after the truck reached the blasting site. All persons in the vicinity were removed to a distance of about 500 feet; guards were posted to prevent entry to the area, and the men ordered to let the truck burn. The fire burned about 1 hour and 40 minutes before the detonation occurred. The explosion left a crater 30 feet deep and 40 feet in diameter. Windows were broken in nearby homes, but no one was injured.
Aug. 12, 1960	Haverstraw Quarry, New York Trap Rock Corp., Haverstraw, N. Y.	0	0	While burning scrap materials from loading of blast holes, detonation occurred that cast flaming materials around several nearby workmen. The materials being burned consisted of polyethylene bags used for mixing AN-FO at quarry loading site, cardboard boxes which originally contained 1-lb. charges of Pentolite primers, wax paper bag scraps of detonating fuse. A fairly high stack of combustibles was burned. After the accident the following safeguards were adopted: (1) burning would be confined to small piles; (2) no detonating fuse scraps were to be burned; (3) careful search would be made to prevent burning of detonators and priming materials.

APPENDIX B

Explosives accidents at mines using ammonium nitrate field-mixed blasting agents
(Cont'd.)

Date	Mine, company and location	No. killed	No. injured	Cause of accident and remarks
Jan. 30, 1961	Jefferson Island Salt Mine Diamond Crystal Salt Company Jefferson Island, La.	1	1	Premature detonation occurred at underground face during charging operations while inserting primer cartridge. The cause was not definitely established but could possibly have resulted from (a) mechanical damage to detonator while inserting or tamping primer cartridge, (b) stray electric currents, (c) discharge of static electricity while using plastic tubing to place primer cartridge in the hole. AN-FO was pneumatically placed in the borehole prior to insertion of the capped primer.
Feb. 22, 1961	Flamingo (strip) mine, Fairview Collieries Corporation, Fairview, Ill.	0	1	Premature blast occurred while connecting leg wires of electric detonator cap to firing lines. The injured, while carrying the firing batteries, erred in placing the leg wires to the battery terminals instead of firing lines. The blast holes were charged with AN-FO with bottom priming and detonating fuse connected to a millisecond-delay electric cap.
Aug. 2, 1961	Little Cottonwood Project Centennial Development Company Little Cottonwood Canyon near Salt Lake City, Utah	0	0	Lightning detonated 6 of 108 charged blast holes in an underground construction project. Blast holes were 3 feet deep in the floor of the drift opening. The blast was intended to loosen floor rock to increase drift height. Each hole was bottom-primed with a millisecond-delay electric blasting cap in a dynamite cartridge and balance charged with AN-FO. The crew was withdrawn when the lightning storm developed.

*Abstracted from unpublished Bureau of Mines reports

DO INJURY STATISTICS HAVE TO BE DULL?

By R. F. WILSON

Mgr., Safety and Compensation, Oliver Iron Mining Div., Duluth, Minn.

It was with considerable apprehension that I accepted the assignment to present this paper on accident statistics. It is my understanding that your program committee put the finger on me because of my "experience." Namely, for the past seven years I have had the dubious honor of tabulating the accident records of all mining companies in the Lake Superior district. This information I have presented at the annual meeting of our Lake Superior Mines Safety Council.

This conference is held at Duluth, Minn., and it is generally agreed that it is a fairly good one. What makes it good, however, is the fact that nationally known speakers are obtained to address a gathering of 600 to 700 mine supervisors, on safety and allied subjects. The fact that I have shared the platform with these gentlemen certainly doesn't prove that my annual presentations of statistics are outstanding or even ordinary ones. All I can say is that there is considerable interest in my paper because everyone attending knows that when I get through they have a real treat in store for them for they will be hearing a fine speaker such as Fred Smith, Arthur Secord, G. Herbert True or Dr. Rosenstem, to name a few.

I don't think I'm telling you anything new when I say that statistical presentations, be they on accidents or any other subject, do not go over well. However, all of us in safety work are faced with the problem of presenting figures showing man-hours worked, days lost, frequency and severity rates, causes, types and much other information connected with accidents and their prevention. It is most important that we don't "bury" the people whom we are trying to inform in a maze of figures.

Many years ago, Benjamin Disraeli, at that time the Prime Minister of Great Britain, made a statement which I'm sure will never die when he said "There are lies, damn lies, and statistics!" Statistics can be misused to prove just about anything an irresponsible person may want to

prove, depending upon the type of approach taken.

For example: Mine "A" has one disabling injury—mine "B" has two. If we say mine "B" has 100 per cent more injuries than "A" this is true but we haven't told the whole story. It could well be that mine "B" has 10 times the number of workers than does mine "A." If that is the case, "B's" accident frequency rate is 300 per cent better. This certainly appears to be a more valid appraisal of the accident experience of the two mines.

Quite often we see statistics presented by means of line graphs. So let's assume, for illustrative purposes, that our accident frequency rate rose 10 per cent in one year. Let's present this same information three different ways.

No. 1

Here we have the whole graph in proportion. There is a zero line at the bottom for comparison. The frequency rate is up the side. The 10 per cent rise looks like 10 per cent. The upward trend is substantial but perhaps not overwhelming.

Now let's chop off the bottom.

No. 2

Now this looks more serious. The figures and curve are the same. It is the same graph. But you get a different impression. Our accident rate has climbed halfway up the chart in a year! What looked like a modest rise in No. 1 has become, in No. 2, a big one.

Now let's try a third method.

No. 3

Here we have changed the proportion between the ordinate and the abscissa. There's no rule against it and it does give your graph a nicer shape. What we have done here is let every mark up the side stand for only one-tenth of the frequency rate that it did before. There is no question about it, this is much more impressive and effective. This could well be called a "free-Whiz" graph. It demands attention.

In presenting statistics at safety meetings I feel it is most important to show them on a screen with figures large enough so that they can be seen by everyone. I don't think there is anything worse than putting up material that can be read only by people in the first few rows.

I also think it helps quite a bit to include a little humor in the material you present. I guess we are all agreed that statistics in themselves are pretty dry stuff. So we should try to spice them up a little.

Next, it's a big mistake to try to cover too much ground or go into too much detail. In an oral presentation of accident statistics—boil them down. Try to bring out the important facts and quit while you're ahead. If your full report has a lot of material in it provide copies that can be reviewed after the meeting.

Finally, try to end your presentation with some kind of a punch line or direct challenge to get action. The only reason for presenting statistics is to give the viewing group the accident "picture." If it's a good record you want them to keep up the good work. If your accident experience is poor you hope the presentation will help stir the group to take corrective action.

Now, in hopes of illustrating what I have just mentioned, I'd like to show the 1960 accident statistics presented at our last annual Lake Superior Mines Safety Council Conference.

No. 4

Here we have a Sherlock Holmes type of individual looking through a magnifying glass. You will notice I've used the same approach in

No. 5

We want to take a look at our accident experience. Another idea would be to have someone looking through binoculars, a spy glass or even a key hole!

No. 6

Here we are telling the viewing group that the yardsticks of safety performance are the frequency and severity rates. We spell out what each rate means.

No. 7

This shows the over-all experience of all mining companies with membership in the

Lake Superior Mines Safety Council. This membership last year was made up of 24 companies—21 were engaged in mining ore and 3 in the mining of copper.

These 24 companies worked a total of 50,970,338 man-hours. There were 678 disabling injuries. These injuries resulted in time charges of 112,498 days. The figure of 112,498 days includes actual calendar days lost and scheduled charges for permanent, partial and fatal injuries as set forth in the American Standard Method of Compiling Industrial Injury Rates, Z16.1 by the American Standards Association.

No. 8

This shows the number of fatalities and where they occurred. There were 13 fatalities. There were 3 fatalities in open pits, 9 in underground mines and one fatality was charged to a non-operating unit. Shops and plants operated for the fourth straight year without a fatal injury.

The fatality rate of .26 per million man-hours worked is the fourth best recorded. In the years of 1951, 1953 and 1955 we did have lower rates. The lowest rate ever recorded was that of 1955 when it was .17.

No. 9

Here is shown the injury rates for the entire Lake Superior Mines Safety Council membership.

The frequency rate of 13.30 is about 4 per cent higher than that of the preceding year. However, it represents the third lowest rate in 20 years.

The severity rate—2207 days lost or charged per million man-hours worked was down 31 per cent from 1959. Reviewing our past experience we find that only in 1953 and 1954 did we have lower rates.

No. 10

Here we show the 1960 accident experience in plants. Ore processing plants in the Lake Superior District worked 9,785,518 hours. There were 60 disabling injuries. These injuries resulted in 5,159 days being lost or charged.

The frequency rate of 6.13 is the second best we have ever had. Our best year was 1951 when a 5.69 rate was recorded.

The severity rate of 527 is up 14 per cent from that of the preceding year.

No. 11

Here is the accident experience of general shops. They worked a total of 6,694,043 hours. There were 37 disabling injuries which resulted in 1505 days being lost or charged.

The frequency rate of 5.53 is up 7 per cent from 1959 and is the highest in the past four years.

The severity rate of 225 is down about 18 per cent from the previous year and is the second best in the past twenty.

No. 12

This shows the record of open pit mines. Open pits worked a total of 13,207,299 hours. There were 87 disabling injuries which resulted in time charges of 24,294 days.

The frequency rate of 6.59 shows a 9 per cent improvement over 1959.

The severity rate was 1839 which is 22 per cent lower than that of 1959.

No. 13

This is the experience of the Lake Superior district underground mines last year. They worked 16,053,114 man-hours. There were 489 disabling injuries which resulted in 75,458 days being lost or charged.

The frequency rate of 30.46 is 6 per cent higher than that of 1959.

The severity rate of 4701 is 40 per cent lower.

No. 14

This shows the various types of operations ranked in regard to the frequency of disabling injuries.

The best frequency rate was made by general shops with 5.53 disabling injuries per million man-hours worked. In second place were plants with a rate of 6.13. Open pit mines were third best with a rate of 6.59. In fourth place and a poor last was underground mines with a frequency rate of 30.46.

Now let's take a "quick" look at the type of accident that occurred most frequently in plants, shops, open pits and underground mines. We should keep in mind that here we will be showing "how" the

greatest percentage of workers were injured and not the causes of the accidents.

No. 15

In plants the leading or most common type of accident was "falls of persons." This includes falls from elevations and also at ground level. There were 12 disabling falls. These falls made up 30 per cent of all disabling injuries in plants. Included were falls due to tripping over spillage on conveyor walkways, stepping back off unguarded elevated platforms, slipping on icy surfaces and falling into unprotected openings. Falls in plants resulted in 1336 days being lost or charged.

In second place were "handling material" accidents. These accounted for 18 per cent of the total number of disabling injuries. In third place was "moving machinery" with 17 per cent of the total.

These three accident types alone were responsible for 55 per cent of all disabling injuries and 70 per cent of all the days lost or charged.

No. 16

In general shops the leading accident type was "falls of persons." There were 11 disabling falls. These made up 30 per cent of the total number of disabling injuries and caused 266 days of lost time. Falling off an unsecured ladder, falling on icy surfaces in shop areas, and slipping and falling while emptying containers and while working on trucks give you some idea as to how some shop "fall guys" were injured.

Close behind "Falls" were "handling material" accidents which contributed 24 per cent of the total shop injuries.

No. 17

In open pits, yes, you guessed it, it was "falls of persons" again leading all other types of accidents. There were 21 disabling "falls." And due to those falls, 6755 were lost or charged. Here are some of the accidents: fell from top of drill mast; fell into improperly covered drill hole; misstepped from shovel platform and fell, striking shovel pads; fell off truck fender while pouring oil in engine, fell down steps of retreating building; fell while getting down from road grader, etc. Falls in open pits made up 24 per cent of all disabling injuries.

No. 18

In underground mines, like in all other operations it was "falls of persons" that lead all other types. There were 71 disabling "falls." These falls made up 15 per cent of the total number of injuries and resulted in 3,853 days of lost time.

"Falls and slides of ground" were in second place with 59 accidents and time charges of 27,773 days. These accidents made up 12 per cent of the total.

In third place was "handling material" mishaps which totaled 44. These resulted in 1,119 days being lost or charged and made up 9 per cent of the total.

No. 19—All operations

A total of 117 workers in Lake Superior area mines, shops and plants "fell down" on the job last year. These falls were responsible for 18,250 days of lost time and made up 17 per cent of the total.

Now it should be a well known fact that "falls" are second only to traffic accidents as the cause of accidental deaths in this country. It is estimated that every day 55 people are killed by falls. "Falls" are the most frequent cause of industrial injuries and, as I have pointed out on this and on many previous occasions when reviewing our annual statistics, "falls" are the leading cause of injuries in mining operations in the Lake Superior district.

The causes of "falls" are usually the obvious things that we all know about. But "knowing is not enough"—to reduce "falls of persons" accidents what is needed is a much more concentrated safety effort by all companies to:

1. Improve housekeeping standards.
2. Emphasize and re-emphasize to all workers the fallacy of using defective and improvised platforms and stagings.
3. Get prompt action in protecting floor openings, open drill holes, excavations, etc.
4. Stress and re-stress every phase of correct ladder usage.
5. Provide sufficient illumination.
6. Take care of icy walkways, steps and platforms before workers get hurt.

7. Provide hand holds and grab irons to the practical degree to aid workers in getting on and off equipment safely.

8. Analyze all work procedures to determine the "fall" hazard. Take corrective action promptly if a safer work method is indicated.

9. Make every worker aware of the fact that one out of every five—20 per cent of all injuries in Lake Superior area mines, plants and shops are caused by "falls of persons!" Do everything possible to get him to think twice—so he won't fall once!

Well there you have it. A brief review of the accident experience in the Lake Superior district mines in 1960. The full report which contains 32 tables is printed in the proceedings and copies are furnished to all persons who attended the conference.

In closing out the presentation I generally have something like this Supervisor's Safety Creed to wind it up.

1. I must have the proper attitude. When I see an unsafe act I will discuss it immediately with those who performed it. I will look constantly for a safer way in which will do the work.

2. At all meetings with my men, I will listen to the worker's point of view. I will make certain that all workers are aware of the safety rules that apply to their jobs and that they understand them.

3. I will observe the work habits of experienced as well as new transferred employees. Wherever necessary, I will review and re-emphasize the importance of my company's safety program.

4. I will accept my rightful safety responsibility. I will not assume that people working for me know or have been told. It is my job to know that they know. I will not assume that safety will take care of itself. I will not assume that I can get by today. Instead, I will teach, I will show, I will repeat and when necessary, I will act promptly to eliminate physical hazards and correct unsafe acts.

5. In all matters of job safety instruction, I will say what I mean and—I will mean what I say.

SUPERVISORY SAFETY TRAINING PROGRAMS FOR THE MINING INDUSTRY

By HAROLD L. BARE

Asst. to Management's Representative, Bethlehem-Cornwall Corp.
Morgantown, Pa.

Supervisory safety training is a worthwhile investment for any mining company, and it should be a basic part of the safety activity of all mining companies, from the small concern employing a few supervisors and less than one hundred men to large mines with thousands of employees, hundreds of supervisors and a special safety department. Supervisory safety training may be likened to a seed which, properly planted and nourished in the supervisor, blossoms forth in the safe attitudes and work practices of the ten, twenty, or thirty employees whom the foreman supervises.

Even though supervisory safety training can pay numerous dividends in areas other than safety, many mining companies, especially the smaller ones, do little or no supervisory safety training because there is no course or program tailored for training mine supervisors. Most supervisory training courses and materials are general in nature and utilize factory type situations for examples or illustrations. Even if it were practical, it would be very difficult to devise a supervisory safety training program that would be acceptable to all mining companies, because of the diversity of mining methods, terminology and work practices.

Since supervisory safety training deals with universal principles which may be applied in any industry, it is to the advantage of every organization to utilize available supervisory safety training materials and adapt them as required to meet the specific needs of the organization.

It is my intent to suggest a range of supervisory safety training activities that will enable practically any mining company to engage in some supervisory safety training, despite varying operating, financial and other restrictions.

DOES YOUR COMPANY REALLY HAVE A SUPERVISORY SAFETY TRAINING PROGRAM?

Most mine managers, if asked whether their organizations had a supervisory safety training program, would unhesitatingly answer in the affirmative. Upon investigation, most of the programs would turn out to be composed of first aid training and mine rescue training courses in which the supervisors participate. Relatively few mining companies have developed their safety training programs beyond this point. What about your company?

It may very properly be pointed out that first aid and mine rescue training is definitely safety training and further that it should justifiably be classed as supervisory safety training because the supervisory force participate in the program and often furnishes the instructors. But does this really comprise a supervisory safety training program?

This question can be answered best by defining the term, "supervisory safety training program." It may be defined as a "plan to train supervisors in the art of accident prevention." A supervisory safety training program will contain all of the following components:

1. It will be a planned program.
2. It will consist of a comprehensive study of safety problems, rather than just one or two areas of safety.
3. Program material will be designed primarily for supervisors.
4. The primary objective of the program will be to motivate, and to enable, the supervisor to transmit the idea of safety to others rather than just to instill the idea of safety in the individual supervisor.

From the foregoing, it should be readily apparent that first aid and mine rescue training, while essential components of a program, do not of themselves comprise a supervisory safety training program.

Therefore, if your company is currently engaged in a program that meets all four

of the conditions listed above, it really does have a supervisory safety training program. If your company's training activities for supervisors do not meet the test of those four conditions, your organization is not utilizing supervisory safety training, a tool that will help to reduce accidents, improve production, and cut costs.

HOW YOUR COMPANY CAN ARRANGE TIME FOR SUPERVISORY SAFETY TRAINING.

Perhaps the most frequent reasons given by members of management for not initiating a supervisory safety training program are the lack of time to devote to training and the difficulty in assembling a sufficient number of supervisors for group meetings over a period of time in order to conduct training.

Managers are human, of course, and like most people, they often cannot find time for things in which they have only an indirect interest. In many cases, therefore, what is required is an abiding belief by management in the value and benefits of supervisory safety training. Once management has attained a sincere desire to train supervisors in the promotion of safety, it is surprising how easily the obstacles of lack of time and the difficulty in getting supervisors together can be overcome.

Therefore, one way to arrange time for supervisory safety training is for management to harbor a conviction that supervisory training is a valuable tool that will pay dividends in accident prevention, production, and cost reduction. If management has this attitude, training time will acquire a priority on the organization's activity schedule.

There are, however, organizations where the management has a sincere interest in supervisory safety training, but because of supervisors' shift schedules, finds it difficult to arrange suitable time for training. There are several suggestions which may be considered to alleviate this situation.

For instance, training sessions could be scheduled for off-shift periods, such as evenings or weekends, when a majority of the supervisors would be available. If these meetings were to be scheduled on a monthly basis, it would not be too great an imposition on the free time of supervision, al-

though some companies might find it advisable to pay their supervisors for such meetings.

If it is desirable to hold training sessions during normally scheduled working hours, regular supervisors might be replaced for a few hours each month by substitute supervisors such as those normally used during vacation periods. Depending on circumstances, it might be practical to hold evening meetings when most supervisors are not scheduled and replace with substitutes those supervisors who are on shift.

If it is not feasible to hold separate meetings for supervisory safety training, thought should be given to the utilization of a portion of other regularly scheduled meetings for this purpose. This type of training is suitable for inclusion in any safety meeting, but it should also be considered as a valid portion of a production or operations meeting, since safety training definitely affects both of these areas.

Many organizations who hold regular foremen's meetings often show films as a part, or as an added entertainment feature, of the meetings. This offers a way to introduce supervisory safety training without scheduling additional meetings. Simply schedule safety training films and your supervisors will continue to be entertained and they will also be trained at the same time. Of course, the program should later be broadened to include other aspects of supervisory training.

An opportunity for supervisory safety training which is overlooked by many mine managers is the use of periods of reduced operations for training sessions. Many companies periodically find it economically necessary to schedule mine operations for a three or four day week, but as a matter of company policy, salaried supervisors are usually scheduled for a five day week.

The non-operating day of each short-time work week provides an excellent opportunity for supervisory safety training sessions, especially since the usual excuses, such as interfering with production, lack of time, and the difficulty of getting supervisors together, have no validity. Since these specific training opportunities occur as a result of economic conditions, and are not prearranged, it is important that a supervisory training program be planned in ad-

vance so that it can immediately be put into effect when the opportunity occurs.

If no preplanning is done, these training opportunities slip past because when a period of reduced operations does occur, the schedule is often back to normal by the time a program is planned and training material obtained. However, if plans are set and training material is acquired in advance, a supervisory training program can be instituted during the first week of a period of reduced operations, thereby taking advantage of an excellent opportunity for supervisory safety training.

Several proposals have been considered which can aid companies in the scheduling of supervisory safety training sessions. If your company is not now engaged in a supervisory safety training program, one of these methods should be adequate for use or adaptation in order to initiate a program in your company. It all boils down to—"Where there's a will, there's a way."

SELECTION AND USE OF A SUPERVISORY SAFETY TRAINING PROGRAM FOR YOUR COMPANY.

Although some sort of supervisory training program can be devised to fit in with the limitations imposed by size, schedules, or operating problems, it goes without saying that every mine cannot, for various reasons, set up a full fledged training program. But every mine can set up a program in which its supervisors will get some supervisory safety training.

Listed below are a number of proposed training ideas arranged to suit varying conditions and operating requirements. If there is no current supervisory safety training program in your company, one of the proposed programs should fit your situation. Unless otherwise indicated, all training materials are available from the National Safety Council.

1. Program for Mines Which Have No Opportunity for Group Training

(Small plants or mines which do not hold meetings or those which have one or two supervisors in a number of isolated locations)

- Foreman's Home Study Course.
- Monthly Mailing or Distribution of the Following Pamphlets:

- Psychology of Safety in Supervision—
Set of Six Booklets by Dr. J. L. Rosenstein.
- Personal Development Series—
Set of Six Pamphlets containing talks given at the Early Morning Sessions of the last six National Safety Congresses.
- Men and Motives in Safety Supervision—
Set of Six Booklets by Glenn F. Griffin.
- Subscription to the "Industrial Supervisor" for each supervisor.

2. Program for Mines Which Have Limited Opportunity for Group Training (Plants or mines which have foremen's meetings on a weekly, bi-weekly or monthly basis)

Many medium-sized plants assemble most of their supervisory force at more or less regular intervals for operations, safety, or combined safety-operations meetings. If no other training opportunity exists, portions of these meetings can profitably be allotted to supervisory safety training.

a. Supervisory Safety Training Course Based on "Supervisors Safety Manual"

Requires approximately 40 minutes of each meeting.

Assign a chapter for reading prior to the meeting and have each supervisor complete the quiz, as given in the Instructors Guide, for the assigned chapter. Have the quizzes corrected during the meeting and discuss the questions at the end of the meeting to make sure all supervisors know the correct answers. The "Supervisors Safety Manual" can be covered in twelve meetings using this method.

b. Foreman's Home Study Course

Supervisors can be enrolled as a group and assigned lessons from the "Supervisors Safety Manual" on a group basis. Examinations, which are more comprehensive than in "a," can be completed by the individuals and sent in a group to the National Safety Council for

correction. Completed examinations can be corrected and returned in time for discussion at the next monthly meeting.

c. Men and Motives in Safety Supervision—

Set of Six Booklets by Glenn F. Griffin.

Leader's Training Guide available. Assign one booklet for reading prior to each meeting. Discuss subject during meeting.

d. Supervisory Safety Training Motion Pictures

1. No One Else Can Do It
2. Fact Finding, Not Fault Finding
3. Foresight—Not Hindsight
4. What They Don't Know Can Hurt
5. Call 'em on the Carpet
6. It's an Order
7. Fragile—Handle Feelings with Care
8. Let's Talk About Safety
9. Take a Talkie Break
10. Setting 'Em Straight
11. Let Everyone Help
12. Knowing's Not Enough (Available from United States Steel Corporation)

3. Program for Mines Which Can Schedule Group Training Sessions for Supervisors on a Regular Basis

a. Supervisory Safety Training Course based on "Supervisors Safety Manual"—

Eighteen class hours based on twelve or more weekly classes. Instructors Guide available.

b. Metal Mines Accident Prevention Course—

Can be arranged through U. S. Bureau of Mines District Health and Safety Offices.

c. Men and Motives in Safety Supervision—

Set of Six Booklets by Glenn F. Griffin.

Use as course of six class hours. Leader's Training Guide available.

d. Supervisory Safety Training Courses offered by some State or Provincial Industrial Commissions. Example: "J" courses in Canada.

e. Supervisory Safety Training Courses which may be offered by your Workmen's Compensation Insurance carrier or your Mining Association.

f. Review of your state or provincial mining act.

g. Review of your company safety rules.

h. First Aid Training Courses (Can be arranged through the American Red Cross, U. S. Bureau of Mines District Health and Safety Offices, or the St. John's Ambulance Corps).

i. Mine Rescue Training Course (Can be arranged through state or provincial Department of Mines).

j. Specific training programs developed by your Company Safety Department.

k. Preparation and use of Job Safety Analyses.

l. Arrange for a professional safety man to accompany the individual supervisor during his regular shift to give him on-the-job training from the viewpoint of professional safety personnel.

Although any company which uses these training ideas will find it difficult to measure their effectiveness, it is safe to say that supervisory training will result in the establishment of safer attitudes and work habits among the company's employees, and that the training can also be counted on to pay additional dividends in the form of fewer accidents, improved production and reduced costs.

NOISE ABATEMENT AT MINES AND QUARRIES

By JAMES H. BOTSFORD

Noise Control Eng., Bethlehem Steel Co., Bethlehem, Pa.

Noise has been an accepted part of the industrial environment for many years. Workers seldom complained about the noise associated with their occupations and in only a few instances was much consideration given to noise abatement. But with the spreading knowledge that sufficient exposure to excessive noise may impair hearing, an impairment which many jurisdictions have held to be a compensable occupational disease, noise and its abatement is currently receiving a great deal of attention.

Noise from certain equipment and operations has been more or less effectively controlled as some examples to be presented later will show. But there are many machines including some used in mining operations which are quite noisy and on which little control effort seems to have been spent. In mining, as in other industries, the tendency over the years has been toward increased production through use of larger, faster, more powerful equipment which, unfortunately, is also noisier in many cases.

It is usually difficult to quiet equipment which was designed without regard for the noise produced as seems to be the case with but few exceptions. Therefore, noise control devices of sweeping application in mining cannot be presented here as the role of this paper might lead some to expect. This paper must be limited to presentation of some fundamentals of noise necessary for an understanding of the problem, to descriptions of some mine noise control efforts which are in progress or completed and to some suggestions for approaching mine noise control in the future.

Noise and Noise Measurement

Noise has been defined as "unwanted sound." Physically, sound is a slight variation in atmospheric pressure which occurs quite rapidly. This pressure variation can be described in terms of its two physical attributes, the magnitude of the pressure variation and the rate of recurrence. The extent of the variation from atmospheric pressure due to a sound wave is generally referred to as the "sound pressure" and the rate of recurrence of the variation

is called the "frequency." As the sound pressure increases, a sound becomes louder; and as the frequency increases, the pitch becomes higher.

Noise is measured with a sound level meter. The sound level meter consists of a microphone and an alternating current voltmeter. The microphone generates a voltage which is a replica of the pressure variation associated with the sound. This alternating voltage is measured by the voltmeter which is provided with a range-selecting switch to permit measurement of sound pressures over a wide pressure range. The meter is calibrated to indicate sound level in decibels (abbreviated db) which is a logarithmic function of the sound pressure.

Three weighting networks are provided in an attempt to obtain readings proportional to the subjective loudness of the sound to the human ear but the correlation of meter readings with loudness is so poor that the weighting networks are seldom used for this purpose. Usually readings are taken using the "C" or "flat" network with which the meter indication is essentially independent of frequency throughout the audible frequency range (approximately 20 to 10,000 cycles per second). Sound level meters are manufactured and calibrated to the specifications of the American Standards Association.

The levels of some familiar sounds are indicated next, ranging from the threshold of audibility to the threshold of pain. Electric welding produces about the same overall sound level as that found inside an auto in city traffic and the level inside an airliner is the same as that inside a crushing and screening plant. From experience, these sounds are quite different subjectively but this difference is not apparent from the overall sound level. To measure the difference which the ear detects, it is necessary to determine the intensities and frequencies of the components of the sound using a sound analyzer.

The sound analyzer most commonly used is the octave-band noise analyzer. When connected to the sound-level meter, this

instrument resolves the sound into eight contiguous frequency bands which cover the audible frequency range, and allows determination of the sound level in each band. One band covers the range 20 to 75 cps; when set to "pass" this range of frequencies, the aggregate level of those components having frequencies between 20 and 75 cps is registered and all other components are ignored.

Another band covers the range 75 to 150 cps and permits determination of the sound level in this frequency range without regard for components of other frequencies. A third band covers the range 150 to 300 cps, etc. In this fashion it is possible to "break down" a noise into eight bands which indicate how the sound energy is distributed with respect to frequency.

Octave-band analysis are usually plotted on a chart. Intensity is plotted on the vertical scale for the various bands shown on the horizontal scale. Several analyses of familiar sounds show that the overall noise levels are much the same but that the octave band analysis curves vary widely indicating differences in sound pitch and quality which the ear detects.

Further information on noise, noise measurement and related topics may be found in handbooks.^{1,2}

Noise Abatement

Octave band analyses of noises at some typical mining operations indicate the range of noise levels encountered and, depending on the noise control adopted, the magnitude of the noise reduction problem. A fairly thorough search of the literature has uncovered very little published information on this subject. There is evidence that noise abatement work is in progress at several locations but the results of this research have not yet been released in printed form. Therefore, it is possible to give solutions to only a few mine noise problems and to indicate what is being done on others.

Pneumatic rock drills are probably the noisiest equipment used in mines and have received more attention in the literature than other sources. Chaffee³ discussed generation of noise by rotary, piston and percussion type tools pointing out that most of the noise comes from the exhaust.

Fisher⁴ found that rock drills produced noise levels 3 to 6 db higher underground

than in open air and that the underground noise levels increase considerably as the cross sectional area of the workings decrease. Tool noise level was observed to decrease slightly after the drill steel penetrated the rock; tool noise also decreased 1 to 3 db for each Kg/cm² (14.2 psi.) reduction in compressed air pressure.

Holmér⁵ began rock drill noise control efforts by investigating the noise produced by a standard percussion rock drill manufactured in Sweden which delivers about 3.5 horsepower to the drill steel. He found that .08 per cent of this energy was converted to noise producing a noise level of 119 db one meter behind the drill in normal drifting operations. Attachment of an exhaust hose and special muffler to the drill reduced the noise level to 110 db. From these measurements he calculated that 87.5 per cent of the drilling noise energy was due to air exhaust and 12.5 per cent was due to impacts in the drill and on the drill steel.

Another investigator⁶ has found that a drifter manufactured in the United States produced a noise level of 114 db alongside the drill at 2 ft. when operating in the laboratory with no drill steel. The noise level was reduced to 108 db when the main exhaust was muffled and to 101 db when the two remaining points of air escape were muffled. These measurements indicate that mechanical noise of the drill alone accounts for about three per cent of the total noise energy.

A Russian investigator⁷ of noise reduction in drilling machines reports that the main sources of noise during drilling are exhaust of used compressed air, vibration of drilling steel and impacts of parts in the drilling machine. These noises can be reduced by built-in and external exhaust mufflers, low-noise drilling rods and sound insulation of the body of the machine. Rod noise can be reduced by damping vibrations and by insulation.

The same investigator reported later⁸ on the development of mufflers for manual drills and stoppers which reduced noise levels 17 to 20 decibels. These mufflers were attached to the drills through vibration isolators, were covered with rubber to reduce vibration and were designed to enclose noisy parts of the drills.

Powell⁹ has measured noise in collieries in England and reported that he was proceeding on the application of noise suppression techniques in mining machinery and operations. Some of his developments may be applicable to equipment used in hard rock mines. From these reports, it appears that percussion rock drill noise is composed mainly of exhaust noise which can be muffled but that mechanical noise emanating from the drill casing and rod must be controlled if drilling noise is to be reduced by more than about 10 db.

The United States Bureau of Mines is conducting a rock drill noise reduction program which the principal investigator describes¹⁰ as follows:

"The United States Bureau of Mines is conducting an investigation of pneumatic rock drill noise at its Rolla Office of Mining Research which is located at Rolla, Mo. The objectives of this research program are to (1) develop methods and devices that will abate the high intensity noise generated by pneumatic rock drills and other mine equipment, (2) obtain fundamental technical data and information that can be applied to the investigation of noise problems occurring in the mining industry, and (3) transcribe the findings of the research into recommendations for practical applications in the mining industry. Descriptions of the research conducted and the findings obtained therefrom will be published in Bureau manuscripts as the material becomes available. Publication of the first paper on the noise abatement study is scheduled for this year.

"The first step in the research program was a determination of (1) the physical characteristics of the drill noise, (2) sources of the drill noise, and (3) environmental conditions in which the noise exists. Sound measurements were made of the overall noise levels of drills operated in a quarry and in underground mine workings. Analyses of the tape recorded sound levels were conducted in the sound laboratory to obtain the frequency spectra. Noise reduction criteria were established from data obtained in this study.

"The next step was to repeat the sound measurements when the same drills were tested with muffling devices attached to the exhaust ports, and when various drill

parts, fabricated from vibration damping alloys, were substituted for the standard steel parts. Findings obtained from this step and the preceding one indicate the avenues of attack that could be employed in the development of methods and devices for reducing drill noise.

"Investigations conducted to develop noise attenuating methods and devices include (1) the application of the principles of sound cancellation to a study involving the operation of two or more drills simultaneously, (2) design and utilization of laboratory models which simulate the acoustical properties of the exhaust systems found in pneumatic drills, and (3) freefield sound measurements conducted in an anechoic chamber.

"At the present time research is directed toward the development of noise attenuating exhaust devices for pneumatic drills and an investigation to determine if the noise levels can be reduced by modifying the design of the exhaust ports. The approach to this research is based on the principles and applications of dynamical analogies. The procedure used is to (1) develop acoustical networks of the devices, (2) construct analogous electrical networks, (3) determine and solve the electrical circuit that satisfies the conditions of the design goals, (4) convert the electrical answers into acoustical networks, (5) fabricate the developed noise attenuation devices, and (6) determine the performance of the devices on operating drills.

When a sound measurement is made of a rock drill operated with a muffler attached to the exhaust ports, the instruments used in the measurement are a 1/3 octave band audio spectrometer connected to a high speed level recorder. Gauges are used to record the air line pressure at the drill and any backpressure that may be built up when the drills are operated with mufflers."

Regarding rotary diamond drills, a noise reduction of 8 db was obtained through use of an exhaust hose and muffler. The muffler used was designed for silencing high velocity air exhausts; greater noise reduction would probably be obtained with a muffler designed to suppress pulsations.

Some drill manufacturers have directed their attention toward abatement of rock

drill noise. One manufacturer can supply a "rubber-muffler" for use on any of his diamond drills which is reported to reduce operating noise considerably. Another supplier offers a "muffler cover" for jack hammers which encloses the drill in a fabric bag lined with sound absorbing material to reduce exhaust and mechanical noise at the same time. One spokesman in the pneumatic tool industry feels that increasingly quiet tools can and will be provided to meet the ever stricter requirements of industry in general.

Thus it appears that rock drill noise has been studied, that the sources of noise are recognized and the methods of controlling them understood and that efforts to find practical means of reducing rock drill noise are continuing. However, general solutions have not been developed yet. There is little the user can do to reduce drill noise because drill design usually makes it difficult or impossible to attach mufflers or other noise control devices. The manufacturers alone are in a position to provide quieter drills and, no doubt, will do so when customers demand them.

Crushing and screening plants are also noisy mining operations and Hoffmeyer¹¹ has reported some noise control methods. In gyratory crushers, and old truck tire can be used for a spreader at the top to eliminate the noise produced when rock strikes a steel spreader. Noise is also radiated from the top opening of the crusher which can be prevented by covering the opening. The side walls of the crusher vibrate during crushing and radiate noise which can be reduced by enclosure where practical. Crushing plants which leave most of the crusher outside the building are quieter inside than where all equipment is contained in the building. Perhaps the simplest method of protecting operators from crushing plant noise is to provide sound proof control rooms.

Rock falling into chutes produces noise which can be reduced by some form of cushioning. Two steel plates were positioned at a conveyor discharge so that rock piled up on the plates before falling into the chute. This rock cushion reduced the noise level from 118 db to 103 db and increased the service life of wear plates in the chutes. An old piece of belting hung at the discharge of a conveyor to prevent the rock

from striking the steel plate behind it reduced the noise level from 106 db to 99 db.

A chute at the discharge of a conveyor was lined with rubber to reduce noise. Gaskets of vibration damping felt were installed behind wear plates in chutes on the theory that impacts would be cushioned and wall vibration reduced by damping. Little noise reduction was achieved but breakage of wear plates was lessened noticeably.

Another approach to crushing plant noise control which has been used is to prevent reverberant build-up of noise levels by providing sound absorbing interior surfaces. The interior panel of an insulated metal curtain wall has been perforated to expose the glass fiber thermal insulation so that its sound absorbing capacity may be utilized. The vapor barrier was placed in the center of the insulation rather than at the usual location next to the interior panel in order to avoid blocking the perforations with the vapor barrier. It is estimated that the crushing plant where walls of this design are being applied will be eight decibels quieter as a result of this simple, inexpensive variation of conventional construction.

Many types of self-propelled equipment produce excessive noise at the operator's location. Trucks, end loaders, tractors, graders, earth movers, drills, shovels, etc., may, depending on design and mechanical condition, fall into this category. The discussion which follows outlines methods of noise reduction, some of which are applicable to all such equipment whether it be powered by internal combustion or electric motors. Some of the suggestions may also be applied to trailer-mounted compressors, pumps or generators.

Exhaust noise predominates in trucks and other types of equipment powered by internal combustion engines. Frequently, exhaust mufflers are inadequate or are not used at all. Mufflers may become ineffective through deterioration of the exhaust system or deliberate destruction of the interior flanges or baffles of the mufflers. Modification of the exhaust system may be undertaken on the assumption that significant increases in power, engine life, and fuel economy follow from the reduced back pressures. While these effects are present, there are misconceptions of the degrees to which they obtain.

Adequate exhaust mufflers are available but muffler size rather than performance attainable is the limiting factor in applications. The volume of an adequate muffler ranges from four to eight times engine displacement and installation may require rearrangement of the exhaust piping. Recommendations of the engine manufacturer should be obtained when considering improved exhaust muffling. Muffler manufacturers can also recommend a suitable muffler for each engine type.

Installation of superchargers powered by an exhaust driven turbine reduces exhaust noise but experience to date indicates that additional noise reduction measures are necessary to obtain acceptable noise levels.

Engine compartment noise may be produced by the engine itself, the cooling fan, the air intake or engine accessories. Each of these sources presents a problem which likely is too complicated for a user to solve. If one such source is an outstanding noise producer, the engine manufacturer's advice on quieting should be solicited. Engine compartment noise may be reduced by providing a sound-absorbing lining constructed according to instructions given later. Transmission of engine compartment noise to the operator's position may be minimized by reducing the size of any openings in the separating wall to a minimum.

Operator's cab noise may be reduced by provision of a sound-absorbing lining on a large portion of the cab interior surface as is practical. The lining should consist of a fiber glass blanket attached to the interior surfaces of the cab and covered by a suitable protective facing if necessary. The fiberglass blanket should be at least 1 1/4" thick and of any density. Where the blanket must be flexible enough to fit contours, the density should not exceed 2.5 or 3 pcf. A covering of cloth may be desirable to prevent shedding of glass fibers or dislodging of trapped dust by vibration.

Fiberglass blankets designed for use in ventilating ducts are available with a special coating of neoprene or other material on the exposed face to prevent erosion, and such duct lining material could be used without the cloth covering and, perhaps, even without a protective facing. Facings of paper, foil, plastic, canvas or any non-porous material are unsuitable as they de-

stroy the porosity of the blanket on which the sound absorbing capacity depends. Where the lining is likely to be bumped or gouged, a protective facing of screen, expanded metal, perforated metal or other material having at least 10 per cent open area is required.

Attachment of the blanket to the surface may be accomplished with adhesive or by mechanical methods. Fasteners designed for attachment of thermal insulation could be used to attach the blanket and any covering or protective facing required. The sound absorbing capacity of the lining will be essentially unaffected if the blanket is compressed by the protective facing where it passes over projections or if there are air spaces behind the blanket or between the blanket and facing.

Electric motor-generator sets used in shovels may be equipped with noisy cooling fans. The noise from these sources may be reduced by (1) ducting the motor or generator cooling air inlet and discharge to the outside, (2) installation of ventilating duct silencers on the inlet and discharge, (3) construction of partial enclosures lined with sound absorbing material. Also, the machinery compartment may be lined with sound absorbing material as described above.

In purchasing new equipment, the vendor should be asked to supply octave band noise levels under operating conditions in the areas to be occupied by employees in order to determine whether hazardous noise exposures are likely to exist. The vendor might also be asked to bid on the equipment with noise control devices such as adequate mufflers provided, giving the noise data applicable to these conditions. With these data at hand, noise exposure may be given due consideration in making a selection from the several pieces of equipment offered.

Air exhaust noise can be reduced rather simply in many cases. A drill sharpener was fitted with a two inch pipe to carry the exhaust outside the shop; this simple alteration reduced the noise level from 122 db to 102 db. The shank hammer of the same sharpener was fitted with a hose to carry the exhaust outside the building which reduced the noise level from 125 db to 103 db.

Where air is discharged at high velocity as from pneumatic cylinders, high turbulence

is created in the region where the jet mixes with the relatively still room air resulting in the familiar hissing noise, which becomes intense for large jets. The muffler is designed to quiet such high velocity exhausts by spreading the flow over a large area permitting discharge to the room at low velocity. Air enters through the threaded fitting, passes vanes which spread the air stream, expands through a deflector and diffuses into the room through a porous disseminator.

Using this type muffler, noise reductions exceeding 20 db have been obtained which are usually enough to make the exhaust inaudible in the presence of noises from other sources. A muffler is available to fit each standard pipe size from 3/4 inch to 6 inches; when the proper size is used, flow is reduced only 3 per cent. The muffler will reduce the noise of pulsating exhausts such as from air motors but is less effective than a good automotive type muffler containing constrictions and expansion chambers.

Ventilating systems in mines can be noisy; an interesting case was found in a temporary system powered by a reversible positive displacement blower. An 18-inch steel line was used to provide air during drilling or exhaust air after blasting at the face about 3000 feet from the blower. When supplying air to the face an intense hammering noise was noticed along most of the pipe which was not present while exhausting blast gases.

The noise level was measured along the haulage way at various distances from the blower while supplying air to the face. It was seen that the overall noise level dropped slightly on moving away from the blower and then rose abruptly to a maximum at a distance of 240 feet. From this point, the noise fell off gradually with distance until at 2750 feet it died out almost as abruptly as it had started.

This behavior was not due to vibration transmitted along the pipe walls or to presence of other noise sources in the haulage way. Rather, the intense pressure pulsations at the blower discharge developed into shock waves after traveling a distance of 240 feet along the pipe. The shock waves were transmitted along the pipe for about 2500 feet before they died out as a result of sound energy loss to the pipe walls.

The need for a muffler was obvious but space limitations ruled out the use of certain types. After much consideration, an air conditioning duct silencer, consisting of a resonator with a section at either end containing sound absorbing splitters, was chosen. The muffler was installed 170 feet from the blower the haulage way noise levels after installation of the muffler was plotted.

The noise level rises near the muffler due to sound radiation from the muffler walls. A weaker shock wave was formed at 240 feet from the blower which died out after traveling about 600 feet down the pipe. These effects are more pronounced in the plot of noise levels in the 300 to 600 cps band. Although the shock wave noise could not be eliminated entirely due to the size restrictions on the muffler, the situation was much improved by the muffler installed.

Planning for Less Noise

Excessive plant noise can best be avoided by considering probable noise levels at the planning stage. Vendors should be advised that noise is a factor to be considered in selection of equipment for purchase and be asked to provide information on the noise output of equipment along with bids. Noise specifications have been used successfully to obtain quiet equipment. It has been found that higher priced but quieter equipment is sometimes more economical than lower priced but noisy competitors when the cost of noise control for the latter is considered. It is believed that vendors will respond favorably when they learn that customers want quiet equipment and are willing to make some sacrifices to get it.

Plant layout and construction can also be conducted so as to avoid noise problems. Noisiest operations may be grouped together and isolated from the rest of the plant. Sound absorbing materials may be used in building construction to prevent reverberant build-up of sound energy. Bare cinder block walls absorb about five to ten times as much sound as brick, steel or asbestos cement board. Acoustical form board is available for fabrication of built-up gypsum roofs which absorb sound effectively and insulate at the same time. Some of the insulated metal curtain walls are available with the interior panels perforated to utilize the sound absorbing capacity of the insulating material. Where high noise levels

are unavoidable, enclosed control stations may be provided for the operators.

A sound absorbing roof deck was installed on a new mill building. The plank is composed of wood fiber held together with a cement binder and is fireproof. It can be erected rapidly using clips for attachment to box-section sub-purlins. The material is also available in panels for curtain wall construction. Architectural supplies catalogs list many sound absorbing materials suitable for industrial building construction which permit economical reduction of industrial noise.

Objectionable noise is a by-product of some operations in almost every industry. Practical control measures are not easy to develop and few ready-made solutions are available. Control of noise at existing operations is the problem of operating management which is best solved by the cooperative efforts of engineering, operating, safety and medical personnel.

Control of noise from new equipment is the problem of the manufacturer who must be assured of the market for quieter equipment for quieter equipment before the cost of necessary modifications can be assumed. Safety engineers must make operating management and vendors aware of the noise

problem now if solutions are to be reached in the near future.

EAR PROTECTION AND AUDIOMETRIC EXAMINATION

By JAMES B. BOWEN
Assistant to Safety Supervisor
Erie Mining Company
Hoyt Lakes, Minn.

Maintaining a comprehensive safety program is of prime concern to Pickands Mather and Company, the operating agents for the Erie Mining Company's taconite plant at Hoyt Lakes, Minnesota and other mining properties. The program includes not only physical devices and educational measures to prevent employee injuries and property damage, but also provides for working conditions which will afford the employees the greatest possible immunity from occupational diseases.

The desire to eliminate all potential causes

of occupational diseases led to the inclusion of noise abatement and hearing conservation as a vital part of the overall safety program. This added feature was installed with the acceptance of the fact that hearing impairment of a permanent nature can occur as the result of prolonged exposure to high noise levels. There are very few industries utilizing modern heavy equipment which do not have high noise levels associated with their operations.

The first step in establishing a Noise Abatement and Hearing Conservation Pro-

noise level. However, it is stressed that nerve type hearing loss does not occur overnight and generally requires many years of exposure to noise. The doctor is again able to put in a good word for a need of cooperation in audiometric testing, and the fact is stressed that tests are the only means of determining if the individual is susceptible to or has a degree of immunity from the harmful effects of noise.

Those in attendance are fitted with ear protectors at the conclusion of the meeting. The fitting of one employee generally takes only a minute or so, but it does give the employee an opportunity to ask the doctor any personal questions and, at the same time, it affords an opportunity for an ear examination.

It is extremely important that insert-type protectors be fitted properly. Ear protectors can be properly fitted by a trained technician or other qualified personnel, but the confidence afforded by a fitting from a doctor is most desirable.

Records of the type and size issued to each employee are maintained by the Safety Department. The employees are urged to report to their supervisor any damaged or lost ear plugs without delay. This information is relayed to the safety department and a duplicate pair is delivered to the employee's supervisor with a minimum of delay.

The doctor, who has displayed a great interest in our program and has conducted our "Hearing Conservation Meeting" is Dr. M. T. Sumner, East Range Clinic, Virginia, Minn. This graduate of Tulane Medical School in New Orleans is a practicing otolaryngologist. His decision to come and his tenure in northeastern Minnesota has been greatly influenced by the opportunity he was offered to participate in our program.

Employees are able to be fitted and receive an ear examination at our plant dispensary at any time the doctor is on duty. The doctor in charge is a general practitioner who is skilled in fitting ear plugs. This gives the employees a chance to be refitted or to change styles if this is indicated.

We have a few employees who are required to wear ear protectors as a condition of their employment. This restriction is based on audiometric test. The great majority of our employees are scheduled for meetings, fitted with plugs after the lecture

by the doctor and given the opportunity for refitting or exchange and this is the extent of our control over their participation. We are not able to say we have a given percentage of compliance compared to the number of ear plugs issued. A study to determine this percentage would depart from the theme of our program which is "education to maintain a high level of voluntary participation."

We do know that our employees are wearing their protectors based on the following: (1) casual observation by supervisors and safety representatives; (2) the number of replacements required for damaged or lost plugs and (3) the only true criterion, the results of the audiometric tests. The statement I made earlier to the effect that we are satisfied with our ear protection program to date means that we are pleased with results of our repeat audio test.

I was associated with a safety-minded construction company not too many years ago and when requested, we supplied ear plugs to drillers and equipment operators. We placed a supply in the accessible tool cribs and printed an announcement which showed that plugs were available, and that for the sake of the comfort and well being of the employee we encouraged their use. Our early supplies were quickly issued. However, it was hard to locate a driller or operator who was wearing them and our follow-up supplies gathered dust in the tool cribs.

This is all too typical of the approach given to this program by many well meaning firms. I don't think the benefits obtained from this approach are worth the cost of the plugs and the damage it may do to a well planned future program could be hard to overcome.

I do not believe the benefits of active medical participation in the establishment and maintenance of your program can be stressed too much. I restate this opinion because I firmly believe this is the most worthwhile piece of advice I have to offer you.

Ear protectors should be compared to other personal protective equipment. Safety glasses will allow the employee to work with complete safety in areas where many eye hazards are evident. Ear protectors will allow the employee to work in areas of high noise levels with the same assurance.

PHYSICAL CLASSIFICATION OF INDIVIDUALS IN THE MILITARY SERVICE

By HAROLD E. OPSAHL, Colonel, MC
Chief, Physical Standards Division, Office of The Surgeon General
Department of the Army, Washington, D. C.

The subject of my talk today is the physical classification of individuals in the military service, possibly more properly expressed as the classification of military personnel on the basis of their physical capacities. This is quite a broad and involved field and in view of the relatively short time allotted I will be required to deal with it in broad and general terms.

Since the earliest period of recorded history, personnel have been selected for military service against established standards of physical fitness and stamina. Necessarily, these standards have changed over the years to keep pace with the changing requirements of warfare and the increasing size of the manpower pool as basic factors, not to mention many secondary considerations which are constantly changing, requiring compensatory adjustments in basic personnel utilization policies.

In general, past policy has been to maintain relatively high physical, mental and moral requirements for peacetime military service, relaxing these standards during periods of national emergency sufficiently to provide functionally capable personnel in numbers required to meet the increased manpower demand. Although our present physical standards for entry into the military service are lower than at any previous peacetime period, this basic policy is still in effect.

Until we were well into World War II no attempt had ever been made to classify the soldier on the basis of his physical or functional capacity or incapacity. The prospective applicant for military service was evaluated against the existing physical standard and found either acceptable or non-acceptable for induction or enlistment on a go-no-go, pass or fail, black or white, ball or strike basis.

In consonance with this policy we adhered to what has been characterized as a concept of exchangeability, that is, the prospective soldier, having been found to meet

the current physical standards for service, was considered physically qualified for training in any military occupational specialty (or MOS), whether it be of combat or clerical nature and it inferred that since all acceptable applicants had survived the same medical screening one was as physically capable as another for purposes of assignment.

It had been long recognized of course that neither of these hypotheses was entirely correct and that there was in fact a wide variation in capability within any group of so-called physically normal men. Except in the case of a small number of individuals brought into service under a categorization of "limited service" during World War II there was no means whereby assignment and distribution agencies could identify or locate the combat fit.

This fact became of major importance during 1943 when the need for infantry replacements for the invasion of Europe became urgent. During the earlier stages of World War II the majority of the physically highly capable members of the manpower pool had been drained off and distributed to all branches of the Armed Forces to fill vacancies in all areas, regardless of the physical requirements of the job.

As a result, a significant proportion of our best physical specimens were serving in combat support or rear area service jobs in the Air Corps and Navy and in technical and administrative services of the Army. (Many of these jobs could have been performed adequately by less fit personnel.)

At this point in the war, draft calls were bringing up from the manpower pool many personnel whose physical stamina and trainability as Infantry soldiers were limited. The Army Ground Forces with the mission of supplying trained combat replacements called attention to the lower order of physical types they were receiving for combat training and pointed out the necessity of obtaining an equitable share of the better

physical specimens among those personnel still in the manpower pool.

In order to be able to identify the physically select and to classify all individuals on a physical basis, the Army, after considering various proposals, decided to adopt a system already in effect in the Canadian Army for use in the American Army. This device was called the PULHES system. The term PULHES was simply a mnemonic device to indicate the factors being considered in the physical evaluation of the individual. The decision was made not to include the individual's mental classification in the profile so the letter M was dropped and the system became known as the U. S. Army's PULHES system. As implemented by the Army in the Spring of 1944 each enlisted man was given a profile serial at the initial reception station, with a review and reprofile if necessary upon completion of basic training. It was not applied to officers and women in service until much later. The completed profile serial was intended to represent an indication of the individual's over-all physical capacity, to be used in channeling him into an appropriate form of military activity.

The system was simple in theory.

a. The individual was evaluated according to six categories of physical factors as follows:

- P—Physical capacity or stamina, organic defects, age, build, strength, stamina, height, weight, agility, energy, muscular coordination, and similar factors.
- U—Upper Extremities. Functional use of hands, arms, shoulder girdle, and spine (cervical, thoracic, and lumbar) to include strength, range of motion, and general efficiency.
- L—Lower Extremities. Functional use, strength, range of motion, and general efficiency of feet, legs, pelvic girdle and lower back (sacral spine).
- H—Hearing. Auditory acuity and diseases and defects of the ear.
- E—Eyes. Visual acuity and diseases and defects of the eye.
- M—Psychiatric. Personality, emotional stability, psychiatric diseases and history thereof.

b. For each of the six categories (PULHES) criteria were established so the examining medical officer could grade the individual as 1, 2, 3, or 4; a progression from above average to below average and unacceptable. In case of doubt, the individual was to be given a higher grade pending proof through performance that the soldier's profile was in error.

c. Suffixes were added to make the profile more informative:

R—To indicate that the individual has a defect usually remediable by corrective treatment. This suffix is still in use.

T—To indicate that the individual had a defect which is usually temporary in nature and to indicate the need for a period of convalescence. This suffix is still in use.

D—To indicate that the individual has a defect which renders him permanently disqualified for overseas duty. This suffix is no longer used.

The physical profile was given initially by medical officers at reception centers, hospitals and redistribution stations. Verification and revision of profile was accomplished by medical officers at hospital level and by a board of three officers known as a profile classification board at other locations.

Individuals with a physical profile serial containing only the numerals 1 and 2 were considered physically qualified for general military service. A profile with one or more numeral 3's indicated that the individual met the standards for the so-called limited service. The presence of a numeral 4 indicated that the individual had a defect making him unacceptable for entry into the military service being below minimal standards for induction.

Unfortunately the PULHES profile system was not implemented early enough in World War II to evaluate adequately its usefulness for the purpose for which it was intended. This purpose as already stated was its use as a gross screening device for the allocation of large numbers of individuals entering the military service.

In actual practice, the profile plan found limited application in assignments and reassignments within major commands, in classification for overseas duty and for pin-

pointing physical defects sustained in line of duty. (Not having been devised for these purposes, the system was not sufficiently precise to be of real value in those areas.)

Subsequent to World War II the procedures for profiling of inductees were continued and the system extended in the Army to apply to officers and females. As a result, every member of the active Army has in his records a physical profile serial.

The PULHES system or plan itself with the exception of a few minor changes has remained essentially the same as it was during World War II. Although the requirement for universal profiling within the Army continued after World War II, no further effective use was made of the PULHES system in regard to gross allocation of personnel to the services. Such use was, in effect, unnecessary since in August 1945 the enlistment program was reinstituted permitting competition for manpower between services (chiefly on the basis of mental capacity).

And in 1951 after study and discussion the Department of Defense instituted the system of qualitative distribution of manpower to the services based on mental groups only. Allocation by physical category was no longer considered necessary since equitable distribution by mental group assures also an equitable distribution by physical capacity.

However, as I have already indicated, everyone in the Army had a profile serial in his records. The information was there, it was readily available, and it was inevitable that attempts would be made to put it to some use and only natural that it be applied to techniques of classification and assignment, which at that time were undergoing study within the Army with a view to modernization.

At this point I think it would be apropos to clarify terms. The terms *classification* and *assignment* are almost always used together in the Army since they are closely allied personnel actions. For purposes of thinking, however, particularly in relation to physical profiling, they should be considered as separate and distinct procedures.

When we speak of physical profiling for classification purposes we are referring to physical evaluation in relation to job placement, to the matching of the physical capa-

bilities of the individual to the physical requirements of the military job or specialty, that is, the MOS. Quite obviously an individual may have a minor anatomical defect or physical impairment which would seriously handicap him in training for one military job or MOS but would be of no consequence in developing a skill or performing duty in another MOS.

It might be difficult, for instance, to train as a clerk typist a man who has lost the tips of a couple of fingers but this impairment would in no way interfere with his development as a top-flight gunner, rifleman or tank driver in the combat arms.

This trend within the Army to "put the right man in the right job," although not a new philosophy, began to gain momentum in the period immediately following World War II and into the early 1950's, compatible with a similar trend in civilian industry.

Also, during and since the war there has been a great increase in the requirement for specialists in the service, secondary to the rapid technological advances in weapons and communications systems. New testing techniques have been developed for measuring mental capacities and aptitudes and new machine records systems which would correlate, store, identify and produce information on individuals became available for use in the development of job placement techniques.

A further factor in the refinement of classification procedures is the necessity for maximum utilization of our manpower. In the past our national manpower resources have been sorely strained to meet military requirements and there is no reason to expect that any future war would not create similar problems. Therefore it can be assumed that careful effective use of military manpower will be crucial to the success of our mission should we mobilize for war.

In order to convert the PULHES system to use as a classification tool it was first necessary to determine the physical requirements of each of the 400 odd MOS's in the Army and to establish minimal acceptable grades under each of the PULHES factors to permit matching with the individual profile serial.

As an illustration the MOS (III) of a light weapons infantry man requires a

profile serial of 111121. The presence of a 3 under E or a 2 in any other of the 6 factors in the individual's profile as determined by physical examination indicates that he is not eligible for training in that MOS.

On the other hand, the MOS of 282, radar and TV repair, requires only a physical profile of 323231, indicating that the prospective trainee need not show a high degree of stamina, mobility or distant visual acuity to embark upon a training program leading to the award of this MOS.

It goes without saying, of course, that an individual with a 'higher' profile than established as a minimal requirement also would be physically qualified for training in that MOS. Also parenthetically factors of education, intelligence and previous or existing skills or experience are carefully considered and are often of greater importance in classification for training than the actual physical requirements imposed.

In any event, once the individual is trained in his MOS he retains it so long as his performance in his job is satisfactory. The fact that his profile may be changed over a period of time to the point below that required for original training in that MOS would not require a change in MOS provided he could continue to function satisfactorily within the specialty. In such a situation performance is given the highest priority.

In the event his physical capabilities have deteriorated while in service to the point where he no longer can perform the duties of his MOS, he is first medically evaluated to ascertain whether he is physically fit to be retained in the military service and, if so, to what other MOS he can be assigned or trained with his physical impairment.

This, briefly, is the extent to which the PULHES profile plan has been utilized, converted or applied to classification procedures. Implemented in the late 1950's, this system is still currently in effect in the Army. Its effectiveness as a classification tool and steps being taken to improve the system will be subjects for comment a little later.

Now let us briefly consider the use of the profile plan in assignment or assign-

ment/distribution procedures as differentiated from classification for job placement.

After having met physical standards for entry into service and completed his training the young soldier is considered fit to perform in his MOS in any type unit any place in the world; there are no restrictions upon his assignments.

However, physical capacity or fitness is not a static thing; it can be improved by training, it can deteriorate rapidly from illness or injury and it deteriorates slowly in all of us as a result of the aging process. Eventually in a significant percentage, particularly of career people, the time comes when as a result of some incident of service the individual's functional capacity has changed. He may have received an injury, perhaps he has developed a chronic disease which has to some degree reduced his functional capacity in some specific area and which interferes with the performance of certain military activities. It may have resulted in a reduced capacity to run, jump, crawl, stoop or march, it may require a certain selectivity in his diet, he may no longer be able to perform pull-ups or push-ups, he may have developed a susceptibility to cold injury or frostbite, or as a result of repeated exposure to heavy gun-fire over a period of years he has developed an abnormal susceptibility to acoustic trauma.

Such medical information is very meaningful to the personnel officer who must, at intervals, assign and reassign to specific units or positions the individual who requires assignment limitations. The frostbite case may perform brilliantly in Panama but would be a medical liability in Iceland; the arthritic or low-back case can perform perfectly well in a unit which is not expected to spend long periods in the field. In a word, we attempt to provide the trained soldier with the highly developed usable military skill with assignment considerations commensurate with his restricted medical capability.

To accomplish this with any degree of effectiveness the assignment agency must have certain medical information readily at hand, and again the PULHES profile system has been called upon to fulfill the requirement although it was not designed for this purpose.

In general applicability, a physical profile containing only 1's and 2's indicates no requirement for special assignment considerations. The presence of one or more numerical designations of 3 in the physical profile indicates the existence of a defect which may require an assignment limitation. In such cases a brief statement of the specific limitation in terms of function accompanies the profile serial and is recorded in the individual's personnel record.

In summary, we do have a working system of measurement analysis and recording of individual physical capacities which has been converted or adapted to application in classification and assignment techniques. The natural question is, "How is it working out?"

Unfortunately the answer is not as simple as the question. On the favorable side it can be said that this system or a somewhat similar system of transmitting by means of a code pattern, medical information which is meaningful and significant to classification and assignment agencies has shown itself to be feasible, practical and desirable. It can further be said that the decision to apply the PULHES system to this end was probably a wise and happy

one since the mechanics were already familiar to using agencies and it provided a point of departure from which we could determine with some precision exactly what we want a medical classification system to do and how best to do it.

On the other hand, we have found several weaknesses in the existing profile system which we naturally could expect from one not specifically designed for the purpose to which applied. However, these deficiencies have been identified in detail and steps are being taken to correct them. Certain changes which will streamline assignment techniques have been accepted in principle, are in final staffing, and should be implemented soon. A comprehensive research project is well under way relating to greater precision in matching physical demands of Army jobs with the physical capacities of those who must perform them.

Our goal is the development of a relatively simple mechanism which will function as a gross screening tool applicable to large numbers of personnel, which is also precise enough to permit the accurate placement of the right man to the right job on an individual basis.

NEW DIMENSIONS IN FLEET SAFETY

By MARK ROBESON
Vice Pres., Yellow Transit Freight Lines, Inc., Kansas City, Mo.

I agree wholeheartedly with everything said about the potential influence of the Motor Transport Conference. The objective of the Conference is to mobilize all possible resources we can and focus them on the problems of the motor transport industry. Accident prevention is largely a psychological and social problem because the biggest part of our problem is people and what makes people behave the way they do—what makes people have accidents.

Throughout our history as an industry we have mainly tried to find our own answers to our own problems. We have had some degree of success in this. But we have ignored the fact that other fields, mainly the social sciences have a big contribution to make to the solution of our problems. It will be the objective of the Conference to work in a closer and more direct relationship with these specialized fields of knowledge so that we can get the benefit of what they have learned and apply it to the problem of influencing drivers to drive better and prevent accidents.

The theme of our Congress this year is "New Dimensions in Fleet Safety." Fleet safety, as you know, has many dimensions and you will hear each of them discussed by outstanding experts during the three days we will be together. In each of these dimensions we want to stretch your mind and open your eyes to new ways so that you can operate within each of these dimensions.

If you take away from this Congress just one new idea that can be successfully applied to your own program, your attendance here will have been justified. But from a study of the program, I am sure that you will get not just one new idea, but many.

There is one dimension of your job that I would like to say a few words about this morning. It has not been included on the program itself, but I feel it is the most important dimension and that is represented

by you yourself and your personal psychology or philosophy as a safety director.

Since I became interested in this whole field of accident prevention, I have made it a point to talk to as many individual fleet safety directors as I can about their jobs and their approach to their jobs. As a result of these talks, I have become aware of what you might call an occupational disease or disability which you seem to regard as peculiar to your line of work.

In casting about for a name of this occupational disability, I have coined the term "tired faith." You've heard of "tired blood." I'm not sure myself exactly what "tired blood" is, but it implies to me a general run-down feeling—a general feeling of debility. Well, "tired faith" is a general run-down feeling in the safety director's approach to his job.

I don't know how many of you are suffering from "Tired Faith" now, but I'm sure you have all had attacks of it and will probably be assailed by it from time to time in the year ahead.

It is that "what's the use" feeling that comes over the fleet safety director when he feels that his program is not getting across to drivers, that management no longer appreciates his efforts, that he is not getting the backing he needs, and that his company and his industry are no longer sincerely interested in accident prevention.

I would not presume to discuss this problem were it not for the fact that it seems to come up in your proceedings and discussions with great regularity. In fact it seems to be almost a theme song with some safety directors that I have talked to.

There are only two things that I would like to say about this disease of "tired faith."

First of all, it is not unique to your profession. Other professional people have attacks of "tired faith," too. Preachers sometimes experience it. It afflicts teachers and

college professors, advertising men, salesmen, and members of management. In fact anyone concerned with trying to influence the behavior of other people gives way to this feeling from time to time.

The reason for this is that the human being is the orneryest, most unpredictable and frustrating critter that God ever created. And that holds true whether he is a driver, a dock hand, a supervisor, or a member of management. Just when you think you have him figured out and have adjusted your program to his needs or demands, he will do something exactly the opposite.

Man is the only animal capable of reason. Yet he seldom resorts to it. He does not behave according to reason or logic, but according to his emotions and feelings. These feelings are never out in the open, but are deeply buried in the man's unconscious mind. They are different for each individual and a list of whims, feelings, emotions that can move a man to action would fill a ten-pound dictionary.

That is why he is so unpredictable and that is why anyone concerned with influencing human behavior as you are, is subject to occasional attacks of "tired faith." But, as I said before, this occupational hazard is not unique to your profession, others have it, too.

The second thing about "tired faith" is that the only way to deal with it is to accept it as an inescapable and necessary part of the job. Sure your efforts are not always appreciated—whose are? Sure the industry sometimes seems to lose sight of the importance of accident prevention—industry management has a host of other problems to deal with—financing, taxation, regulation, maintenance, sales, operations, public relations, and a host of others. That's why you were hired—to worry about the

safety problem. As President Harry Truman said, "If you can't take the heat, stay out of the kitchen."

Dealing with human behavior is no profession for a perfectionist. A perfectionist would die of ulcers within a year's time. When you deal with groups of people, you have to deal with averages. You can't bat one thousand, you can only strive for as high a batting average as possible. And to do that you have to have a strong not a "tired faith" in yourself and in the tried and tested techniques of your profession.

For many years I have worked in the field of sales. A salesman deals with people and tries to influence their behavior, too. He has to be a master of practical psychology. He must know how to apply it to turn a prospect into a sale. He doesn't bat a thousand, either. But that doesn't discourage him. He keeps slugging away for as high a batting average as possible. And the most important practical psychology he uses, is the kind he uses on himself.

He has to have faith in himself, in his product, in his market and in his sales approach. He must never allow himself to become defeated or discouraged. He must always be out there on the firing line—doing something more than just going through the motions, more than just putting one foot in front of another (although that's important, too). He must be out there with real enthusiasm, real confidence and real faith in his ability to do the job.

I hope each of you will get something more than new ideas. I hope you acquire a new shot of enthusiasm for accident prevention, a new faith in yourself and your ability to do the job. If you do, I'm sure that you'll be able to deal with those attacks of "tired faith" that will surely come during the year ahead.

THE HUMAN DIMENSION IN SAFETY

By DONALD S. BUCK

Dir. of Safety, Headquarters, Continental Command,
United States Army, Fort Monroe, Va.

The human dimension is the most important and least understood aspect in traffic safety. It relates to just about "everything in traffic safety," roads and equipment are designed by people, vehicles are operated, controlled, supervised, maintained, and wrecked by people.

The traffic safety effort is primarily—(1) modifying the driving environment to make it safer for humans, and (2) adapting the human to make him safer, despite the environment.

To modify the driving environment, roads are built flatter, wider, and straighter. We thaw ice on roadways, dispel fog, remove snow, fence against animals, and provide illumination. Adjustable seats, power brakes, power steering, seat belts, and energy-absorbing interiors make the environment of the vehicle safer. We separate opposing traffic lanes, provide cloverleaf overpasses, install traffic lights and controls, and employ reflective markings.

We adapt humans to the driving situation by testing, training, warnings, threats, punishment, reward, diet, glasses, hearing aids, coffee breaks, and the countless influences which comprise a traffic safety program.

Some wag said, "People cause accidents—and accidents cause people." There is truth in this adage. People cause accidents and to such degree that thousands assemble in the National Safety Congress annually in quest of means to influence people to cause fewer accidents.

I hasten to admit that, to date, no organized effort has been made by the National Safety Council to address itself to the vexing problem referenced in the other half of the adage—"accidents cause people." However, the adage can be made more applicable: "People cause accidents—and accidents cause people . . . to seek the reasons why."

Every person who drives is guilty of mistakes and oversights while driving. Some drivers commit far more than their fair

share of errors, comparatively; hence they have a propensity for accident involvement, the human penchant for committing driving errors likely never will be entirely eliminated; however, it can be profoundly reduced. The human dimension aspect should be approached with the understanding that perfection behind the wheel is improbable and inhuman. However, it is reasonable to presume that application of certain proven methods will "humanize" humans and improve their driving.

Every accident is evidence of human failure to measure up to the driving situation. Although simply stated, this is difficult to prove and apply. Most persons will agree that their accidents were caused by persons—persons other than themselves! The most difficult aspect of this problem is the earnest conviction by most drivers involved in traffic accidents that they were the victims of providence and other persons concerned.

We must strive to control and improve the behavior of humans so they commit fewer errors of judgment, operating failures, and over-sights.

It is normal for humans to have accidents! Accidents are common-place throughout nature; humans are not excepted. We expect a child to stumble. We quote: ". . . to err is human . . ." but when an adult operator of a vehicle commits an error resulting in an accident, we tend to regard him as criminal or psychotic.

We should admit that freedom from accidents is *unnatural*, hence *abnormal*. To be safe, a driver must put forth unnatural effort and suppress his normal impulses. This self-discipline and regimen results in what we call "safety." It is something above and beyond the normal behavior! The man who avoids accidents should be identified and publicized as *The Exception*! This concept is in contrast to the current practice of trying to label as unusual and exceptional those who have accidents. No one wants to be average—but accidents are the mark of the average person. In other words, "don't be normal or just average, be safe."

Let's examine the contention that accident involvement is "normal circumstance." Will each person here who has never been involved in any kind of traffic accident (e.g., collision, upset, fender scrape, backing into a parked car, denting the fender, running off the road) raise his hand, please? Raise your hand only if your driving record is absolutely free from all accidents, regardless of cause or severity. Now, look about you—those few upraised hands likely belong to persons who are abnormal, lucky, or unlicensed! Most of us, because of our accidents, were unable to raise our hands. This illustrates why I contend—*It is normal to have accidents*. "Safety" is not normal, not average, not typical and not usual in the human society. Safety is abnormal.

Because safe driving is "abnormal," is it out of reach? No! Abnormal performance is within reach of determined men.

In athletic contests, some men run, jump, throw and perform in an abnormal manner. In combat, soldiers override the fear complex to reach heights of abnormal courage and performance. In driving, some men also attain the pinnacle of safety because they have been properly trained and motivated.

Recently our President stated, "Any dangerous spot is tenable if brave men will make it so." To paraphrase this, "Any dangerous spot is safe for traffic if determined men will make it so!"

"The Profile of a Safe Driver" was outlined in a feature article in *Traffic Safety* (November 1960). Based on responses by 3,000 professional drivers to a questionnaire it was found that the safe driver, on the average:

- Is approximately 57 years of age.
- Is married.
- Is of medium size.
- Has driven professionally for 32 years.
- Has worked for the same employer for 30 years.
- Drove 8,000 miles off duty.
- Is easy-going and non-aggressive.
- Drives 20 per cent at night (professionally).
- Signals his intentions.
- Drives a truck.
- Plans his driving well—and is ready for any situation.

Has won an NSC award for at least 23 years.

Has above average knowledge of operation, rules and mechanics.

Has completed 2 years of high school.

Has no military service (too young for WW I; too old for WW II).

Has no traffic violations against him—ever!

Has learned to define and automatically respond to the traffic situation.

Is fairly non-competitive, and generally satisfied with present attainments.

Drove 18,000 miles last year on the job.

Drives cautiously, carefully and courteously.

What does the unsafe driver look like? A glance in a mirror will give us a pretty good idea. The trouble is, our profiles change from day to day, hour-to-hour, minute-to-minute. We may feel decent and cooperative one moment and disposed toward mayhem the next. We can be a decent sort of courteous driver until the chap behind us blasts his horn impatiently to rupture our eardrums. Then, how do we feel? And are we subsequently safe?

However, there are some specific and adverse characteristics which fleet supervisors and foremen should look for in their drivers and regard as stoical warnings of accidents:

1. **Manner**—Tense and troubled. Exhibits anxiety, strain, sadness, pre-occupation or worry.
2. **Behavior**—Excessive and chronic absenteeism and tardiness. Loss of interest in prior pleasures. Loss of appetite. Increased drinking and smoking. Increased near-misses, and minor accidents.
3. **Attitude**—Lessened concern towards work, safety, and near-accidents. Increased grievances, and hostility toward supervision. Withdrawal from "the gang"; aloofness. Increased and unwarranted "griping" about condition of equipment routes. Increased complaints about minor bodily discomforts with repeated "sick calls." Diminished enthusiasm in work, life, and interests.
4. **Emotional Stability**—Irritable, quarrelsome, edgy, restless, impulsive, and

of drinking alcohol in causing traffic accidents. It finds deficiencies in side vision to be more frequent than shortcomings in any other of the visual traits tested. It reports a high percentage of accident-repeaters to have low systolic blood pressure. It comments on many illnesses and diseases that may impair one's ability to drive safely.

Do these findings on personal factors have a familiar sound?

It is significant to note that this study was published 20 years ago! For the 30 long intervening years we have tended to devote ourselves to identifying traits characteristic of accident-prone drivers. We stressed a program of selection, rather than improvement. Those test findings were, and likely are, still valid. But we need to go further and develop and apply positive and effective measures which will change and improve men so they will drive better and safer. We cannot be content with separating sheep from goats; we need to improve them all in driving.

Knowledge and Interests

Knowledge among drivers is derived in different ways:

1. One may learn from his own driving experience. Just ask those involved in accidents, the survivors, the injured, the scared, the arrested! They may have learned a lesson, but this is such a hard way!
2. One may learn from, and watch his interests by, driving experiences of others—this tends to be the majority. They are generally accident-free, wiser, and happier. Here is justification in reporting accidents—it enables the willing to learn from the weak. And here is the reason why you should always set a proper example while driving the family car. Your children tend to pattern their driving attitudes after yours. The family car is the classroom for tomorrow's drivers.

3. Some rugged individualists refuse or are unable to learn from experience, whether their own or someone else's. They are truly accident prone, and they are living fools with a temporary lease on life. They tend to leave a wake of human misery and death, and their disproportionate involvement in accidents is quickly blamed on others. Since they do not learn from hard experience, we are kept busy burying their mistakes.

Personality Traits

This brings us to the dimension of personality and attitude traits. Important breakthroughs are being made in this area.

According to the Association of Casualty Companies, 15 per cent of all accidents come from defects of roadway or vehicular equipment. The balance of 85 per cent result from the human dimension! Human frailties—such as lack of skill, lack of knowledge, wrong attitudes—cause most accidents. The accident investigator may report "passing on a hill" to be the specific cause; however, the real cause is more likely to be found in the attitude or emotions of the chance-taker—his unconcern, his willingness to gamble, his lack of forethought, his impatience, or the lack of general savvy which let him disdain the obvious danger of attempting to pass where he could not safely see a clear distance.

Personal attitudes and traits are increasingly being recognized as the factors which govern driver behavior. Several studies are underway to investigate them, and to determine whether group treatments will improve driving behavior. I am confident that these studies will confirm what common sense tells us: attitudes can be changed and improved by treating the mass population. Adverse driving attitudes are manifested by traits such as, drunken driving, excessive speeds, inattention, discourtesy, and failure to take a rest stop when fatigued.

Anti-social traits, commencing early in childhood, seem to carry through to the adult—emotionally unstable, a feeling of inadequacy, and immature behavior. These kids grow up—physically—to become drivers with immature, childish attitudes. Has it ever occurred to you that our show-off performance on a tricycle or bike, when we were kids, is quite similar to our show-off, chance-taking driving when we have grown to adulthood? We trade the "trike" for a truck; but we don't always trade immaturity for manhood.

In studying the "hot-rod" driver, psychiatrists at the Menninger Clinic found (in a study of 30 cases) that the "usual hot-rod driver, then, is a precocious, physically strong boy. He is aggressive of temperament, and early history shows evidence of emotional deprivation. His relationship with his mother is usually a very ambivalent

one ("Yuh gotta have mothers, but I can't stand 'em. They're bossy.") . . . interest in sports which employ interaction (team-work) was lacking in these adolescents." How obvious the implication of this human dimension with regard to traffic safety!

We find that faulty attitudes may be either temporary or permanent (mood or neurosis). At some time or other most of us have driven excessively fast, and for various reasons. But some of us may be inclined to repeatedly and continuously drive excessively fast. When we subscribe to the popular idea of "getting those speeders off the highways," we mean, of course, those others who seem to be the chronic speeders.

The same analogy holds for the drinking driver. We agree the drinking driver should be denied all driving privileges, but don't enforce this concept right after the next lodge meeting or the next cocktail party!

Our safety effort should be more strongly directed towards self-improvement! We need a do-it-yourself kit to help reduce the times when all of us demonstrate faulty attitudes. We devote much fine effort to identifying the relatively few psychoses who drive. All of us, on occasion, however infrequent, are to be counted among the "nutty" (unsafe) driver. Few of us can survive it on a full-time basis.

Two aspects of age take their toll: immaturity and old age. There is an exceptionally high accident rate among male drivers below 20 years of age. Those over 65 also show a rate well above average. "They're either too young or too old!"

If we could clearly categorize driver attitudes on a continuing basis, the problem would be simple to control. We'd bar from driving all the stupid jerks who have faulty attitudes. But each driver's attitude is chameleon! Enroute to work in the morning, rested, in no hurry, under no stress, a driver may be a paragon of emotional stability behind the wheel. But after a day of stress and frustrating effort, he crawls into a steaming hot vehicle to fight his way home in congested traffic.

He will be tired and perhaps in a hurry because of some extra-curricular activity. Now, "little things" may inflame him. Emotion displaces reason. Combativeness replaces cooperativeness. He is not a different

man, but he surely acts and feels differently. Pooped drivers drive poorly!

Our responses to the driving situation (our emotional stability) can be markedly changed by stress, fatigue, anxiety, sleepiness, hurry, tension, anger, distraction, or romance.

Individually we may have many different moods—some good and some bad. If we, personally and individually, can find means to help prevent or temper bad moods of drivers, we will contribute to accident prevention. Bad moods are caused—they can result from bellyaches, bawling-outs, blaring horns, break-downs,—and a billion other factors. Good moods are also caused; by providing the driver a reasonable and understanding environment, by helping him understand himself, and by removing needless irritations.

If it were possible, we should dispatch drivers on the basis of their current feelings (instead of their abilities). We desperately need a "Feel-O-Meter"—a gadget which will "blow the horn" on the driver when his blood pressure goes up, or his attention goes down!

Treating faulty attitudes (adverse personality traits) is a new conceptual approach. In the June 1961 issue of *Traffic Safety Research Review*, a paper entitled, "Emotions and Traffic Accidents," by Samuel S. Dubin, identifies two categories of problem drivers whose attitudes require careful attention:

1. The habitual violator.
2. The youthful driver.

A new attitude test has been developed which successfully predicts whether the male aged 16 to 25 is likely to be a safe driver. This test, developed for the Farmers Mutual Reinsurance Company by psychologist Charles F. Haner, of Grinnell College, Iowa, is purely psychological. Using test results, lower insurance premiums are granted to the under-25 male drivers who score well on the test.

In two year's experience with 4,000 young male drivers, the test has predicted well: putting 40 per cent into the higher risk group, they responded with 60 per cent of the accidents. More serious accidents, and more than their share of accidents caused. This 40 per cent further distin-

guished itself in several unsavory ways. It claimed 87.5 per cent of the licenses revoked or suspended.

Insurance-wise, it caused insurance losses three and one-third times group one. The bottom 10 per cent submitted 25 per cent of all insurance claims. On the other hand, those having top scores turned in half as many culpable accident claims as might have been expected. These results corroborate the realization that proper attitude is the key to safe driving.

The question facing us is: What can be done to these human dimensions to gain safer performance?

1. *Improve Self.* I suggest we start by improving ourselves. We should exemplify in word, deed, and driving the attitudes which we desire of our operators. What is right and safe for us to do while driving will seem more so to them—after all they are the professional drivers. If we consider it safe to hit the road after a short snort, why not them? They know more than we do about the practical side of driving. If we feel conscious-free at burning up the road, why not them? They drive so much more than we do that they should be privileged to at least emulate our amateur privileges. Above all, set a good example.

2. *Test.* Since this subject is being covered by another speaker, I will restrict my remarks to urging that all drivers be tested initially, and re-tested at least once every 3 years. Include in the test procedure an evaluation of emotional stability, personality, maladjustment, attitude, judgment, and ability to act in emergencies. Acquaint each driver with the deficiencies detected in his testing.

3. *Train.* Next, we need to teach them all the know-how possible. This includes not only operating techniques, but the who, what, why, when and how of accidents. They should know the impact of accidents on operating costs—(how many extra jars of nickles must the company sell to offset a single accident?) Help the driver to appreciate the importance of proper attitudes. Then train drivers as to the effective ways for coping with the practical problems of driving. For example, it is not uncommon for drivers to get sleepy.

Fatigue (or sleepiness) merits attention as to ways to prevent and offset it. Many

accidents ascribed to inattention may have actually resulted from drowsiness. Drowsiness besets me while driving after lunch, especially on a warm afternoon. I cannot will myself into a state of alertness. It does no good to admonish me to keep awake! I do carry a thermos of ice water so I can sponge my face and neck with an icy cloth. This really rouses me! It is somewhat like a cold shower. I shudder to think what sort of driver I would be, if I did not have my thermos of ice water to wake me up, when my eyes grow heavy. Conjecture as to how many oncoming drivers similarly are sleepy, but lack means to rouse themselves also helps to produce wakefulness.

I am convinced that many accidents could be prevented by instructing drivers how to effectively offset drowsiness while driving. Coffee breaks help. Some men munch on popcorn or peanuts to offset drowsiness. Dismounting and exercising vigorously stimulates circulation and sweeps away the cobwebs. Some drivers thrust a toothpick between their front teeth, to preclude sleep. A "catnap" along the road (in a properly parked vehicle) does wonders. The point is: we should instruct our drivers on practical ways to keep awake.

For simple, effective training, I recommend use of the National Safety Council's materials, such as "Five Minute Safety Talks for Driver Supervisors." These books apply to drivers in large and small fleets and to drivers of all types of vehicles.

4. *Motivate Drivers.* Give men a reason to want to drive above average. What is it for them? Improve their morals (as a group) and their job satisfaction (as an individual). Men need incentive to try harder—to put out more effort. Re-inforce the ego and security of drivers—remove their uncertainties. Of particular help in understanding the relationships between human behavior and accidents is a series of booklets entitled "Men and Motives in Safety Supervision," recently published by National Safety Council. These comprise an excellent short course in human relations, and each booklet presents a different aspect of the relationship between human behavior and accidents. Their universal themes are most applicable to the traffic situation:

- (1) People Cause Accidents.
- (2) Believing in Safety.

- (3) Job Instruction.
- (4) Big Little Difference.
- (5) Runaway Feelings.
- (6) Saying it Right for Safety.

5. *Change Attitudes.* It is possible to change human behavior. And, this is necessary if we want drivers to conform to the desired pattern. Establish our traffic safety clinics to deal with accident repeaters and habitual violators.

In considering human dimensions in traffic safety, the most heartening aspect is that men can be motivated to change their performance. Improved driving can be obtained, even from a mediocre operator.

To improve driving behavior, the driver must:

- (1) Acquire a new behavior pattern, and/or,
- (2) Discard the undesirable practice.

There are several courses of action whereby driving behavior may be influenced:

- (1) Change the driving environment (a different route, territory, vehicle, or assignment).

(2) Change attitude towards current environment. (This is not easy. Drivers have fixed ways of feeling and acting, which become habits. They resist change, per se, and tend to defend their way of thinking and feeling to be correct. Emphasize the more socially acceptable position of safe driving. Stress the distinction which attends the really safe driver. The driver is apt to effect the desired change if he is given opportunity to relate and consider his experience as well as his own thinking and feelings. Drivers tend to drive as they feel—and it is their adverse feeling which should become the targets of our safety effort).

(3) Change attitude toward the trivial accident, and the accident cause. Get at the latter by including in each report of accident, an account of the history of events prior to the accident. Collect information on violators and accident repeaters in a central agency or file—and let the driver's realize the value of a good record.

The concept of "strategic driving" (which I helped Driver Safety Services, New York City to develop) favorably impresses me. Strategic driving is planned driving. The

plan for coping with the enemy is not left to guesswork nor to deciding on a course of action after a hazard presents itself. It is logic on wheels, plan in motion, hazards contained before they become a serious threat. This concept arms the driver with the big guns from the arsenal of safety: *know-how, will-do and be-ready.*

The term "strategy" is commonly used in speaking of situations (e.g., war, economics, politics, chess or stud poker) which:

1. Present a complex sequence of events.
2. Involve two or more people in some kind of give and take.
3. Involve important stakes.

Thus, it seems apropos that the spirit and concept of strategic action be employed in vehicle operation. Warfare and traffic accidents are each national struggles—and the campaign against each is most effectively accomplished by vigorous application of sound strategy and tactics. Strategic driving sounds like a direct way to go at the problem, rather than wait passively until the hazard presents itself. It is safety in action.

This concept intrigues me because it positively emphasizes *what-to-do's* of driving rather than the time-worn *what-not's*. It goes far beyond the traditional emphasis on courtesy, slowness, sportsmanship, carefulness and compliance (since these tend to be the end—not the means—of safe driving). It seeks not only to develop the skills of good driving but proper *attitudes* as well. The strategic driver learns to take the offensive against hazards, rather than persons, and he employs a plan of action to reduce needless risks.

1. One aspect of strategy—and of strategic driving—is *plans and preparation*. This means get ready before departure, and be ready for any eventualities.

2. Strategy also calls for *anticipation*, upon which the driver makes decisions for action; the basic tactic emphasized is *communication*. The strategic driver expects surprise maneuvers from others; he learns to read early warning signs concerning other-drivers' plans, and he learns to let others know unmistakably and as soon as possible, of his intended action.

3. Another important element of the strategic driving concept is the strategy of *mer-*

gency. This means planning an "out" for every possible situation, knowing what to do in the emergency, and practicing against emergencies.

Strategic driving is a new and advanced approach to vehicle operation. Its concept is borrowed from the military whose aim in war is to overcome the various forces of the enemy. Applied to the driving situation, it encourages the driver to become a leader, strong, certain, alert, and to have a solution "in his pocket" for every conceivable problem. His tactics will include plan, check, timely departure, application of proper procedures, and constant diligence. The concept of strategic driving boils down to this: anyone can drive—so long as things are normal—but a strategic driver can be expected to drive safely, come what may. Some of your drivers instinctively apply this concept; many others might be trained to respond to its logic and challenge.

6. *Provide Safe Equipment.* Drivers are no safer than their equipment. Pot-flares which are empty or inoperative are built-in hazards. Comparatively simple improvements could be adopted in defogging and defogging equipment, arrangement of vehicle lighting for more positive identification of the presence and actions of other vehicles and drivers, and the positioning of instruments and foot controls to serve more nearly the functional demands of safe driving.

The vehicle of tomorrow may feature capsule chairs, protection from rear-end collisions, seat belts, flexible or telescoping steering shafts, protection for head from whip-lash, rectangular steering wheel to safeguard knees, smaller wheel for better visibility, improved maneuverability, unitized energy-absorbing bodies, automatic fire extinguishers, power and safety brakes, roll-over protection, penetration-resistant windshields which also screen out ultraviolet rays and heat, reflective licence plates for darkness, and supports for each of the driver's arms. These improvements are feasible; however, I wonder if we are willing to pay for protection against crashes?

In the October issue of *Saga*, Representative Kenneth A. Roberts (Chairman, House Subcommittee on Health and Safety) stated:

"If you and I can persuade Detroit . . . to make use of inventions already proven, already available, but almost totally ignored,

then the cars Detroit turns out next year and the years after will be even more remarkable. For these cars will be just as handsome, just as convenient—and they will be almost immune to accidents. An achievement greatly to be desired.

"A miracle of chemistry (Enso-lite), a marvel of engineering ingenuity (Professor Ryans "magic" bumper), a commonplace device borrowed from the aircraft industry (the seat belt) and some simple changes like dashboard-redesigning can make the accidents of next year end with people driving away in their cars, instead of being carried away on stretchers."

We can go a long way towards providing safer vehicles if we regularly inspect vehicles. Why wait until a police check catches us with our safety equipment down. We can prevent arrests, fines, and accidents by beating the police to the punch!

7. *Accept Responsibility.* The most significant aspect of this problem is the universal unwillingness of individuals, communities, and organizations to accept some degree of responsibility for the general mess that we all call accident causation. Everyone conveniently disclaims responsibility and conscientiously transfers the "blame" elsewhere. This is true of fleet owners and fleet drivers; management and labor; vehicle maintenance men and highway maintenance men; federal government and state governments; legislatures and laymen; professional drivers and amateurs; young and old; rich and poor; male and female; experienced and inexperienced; home folk and strangers; parents and children; teacher and pupil; manufacturer and customer; pedestrian and rider; speeders and slow drivers; and all others who have some part in this problem.

We are a nation of finger-pointers when it comes to facing up to accident causation. No real progress in safety can be expected until there is an upsurge of moral character, a public confessional on the sins of accident causation, and a cooperative joining of all forces and individuals in a common endeavor to identify ourselves, individually and collectively, with accident causes so that the mass effort and feeling will overcome the problem.

In summary, the human dimension is the most important aspect in safety. People cause accidents. Safe driving is "abnor-

mal," but attainable. New yardsticks for measuring human dimensions have been developed. There are tests available which evaluate, with decreasing accuracy, physical characteristics, abilities and skills, knowledge and interests, and (importantly) personality traits. We recognize need for psychophysical testing but disagree on the standards. Human engineering in vehicle design shows promise. Safer vehicles can be built, but are people willing to pay the price? Drivers get sleepy and need instruction on keeping awake. Tests of abilities and skills should lead to improvement measures.

Strategic driving is a promising concept which emphasizes what-to-do instead of what-not-to-do. Driving behavior can be changed by changing attitudes. Personality traits can be tested to predict performance. Some may learn from their own experience, some from

experience of others, and some never learn. We considered the attitudes are chameleonic. The publication, "Men and Motives in Safety Supervision" provides guidance in understanding attitude relationships.

We advocated: Safety clinics for violations, personality traits tests, periodic re-examinations, emphasis on importance of attitude, centralized accident data, investigation of events prior to accident, research on attitude and prevention measures, incentives, emphasis on minor accidents, and a good example in driving. The human dimension is the essence of the safety problem.

Just as dimensions are considered important in assessing the physical attractiveness of a lady, it is high time we accord to human dimensions the same degree of importance in safety.

THE MORAL DEPTH OF SAFETY

By ARTHUR B. LANGLIE

Pres., The McCall Corp., New York City; Chairman, National Committee of Religious Leaders for Safety, N.S.C.

My subject is "The Moral Depth of Safety" and I am talking to professionals in the business of operating transportation vehicles.

We have professionals today in almost every area. We are in an age of specialization and as a result of that we all do the best we can within the framework of the law and the environment in which we find ourselves, and sometimes stretch the law, sometimes stretch the environment, because in a competitive society we want to make a living and get ahead.

This is the basis upon which we've been operating and I must say that, at this time, we are challenged to take a look at ourselves by an ideology that says we don't really believe what we stand for, or what we say.

We have made some progress but the real guts of our problem still haven't been touched. That's in the individual, his motivations, his moral stamina and character that implement all that we learn and hear and know about these things.

Our society today is recognized as being a little careless in some of the things that we stand for, as far as our spirit and idealism is concerned, and it is in this area that the National Safety Council has tried to reach out and set up a special committee that works in the field of religious activities, trying to encourage religious leaders to become more interested in safety in order to communicate to the people down below.

Norman Cousins wrote a book about our revolutionary forefathers entitled *In God We Trust* and in this book he gave a rather brief description but a succinct one of these men and their general attributes. He said that they believed that the end of government was to transform freedom into creative growth. They believed deeply in the ability of the human being to learn and to take part in self-government. They believed in the capacity of people to make sense of their lives if given reasonable conditions in society itself. They believed in the responsive power of men when exposed to

great ideas, and in people's ability to stand upright spiritually without ornate or complicated props.

We are not without hope in this day because we are being challenged by an ideology that is really crowding us hard. They are saying we don't really believe in our ideals, and they're forcing us to take a good look at ourselves. All over the country men are beginning to look at the moral responsibilities of the individual, to think in terms of the other fellow, and to do something about building the right kind of ideals and strength in America.

Just last week the National Foreman's Institute wrote to me as chairman of the board of my company and said:

At the request of the United States Navy, the National Foreman's Institute has created a new publication under the moral responsibility leadership program, for their services to civilian supervisory personnel. The decline of integrity and rise of moral turpitude over the last decade were brought before the public view during the Korean episode, and also by several widely publicized incidents in the business world.

This new monthly publication is being called to your attention, since the program involving moral responsibility must start from the top executive level and work downward through all supervisory personnel in order to be effective. Moral responsibility is an integral part of supervisory development. This publication should be utilized as a vehicle of discussion, each month at every level of supervision, on the basic tenets of moral responsibility.

Well, what do the space scientists think about this kind of business? I am encouraged that a man like Werner Von Braun will say this about immortality.

Today more than ever before, our survival, yours, mine and our children's, depends on our adherence to ethical principles. Ethics alone will decide whether atomic energy will be an earthly blessing or the source of mankind's utter destruction.

Where is the desire for ethical action to come from? What makes us want to be ethical? I believe there are two forces which move us. One is belief in the last judgment, when every one of us has to account for what we did with God's great gift of life on the earth; the other is belief in an immortal soul. A soul which will cherish the award or suffer the penalty decreed in the final judgment.

Belief in God and in immortality give us the moral strength and the ethical guidance we need for virtually every action in our daily lives. In our modern world, many people seem to feel that science has somehow made such religious ideas untimely or old fashioned, but I think science has a real surprise for the skeptics. Science, for instance, tells us this, nothing in nature not even the tiniest particle can disappear without a trace.

Think about that for a moment: once you do, your thoughts about life will never be

the same. Science has found that nothing can disappear without a trace. Nature does not know extinction. All it knows is transformation.

Now if God applies this fundamental principle to the most minute and insignificant parts of his universe, doesn't it make sense to assume that he applies it also to the masterpiece of his creation, the human soul? I think it does, and everything science has taught me, and continues to teach me, strengthens my belief in the continuity of our spiritual experience after death.

Nothing disappears without a trace. While we have this freedom, and we feel that we enjoy it, we think it's the greatest system in the world—it has given us the highest standard of living, it's made us feel happy and successful as a people—but it isn't something that we can just exploit.

The real definition of freedom is, that atmosphere in which the spirit of men and women, boys and girls can grow. Now what has this to do with safety? Well I think it's the greatest reservoir of safety action there is left to us.

I know what these other things can do. We did it in the state of Washington. We used education, we used engineering, we used enforcement like no other state in the union. We took police officers, put them in plain clothes, in unmarked cars with out-of-state license plates. We used radar, airplanes and helicopters to spot law violators and enforce the law, and in two years we saved 200 lives. For every life that was saved there were 25 or 30 injuries that did not happen. We cut our insurance rates, we made a wonderful showing.

It was talked about all over the country, but we still killed more than 400 people on the highways of our state in one year. More people than we lost from the state of Washington in three years of the Korean War.

Now I know this is ridiculous, and why is it? It's because people will not take to themselves the moral courage to do the things that they should do if they're really Americans. Now frankly I don't know a better way to be a good American than really to take to heart all we know about operating vehicles on our highways, all we know about the engineering of highways, all our relationships in churches and other places, and doing something because we really believe in it.

If we do that, the impact on this whole program will be so far in excess of any

thing that we have seen that it will be the most rewarding thing we have ever done, and it will begin to teach us the kind of responsibility to apply in every area of our lives as American citizens, whether it's in religion, or in politics, or in business, whether it's in the professions, or in our social life. We must begin to live like responsible, free, citizens and give this country the greatest shot of vitality it's had since the Continental Congress and the Declaration of Independence. This is the kind of a frontier we must face. We can no longer take on every hand, play the game safely as we go along, and let the other fellow take care of himself.

I know of no area where we can demonstrate so clearly what a good American can do as in traffic, because it is so great a part of the American way of life.

Fifty young men completely changed the government of the city of Seattle. That city used to be the worst run in the whole United States. It was run by the police department, and the only thing we ever settled in Seattle for years as we elected a mayor every two years was which fourth of the police department would go down on skid row and collect the graft and which fourth would go out in the sticks and start working the campaign for the next election.

The city was in debt, the streets were run down, its transportation system was a mess, its parks were terrible, its purchasing practices were awful. It was a beautiful city but in an awful state, and 50 young people with ideals got together and said, "We're going to find some candidates, we're going to ask them not to take more than

\$25 in campaign funds from anybody, we're going to go out and support them with our work, door to door, and see if we can't get some honest officials who are motivated right and who will serve their government rather than try to take from it."

To the amazement of everybody they finally squeaked one young fellow into the city council. He in turn, through courageous battling, brought in three others. They finally elected a mayor, and in two and a half years the city turned completely around and has been one of the better governed cities of the country since.

We go to church to get ministers interested in safety. This is fine, it's the trickle-down theory and it's good. You've got to start someplace, the image at the top has to be good, but when people who are living with these problems conscientiously throw themselves into a crusade to do something about it, you get real action. And this is what, of course, we really need.

We as Americans must quit thinking about what we can get out of things and do as our President suggested in his inaugural address, "Think not what you can take from your government, but what you can give to it." And believe me, when we do that we'll find out that we're investing in a resource that doubles every time we put something out. This is the area where we need action. This is the greatest reservoir of safety left. This is where the profits are. It takes a little faith.

Do we really believe that safety pays? Do we really think there is something morally sound about it? Do we think it's in the interest of our fellow men?

MOTIVATION — THE ART OF LETTING PEOPLE HAVE IT YOUR WAY

By EARLE S. HANNAPFORD, PH.D.
Safety Engineer, Long Lines Department, American Telephone and Telegraph Co.
and Vice President for Industry, National Safety Council

Stripped and shorn of all its high-sounding descriptive phrases and plumage of words, motivation is just what our title says: "The art of letting people have it

your way." And that seems to be the popular conception of it also.

In an age when we are literally up to our ears in motivation—product motiva-

ring to buy cereals, soaps, compact automobiles, and to actively support national and local movements of all kinds—folks are justified in being skeptical and at times obstinate if they suspect they are being motivated against their own will and interests. And all the recent talk of subliminal motivation on an unconscious level tends to make people even more skeptical and suspicious.

So before we go into the interesting and absorbing story of how motivation works, let's make sure just what we mean by motivation—what it is and what it is not. After that we shall talk about how to motivate people successfully and then complete our discussion by talking about how we can check to see if motivation is working.

There is one thing to keep in mind at all times. What we shall talk about is fundamental and true of all motivation, even though our applications of it and our illustrations will be in the field of safety.

What We Mean By Motivation

Current misconceptions and fallacies about motivation demand that we clear up some of them even before we settle upon our basic definitions. First let's mention some of the things that *motivation is not*. It is not some subtle potion brewed of words, ideas, hypnosis and thought control that enables us to manipulate people to our own advantage against their will.

Motivation, as we are going to talk about it, is based upon *not* disabling or eliminating our American democratic freedom to think for ourselves, but using it. It does not violate the God-given right to make up our own minds and to choose for ourselves.

It is true—only too true—that perversion and distortion of what we shall talk about has given birth to the maniacal, ruthless devil's brood of propaganda, thought control and brain washing. All of these reduce man to mere automation or robot, a slave of the will, spirit and emotions of another—a much worse form of slavery than forced physical servitude.

In safety as in all motivation for sane, rewarding living, we seek to motivate for the good of the ones motivated. This calls for arousing the voluntary persistence and perseverance of a person from within himself, from the free spirit itself. Yes, without any doubt, in discussing the compellingly interesting subject of human motivation we

are dealing with powerful forces, forces which improperly used are just as disastrous, and probably even more so, than the nuclear weapons which cause us so much anxiety today. Pause a moment if you doubt this, and reflect on Nazism and Communism and the physical slaughter of millions which was compounded out of the horrible obsession and motivations from which they sprang.

True motivation of a positive nature operates without using the negative controls of fear and anxiety. Furthermore, it does not destroy the individual's perceptive and ethical values, nor does it seek to produce negative motivation through depression of physical, mental or emotional responses and reactions.

Note that we said positive motivation does not use the negative controls of fear and anxiety as such. This is based upon one of the key axioms of all learning—and motivation is directed learning. Dr. Lester Sontag states it this way: "The basis of all learning (positive motivation) is the striving by the individual to *lessen anxiety by mastering problems as they arise*." Keep this in mind, for we shall use it later.

Having oriented ourselves with respect to what motivation is, and what it is not, we can define it with confidence that it will not be misinterpreted. I am going to use what I like to call a "sequential form of definition." Actually it's simply this. First I will define motivation and then the key concepts composing it as follows:

Motivation—Sequential Definition

1. *Motivation* is supplying the *incentives* which impel an individual to achieve a pre-selected goal.
2. An *incentive* is anything which an individual feels will satisfy a *drive* or a *motive*.
3. A *drive* is a persistent stimulated condition usually arising out of body-tissue needs and which demands immediate satisfaction.
4. A *motive* is any condition, usually emotional, that arouses, sustains and directs an individual's activity to a preselected goal.

Obviously from our definitions it would seem that motivating people for safety would center primarily about providing *incentives* which satisfy a *motive*, since safety is not

a "one shot" thing but calls for sustained, persistent, directed activity on a continuing day-after-day basis. Moreover, it has a high emotional content.

Drives, Motives and Incentives

Before we make any more conclusions and comparisons with respect to *drives*, *motives* and *incentives*, let's list the basic *drives* and some *motives*.

All of us are, no doubt, familiar with the natural, instinctive drives which I have shown in their order of dominance: thirst, hunger, sex, exploratory, and a recent addition, mastery.

Actually, *mastery* probably lies between *drives* and *motives*, but many recent research developments place it nearer to tissue-need *drives* than *motives*. This is a natural deduction because there is new evidence that our *motives* have their roots in the natural *drives*.

The really important thing to remember is that *drives* have an order of *dominance*, or in other words a precedence which operates so that the strongest one in that order of precedence gets attention before the others. With *motives* it's a different story. *Motives* being emotional do not have a natural, fixed order of dominance, but can vary in strength, depending upon the appeal to the emotions. Since many *motives* can be and usually are competing for our attention at the same time, the one that appears to offer the most reduction in anxiety, fear and tension usually wins out over the others.

A *motive* must withstand repeated competition with other *motives*, repeated diversions and assaults over a period of time. *Drives* with their tissue-need origins and order of dominance and precedence do not have to face such competition. In fact, it is obvious that when thirst and/or hunger are extreme they usually override all else. *Motives* are overridden, but once the thirst and hunger are allayed, *motives* can be revived and with the proper *incentives* resume their striving for the goal.

Thus we see that a particular *motive* can have several fates; it can:

1. Be successful in the competition with other *motives*.
2. Be only partially successful.
3. Be replaced with another; i.e., give way to a substitute.

4. Be completely blocked or inhibited.

From this we see why *motives* must be pretty strong rugged fellows. In this struggle, the survival of the fittest rule certainly applies. And from experience we all know safety has strong competition. So it behooves us to know the facts and be able to use them realistically and effectively.

Let's list some of the *motives* we've been talking about: Social approval, conformity, security, achievement, belonging, attitude, self-expression, interests—likes and dislikes, and prestige.

Probably you are wondering why I haven't included many familiar terms such as praise, reproof and rewards. That's just my point. Before we can arrive at the secret of *motivation* we must be sure of just what we mean by *drives*, *motives* and *incentives*, for there is a great deal of confusion as to just what each is and its functions. All too often *incentives* and *motives* are used interchangeably in talking about them, and this is wrong. It leads to poor, conflicting, and confused efforts to motivate.

The underlying truth is this. *Drives* and *motives* are the same for everyone. They are broad concepts. *Incentives* vary with the individual, for they are the intermediate achievements which impel the person to achieve the goal.

Remember our definition of motivation?

Motivation is supplying the *incentives* which impel an individual to achieve a pre-selected goal. And an

incentive is anything which an individual feels will satisfy a *drive* or a *motive*.

Such things as praise, reproof, rewards, rivalry, participation, etc., are *incentives*; and it's the *incentives* we must supply, not the *motives*. The *motives* are universal, human conditions which are the same for everyone in just the same way as *drives*.

Remember in our definition of *motive* we said it is any condition, usually emotional, that arouses, sustains and directs an individual's activity to a pre-selected goal. Note we said a *motive* is a "condition."

We also said a *drive* is a condition, but of a different kind. A *drive* is a persistent stimulated condition usually arising out of body-tissue needs and which demands immediate satisfaction.

Here's the important, vital concept that distinguishes *drives* and *motives* from *incentives* — *drives* and *motives* are *conditions*. A *condition* is something that necessarily precedes and sets up the climate for an action and its result, but which does not of itself produce the result. It is the *incentives* which produce the result; i.e., an achievement of the goal, if and when the *drives* and/or *motives* provide the necessary conditions under which the *incentives* can function effectively.

Before we sum up and list the key facts about *drives*, *motives* and *incentives* so we can use some actual accident situations and cases as illustrations, there is one more very interesting and also pivotal concept. I call it "pivotal" because it is the point of departure which determines whether we are going to motivate in the true sense we described earlier or pervert and divert into the "devil's brood" of thought control, brain washing and propaganda.

The "pivotal concept" is simply this: There are two kinds of *motives* — *positive motives* and *negative motives*. In the partial list of *motives* we looked at a few moments ago only *positive motives* were shown. All too often discussions deal exclusively with *positive motives* alone because, mistakenly, it is thought only the things that give pleasure reduce tension. But that gives a distorted, one-sided picture.

The following diagram shows the relationship between *positive* and *negative motives*.

As we can see from our diagram, there are some four motives which can be either positive or negative. They appear on both sides of the "pivotal point" which is shown as 0 (zero), the point of no motivation. These four motives: discipline, punishment, tension and attitude are what psychologists call ambivalent. They combine two possible impulses which are as opposite in nature as love and hate.

Let's take discipline as an example, for it is very important from an on-the-job captive group standpoint—it's their climate. Understanding discipline in the interests of the persons being motivated is positive, while discipline solely in the interest of the motivator, and particularly when not in the interest of the motivated, is negative. And the same is true of punishment. When both are

negative they have a close kinship with fear and anxiety, two highly and solely negative motives which can disable our perceptions and in their extremes cause panic.

When they are positive they are among our strongest motives. It is unfortunate that these two motives are so often viewed only from their negative standpoint. The same is true of tension. However, people see attitude a little differently. Most folks agree it can be either good or bad. As we can see, it is further out from the pivotal point.

Now here's a very vital and interesting thing about these ambivalent motives. Something that recent research has given new meaning. An ambivalent motive has an unconscious added impact on an individual, and when he senses the intent behind it, its effect is intensified and amplified. This can be and is true even when the person is "gripping" about it.

Why? Because these ambivalent motives are those associated with and ascribed to

authority figures." And when we have confidence in and respect for the "authority figure" we get a relief from tension by his assuming the responsibility.

The emotional content, impact and positive or negative nature of these highly powerful ambivalent motives are wholly dependent upon the use made of them by the motivating authority figure.

The solely positive motives are obviously effective motivators and the solely negative ones are often barriers to goal seeking and attainment. Even so, negative motives, fear and anxiety, can at times be strong motivators. Here's an interesting example of their use in a field that requires strong motivation — that of collecting debts as done by collection agencies. Dr. E. H. Barnes, psychologist for the National Accounts System says, "The basic approach in the collection of debts is creation of fear and anxiety in the debtor, which he can only dispel by paying the debt. You can't get away from the use of fear and anxiety as motives and the collector has to make sure that a certain amount of anxiety is present." Obviously, the creation of fear and anxiety are not the preferred motives in accident prevention because of the ease with which they can develop into panic, even when closely controlled.

Now here are some facts that will put things into focus, for Dr. E. B. Hurlock's work with the effects of three carefully chosen incentives of the discipline motive are really startling.

He used four groups:

A control group which was given no incentives.

A group which received high praise.

A group which was given severe reproof in their own interest, and

A group which was ignored, but heard the praise and reproof given the others, since only the control group was separate.

Here are the results in terms of their performance, using the control group as 100.

Group	Performance
Control	100
Ignored	144
Reproved	158
Praised	180

The use of reproof as an incentive of the discipline motive for their benefit resulted in 58 per cent improvement over the control group. The ignored group which heard both the other incentives being used improved its performance by 44 per cent over the control group.

Discipline of a positive nature is a motive which is inherent in all captive groups — it's a condition, a climate of such groups — and it is effective when properly used even on someone else.

Note, though the praised group increased its performance by 80 per cent over the control group. This is direct and clear testimony as to the solely positive social approval motive's effectiveness when praise is used as an incentive.

However, we must keep in mind that the praise was given to a captive group operating under a general overall state of discipline and the praise was warranted. Actually this incentive (praise) can be associated with both the discipline and social approval motives. In this case it was closer to the discipline motive.

Please understand why I have dealt somewhat at length with these ambivalent motives, particularly discipline. It is not because I am ranking them above the solely positive. It is because of their key position and impact and also because their nature and use has been so misunderstood. Furthermore, all on-the-job safety motivation takes place in a setting where discipline and controlled operation exists as the way of life — not "free choice," as off-the-job.

Returning to the main stream or central core of our discussion, I want to re-cap this way.

When we *motivate* we select a goal, decide upon what *motives* are most carefully related to the goal and then provide the *incentives* which will appeal to the individual or group as satisfying that *motive* or *motives*. Obviously, because of the possible mortality or "fall out" of *motives* it is best to use several and choose your *incentives* accordingly.

We don't supply or provide *motives*, as people often say. We supply *incentives* which satisfy *motives* which already exist for all of us.

Illustrations of Goals, Drives, Motives and Incentives

Let's use a few simplified illustrations to sum up.

Goal—Survival. **Drive**—Thirst. **Possible incentives**:

1. Tissue-need stomach pain
2. Seeing someone else drinking
3. Advertisement for soft drink

Goal—Save a life by rescue breathing. **Possible Motives**—Achievement is +. **Possible Incentives**:

1. Desire to help
2. Knowing what to do
3. Praise, awards, etc.
4. Fear is —

Goal—No eye injuries. **Possible Motives**—Security. **Possible Incentives**:

1. Publicizing loss of sight cases
2. Publicizing cases of eyes saved by safety glasses
3. Provide safety glasses cost-free
4. Taking personal responsibility
- + Discipline

1. Enforcement of rule requiring use of safety glasses at all times on the job

Note that these three simple illustrations included the competition of motives in the "rescue breathing case" and multiple possible motives in the "no eye injury case." Apropos of previous comments on positive discipline as a motive, when we tried to get full use of safety glasses by paying for them and the prescriptions and using several motives, we got about 70 per cent reduction in eye injuries. But when we made it mandatory to wear safety glasses at all times on the job and enforced it, eye injuries were practically eliminated in the outside construction and maintenance forces concerned.

How to Motivate People for Safety Successfully

In talking about "how to motivate people for safety successfully," we must be realistic. To do this I am going to use four actual cases. Two will concern group motivation and the two others will deal with the motivation of individuals. Please keep them in mind.

Case I—Large group, 17,000 women. Frequency rate 1955 was 0.93. Placed last in 19 competing companies.

Frequency rate 1957 was 0.21. Placed third in 19 competing companies.

Case II—300 men in outside construction work.

Frequency rate 28 under normal working conditions.

Frequency rate 0 under disaster service restoration—abnormal hazardous working conditions.

Case III—Individual employee (male). Individual bus driver with poor accident record given planned motivation resulting in five year accident-free performance to date.

Case IV—Individual employee (male). Individual craftsman with five year accident-free record suffers loss of finger—neurotic paradox of motivation and the forced choice.

Since we took the time to explore just what motivation is and is not and also developed and discussed basic definitions, we can cash in on it now. All we have to do is put the "pattern of successful motivation" in "flow diagram form" and use it as a guide in discussing our four cases.

The only term we've introduced in talking about our motivation pattern is "goal gradient." It is simply this: If the motivation

The Pattern of Successful Motivation (Flow Diagram)

is working, the nearer we get to a goal the stronger the motivation. It also applies when we divide a continuing, long-term goal into intermediate successive goals.

If we analyzed and discussed each of our four cases in detail, it would take hours. So I'm going to describe briefly what was done and then just mention some of the factors involved.

Case I—Large group—17,000 women.

Frequency rate 1955 was 0.93. Placed last in 19 competing companies.

Frequency rate 1957 was 0.21. Placed third in 19 competing companies.

A careful and detailed field study showed that safety programs and activities were basically oriented to men's needs, objectives and thinking.

A women's committee on safety was organized. It developed objectives, programs, materials and activities in terms of women's motives, needs, incentives, interests and thinking. The program activities were given to the women by women supervisors. As stated, in two years the women's frequency rate decreased from 0.93 to 0.21, and they moved from 19th and last place to 3rd and also bettered the men's performance.

Here are some of the motives and incentives used. (In each of the four cases I'll try to comment on different ones, i.e., motives and incentives.)

Actually there were more motives and dozens of incentives used. All of these items were designed to follow the "pattern of

successful motivation" and there was ample evidence that they did.

Remember our second case?

Case II—Departmental Group—300 men in outside construction work.

Frequency rate—28 under normal working conditions.

Frequency rate—0 under disaster service restoration—abnormal hazardous working conditions.

This case differs from the preceding group motivation. It has "situational motivating factors" which Case I did not have.

When hurricanes strike and telephone lines are down, towns and even cities can be isolated. Construction crews and their equipment are rushed to the disaster area from all parts of the country. They work day and night under the most hazardous conditions to restore service, for lives are at stake.

And yet there are far fewer injuries than under usual working conditions. The case quoted above shows that.

Looking at our "pattern for successful motivation" we can see that the goal is sharply and starkly defined; the previously developed safety attitudes, habits and training all are brought into focus through urgency for serving others. Without question, achievement is constantly before them as is information as to progress, and warranted commendation and praise are quickly given by everyone, including the public at large.

Added incentives arising out of the situational motives operate to strengthen the whole pattern of motivation. The incentives? They are multitude—for some the desire to help in time of dire need, for some the rewards of overtime, the group effort, and individual rivalry within gangs—all come into play.

The critical thing about "situational motivation" centers about this one fact. Unless the situational impact has been preceded by good sound safety attitude development, training and habit formation, it has nothing to build on and may well increase injuries instead of preventing them.

Case III—Individual Employee (male). Individual bus driver with poor accident record given planned motivation resulting in five year accident-free performance to date.

In both this case and the following one I'm going to limit our discussion to their unique aspects rather than reiterate principles we've already covered.

This case concerns a bus driver who had a very poor accident record, but whose physical and mental qualifications were satisfactory.

The company psychologist and safety engineer developed this plan. The incentives were group and individual rivalry, financial rewards and participation with the motives of achievement, conformity and identification doing the conditioning. Here's how it was done. The poor performer was put in a group with three drivers with very good records and these rules made:

Each driver would get a \$50 bonus at the end of an accident-free year.

If all four drivers had an accident-free year, all four would receive an additional \$100 each, making a total of \$150. Naturally the three good drivers assisted and "worked on" the poor one. He tried to conform and identify with the good ones. It worked so well that all drivers in that company now are competing on the "group of four" plan.

Probably most folks would say "sure it worked—they gave them some money." Actually money was not the key. The same plan worked when the reward incentive was not money and moreover even when there wasn't a material reward. It was the rivalry that turned the trick.

Notice how well this ties in with the following research results on the value of rivalry as an incentive where no rewards were used.

Dr. V. M. Sims used three groups:

1. A control group in which there was no special motivation.
2. A group in which only group rivalry and participation was used.
3. A group in which only individual rivalry and participation was used.

Here are the relative results, assigning the score of 100 as a starting base.

Group	Score	Per Cent Gain
Control	108	8
Group rivalry	115	15
Individual rivalry	153	53

The "group of four plan" combined the motivating values of both the group and individual rivalry incentives in a most effective manner, and these figures show why it worked so well.

Case IV—Individual Employee (male). Individual craftsmen with 5 year accident-free record suffers loss of finger—neurotic paradox of motivation and the forced choice.

This case illustrates the competition and clash of motives and their implementing incentives. Briefly, here's the story of the accident.

A craftsman with five years accident-free service had to make some changes in equipment panels located 10 feet above the floor. Another employee was using the ladder on the other side of the office. Instead of waiting a few minutes and walking across the office to get the ladder, the employee secured a small table 30 inches high and stood on it to make the adjustment. His supervisor saw him do it but did not stop him.

After making the adjustment the employee, who was six feet four inches tall, elected to descend in one step to the floor. As he did so his wedding ring caught on an equipment detail eight feet above the floor. His body and full weight being in motion he couldn't stop and the ring severed his finger at the first joint. The remainder of the finger had to be amputated later.

Without going into detail it's pretty clear that the clash between motives ended with the motivation for safety, which had been working for five years, losing the battle. It failed. Also notice the absence of the discipline motive when it was needed to re-enforce the ones that weren't functioning. Understanding discipline is like the "safety man" in football—it can save the day if the individual carrying the ball fumbles.

The Neurotic Paradox of Safety Motivation

I chose this fourth case for another reason besides its aptness for illustrating the conflict of motives. It also depicts the underlying basic problem of all safety motivation, "The Neurotic Paradox." In his significant contribution to the new concepts on motivation, Dr. O. H. Mowrer, research professor of psychology, University of Illinois,

states it this way. "Why does a person sometimes persist in unrewarding and self-defeating injurious behaviour when he knows he should not and is familiar with the safe rewarding behaviour?"

In our fourth case the employee knew and had practiced the safe procedure for five years. Recent research indicates we have not been fully conscious of the very high motivating element in a forced choice between opposites. Opposition, from sources outside ourselves, to our choice reinforces our unconscious drive to do things we are told not to do, and we have what is the commonest of all emotional blocks—pressure to resist anything that may be felt to be coercion. This is the core of the motivation problem since, as we said in our introduction, we do not use the perverted motivation of propaganda, thought control and brain washing which destroy the free spirit and creative initiative.

In our fourth case the discipline motive and incentives of direction and enforcement would have saved the day. The general procedures are incorporated in our flow diagram. More particularly, though, incentives must personalize for the individual and work through the properly selected motives, i.e. conditions which give the emotional kick to put and keep the person in the safety orbit. The more strongly the desired goal is perceived and reiterated the stronger the motivation, particularly when the development of the proper attitudes, i.e. "mind sets," puts the desired goal in favored position.

How to Tell Whether Motivation Is Working

There are four simple checks we can make to see if our motivation is working.

1. The effectiveness and efficiency of the desired learning is increased (other things being equal).
2. The individual or group efforts to achieve the goal are persistent.
3. The goal gradient effect is clearly evident.
4. The individual or group voluntarily expresses interest, satisfaction and desire to achieve the goal.

In the first three of our four illustrative cases it is obvious from what I have said that these four tests were satisfactorily met and would be observable to anyone making the check. In the fourth case, when the motivation failed it was and should have been evident to the supervisor that these four tests were not being met and that there was need for immediate action, as is shown in our previously discussed "motivation flow diagram."

Conclusion

It may be difficult for some to believe that what we have discussed here, motivation, is the key element in our lives. But its effective use spells the difference between success and failure in all we do. It determines also whether happiness or misery will prevail. Moreover, it holds the solution to emotional adjustment in lieu of maladjustment for, mark you, what we have discussed contains the key to self-motivation as well as the motivation of others.

There can be no continuing safety without motivation. And in a broader scope even our conquest of outer space and solution of the problems of nuclear energy will be hollow, meaningless and, yes, disastrous Pyrrhic victories if we fail in solving the problems of our own behaviour.

COMMERCIAL VEHICLE SECTION

AUTO DRIVING FITNESS AND THE PHYSICAL EQUATION

By ABRAHAM J. MIRKEN, M.D.

Member, Committee on Medical Aspects of Automobile Safety
American Medical Association, Cumberland, Md.

The topic assigned was "the physical equation." I choose to broaden it a little bit and talk about "auto driving fitness," because I think it encompasses more of what we as physicians are interested in. When a disease kills almost 40,000 people a year and affects them physically to the extent of four and one-half or five million more a year, it certainly is not unnatural for physicians to be interested in it.

Automobile accidents last year did just that. For quite a few years physicians have been interested in the problem, but primarily from the point of view of treatment of casualties, and rehabilitation. It's only in the last 11 or 12 years possibly that physicians began to look upon this as a preventive disease; it should certainly fall into the province of general medicine and not just the surgeon, the orthopedist, the physical rehabilitation specialist, and so forth.

The American Medical Association has for some years felt its responsibility and has had a committee interested in this. Until this year, the committee was called Medical Aspects of Automobile Injuries and Deaths, but in the last two months was changed to Medical Aspects of Automobile Safety.

As Mr. Fine has stated, expert drivers, with 20 years of experience, or better, in driving safely, did not measure up to what we as physicians felt should be ideal standards for selecting drivers. They were all older—they probably didn't coordinate as well, their reflex timing was not as good as for younger people—and they certainly did not see as well at age 59 as they did at 18 or 20. They probably didn't hear as well—their fields of vision might have been somewhat impaired.

We know for a fact that their ability to

see at dusk and at dawn was definitely impaired. At 60 or 65, one becomes less capable of seeing in the hours when there's not quite enough daylight.

There's no substitute for the judgment that maturity brings. When a fellow is stable enough to stay on the job for 33 or 34 years and to respect the customs and the opinions of his community, he's one who should be a good driver even though on a testing machine or device he may not check out so well.

The physician is interested in preventing accidents by trying to determine the individual's ability to drive, and also the particular things that impair the ability to drive. His sole concern, I believe, is with the driver's physical make-up—how tall, how short, how obese, how old and so forth—and his physiology—is he able to move all his extremities, turn his neck, see over a wide enough range when looking straight ahead, or perceive that he has just enough time to get by in changing lanes and passing?

These things are very difficult to measure, but they can be impaired by certain diseases and by taking medication, drugs and alcohol. The physician also tries to sort out the people mentally or emotionally unfit to drive. The moron, or individual with an IQ of less than 70, should not be driving any vehicle, especially a commercial one, or one that transports passengers.

Emotionally disturbed individuals whether psychotic or severely neurotic, or just upset by a bout with boss or wife, are not as good drivers as the normal individual.

Last we come to the effect of specific diseases on the body, the effect of drugs and medications on the ability of the individual to work, see or judge, and the effect of alcohol. One doesn't have to be

a chronic alcoholic or abject drunkard to be a bad driver. We are concerned with the fellow who has one or two cocktails and then proceeds to drive home thirty minutes after the last one. It's been determined time and again that even one beer or 1½ ounces of whiskey in the blood stream will be sufficient to impair physical ability.

The figures of 1957 still hold true in 1960. There were 39,000 killed last year and the 1½ million mentioned as being injured are those who missed a day or more from work. Actually there were 4,700,000 reportable injuries, and the prediction that one person in every ten will be injured or killed in a motor vehicle accident in the next 15 years still holds.

Obviously there are three facets that are involved in an automobile accident. One is highways. We are going to have dream highways where cars will be locked on electronically, and the driver may take his hand off the controls and not touch them until he gets off the highway, but that's in the future.

Second is the motor vehicle. This has become faster moving, more maneuverable, and truly has fewer mechanical failures causing accidents. One thing that I'd like to emphasize is that the automobile can be vastly improved as a means of packaging the driver and other occupants.

Statistics show that human failure is the most important factor in the causation of accidents. The human mechanism has to be not only physically fit but also able to function and unmodified by drugs or alcohol.

Drivers having repeated accidents or a high accident rate are usually of lower intelligence, youthful, or have certain emotional problems, such as egocentricity, resistance, or social irresponsibility. However, most accidents involving personal injury take place between drivers who have never been involved in a personal injury accident before, or been injured themselves. That's a little surprising in the light of the three factors compiled above.

How can we determine safe driving ability? There is no law that I know of in any state which compels a physician to report to a motor administrator the physical, emotional or mental disabilities which in his opinion may result in the impairment of his

patient's driving ability. The only possible exception is epilepsy which some 22 states have designated by law as a reportable disease.

The individual who suffers fatigue while driving may be more likely to have an accident. And he will usually have that accident in the first two or three hours after he starts driving. I think that statistics have borne this out. Usually his fatigue comes from some activity he engaged in prior to driving. The physician and the safety engineer should both be on the lookout for the fellow who has not slept properly the night before, or who has engaged in some physical activity, such as golf, tennis, or week-end camping trip. He should be warned about his ability to drive.

The individual likely to faint or become confused, whether due to disease or because he has been taking tranquilizers, must be watched. Temporary impairment may be induced by certain drugs like marijuana, cocaine, morphine or their derivatives, and from the use of alcohol. There is no single opinion about what constitutes the best vision, but certainly if everybody had 20/20 vision we would have better drivers. It's the feeling among most practitioners that at least one eye should be correctable to 20/40, and the other to not worse than 20/70.

The value of good hearing is something else again. We know that many drivers don't hear well, and that a man who is driving a tractor-trailer or a large bus, and who is hard of hearing, can't do as well with a hearing aid as without one. Also, drivers who know that they are hard of hearing can compensate for it by using their other senses to greater advantage. Sometimes these men are quite competent drivers.

It goes without saying that a person should be able to operate the controls of his car. He should be able to use his arms, should have enough strength in his legs and thighs to use brakes and clutch pedals, and should be able to rotate his neck in both directions so that he can see over both shoulders. The individual who has a cast or a splint on one arm and is otherwise well should not drive an automobile, particularly a commercial vehicle.

A physician can only advise a patient but certainly his responsibility is great to advise that patient not to drive with a

Commercial Vehicle Section

cast, or a patch over one eye. The individual who is blind in one eye and drives over a period of 10-12 years learns to compensate for the loss of that eye, although tests reveal inadequate depth perception in car handling; but an individual temporarily blinded in one eye has depended for so long on both eyes for binocular vision that he is temporarily incapable of doing a good job in depth perception. Such an individual should be warned by a physician or a safety man that he must not drive until his eye is healed.

Emotional instability cannot be measured. There's no test which, in 5 to 30 minutes, can rule out the emotionally unfit as drivers. Long interviews are necessary, and even then, as we learn from racing experience, they don't work. Many a man is a competent driver on a practice course—a sober, stable individual when you talk to him in a physical interview—yet when he gets into competition he becomes terribly aggressive and abusive, and dares to disregard not only his own welfare but also that of those around him. Such an individual has to be taken off the course immediately.

There are certain endocrine glands—organs of internal secretion, such as the pancreas, the pituitary, the ovaries, the testicles and the thyroid—which affect our emotions, our behavior, our physiology, our ability to work; and there are certain diseases and certain drugs which affect these glands. Some of the diseases cause a motor weakness in which an individual cannot temporarily do simple things with his arms, legs, or back muscles which he could do before. Such an individual shouldn't drive.

There are some diseases in which one particular muscle is weakened, as from a cerebral stroke in which paralysis on one side results in a loss of an arm or leg. No one would disagree that such a man cannot drive. There are certain diseases of the endocrine system which produce spasms and convulsive movements, not due to loss of consciousness, but due to an overpowering, uncontrollable muscle contraction. Such a disease is hypoparathyroidism, which fortunately is not too common.

Sudden episodes of vertigo, or dizziness, appear in certain diseases. Individuals who have them should not be permitted to drive, and it goes without question that anyone

who suffers loss of consciousness, whether it be due to blocking of a cerebral blood vessel, epilepsy, or any of the convulsive disorders, must not drive.

How can we discover the individual who has these? If he seeks medical advice, his physician, if he is competent and zealous in his work, can make a pretty accurate diagnosis. But the physician's hands are tied as far as doing anything more than advising that individual not to drive is concerned.

When it comes to commercial drivers, there is a controlling organization with its own medical department, but we all know there are individuals under the care of private physicians who have certain diseases which would preclude their driving a commercial vehicle. Yet, the organization medical department does not know about it because the individual has never been in trouble in the plant. When discovered, he must be prevented from further driving.

The problem of diabetes and dropsy is rather serious and complex. There are a tremendous number of diabetics in this country, and an untold number who have never been diagnosed, or have no idea themselves that they are diabetics. The medical profession feels that if the diabetes is mild enough so that only diet is necessary to control a man's blood sugar, then he may drive all vehicles. If diet and one of the oral antidiabetic drugs control his blood sugar, he may drive all vehicles. If insulin is needed in addition to diet control, he may drive a private car but he should not drive a commercial vehicle or a passenger transportation vehicle.

People are going to differ about that. If the individual is seriously diabetic, so that dry insulin alone does not always control his diabetes, he should not be permitted to drive any vehicle. The reason is that, if his blood sugar suddenly goes up too high, he may become unconscious or semi-conscious. This can sneak up on him without much warning.

On the other hand, if he's taking insulin, and for some reason didn't eat his meal or didn't eat as much as he should have, he may go into insulin shock, an abrupt drop in blood sugar resulting in loss of consciousness and even convulsions. Such an individual should not be behind the wheel

of any vehicle. The feeling of the American Medical Association is, if the individual is taking insulin, whether his diabetes be controlled by it or not, he should not drive a commercial vehicle or a passenger transportation vehicle.

A person should not be allowed to drive when he is under influence of drugs which impair sensory, mental or physical functions. As we know, there are many drugs that cause drowsiness, lack of coordination, etc. Today, people are taking tranquilizers, sedatives, hypnotics, even small doses of narcotics, if they have chronic muscular disorders.

Drugs are being used more and more today to control high blood pressure and, surprisingly enough, in many individuals, cause a certain amount of drowsiness and slowing-down of reflex time. Furthermore, the individual usually has to take this kind of preparation every day. Antihistamines, considered not long ago as a cure-all for the symptoms of colds, cause tremendous amounts of drowsiness.

Tranquilizers also cause drowsiness, or dull one's mind; there are some drugs which relax one's mind, make one feel that everything is fine when it isn't. Both these kinds of drugs are harmful to the driver.

We know that drowsy drivers are capable of losing attention, their reaction count has slowed down, their ability to see is definitely impaired, and they are dangerous. They should stop and rest; if possible, they shouldn't work that day. In general, fatigue affects the mind, the eye, and the whole body. It is recommended that no one drive more than eight hours and that an individual stop every two hours. I might mention that these are recommendations made for the average passenger car driver, and not necessarily the commercial vehicle driver.

One of the best drugs we have to keep you from falling asleep is caffeine, from coffee, colas, or the caffeine tablets. We don't recommend that drivers take benzadrine tablets before making a trip. Heart and blood vessel diseases are dangerous only if they cause a sudden loss of consciousness. High blood pressure itself is not a complication to driving either a passenger car or a commercial vehicle. The effect of high blood pressure on an individual—on his brain, kidneys, etc.—should be evaluated

from the point of view whether there has been damage to renal vessels or whether kidneys are failing and the driver is likely to go into a coma. I return to consideration of the visual acuity necessary for safe driving. Double vision should not keep an individual from driving. Color blindness is not a significant hindrance at all. Dark adaptation and glare are problems in themselves. An individual hitting 60 or 65 does not adapt very easily to the change from daylight to dark, or from dark to daylight, at dawn.

It has been shown that an individual who smokes three cigarettes will impair his dark adaptation to the same extent as if he went up 7,300 feet in altitude in an airplane. The higher you go without an oxygen mask, the less oxygen you get, and the poorer you see in dark and twilight.

An individual who has an artificial opening in his wind pipe through which he breathes, as a result of tracheotomy, should not be allowed to drive a commercial vehicle, because he may be easily choked by breathing in foreign matter.

The person suffering from convulsions, such as epilepsy produces, or any disease causing faintness, weakness, or like disorders, should be avoided in selecting drivers. There are no two states in the union having epilepsy laws that agree, but most of them feel that an epileptic may drive safely on no medication if he has had no attacks in two years; others allow medication. There are certain things that will induce an attack in an epileptic person—undue fatigue, alcohol, and emotional tension or stress.

Any individual who gets emotionally upset can have his driving impaired in three different ways. He may be so absorbed in his own problems that he is inattentive or indifferent to driving. He may be so depressed that he is unable to work. He may have such violent antagonism to the world or to people around him, that he becomes repulsive, aggressive, loses his good judgment and his sense of caution.

Every individual who is neurotic should be carefully evaluated by his physician and safety engineer. He should also have evaluated the effect of any drugs he is taking to control his neurosis before he is permitted to drive.

A psychiatric patient who has been hos-

italized should not drive. A patient being treated by a psychiatrist with drugs or by shock therapy should not drive, and anyone whose psychiatric status slows his behavior and reflexes should not be permitted to drive.

Thirty-five milligrams of alcohol per hundred milliliters of blood impairs ability to function physically. With 50 milligrams, or 0.05 per cent, there is definite measurable impairment. The third drink can get you

into trouble with the police. In many states there is an arbitrary limit of either 0.10 or 0.15 mg./ml., above which you are considered drunk. Some states do not have an arbitrary limit, but the blood alcohol determination is easy to make and, if you have alcohol in your blood, and it can be shown that you did not operate your vehicle with the same judgment and skill that you would have had you taken in no alcohol, then you may be prosecuted.

SLIDE RULE TO SAFETY

By JEROME L. FINE

Research Coordinator, Safety Research and Education Project
Teachers College, Columbia University, New York City

The dictionary defines a slide rule as "a device for rapid calculation." Unfortunately, this sort of device does not presently exist in the field of traffic safety. After several decades of experience and research we are still attempting to select, evaluate and understand the automobile driver and his behavior on the road by using any number of methods, from the simplest interview to the most complicated battery of tests. These methods, however, have at least one thing in common—each is grossly imperfect. We simply do not possess accurate, rapid devices for driver assessment, and due to the complexities of the traffic situation none seem forthcoming in the foreseeable future.

This, of course, makes the title of my address somewhat of a misnomer. As far as can be determined there is no "slide rule to safety." There are no shortcuts to understanding the actions, feelings and thoughts of a complicated machine, the human being, operating in a complex situation. Recognizing this state of affairs, the Safety Research and Education Project at Teachers College, Columbia University, came into being just four years ago. Its main purpose was to investigate the causes of accidents, primarily traffic accidents.

After carefully studying the many possible causes we decided to focus on the driver since he appears to be the most significant among these. Under the able leadership of Dr. J. L. Malferi, the project activities have grown to encompass three general areas:

1. Determining the characteristics of safe and unsafe drivers and translating these into tests which might be used by licensing authorities, fleet operators, insurance underwriters and others.

2. Improving driver behavior through education.

3. Studying automatic devices to take over for the driver when he fails.

While seemingly unrelated there was a logical progression from one area to another. First, we wanted to find out something about automobile drivers. Then we wanted to use that knowledge to develop ways of choosing those individuals who are liable to become accident statistics before they are able to damage themselves or others. Once the unsafe or potentially unsafe driver has been identified, not allowing him to have a license or refusing him insurance did not seem to be enough.

Some positive action was indicated like rehabilitation or education in the essentials of safe driving practices which includes training in attitudes, skills and knowledge. But this kind of training is at best a slow process and even individuals who are generally safe drivers may at times break down and become unsafe, sometimes due to circumstances beyond their control, such as cardiac seizure. Hence, our interest in electronic or automatic devices that function to supply the lost control and direct or stop the vehicle in a safe manner.

While the project's framework and long-range objectives concern the reduction of accidents, urgency has led to a concentration on applied research in areas where immediate action may be taken. One investigation, for example, involved working with the Driver Improvement Clinic of the Automobile Club of Cleveland. We studied the psychological differences between teenage traffic violators and non-violators ultimately developing a battery of tests to predict violators. In summary, we found that the violator does not think things through and see the consequences of his acts. He may see from A to M—but not to Z. More about this extremely important point later. He doesn't get along with people, including those closest to him. While loving freedom and himself, he feels held in check and is rebellious. His over-sensitivity, lack of self-confidence and feelings of unworthiness make him one of the "angry young men" who may resort to erratic and ill-considered actions, using the automobile as a weapon.

Also of great interest, was that his parents displayed similar anti-social tendencies. They are not very civic-minded and stay pretty much to themselves. They feel little responsibility toward the rest of society. This philosophy of "Every man for himself; just take care of Number One," has evidently rubbed off on Junior in his automobile. One relevant though poignant example occurred recently in California. A young man speeding excessively was killed but the police could not find his father; he was in court paying a fine for reckless driving and speeding.

There are two reasons for my reporting these findings about teen-age violators and their families. On the one hand, it documents dramatically the importance of enunciation or example in the formation of driving attitudes which begins at quite an early stage of development. It is not infrequent for the child learning to count and read to ask his father why the sign on the road says "45" and the arrow on the speedometer points to "60."

On the other hand, this study typifies along at least one dimension the kind of research presently being conducted. It concerns the "pathological" driver, the one whose record reveals him as dangerous when behind the wheel of an automobile.

Through the years research has produced an ever-growing list of traits, attitudes and actions which are significantly related to "bad" driving. In contrast, there is little information and even less conceptual clarity about the nature of "good" driving. In terms of our culture, this is not particularly strange. I wonder if you realize how many of our standards are based on the characteristics of marginal or totally maladjusted individuals. As a psychologist, I have frequently attempted to measure neurotic potential and character disorder. But there are no scales for measuring *healthy* potential or character *order*. Traffic safety is no exception. Violation point systems, for example, are arranged so that 0 is the best score.

Equally important is the fact that "good" driving is not just the obverse of "bad" driving. In an older study, we collected over 2,000 incidents typifying "good" and "bad" driver behavior. Although the results are not yet complete, the analysis definitely indicates that certain actions ascribed to good drivers cannot be classified on the bad side of the ledger. The individual who interrupts his journey to clear a dangerous obstacle from the roadway has no "bad" counterpart. Isn't it about time we started to model our standards after people who did things well. It certainly seems we can learn at least as much from good drivers as we can from poor drivers.

It was in this atmosphere that we especially welcomed the opportunity to work with a group of proven safe drivers. It was frankly refreshing to work with people who were normal or better-than-normal. Collaborating with the National Safety Council, the DuPont Co., Remington-Rand, Univac Div., Dodge Corp. and many helpful individuals, we examined the characteristics of over 2,000 drivers who had received the National Safety Council Safe Driver Award for 20 years or more.

Incidentally, the opportunity to test a large group of individuals for whom orderly, accurate records over a long period of time were available is rare in itself, and to a considerable degree serves to offset some of the more serious limitations concerning doubtful driver classification due to inaccurate or inadequate records imposed on many studies in this field.

For the first phase, we prepared a questionnaire which was distributed to the drivers by the National Safety Council. The questionnaire contained 22 items relating to biographical and driving records. Some of the results may be of interest to you. The profile of the 20-year award winner reflects social stability and conformity. He is 39 years old, married and has two children. He has been driving professionally for 33 years, has worked for the same employer for 32 years and has had, on the average, only one previous employer. In fact, like most of his fellow winners, he has been with the same company for his entire working life.

He has never had a single traffic violation during his personal and professional driving career, has had only one preventable and one non-preventable accident during his vocational driving career and no preventable accidents otherwise. In 1959, he drove about 17,000 on-the-job miles and added another 8,000 in personal driving.

With the help of Remington's high-speed computer, Univac, we ran these characteristics through and selected six drivers largely on the basis of an accident-exposure index. The process took twelve hours on the machine. According to Dr. Mahoney, it was reminiscent of winning in the hospital lobby for one's first baby to be born. Being a bachelor, I must confess to feeling a little "inadequate" but feeling after several hours my anxiety complex turned to sheer excitement. After being told the information at 6 p.m., Univac's digestive process took until 11 a.m. the following morning before it punched out twelve names and last pilot selected received its selected plates.

Six of our twelve highest ranking drivers were available for the tests on which intensive, depth testing had been scheduled. One week end, here in Chicago, the "chosen few" were assembled and subjected to twelve solid hours of tests divided as follows:

Medical	2 hours
Driving performance	2 hours
Psychological	4 hours
Knowledge	4 hours

The tests were administered by specialists in each of these areas. Specific items were selected according to the specialist's concept of what the ideal characteristics of the safe driver should be or established operating

standards for drivers such as those found in licensing and fleet driver examination. Because only six individuals were involved, some results of the highly personal tests cannot be released, but I am sure you will find the results that can be made public most provocative.

Items on the medical examination ranged over several areas which include, among others, five different visual tests, a neurological and cardiovascular examination and eight different psychomotor tests. The results indicated that the subjects were average and below average in terms of suggested standards for medical fitness to drive and in terms of some of the physical standards currently used in licensing. They were no better physically than the average man in their age bracket.

In most cases, however, they knew their physical deficiencies and had compensated for these in the driving task. More specifically, suppose the ability to see signals and other vehicles was impaired or simple reaction time was slow, they would then look harder for signals and other vehicles, and when they saw these they would know instantly what to do. Their concentration, caution, ability to anticipate and make quick decisions, evidently more than made up for whatever physical deficiencies they might have.

The psychological battery included the Rorschach "ink-blot" test, other projective tests, an intelligence test and a personal interview. The results indicated that all subjects operate in at least the average range of intelligence. In general, they are non-aggressive individuals with a high level of impulse control. They are loyal, dependable, sober, saving, cautious husbands and fathers as well as dependable, loyal, hard-working employees. A high degree of vocational and social security seems more important to them than competitive, aggressive strivings.

These characteristics are reflected further in their tendency to plan conservatively and well for financial commitments, retirements and other phases of their own and their family's future. In doing so, they invest in safety and security to the exclusion of other potential gratifications. In addition, all share a strong preference for an outdoor job—that is, one which does not require a formal, long-term and close relationship with others.

As a group, they are highly sensitive to the opinions of others and to the mores of society. While quick to recognize a threat to their well-being, they try to avoid, deflect and deny such threats before they evoke retaliatory feelings. This is particularly true of threats which normally arouse anger so that, for example, they do not seem irritated by the bad manners and poor driving skill of others. Impulsivity or rebelliousness are totally foreign to their patterns of adjustment and their behavior seems modeled after a parent who is easy-going and non-aggressive. In the light of these factors, their social behavior is probably very stable even though the evidence suggests that a high percentage of these men underwent extremely stressful childhood experiences.

The performance test consisted of driving over a pre-set course in a specially equipped car. The course was selected to meet the requirements of containing 24 major driving incidents which included 136 separate items. In addition, seven general driving practices were assessed. The results—all six subjects did better than average. In fact, all rank in either the "excellent" or "good" classification. Not a single one ranked as low as "average driver." Five positive characteristics, common to all subjects, stood out on the performance test. These were:

- (1) Signaling intentions when slowing down, stopping, turning or changing lanes;
- (2) Correct use of the eyes in traffic, at intersections and in the open road;
- (3) Courtesy towards pedestrians and other drivers;
- (4) Perfect timing when passing and changing lanes;
- (5) A manner of driving that caused passengers to rest at ease at all times.

In the knowledge area, each driver was given several standard tests totaling almost 200 questions. The subjects included mechanics, law and regulations, vehicle operation and first aid. The results—five of the six drivers scored average to poor, one scored good.

It is evident that the information gathered

in each of the areas tested raises some serious questions. In general, we compared our drivers to the ideal safe driver and on the whole they did not make the grade. But we tested the "genuine article" and ideals are, at best, good guesses. Should we not consider re-evaluating our concept of the ideal driver in order to make it more realistic? Stated in a positive manner, we should take a long, hard, look at theoretical licensing and selection standards which are not validated pragmatically.

Admittedly, this is not an easy task. Results to date suggest that if driver behavior is divided into three stages—input, organization and output—then the mature, safe driver excels in organization or the ability to make a correct decision and to adjust his behavior so that it is in accordance with his ability. Compare this profile to that of the teen-age violator whose visual input and reflexive output are probably at their respective peaks, but whose organization or decision-making machinery has not been fully developed. Organization, however, is probably the most complex, difficult variable to isolate and study.

The fact must be kept in mind, the results of our study, no matter how interesting or disturbing, are based on the records of only six men. More definitive information is needed before any change based on these findings can even be contemplated. With this purpose in mind, and with the cooperation of the National Safety Council, we have proposed a larger study which seeks to test comprehensively in much the same manner as the pilot study, some 1,000 proven safe drivers throughout the United States.

The concentration of public attention on the safe driver in itself should serve as a quiet step in the reduction of traffic accidents. We also believe that the knowledge to be learned from the nation's safest drivers will be an invaluable aid towards the total understanding of our traffic problems. We are, of course, still vitally interested in the characteristics of all drivers; but perhaps now is the time to quietly rehabilitate the bad drivers and publicly applaud the good drivers.

duction employees, an endeavor to determine whether a special driver index could be developed through the ARII was undertaken. Sufficient data for this study became available only late this summer. Now to do a job like that you need large samples, because you are very likely otherwise to capitalize on chance.

A preliminary driver index has been developed now from other data and applied to the southern trucking firm to try it out. When the truck drivers of this middle southern firm were scored with the new key, the results were highly satisfactory. Correlation between the new safety index and accident data was .75—an extremely significant relationship.

This result strongly suggests the desirability of utilizing samples in the refinement of this driver index for general use.

At this point I wish to emphasize an important difference between the accident problems of over the road drivers and stop and go drivers. That is, in addition to accidents involving collisions either with vehicles or pedestrians, the stop and go urban bus driver seems to be charged with the responsibility for injuries to passengers for which he is not primarily responsible. For instance, when stopping, a standing passenger may fall and sprain his ankle. Who is responsible?

This strongly suggests that accidents in this field should be classified not only for levels of negligence in colliding with vehicles and jaywalkers, but also be broken down into three categories as follows: collisions with vehicles, collisions with pedestrians, injury to passengers on a bus not involved in a collision.

Our investigations to date reveal the extreme importance in recording detailed information about each accident if you're going to do a study like ours. This is important in order to clarify and assess the nature of the accident risk which an applicant for a driver's job may present. I have already referred to the importance of determining level of negligence on the part of the drivers. It is just as important to factory workers, but it is sometimes very hard to obtain. That is one of the difficulties I had in the production field. The level of negligence is not enough. We also need to know the length of service with the

firm, so that the accident record can be properly weighted for length of employment. Now a few concrete examples will reveal the need for this.

For instance, one firm presented accident records for 17 months. During this time one driver had a serious accident involving gross negligence. Yet management classified him as their best driver. Another company tested a group of drivers whom they considered as accident repeats. Yet the records over a three year period showed, and that's only if we had the records for a three year period, showed that 7 of these drivers rated as unsafe had had no accident during this three year interval.

Well what can you do with data like that? Examples like these reveal the prime importance in obtaining accident data over the entire period of employment. A man may have a serious accident involving gross negligence in 17 months, yet management may base its opinion of the driver on a record of a twenty year period of employment. Let's have all the facts.

Test users sometimes develop the habit of depending entirely upon test results—very sad if they did. As you know, this would be a great mistake. In hiring, a wise employer takes into account all the data at hand, such as interviewing, and previous job history.

Test results are never perfect. The same could be said for many medical discoveries. The Salk vaccine for instance has decreased the incidence of polio, but it has not eliminated it entirely. It would be difficult to find anyone, however, who would say that this lack of perfection was a good reason for giving up the use of the Salk vaccine.

Primary concern for the tester, however, is to refine these tests as much as possible with industry's cooperation to achieve two purposes. To see reduced to a minimum the probability of eliminating a good risk, while increasing to a maximum the probability of identifying a poor one. Eliminating the poor risk is most likely to effect reduction in the cost of accidents. Moreover it might be helpful to direct special attention to re-training the driver who has had his first serious accident.

In closing this report, we can make a few suggestions. We already know that the driver index can be a useful aid in select-

ing the over the road drivers who are least likely to become involved in accidents. But it is also important to learn how the driver index applies to other driver operations. To

carry out such studies it is essential that accurate records of accident levels with degree of negligence for the entire period of employment be presented.

SECOND DIMENSION OF FLEET SAFETY

(a) DRIVER PERFORMANCE—A TRUE MEASURE OF MOTIVATION

By ROBERT PERLOFF

Dept. of Psychology, Purdue University, Lafayette, Ind.

I should like to begin my remarks by warning you that I come here this morning not as a prophet of psychology, nor as a sage in safety, for I am neither, but rather as one whose modest contribution to your deliberations this week may, at most, be characterized by whatever merit there be in the impetuosity of naivete. I am naive. That is, my ignorance in the field of safety may help you, through your depth and knowledge of the problem, through your untimely with accidents, and through your compassion with the human operator of vehicles and the multitude of pressures that never leave him—obtain a fresh start or at least a different view of this enigma of highway accidents which you have been wrestling for decades.

At the outset, let me set the record straight by advising you that, notwithstanding the original notions of the program committee as well as my own vague ideas when the subject of participation in this symposium was broached last spring, I will be concerned neither with motivation research nor with measurement techniques as explicit topics. Let me tell you why.

Motivation research, as many of you know, seeks to probe, oftentimes beneath the level of the individual's conscious awareness, for underlying or basic motives responsible for the individual's behavior. Typically, motivation research studies have been conducted in the context of consumer research in marketing, advertising, and selling. To illustrate, the conventional motivation research activity might reveal that "Milady's" soap is preferred (by your lady,

and mine) not especially for its cleansing qualities, but rather because of the way it caresses the skin, tenderly and lovingly. Motives or reasons such as these are scarcely capable of being revealed unless considerable probing is used by skillful and professionally trained interviewers.

While the clinical techniques employed in motivation research, projective tests for example, are indeed appropriate for and have been used in safety research, I am now convinced, having sweat through some of your voluminous safety research literature, that the time has passed when we can afford to view the individual as an entity divorced from other factors with which he interacts in committing traffic violations or accidents. To be sure, a small piece of the explanation of accidents may be brought to light through motivation research, but so far as I am concerned there are other approaches that appear to be more promising, at least at our current level of knowledge of driving behavior. But more about this later.

Permit me to illustrate but briefly the type of frustration one faces in reviewing the psychological literature bearing on driver safety. An excellent summary of behavioral research in this field was published recently by the Driver Behavior Research Project of George Washington University (Goldstein, 1961). An examination of this objectively oriented statistical digest revealed a multitude of depressingly meager relationships (either correlational or in terms of significance tests) between personality measures (the nuclei of motivation

research) and actual driving performance. If these objective studies, embracing personality measures of all descriptions and inferred from thousands of cases, are incapable of unmasking the riddle of driver safety or of differentiating between safe and unsafe drivers, then what chance is there for motivation research, along with its handful of clinical interviews and its probes in depth and its assortment of projective devices, to do hardly more than provide a few clues, not definitive answers, in our search for truth?

Hence I decided not to try your patience by speaking about motivation research and driving behavior. Alford you, I am not saying that motivation research does not have a legitimate role in psychological research, but rather that in my judgment it is not a primary tool of inquiry appropriate for use at a time like this, in 1961, conspicuous for its shapeless understanding of the parameters of driver behavior.

Moreover, a review of your literature documented my intuition that there is no famine of research or statistical talent in the ranks of the psychologists engaged in driver behavior studies. Hence it would be prodigal to pontificate on measurement problems in safety research.

To help you understand better, or at least sympathize with, the position I shall espouse, I would like to recount for your suzerainty the disappointments I endured by discovering, one by one, piece by piece, in study after study, the reasons why safety research has germinated, not the towering Redwood tree or the defiant excavator, but dwarfish shrubs or diminutive motor scooters, healthy little shrubs and peppy little scooters, mind you, but still, alas, only shrubs and scooters, not Redwoods and excavators. The list of reasons why driver safety research has languished includes, but is not necessarily restricted to, the following items:

1. The statistics of violations and accidents are horribly muddled, unreliable, lacking in uniformity so that data can not be combined meaningfully and interpreted sensibly.
2. The nearly unimaginable variations among traffic laws, or at least certain in the subjective nature characterizing the traffic officer's interpretation of violations.
3. The fact that variations within drivers are oftentimes greater than variations among drivers, one of the sorriest and most pessimistic observations that one encounters in this area.

4. Because driver attitudes are easier to measure than actual driving behavior, considerable work has been done in this area. However, there is incongruity between attitudes and behavior, viz., between what a person says he believes or says he will do and what he actually believes or actually does.

5. The operation of chance, and hence unpredictable, factors in the accident complex.

6. It has been disappointing to find that no test, or even test battery, appears to be clearly outstanding accidents, despite the fact that numerous predictor tests have been studied, including those that seek to assay individual differences in the realm of man's sensory, motor, intellectual, and personality qualities. (Reference here is not meant to include extreme cases such as drinking, fatigue, emotional disturbance, youth, inexperience.)

7. The generally poor relationships between indices of performance in driver training courses and later accident records. "Grades in driver training courses apparently have no validity for predicting who will receive traffic citations or have accidents. Socioeconomic and geographic variables also failed to show any important relationships to traffic citations or accidents. The dark coloring factor failed to have any loading for the accident or citation variables tending to suggest that Mexican and Negro groups are not markedly different from other groups in these respects." (Comrey, 1958, pp. 220-23)

The foregoing list of reasons, and more, are documented liberally in the psychological literature (Comrey, 1958; Goldstein, 1961; Stewart, 1954; Thorndike, 1951).

Several facts and hypotheses are readily inferred from the studies from which the above state of affairs are derived. To begin with, it seems that most approaches to the problem have been explorations of single factors or systems of variables, rather than of interactions among factors. These interactions suggested to me a crude model out of which the nature of accidents might be teased or glimpsed. Let us assume that accidents are some function of the driver, the vehicle, and the environment. This function might consist of some weighted combination of driver characteristics, vehicular characteristics, and environmental characteristics, plus driver-vehicle interaction, driver-environment interaction, and vehicle-environment interaction, plus, finally, driver-vehicle-environment interaction. Simple as it is, when such a model appears in front of one, on paper, some possibly interesting clues of accident etiology are exposed. Let us see what these clues are.

It is apparent that if our model is correct we will get nowhere by studying the individual, the vehicle, and the environment, each, in turn, as a discrete entity. True,

from this restricted kind of study, we will learn something about accidents, but never much, I fear.

What about the next level, the double interactions? These will open the curtain a bit wider, to be sure, than was possible through an examination of discrete entities exclusively, suggested in the preceding paragraph, but the stage revealed by the partially opened curtain will disclose a few of the principals but not the entire cast of factors, without whom the drama and the tragedy of highway accidents will never be fully understood. These double interactions, while not the full story, are significant, and include such interactions as these:

1. The driver-vehicle interaction, relating the individual's physical and sensory dimensions with the design of the vehicle.
2. The driver-environment interaction, telling us that certain kinds of visual defects will be a distinct handicap for night driving, and
3. The vehicle-environment interaction, advising us that time and wet roads provide an ideal condition for slippage.

There are doubtless numerous interactions of the driver-vehicle, driver-environment, and vehicle-environment varieties that have not been uncovered in the studies conducted thus far. However, it is with another order of interaction that we might be concerned, which for want of a more definitive map of driver behavior I should like to "house" under the triple-order, or driver-environment-vehicle interaction. Let me suggest three of these generic kinds of interactions, each of which is capable, I believe, in producing through systematic, programmatic research an abundance of specific, measurable interactions:

1. There has been some, but I suspect entirely too superficial, effort to determine what happened to the driver before the accident, i.e., where he was coming from, both physically and psychologically, and where he was heading, again both physically and psychologically. Reference is made not only to the driver who left the loading dock in a rage over some basset or another, or to the driver with fits of anxiety regarding someone he is planning to visit. Rather, the reference is to something considerably more subtle than the foregoing illustrations. It is, in a word, to the intricate, over-burdening social milieu in which we live. In this milieu, for instance, the breadwinner, whether he operates a passenger automobile or a commercial vehicle is irrelevant, is a father, a son, a husband, a member of the PTA finance committee, a tankard with power tools and maybe even a member of his local "great books" discussion group. But wait! He is also a suburb

dwellers, spending more time taking more members of his family to more places, and is concerned, too, with zoning problems, school reorganization plans, and the pros and cons of municipal annexation. So here we observe a man, a vehicle operator being but one of dozens of roles he must play, interacting with a powerful engine in night environments or on secondary roads environments, or both, a man whose multitude of responsibilities and preoccupations are perhaps pushing precariously the bounds of man's capacity to attend adequately to whatever task is at hand. Perhaps this task, call it driving, is punctured by the numerous other tasks to which the individual is addressed psychologically. I am not proposing that drivers have fewer activities, which is clearly not my business, but rather that this complex business of the extensive tasks or activities that most of us hope to manage may, indeed, be the focus of some of the explanations underlying the riddle of driver safety. Specifically, if we could study the individual driver as part of a system of events, including where he was and where he was going when "crash" the accident occurred, then we might be able to isolate a number of factors that seem to interact with each other in such a way as to discriminate between individuals who have accidents (one or more) and those who do not.

2. There are, regrettably, a number of things that people can not or will not regard with concern or with that degree of motivation needed to modify their behavior. I refer, illustratively, to:

- a. Smoking—people continue to smoke despite strong statistical studies linking smoking with cancer.
- b. Fatigue absters—people by and large do not have them, yet they may, feel are aware of the consequences of being without a shelter in the event of a nuclear attack.
- c. Exercise—one hardly does enough, though the relationship between lack of exercise and certain cardiovascular diseases is publicized constantly.
- d. Diet—excessive calories, foods with high cholesterol content, and other dietary defects are purported, again, to be associated with diseases, with reduced longevity, a fact which is apparently disregarded by thousands upon thousands of people who would never admit that they seek illness and shortened lives.
- e. Voting—the failure to cast a ballot on election day is associated with an indifference leading to inefficient government, waste, injustices, but still millions of eligible voters fail to exercise this responsibility.

3. Driving—we are told not to follow behind the car in front less than a prescribed distance under different conditions of speed and other factors, lest we seek collisions, injuries or possibly death, and unplanned expenses, but we still hug the back bumper of the fellow in front. Why? Why? Why?

Quite possibly a kind of triple interaction of person with vehicle with environment is at work in which the individual may simply disbelieve that his operation of the vehicle in a certain way in a particular environment is capable of involving an accident. How can we understand this lack of belief, this ostensibly incredible but unqualified faith the individual has in his skills or in the protective qualities of fate or the environment? Under what conditions are these incongruities entertained? How can such incongruous behavior be remedied? A suggestion will be advanced in a few minutes.

2. It is extremely probable that when an individual learned to drive an automobile this learning took place under an entirely different set of conditions which characterize driving once the skill has been allegedly mastered. Specifically a number of things occur in practice that do not occur during the learning situation. Of course, you are far more conversant with these divergencies than I am, but I should like to mention just one of these, merely to make sure that I have communicated fully the concept I am now seeking to suggest. Let us take speed, as an illustration. While learning to drive, you were rarely if ever in haste, but this is a state of affairs clearly different from those in which we operate from day to day as so-called experienced drivers. And haste, or speed, brings on excessive risk taking, driving too far in too short a period of time, leading in turn to fatigue and an overstraining of already limited sensory capacities. Certainly I am not suggesting that the learner be encouraged to speed while learning to drive, or that he be deliberately placed in a state of fatigue. But I am suggesting that he be over-trained, that he over-learns, so that his knowledge of the fundamentals is so complete that his reactions in dangerous situations are nearly automatic. How can this over-learning, or more efficient learning, occur? How may the entire process of driver training be improved by some significant increment? A suggestion along these lines will be made a bit further along the pike.

The question now arises, what can be done? Granted that the three kinds of interactions mentioned above are capable of giving us more insights into the nature and causes of accidents, how can we introduce this salutary state of affairs?

You will recall that the three generic interactions to which reference was made, are (1) the social milieu in which people, including drivers, are possibly best, provoking for certain people and under certain conditions a set of factors favoring accidents; (2) the incongruity between idealized driving behavior and actual driving behavior; and (3) driver training, or learning.

Here, then, for each of the three hypothesized interactions are some simple recommendations for better understanding the structure of these interactions and for applying this understanding to the process of remediation:

1. A study of the social milieu encompassing the individual is no mere academic search for understanding better the human condition, but rather is capable of teaching us more about the antecedents of poor driving habits leading to accidents. The closest suggestion I have seen for the kind of thing I have in mind here is discussed in a Conference on Traffic Behavior: a summary of the conclusions of a meeting called by the President's Committee on Traffic Safety at Williamsburg, Va. (1959). The Committee's recommendations include:

A. A systems approach to traffic flow and driver behavior.

B. A study of the psychology of driver behavior.

C. An examination of the social content of the automobile.

This last point suggests that consideration be given to the "place of the automobile in American life and in different subcultures that make up America." In order to discover how the automobile is linked with our total pattern of life, "historical, political, legal, economic, recreational, technological, familial." This is patently sensible and a recommendation I am confident each of you would endorse, but is still somewhat short of what I mean by this "social milieu interaction." It is my suggestion that we seek not only to relate the automobile to other facets of life in America, but also to relate the individual as a driver to other facets of his life and then to hunt for those clusters of relationships that distinguish among critical driving behaviors linked with accidents, on the one hand, and with safety, on the other. Putting it differently, I am saying that we need to know not only how the automobile is in harmony or in conflict with facets of our total life pattern, but also to know how the individual as individual fits in with or moves about in this life pattern. The automobile *qua* automobile is a rather sterile object, but the individual's interaction with this automobile in this life pattern—that is another matter. While I recognize that it is not the responsibility of the driver behavior researcher to chart life patterns, but rather that of the psychologist, sociologist, and perhaps the social philosopher as well, I believe that it is the responsibility of the driver behavior researcher to look for driving behavior in the total life pattern, and to be satisfied not with a glimpse of the automobile *qua* driver in this life pattern. Putting it plainly, if accidents arise to some significant degree out of the complexity of modern living, then let us stick our noses into this complexity and see if it can steer us closer to man's misuse and abuse of the automobile.

Another way of getting across to you the concept I am seeking to develop is by considering the predictions that are made for accidents during holiday week-ends, viz., Labor Day, Memorial Day, Christmas, New Year's Day, and Independence Day. Now we cannot quarrel with the fact that each of these national holidays is a chunk of the social milieu comprising the total life pattern in the United States. The "holiday spirit" induces excessive drinking, excessive anxiety to be with loved ones and hence excessive speed, or other excesses or distractions which nibble away at the attention that needs to be given to the task at hand, the driver's interaction with 250 horses or so, a muddy track. However, besides these holidays and the excesses and anxieties they engender, there are other elements in our social environment, things like the groups or associations to which we belong and the thousands of other items filling our heads. These, I submit, are just as capable of pulling us away from the job of attending to driving, as are revelry and fatigue, and in addition these are the kinds of factors that operate 365 days of the year, not only on holidays.

Identify these social elements, compare them one with the other, give them their proper weights, and we might reduce accidents appreciably.

2. The second interaction, dealing with the incongruity between idealized driving behavior and actual driving behavior, suggests incidental to my major thesis that a conspicuous void in safety research, at least with the psychological parts of this research is that to the best of my knowledge there has been no real effort to view driving behavior systematically in the framework of some accepted theoretical position purporting to offer a model for explaining behavior. Theory is suggested, not because it is elegant or fashionable to do so, but rather because it is impractical and wasteful not to seek to view one's data or interpret one's findings in the light of some reasonable theoretical position. Theory gives direction. Theory helps us make sense out of what would otherwise appear to be isolated phenomena. Hence talking in one's sleep is no unexplained mystery if it is viewed as part of some Freudian type of theory seeking to link behavioral responses to subconscious states.

Accordingly, the driver's responses are probably more capable of being understood, forecast, and controlled if these responses are viewed not as isolated bits of behavior flitting with us here and popping in on us there, but rather as part of some reasonable or promising theoretical framework embracing man's behavior.

There are several theoretical positions one might discuss I will select one described by Leon Festinger (1957). He calls it a "theory of cognitive dissonance." This theory maintains that an effective motivating state for impelling the individual to action is the joint appearance, existence, or occurrence of two dissonant, or disagreeable, or incompatible cognitions or bits of behavior. To illustrate, a situation of dissonance is upon the individual who, on the one hand, smokes a couple of packs of cigarettes daily and, on the other, is bombarded with threats of premature death stemming from excessive smoking. Rational individuals are motivated to action when confronted by a situation of dissonance. They seek to bring harmony or consonance to the situation. This can be done either by (1) modifying the individual's behavior or (2) rejecting the cognition which appears to be in opposition to, or antagonistic with, his behavior. In the smoking illustration, dissonance is removable by modifying the individual's behavior: he stops smoking, or by rejecting the cognition: he does not believe that smoking will shorten his life.

Do you see how this begins to make sense in the driving situation? Essentially, poor driving habits, combined with the driver's knowledge of the consequences of these habits, if a situation saturated with dissonance. Unfortunately, the dissonance is removed usually, not by modifying the driver's behavior, but rather by rejecting the validity of the consequences to him (it will happen to the next fellow, not him) of this faulty driving behavior. He says that "I can stop faster than they say," can "therefore," my driving so closely behind the fellow in front isn't such a dangerous practice, or at least for me it's not." What he should do, of course, is remove the dissonance by modifying his behavior: by maintaining a safe or wider distance between him and the fellow in front. But this he does not do? Why? Perhaps his self-image as a driver is too favorable, too unrealistic. If he had better information about his limitations, he too might have such a strong view of his driving capabilities and would hence be more inclined to change his driving behavior in a situation

of dissonance than to reject the facts of what will happen if his behavior is not changed. Another possible reason is that the facts of the case are simply not believable to him. That is, he cannot see that following too closely is an invitation to a collision. Perhaps certain key situations like this could be simulated, or even under careful supervision mildly engaged in, during the learning stage of a driver's interaction with vehicle, road, and other vehicles. Then, whenever stories of the consequences of faulty driving practices are disseminated, he would be reminded of his experiences during the learning situation and hence his belief in the reality of these consequences would be genuine, deep and reinforced. Perhaps then it would be easier for him to achieve consonance by modifying his driving behavior.

Another insight into this matter of credibility may be inferred from research in social psychology (Hovland, Janis, and Kelley, 1953; Janis, and Fishbach, 1953), indicating that "a strong threat may be less effective than a mild threat in inducing the desired opinion change" (Abelson, 1953, p. 16). The studies by Hovland, Janis, and Kelley, and by Janis, and Fishbach, are summarized by Abelson (1959, p. 16):

Three fifteen-minute illustrated lectures were prepared on the topic of dental hygiene. All of them contained information on the causes of tooth decay, and all of them suggested proper ways of caring for the teeth and gums. Each of the lectures differed in the description of what might happen if the teeth and gums were not properly cared for. The strongly threatening lecture included the possibility of cancer among the many consequences of poor oral hygiene habits. The mildly threatening lecture condemned people who neglected their mouths to poisoning worse than a few cavities. The third form of the lecture was intermediate in its degree of threat.

Three groups of students from a high school freshman class were used as subjects. One group for each form of the lecture. A fourth group of freshmen were used as controls. A week before and a week after the lecture, the students filled out a short questionnaire designed to find out about their dental hygiene practices. Right after the lecture, the students filled out a questionnaire which asked them how worried they were about the condition of their teeth.

Findings. The more threatening the lecture, the more the worry that was expressed immediately after it about the condition of the teeth. But when the students were asked a week later how well they were actually conforming to the recommendations of the lecture, the group who had been subjected to the least amount of threat were found to have conformed the most. Those who had heard the most threatening lecture conformed the least. In fact, there were no differences in amount of conforming between this most threatened group and the control group that did not hear any form of the lecture.

The suggestion, "A strong threat may be less effective than a mild threat in inducing the desired opinion change," implies that in the driving situation perhaps one should not "play up" death, or show pictures of twisted steel or mangled bodies resulting from automobile accidents. The principle suggests, possibly, that the mild accident

should be presented, allowing the driver to form a mental picture of the little, everyday inconveniences that can happen and, indeed, may have happened to him or an acquaintance. Stress injuries, not death, dented bumpers, not automobile front-ends resembling a squeezed accordion.

Or at least these are reasonable hypotheses deserving of some hard-headed research brains and dollars.

3. Finally, with regard to the process of learning, driver training, and over-learning, I should like to submit for your consideration the concept of *programmed learning*, about which you may have heard in the context of teaching machines.

To understand what is meant by programmed learning, one must first consider the process of learning. What is learning? We say that a person has learned when some aspect of his behavior has been changed as a result of experience, practice, or training. One outcome of learning is the driver's depression of the brake pedal as he approaches a red traffic signal.

The learning process has been studied by philosophers from Socrates to William James, by educational psychologists like S. L. Pressey, and more recently by experimental psychologists like B. F. Skinner. These men have codified for us the conditions under which learning may occur, endure, and be extinguished. One of these conditions, and there are many others, is the rewarding, or more technically the reinforcing, of particular responses associated with the behavior one is seeking to shape. Hence, in our context we would seek to shape the behavior of maintaining a minimum though safe distance from the car in front. The question then arises if this is the response we are anxious to shape, how may that response be appropriately rewarded or reinforced, in order to assure its recurrence again and again and again? Since the reinforcement of a particular response increases the probability that that identical response will occur again, it then behooves us to search for the conditions, including adequate reinforcement objects and schedules of reinforcement, under which any one of a multitude of driving responses may be repeated.

Now what is programmed learning? Learning material broken up into tiny sequenced bits or frames, more or less approximating chunks that are intellectually digestible by the learner, and organized logically, in deference to certain principles of learning, is called programmed learning. A highly readable book has been recently published (*Programmed Learning, Working Principles and Industrial Applications*, 1961) which summarizes ably, clearly, and sometimes even entertainingly those fundamentals and applications of programmed learning which should be of special interest to you people. (A digest of this book, along with one or two comments of appraisal, appears in a book review prepared by Perloff, 1961.)

In brief, I am commending for your consideration the examination of the concept of programmed learning, with or without the teaching machines which in many cases facilitate this learning, in teaching certain phases of driving as well as for refreshing

courses for experienced drivers. Programmed learning, or I should say, good learning programs, should go a long way in accomplishing better learning, less forgetting, and perhaps more automatic behavior, in situations where responses must be immediate . . . and correct.

In conclusion, while I am not certain whether I have given you men and women anything worthwhile to contemplate, I am sure of at least one benefit: as a result of preparing my remarks I have become a strong safety partisan. If my own behavior and that of those I am able to influence results in an increment of additional safety, then perhaps this presentation will have been worth the while.

(b) THE WIDE ANGLE VIEW

By HAROLD L. SMITH
Harold L. Smith & Associates, Los Angeles, Calif.

In carefully screening our drivers we have to give them physical and visual examinations. We have to teach them how to handle our complex truck equipment, and we have to impress on them the necessity of understanding and adhering to the rules and regulations.

After all that has been done, we're still not satisfied with our accident frequencies, we still have too many preventable accidents. The answer to further improvement lies, in our opinion, in the direction of better driver seeing habits. And in order to get into perspective so that we fully realize the magnitude of the job we face, I'd like to start with some statistics.

The latest *Accident Facts* reveals that, at the end of 1960, we had accumulated 87,000,000 licensed drivers. The population now is 180,000,000; it would seem that almost everyone who is of legal age or in other ways qualified has a license to drive.

In 1960, these 87,000,000 people rolled up a fantastic toll of 10,500,000 accidents.

Who are the people having these accidents? We read a lot of articles. The people that we read most about have a certain amount of drama—the tire peeler, the ninety-mile-an-hour maniac going through the city streets, the guy on the wrong side of the highway on a toll-road, trying to kill people in head-on collisions.

We definitely have people that shouldn't be on the highways, but they only amount to one per cent of all drivers; they are a problem because they account for 15 per cent of the total accidents. It is obvious that our police and courts have a job to do.

We have a small percentage of drivers who are experts. These are the people who, by their habits of driving, can go a lifetime without contributing to the accident toll in any way; but they're only three per cent. Think of this for a moment: we have had the automobile for some 60 years, during which were accumulated 87,000,000 drivers whose collective years of experience would amount to hundreds of millions, and we have only been able to produce

out of all these years three per cent of the driving population in the category of the Mickey Mantle or Sam Snead.

Obviously, experience is not the best teacher. That phrase does not fit the business of driving. People should be made aware of the skill and knowledge that they need to join the ranks of these expert drivers.

The rest of this problem is simple arithmetic. Ninety-six per cent of the people who drive can be called average. For the most part, they're good people with good intentions, that just don't know how to avoid accidents. By their subconscious habits of seeing and reading the traffic signals, every time they get into a vehicle they're practicing for an accident without knowing it.

Most accidents these days involve good driving. What we mean is that most accidents involve good people, not safe driving. Deliberate traffic violations that lead to an accident are rare. Most drivers violate, but few drivers deliberately violate traffic regulations.

According to *Accident Facts*, 9,000,000 of those 10,000,000 accidents that happened last year and the year before happened at speeds below 40 miles per hour. And yet the public in its reading of traffic articles is led to believe that high speed is the big problem. We need more policemen, more radar, more crack-down.

I saw, and I'm sure many of you did also, the CBS report on the 1960 Labor Day weekend accident toll. After I saw it I was sad because I knew that the public, not knowing how to interpret these things, could only conclude after the program that, "That's just what I believed all the time—a teenager, a couple of drunks, a wild, reckless so-and-so and that's the accident problem today."

Unfortunately, this is the impression that kind of reporting leads to with the general public. We're trying to reach people with an intelligent approach to get their cooperation, and make them sit up and listen, and then we give them a distorted picture of the entire situation.

jects in clear detail. You have another set of seeing equipment with which you can look straight ahead at a given point, and, standing with your arms extended from your sides, wiggle your thumbs and see motion.

You are able to move your eyes quite freely because seeing takes place so rapidly—one one hundredth of a second. This enables you, with tiny eye movements, to see a picture broader than a five foot circle at one hundred feet. Perhaps you know that your vision narrows as your speed rises, and your vision disappears completely when you are giving all your attention to one detail.

Let me elaborate. I always have people who can't believe the cone bit; it just doesn't seem possible to them. I suggest that you just pick a word out of the middle of a sentence, fix your eyes and your mind on that word, concentrate real hard, and I'll give you a hundred dollars if you can identify, while you are concentrating on that word the second word to the left or right.

Now that should prove to you that your central vision is only a tiny cone. This doesn't mean that you can't read a whole sentence or a whole paragraph, and people who are trained in journalism can read a whole page in a matter of seconds. This is known as the scanning process. The similarity of driving a motor vehicle is that you must scan as long as your wheels are turning, since the picture is changing every second or split second, and as long as the picture keeps changing you have to be right with it. Those who get into trouble with the motor vehicle let their vision stop while the wheels are still moving.

There's a lot to be learned about the use of seeing equipment. First of all, I assume that all fleet owners are giving their drivers some kind of physical eye test to find out if they have the equipment with which to see. If they need it, get professional help to bring their sight up to the highest possible standard; and then explain to them the equipment they have, and how it is to be used in driving.

We see by fixing our attention on a small part of what we look at. Attention normally shifts from one detail to another causing an automatic eye shift, but when you have a fixed stare it's because some-

thing is holding your attention. A blank stare occurs when your eyes stay longer than two seconds on some detail of no importance.

I believe that the blank stare is the first stage of highway hypnosis. I have nothing to confirm this belief other than observation; it is being researched right now in many areas.

The correct seeing habits will help prevent you from being victims of either the fixed or the blank stare. For example, most people that have driven for any length of time have at one time or another unintentionally gone through a red light. We don't deliberately go through traffic lights without recognizing that this can be a dangerous habit. Usually, when a driver goes through one, if he's caught, or if he's aware of what he did and isn't caught, he makes the excuse, "I didn't see it."

If asked why he thinks he didn't see it, his usual comment is, "I had something else on my mind." Well, that's logical, we've been telling them all these years that these distractions are the causes of accidents, so he thinks it was because he had something else on his mind.

Well, I'll tell you what I think in this particular case. A driver, going down the center of a four-lane street in light traffic, with cars parked on both sides, finds himself half a block from an intersection—where the traffic light is green. Another driver who for some time had remained a block ahead of him at a constant speed now pulls up and stops.

He quickly analyzes the situation and says, "If that fellow decides to back into the parking place ahead of which he stopped, it will throw the front end of his vehicle into my lane and affect his and my safety."

"Or if he's just going to leave his car there and run in someplace, when he opens the door it's going to come over into my lane and affect our safety. Or he could be preparing to make a U-turn, and that would affect our safety."

He's looking at that fellow with that cone of central vision; he has his eyes and his mind on him and his car. He has just covered 220 feet with nobody watching the store. He never uses his horn. I know that.

Well, his buddy didn't do any of those three things—he just sat there.

Our driver got up alongside him, still looking at him, took one final look to congratulate himself on how well he handled that situation, and WHAM, he was in the middle of the intersection on a red light.

All he had to do was tap the horn to let his buddy know that his mind had left the street, shift to him the responsibility, then get those eyes back up to see what color the light was. He spent too much time looking at one thing—his eyes had stopped but his wheels had not.

That cone of sight too often comes to a halt on the vehicle ahead or on the road ahead. Expert drivers almost never let it, average drivers let it occasionally, and poor drivers let it consistently. It's the frequency of that error that either makes you an expert driver, an average driver or a poor driver.

Expert drivers protect themselves by recognizing consciously or subconsciously that there are two basic requirements for operating a motor vehicle. First of all, you have to have a place to put it, so space is essential; and secondly, you have to have visibility. This is basic.

There is a driver right this minute following a truck down one of Chicago's main streets. For fourteen blocks he's been in that spot looking at the brake lights on the truck and making no effort to get out.

Now we can't say that this driver doesn't have space and visibility, because we know he has, but we know he can hardly shave it any thinner. His eyes are leading the front of his vehicle physically by one second. He must keep his eyes on the brake light every second he's in motion.

If he drove that way all the time, he would get about a 20 per cent seeing-quotient, he'd be expected to have about three accidents a year, and he would either kill himself, or the state would come along and take away his license.

The expert driver, on the other hand, is a fellow that can manage for himself in the traffic stream, in any town at any hour, so long as traffic is in motion. In a comparatively few seconds, this fellow places himself in the stream all alone. He doesn't have any fixations that are robbing him of his ability to see, he's free to lift his sights up to horizon and take a time lead of 8 to 12 seconds.

He is looking up and down, back and forth, checking his mirrors—he's on top of the situation all the time. In the next block, he sees a salesman come out of an establishment with a briefcase, walk around, open the door, get into a car and start the engine. He knows exactly where he is going to be about the time that fellow has his engine running, his wheels cut, ready to leave the curb. If we can reduce the frequency of a driver's surprises, we're bringing him up to the threshold of accident-free driving for the rest of his life.

This is what expert drivers do—they keep a stopping and swerving space open as much as possible. By consciously watching other people they learn how to predict the actions of those people who could cause a conflict.

Accidents follow a consistently simple pattern and anything that has such a simple pattern as a driver accident must have a simple solution. We think we have the simplest program in the world, but still it takes a lot of pick and shovel work, and a lot of sweat and tears, to get out and get the job done.

There is no short cut to teaching people how to drive better. You've got to get out on the streets in the vehicle to do the job, but otherwise the program is very simple.

Five simple rules follow. The first is aim high in steering. Correct steering requires use of a high-aim steering formula. This calls for repeated glances well ahead at the center of the intended driving lane. The vehicle will then follow in the middle of this path. The same rule applies when turning a corner.

Use of high-aim steering at night is also essential. When no other cars are in the immediate vicinity at night, check beyond your own headlight ray for dark shapes or outlines. With oncoming cars check lane position while they are still a long distance away.

Low-aim steering is often the reason why the driver has difficulty in holding his position in the center of his lane. Here are some earmarks of the driver using low-aim steering: (1) hogs left side of lane, (2) reels too far left to avoid object on right, (3) swings to right in turns, (4) at night, apt to use upper beams in overtaking, (5) sits

on edge of seat peering at front of bumper. (5) fails to reduce speed under conditions of poor visibility.

Rule two is how to get the big picture. This involves being able to see all the roadway scene and consider the objects immediately ahead as only a small part of it. The eye should sweep over the scene for a full city block, or for a half-mile on rural roads. The sharp central vision is not permitted to fix on anything for more than an instant.

To help drivers get the big picture, a new formula has been developed which includes three basic procedures: sweeping the eye over the scene, keeping proper space between vehicles, and getting into the broad viewing habit.

The first procedure, sweeping eyes over the scene, pausing only for an instant on any one object, results in the driver's being able to (a) observe problems facing other drivers in time to avoid being forced into abrupt changes in speed and direction, (b) make a better check at intersections, using repeated glances, and (c) pick a safe time to look away from the road.

The driver who doesn't sweep his eyes over the scene, but limits himself to one small part of the traffic picture is guilty of small-picture viewing. The penalty for this poor seeing habit is practically certain to be a serious accident. Clues to small-picture errors should be learned, as they are a tip-off to the incorrect seeing habits that cause accidents.

Important clues are: close following of other vehicles, hard stops or turns, traffic delays due to poor positioning or timing of moves, delayed response in reactions to signals of other drivers or in observing traffic situations.

The second procedure in the big-picture viewing formula requires proper spacing between vehicles. The rule is to allow more than one car length for each ten miles per hour. This rule must be observed in order to give other seeing rules a chance. As a result, drivers (a) are able to see the big-picture, because the scene ahead is not blocked out by a vehicle immediately in front on which attention must be concentrated, (b) have time for making proper responses, because space is provided in which to move safely while observing and adjust-

ing speed or action, (c) allow adequate braking distance as would be necessary if there should be an emergency ahead.

The third big-picture procedure is to build the ground-viewing habit. Glancing at the ground beside the front wheel of other vehicles before overtaking to pass or before meeting on-coming cars is a valuable habit. Any right or left swing of the wheels tells you instantly that the vehicle is about to veer. At the same time, relate the position of the other vehicle to adjacent fixed objects, to aid in judging its speed.

Rule three is to keep your eyes moving. Several key points must be observed. First, build a habit of shifting the eyes every two seconds. Keep glancing near and far, and to each side. Constant eye movement prevents the loss of fringe vision, which occurs when the central vision fixes on an object. Second, keeping your eyes moving calls for you to dispose of eye-holding problems quickly by adjusting speed, changing lanes or signalling, or all three if needed.

Dispose of the problem of conflict—don't romance a potential hazard. A real one may exist elsewhere in your path. The habit of disposing your eye-moving problems promptly has these results: (a) it forces an adjustment of speed to visibility along the driving path, (b) it prevents overconcentration on one part of the scene while moving blindly into an accident-producing situation, (c) it prevents the over-relaxing that invites sleep or highway hypnosis and provides the slight tension necessary to clear vision.

Third, keeping your eyes moving permits a check of mirrors at least every five seconds. The instant a conflict is indicated ahead, double check the rear for clearance before applying brakes or changing lanes. The habit of frequently checking in the rear-view mirror pays off because the driver (a) is aware of other vehicles and can judge speed and position of traffic behind him more efficiently, (b) can more quickly determine his clearance on swerves, etc., (c) knows when to signal drivers behind in order to alert them.

Rule four is continuously leave yourself an out. There are three major guideposts you use to accomplish this: First, strive for better spacing by moving forward or dropping back, pick a lane when a choice

of lanes is legal, with the best view of traffic and with the least chance of conflict from the front, rear or side. Allow extra space ahead when boxed-in with no swerving space on either side, on slippery or irregular road surface. Avoid a very restricted type of view that obscures the path ahead, or presence of a vehicle close behind.

The second principal in leaving yourself an out is to adjust speed to visibility. Reduce speed when rounding curves, topping hills and when darkness or other hazards lower your visibility; also at blind or unmarked intersections when no other vehicle will yield right of way to you. Speed must be appropriate to visibility.

The third principal is leaving yourself an out in doubtful situations by reducing speed and touching brakes. Children, animals and absent-minded pedestrians are common causes of doubtful situations for the alert driver. Other examples of doubtful situations: (a) traffic light is still green, ready to change; be able to stop the instant the yellow shows; (b) drive watchfully when near any fixed hazards; (c) cautiously pass a parked car with a driver at the wheel, who could pull suddenly into the traffic lane; (d) watch out for on-coming vehicles that may turn left in front of your vehicle, and (e) for drivers approaching too fast at an intersection.

Rule five is to "make sure they see you." This means that you must be certain that any pedestrian or other drivers who might cause a conflict have seen your vehicle. Proper communication with them is essential to safe driving. The experts signal others of his intentions early, while he still has the time and space in which to avoid them if they do not respond.

There are three situations in which other drivers or pedestrians are most apt to become a hazard to you.

(1) They are in the path ahead and could cause a conflict. Signal immediately if they do not recognize your right-of-way. Signal with a tap on the horn, or a flick of the

lights, or both. Make certain they stabilize in response to the signal.

(2) A driver might cause a conflict from his position behind your vehicle. If a sudden slow-down is unavoidable, warn the driver in back immediately. Get your brake light on early to warn the drivers behind you. If turning, get in the proper lane early, signal well ahead of the maneuver.

(3) A conflict is always possible when meeting or passing another vehicle. Check the big picture. Is there anything that might cause its driver to change plans? Signal before passing if there is any doubt that the driver may hold a steady position. Once he stabilizes, get your eyes up in the center of the road ahead and pass briskly.

The conflicts occurring in the daytime are most frequently one of the following types:

(1) Slow down or stop and being hit from the rear.

(2) Start up, and being struck from the side or the rear.

(3) Crowding or blocking other vehicles when changing lanes.

The common conflicts at night that result in accidents are usually:

(1) Striking an object in a forward path.

(2) Swerving from the driving path into the other lane or off the road.

Here's the acid test of an expert driver—drives five to ten years without even a tire skid or a violent swerve to escape an accident. The experts do it, you can too. If you practice this system of expert seeing, you can acquire the skills necessary to pass the acid test. Accompanying these skills must be a full understanding of your physical limitations—of the rules and the control of the vehicle.

Finally, the determination to drive as well as possible is mandatory—if your skill, understanding and experience are to make you an expert driver. The art of expert seeing can be summed up in the five seeing steps. Use them as the framework on which your expert seeing habits are built.

THE STRAIGHT LINE OF COMMUNICATION

By HIDEYA KUMATA

Assoc. Prof., Communications Research Center
Michigan State University, East Lansing, Mich.

Last year, I suggested that the problems of attitude change hinged around a firm understanding of communication as a process. We pointed out some of the important elements in this process and their relation to safety messages. I'd like to amplify those remarks today by concentrating upon some of the common faults committed by people engaged in trying to change other people's behavior.

1. *We take a very short run view of our efforts in trying to change safety attitudes and behavior.* We know that there must be preparation for change and that change is apt to be a long and tedious process where those who must change do not see immediate benefits. Even in those instances where the outcomes seem clearly advantageous to the people adopting change, adoption and system may be slow in coming. Hybrid corn, something farmers now take for granted, took almost 13 years for farmers to adopt. This in spite of extensive work by agricultural extension workers.

The point here is that those of us who want change may take a very short run view of our efforts. We perhaps need a different time perspective in talking about attitude change efforts. This is especially true for campaigns which are not seen by the people as particularly crucial.

2. *We need to understand the communication process involved in adoption of new practices or change of ideas.* We plan campaigns based on what we think are the needs of those who are to be affected. We assume that if we get through with information, the sheer weight of evidence will be enough to persuade. Thus we concentrate on ways of getting people exposed to appeals. That this may be a grossly oversimplified view of the world has been demonstrated more than once.

People do not simply absorb statements of fact. They consider who has made them, they define the situation in a particular way, they interpret facts. This interpretation is made to fit existing beliefs of the individual.

If the person needs help in interpretation, he will turn to others like him for discussion, not to an outsider such as persons conducting the campaign.

People who have studied change programs tell us that a person goes through the following stages before adopting the new idea: he becomes aware of the problem and interested, he tries out the recommendation in one way or another, he evaluates the results in his own way and then finally makes his decision. Different styles of communication accompany these phases.

Awareness and interest is often accomplished through mass media campaigns and through the efforts of experts and workers for the campaign. Evaluation and adoption is accomplished mainly through face-to-face discussions with friends and neighbors. The convincing, the persuading is most often carried out by insiders, not outsiders.

3. *We do not take informal leaders into account in planning campaigns.* It is natural, I suppose, that we define leaders in a certain way. These are people of public prominence or high status people who are influential in a formal way. Most certainly these people are needed to give legitimacy to any action program. However, if it is true that the core of the problem of having people make up their minds lies in the intimate friendly discussion sessions which people have, then attention should be focused also on leaders of such discussions. These may not be people in the public eye and they may not have positions of formal leadership.

4. *We communicate with the wrong people to carry our message.* Organizations which push safety campaigns recruit membership from certain segments of the organization or the community. These people are the active well-informed, the better educated. Volunteers for the campaigns come from these people. The credibility of these people may not be as high as one might hope among those groups which have to be convinced in order to make campaigns successful.

5. *We do not train our communicators.* Well intentioned people often fail. This is not because their motives were awry or that they lacked enthusiasm, but that they have not been prepared adequately. For example, some notions of basics in persuasion—one sided versus two sided arguments, the efficiency of participation, the effect of source credibility, emotional versus rational appeals, the effect of varying strength of appeals, the notion of perceived rewards—might be included in some training sessions.

Mobilization of resources means more than getting enthusiastic endorsement by people willing to help out. It means careful preparation of campaign strategy and tactics which include training.

6. *We overlook prevailing values and attitudes some of which we have helped to establish.* Our safety campaign is but one item in the communication atmosphere. How do we fit our message into this mass of messages? We meet ourselves in some of our campaigns. What is vexing is that when we do meet ourselves, we find that some of our campaigns of the past are back to frustrate us. We have molded some of the attitudes which must be changed in order for the new campaign to succeed.

7. *People make up their minds on their perceptions of the situation, not necessarily on reality.* The impact of our educational system is to teach disciplined rationality. The products of our educational system often fail to show such training. However, we plan in terms of a rational approach. Then we wonder why people do not become convinced. Let me repeat—statements of fact are not in and of themselves persuasive. Conclusion drawing by people does not necessarily follow established formal rules of logic. If we, then, can get some forewarning of the perceptions of people, then we can plan more efficiently.

8. *We find it easy to talk to those who are already favorable.* A false sense of elation is easily obtainable in campaigns. Our circle of discussion usually is with like-minded persons. Those who are already for the point of view do not need more convincing. It is those who are opposed, or more important, those who are apathetic who need to be taken into account. In terms of energy expenditure, it is uneconomical to concentrate upon those who are firmly opposed. Attitude change campaigns

seldom convert firm opposers. The apathetic, the passive, the mildly interested provide the greatest opportunity.

However, the apathetic and the passive are not reached through mass media campaigns. The mass media attract those who are already interested and support the issue and do not attract others. It is direct face-to-face campaigns which have maximum effect with these people. But, if we have a tendency to talk longer, to talk more easily with those who are sympathetic to us, then we will slight our attempts with those who have little interest.

9. *We evaluate campaigns in faulty ways.* If we are to learn from experience, we must ask the right kinds of questions of the right kinds of people. Evaluation of either successful or unsuccessful campaigns often is done by talking to people like ourselves. We pool our ignorance and guess at why particular segments did not support the issue. We seldom go to these segments to get some feedback. Experience is a good teacher only if we get the right kind of experience.

10. *We overlook the importance of the competition.* The people directly opposed to us are easy to spot. We can pass them off as crackpots or the lunatic fringe, but their efficiency means that we ought to give more study to what they are doing. In addition to the direct opposition, we might at some time take a look at the demands of the individuals made by other organizations and agencies. These are competitors in that we are both vying for attention and time.

11. *Verbal support is not the same as action support.* To take a person from verbal agreement with your position to some action is a difficult task. We often end our efforts with verbal agreement. When the time comes for action, we are disappointed. Some means of commitment to action is necessary beyond verbal agreement. In our training sessions, some attention should be paid to this aspect of moving people to change.

These are but some of the factors one could mention in connection with safety campaigns. In the final analysis, the success of any program depends upon our ability to take the recipient's point of view keeping in mind that all of us view the world through our perceptions of what it ought to be rather than what it really is.

TRANSIT SECTION

PROBLEM OPERATOR CLINIC

Moderator—ELMER R. SCHUEMANN, Supt. of Transportation & Safety, United Motor Coach Co., Des Plaines, Illinois.

Clinical Experts: G. WRAY THOMAS, General Supt., Surface Depot Operations, Philadelphia Transportation Co., Philadelphia, Pa.;

GEORGE A. RILEY, Asst. Supt., Operating Stations, Chicago Transit Authority, Chicago, Ill.;

THOMAS L. WARD, Supt. of Training, Milwaukee & Suburban Transport Corp., Milwaukee, Wis.;

D. L. WILLIAMSON, Supervisor, Training & Accident Prevention, Cleveland Transit System, Cleveland, Ohio.

Case History . . . Driver, 51, with the company 16 years had compiled a satisfactory record. He developed a drinking problem which seemed to be off the job, but later alcohol on his breath was noticed while he was working. He was discharged.

Comments . . . Mr. Ward commented that his company had had relatively little experience with the drinking problem, but that they had found rehabilitation to be unsuccessful. Mr. Williamson felt the drinking driver should be given a second chance. Mr. Riley thought that few drinking drivers could be rehabilitated, but that they could be placed in non-driving jobs. Mr. Thomas was opposed to any kind of rehabilitation program. He said his company fires drivers who are found drinking or drunk on the job.

Case History . . . Operator with 17 years of experience had a below par accident record. There were occasional complaints of recklessness filed against him. It was discovered he was using paragon. He was warned and given a second chance, but he failed and was discharged.

Comments . . . Mr. Williamson agreed that the man should have been fired or given a non-driving job. Mr. Ward questioned the effect on the other employees of the driver being given a second chance. Mr. Riley felt that the man should have been discharged on the first offense.

Case History . . . The 60-year-old operator of a one-man streetcar had a series of

rear-end collisions. He had had 28 years experience on his particular job and a satisfactory accident experience.

Comments . . . Mr. Thomas said he would give some consideration to the man's experience, and would suspend him for from 5 to 7 days for negligence. Mr. Riley would consider the man's service and the pension fund he had built up. He would give the man a medical exam. If it revealed nothing the instruction department would follow-up with a refresher course. Mr. Ward thought his performance should have been checked on before a series of accidents developed. Mr. Riley suggested that once-a-year physical exam would be a good thing for older drivers. Mr. Schuemann stated that tests showed that the man's reflexes had slowed down and that he had a serious heart condition.

Case History . . . Operator with 22 years of service as a streetcar and bus motorman (He had proved unsatisfactory in a supervisory role) had a series of accidents spaced over a six-year period. There was no recklessness involved. It seemed to be a matter of poor judgment on the driver's part. Driver did have a mild heart condition, but there appeared to be no connection between this and the accidents.

Comments . . . Mr. Riley suggested retraining. Mr. Williamson also suggested retraining to correct the driver's bad habits. If this didn't work out, discharge should follow. Mr. Thomas agreed that retraining

should be given, but if trouble continued and the man's health was okay, he should be fired. Mr. Schuemann then explained that the man suffered from a mild form of epilepsy. When this was discovered he was transferred to a non-driving job.

Case History . . . Operator with 36 years of experience and an overall good record had a slight accident. Investigation showed he never had gone as long as three years without an accident. They were never serious and there was no pattern.

Comments . . . Mr. Williamson said this situation should not have been allowed to go for so long. The operator should have been given retraining and had a vision check. Mr. Thomas thought the driver had earned some consideration for the 36 years and should have been urged to retire. Cited from the floor was similar case. The driver

had been so well-liked by passengers that he was distracted by conversations.

What to do with drivers who have heart conditions serious enough to prohibit their continuing to drive was a problem considered by the panel. The panelists agreed that every effort should be made to place them in non-driving jobs within their company. But this is not always possible, and sometimes they must be discharged.

It was suggested that driving record reports be sent to the operator's home, where his family could get a look and possibly influence him to do a better job. One case cited was where an operator's father had been a bus driver with an excellent record. The father helped the son (who did not have a good record) and improved his driving greatly.

WHAT OPERATORS THINK ABOUT ACCIDENTS

By BURNS M. FRANKLIN

Dir. of Training, St. Louis Public Service Co., St. Louis, Mo.

The employee-employer (or supervisor) relationship in industry has gone through three definite psychological stages. These might be designated as the "or else" era, the "powder puff" era and the "sandwich" era.

In the "or else" era the corrective procedures for failure of employee to meet standard of job performance were simple. The boss or supervisor who was not satisfied with the employee's job performance or behavior simply told the employee he must do a better job "or else." This approach was based upon the threat of job security. It was an effective means until jobs became more plentiful, then the erring employee simply beat the boss to the punch by leaving.

Then came the "powder puff" approach. This suggests that the supervisor "condition" criticism with praise. By praising the worker, said the psychologist, "you create a receptive attitude, that will make your criticism more effective." This was an improvement over the "or else" negative ap-

proach based upon the fear of insecurity. But it wasn't long, however, until the employee expected criticism to follow every praise. In fact, the effectiveness of any bona fide attempt by the supervisor to praise an employee was defeated by the mental block created in the employee's mind as he attempted to anticipate what the "old man was leading up to." Such conditioning destroyed the effectiveness of constructive corrective measures and reduced the value of sincere praise.

So the psychologists then recommended the "sandwich" technique. First you praise—then criticize—then praise. This is a softer approach than the others but the interviewee continued to build up defenses to meet the corrective suggestions. When they do not come out, the employee does not accept the praise wholeheartedly and misses the point of any corrective suggestions.

There exists a false opinion that the sole reason for an effort towards self-development is the desire for recognition. It is true that every person appreciates

recognition of a job well done. This is an outgrowth of the inner force, found in each organism, to express all its capacities. But all too few are willing to work up a sweat to get recognition.

There are forces at work that condition this desire for recognition. Such things as lack of a feeling of belonging, safety, respect, love, self-esteem, and many other needs. Unless these are satisfied they have a tendency to overpower any desire for recognition.

Most of us have believed for a long time that we Americans have the desire and the capacity to overcome our weaknesses. Recent surveys have indicated that we just don't understand Americans. Some report that three-fourths of the workers in industry today have small capacity, much less a desire for genuine self improvement or self direction. An alarming number don't want to improve themselves if it requires effort. Few want jobs that require responsibility. Employees it appears want a safe place to work, job security and some one to do their thinking. They wait for someone to tell them what to do. They avoid any decision-making.

When appraising an employee's job performance we must recognize these factors. We must not approach the interview as a means of warning him that he must do better, or to prepare him for a better job, or to change his personality. Our objective is to get the employee to improve his present job performance by recognizing his weak points and realizing what he must do to attain this improvement. Our approach on a recent safety project was to get him to talk about his job performance so he would ultimately recognize his operating faults. We wanted him to take a good look at himself. The counselor was not to give advice or make any other comments unless it was requested.

Even when the operator requested help the counselor was advised to try to get the operator to think his problem through by using the retort technique and ask questions, such as—"What do you think you should do?"—"What is your idea?" The interviewer must attempt to get the operator to make his own decisions. Once a person understands his own wants and needs, his own reaction to work, his own reaction to authority, his own moods and habits, his

own abilities and disabilities—the more openly and clearly he can look at his faults and the more likely he will come up with effective corrective measures.

In January of this year we experienced a sudden increase in accidents due to collisions between company vehicles, collisions with fixed objects, and run-away buses caused by faulty parking. When the increase continued through February we began a campaign to correct the trend.

We assigned an instructor to each division, with instructions to talk with each operator about this increase in accidents. The object was to get the operator to give his opinion of the cases for his accidents and to offer explanations for accidents caused by other operators.

The interviews were to be scheduled at a time convenient to the operator, on his own time, and in a private place. Every precaution was made to secure clear, accurate and unbiased statements from the operator.

The instructor was cautioned to keep his ideas and judgments out of the interview. His job was to listen, with an open mind, and to concentrate on understanding the operator's statements, ideas and attitudes. The instructor was to remain in the background and be extremely careful to avoid doing anything that might influence the operator's statements.

This is a difficult assignment because every person has a tendency to want to control the discussion, offer suggestions, especially when the ideas expressed do not conform to the observer's opinions.

The instructor made it clear to each operator that anything said or discussed would be kept strictly confidential and would not be placed on his record or brought to the attention of any other person. It was emphasized that personalities would remain anonymous in so far as these interviews were concerned. The instructor, of course, knew each operator he interviewed. He was familiar with his record and knew something about his behavior pattern. He was instructed to ask questions only when necessary to stimulate discussion. He was to ask questions only about the way the operator handled the incident and the results. He was never to question the operator's intentions nor compare him with other operators.

Each instructor was cautioned to avoid any tendency to "play God" by assuming himself capable of analyzing each statement and incident with psychological perfection. He was also cautioned to avoid giving a "halo effect" to his report by letting his personal feelings or friendship with the operator influence his observations.

During the interview the interviewer was instructed to make mental notes of specific items the operator mentioned. Immediately following the discussion he made a written report of his observations and a personality rating for each operator.

The reports made by two instructors indicated they had done a thorough and objective job of interviewing. We selected at random 244 reports made by these two instructors as a study sampling.

Thirty-seven of the operators in the sample group had three or more accidents in 1960 and they were arbitrarily placed in a "poor" category. The remaining 207 operators were considered as "good" operators. The reports were then reviewed, the personality ratings tabulated and instructor observations recorded.

A comparison of the personality rating of the two groups indicates there isn't a significant difference between the personalities of the "good" and "poor" operators. A higher rating in mentality was given to the "good" record men. The good operators were credited with better ability to express themselves when talking. However, in factors which we usually agree as having a major influence on behavior, such as aggressiveness, poise and maturity, judgment, and job enthusiasm the ratings placed them about equal. This however should not be cause for alarm or used as a basis for forming judgments. We must remember that all of these men were subjected to selective procedures when employed and this would tend to eliminate extreme variability.

Actually, about the only thing gained from those personality ratings was an indication that the interviewer making the rating did a fairly accurate evaluation of each operator.

The operators' most frequently mentioned comments were grouped according to their relationship with operational practices. Some that were mentioned only a few times were recorded because the lack of operator's concern seemed to add to their significance.

The impact of these comments becomes impressive if we remember that they are voluntary statements—made without suggestion, direction or force.

One rather startling revelation came from these interviews. We had, we thought, made every operator conscious of the increase in the number of rear end collisions, collisions with fixed objects and run-away buses. However, the interviewers were startled by the number of operators, estimated to be as much as 20 per cent, who knew that there had been greater number of accidents at their division but they did not know that these three types were the ones that caused the increase.

An encouraging observation was the reaction of the men when they discovered accidents of these classifications were prevalent. The operators were unanimous in their opinion that they were inexcusable. Even operators who had had accidents of this type stated they just "goofed." They, quite humanly, at first offered alibis and excuses but eventually concluded that if they had been more alert the accident could have been avoided.

Any one who has had contact with mass transit operators will be aware of their concern for more running time and longer layovers. Any discussion with them about accidents, sooner or later, brings up these two items. However it seems from these observations that their "off guard" statements indicate that they do not really believe these are the causes. The operators with poor records gave less credit for these factors as contributing to their accidents as did the good operators.

The men indicated some concern for the heavy traffic on the streets, and especially the increase in the legal speed limits. We now have different specified speed limits in St. Louis. We operate on some streets that have speed limits of 15 mph, some 25 mph, some 30 mph, some 35 mph, and some 40 mph, and on expressways 55 mph. A street may have a district of ten or twelve blocks where the legal speed is 35 mph, then drops to a speed of 25 mph. This has caused them some concern because motorists, at present time are not familiar with the break points in the districts and travel at speeds that do not conform with the legal rate.

4. Annual age examinations. 5. Special examinations.

The pre-employment examination is one of, if not the most important type of medical screening we have. The examination of the applicant is just as important as that done on the employee. Let me make it clear here that employment of the handicapped is very important and necessary, in general. However, in public transportation companies where the safe operation of vehicles is paramount there is very little opportunity to place these people.

Our aim is to select the most nearly perfectly physically and mentally fit individual. This is done by taking a careful medical history and doing a detailed physical examination, including a urinalysis test.

The additional examinations which we found helpful in selecting a healthy applicant are X-rays of the chest, and electrocardiogram, plus additional laboratory work which may be indicated in certain cases. Also a very important part of the pre-employment appraisal is the record of the individual's military service medical record. This is of great help in evaluating the applicant's ability and physical status. Sometimes applicants misrepresent their medical history by deliberately falsifying their record, especially in cases where the medical condition is not detectable by routine physical examination. The following illustrates the point:

We request a military service medical record. Our pre-employment medical record shows a "No" answer to a question "Did you ever receive or apply for any disability pension or compensation for any injuries or diseases?" but a report from military service shows applicant is receiving disability.

Examination of the employee who is presently on the sick list gives the doctor the opportunity to make as many examinations as may be necessary. This type of examination is very important because sometimes unsuspected conditions unrelated to the original illnesses are discovered. For example, an employee may sign off with pneumonia and then report to the medical department several weeks later for a return to duty examination. On examination it is revealed that the employee has diabetes or high blood pressure. Unless these conditions can be corrected, the whistle is blown and

the employee is transferred from an operating job to a non-operating job.

Compensation caves—all of the employees, no matter what the injury is, providing they have been off more than seven days are given a thorough examination. Any previously unknown disease found by this method is treated in the same way as described above.

The annual or periodic examination is very important and different from the preceding types of examinations. This is true because the examinations are made on employees who are working daily. They are not on the sick list nor have they been injured. Yet surprisingly enough we find certain conditions which are disqualifying for operators. In these instances the employee may be temporarily disapproved, placed on the sick list and under the care of his own family doctor. He is also checked in the medical department at regular intervals to determine his fitness to continue working.

There are several possibilities in all these cases under discussion. First, medical treatment may bring improvement so the employee may safely resume work; or secondly, it may be necessary to transfer him to a non-operating job if good recovery is not obtained; and finally, there is the employee who becomes progressively worse and is unable to do any type of work. In such instances the employee is placed on the total and permanent disability list.

Some of the more common disabling conditions discovered on the medical bus examinations are hypertension, heart cases of all kinds, particularly coronary, diabetes, psychiatric cases and defective vision.

Special examinations—may be requested by the department head whenever there is anything unusual about the employee's ability to continue working. For example, when an employee has frequent accidents or complaints of blurring of vision, or has a blackout on the job, he is sent to the medical department for an examination. The medical department will sometimes discover in these cases any one of the defects mentioned above.

In conclusion, we find that frequent periodic physical examinations are important and necessary to disclose physical defects. It should be emphasized that these exami-

nations are not done primarily to disqualify the employee. On the contrary, they are done to improve the general health and thereby keep the employee at work longer. We feel very strongly that early diagnosis and prompt efficient treatment of the dis-

eases or defects represent the basic principles of our program. This plan benefits the employee and the employer. The final analysis and evaluation of these examinations tells the medical department "when to blow the whistle."

Front Section

INCREASING THE OCTANE RATING OF YOUR SAFETY MEETING

By FRANK BURROWS
Field Service Dir., Citizens Traffic Board, Chicago

I want to create an enthusiasm within you so that you will increase the octane rating of your safety meeting by using what I call "advertising gimmicks." May I refer to them here as enjoyable, methods of improving your "raising up." This richer mixture will add more miles per gallon to your safety message.

I hope to impart to you a variety of ideas to advertise good safety tips. This collection of ideas first began to accumulate when I was asked to lecture at Northwestern University Traffic Institute. Since a large part of my work consists of lecturing before all kinds of groups, old and young, large and small, a need to do something other than just talk safety arose. I discovered, and I am sure that you have, too, because it has happened to you, that a large part of the audience does not receive the safety message, so I began to incorporate little attention getters to hold interest. In other words, I enriched the mixture and the audience received the message more strongly.

To understand how an idea, or gimmick, should be used, one must keep in mind three definitions which when used through all your safety planning will enable you to attain the maximum results. The three definitions are:

Safety—Doing the "job" the right way. Job is anything a person undertakes to do—standing, sitting in a chair, driving a car, running a machine, peeling potatoes, improving your safety record.

Safety Education—The art of making a man want to do what he ought to do.

Safety Program—To create an appetite in people who are not hungry.

Keep these definitions in mind. Observe the next ten minutes of my lecture. I am going to demonstrate how I tell safety . . . (here the audience viewed a short part of a traffic safety lecture in which several visual aids, gimmicks, magic and humorous stories were used as an example of what adding a touch of glamour to a safety message means) . . . and that is the way I attempt to present the safety message to the people here in our area.

You know, sometimes those of us who have a safety message to sell overlook the obvious. Sometimes we create our own illusions. Our own most trying problems are often the result of self-deception. And are often the result of self-deception. And too many people selling an intangible safety message are prone to assume that the doors are locked against them when the difficulty is actually a mental block. Remember Harry Houdini? He was an ingenious entertainer.

Behind Houdini's skill as an illusionist was a profoundly scientific mind and a keen grasp of the application of modern mechanics to intricate physical problems. He matched wits with locksmiths and prison wardens, and never failed to escape within the time limit. But he almost failed on one occasion by overlooking the obvious.

The warden who nearly outwitted Houdini used a simple artifice. He placed Houdini in an "escape-proof" cell and closed the door. Houdini tried all his ingenuity on the lock but could get no action from the mechanism. A few minutes before the deadline, in desperation, he tried the knob of

the ponderous door. Presto! It opened. It hadn't been locked in the first place.

Use gimmicks, humor, or anything else you can think of to enrich the mixture and add more gallons to your safety mile.

Let me encourage you to use some of these ideas. You will enjoy it more, and you will be creating an appetite in people who are not hungry by making them want to do what they ought to do—that is, to do every job the right way.

Look at some of the ideas I have here. You could build a whole routine around these gimmick types of glasses. "Goo-goo" glasses—funny to look at aren't they. Goggle glasses—make me look sick, don't they. Open and shut glasses, and what about this pair here that makes me look as if I'm pop-eyed. When I'm wearing these I could tell you that I want to see what's actually causing accidents. See what you're doing, you're laughing at what I'm doing and how I look while I have these glasses on. But think, while you're laughing you're listening to my message. This is what you have to do with your safety program. People will enjoy it more, and they will receive more from it.

How about these articles here. I have a little police badge, a little boy's police cap, his gun, his whistle and his handcuffs. Anyone of these items can be tied into a safety message. You can tell the audience while twisting the handcuffs that with their cooperation you can "handcuff" a certain cause of accidents. With the gun you could pretend that you are out "gunning" for crime and that is the thing that causes accidents in a specific field. Blowing your whistle can be tied in with blowing the whistle to stop accidents, and so forth. You could build a whole safety message around dollar bills that come in many shapes and sizes—large comic dollar bills, little dollar bills, rubber dollar bills. With a little bit of imagination you could tie in the cause of accidents or stretching your money, stretching money through the prevention of accidents. See what I mean, ladies and gentlemen. Such "gassing up" will enrich the mixture and give your safety program extra mileage.

Earlier I was able to plant a piece of corn in everyone's pocket or purse. I have developed a little SAFETY SIX PACK in

order to help you plant a safety message in everyone's mind. This six pack contains six items which have retention value and are very inexpensive. The six items are:

1. A piece of string—"string along with our message of safety."

2. A kernel of corn—a pocket or change purse reminder of the need for cooperation of the individual in the safety program.

3. A safety pin—to be pinned on one's clothing as a reminder to keep one's guard up against accidents and be safe at all times.

4. A band-aid—to be placed on the back of the hand or dashboard of a car as a reminder that traffic laws or good safety rules practiced will hardly ever result in an injury serious enough to need more than a band-aid for repair.

5. A rubber-band—"you must stretch your efforts for safety."

6. A lollipop—"don't let accidents make a 'sucker' out of you. Work hard to 'lick' the problem of accidents."

Let me give you an idea of how to think about sparking up your safety message. I have here what's called a "Hypo-Phony." This looks like a regular doctor's syringe, and, as you can see, it looks as if I am drawing blood right out of the air. I saw this article in a drug store. It costs a buck and a half. I felt I could use it in a safety message, so I purchased it. Shortly thereafter, I received a telephone call asking me what the title of my lecture to be presented before the Woman's Auxiliary to the American Medical Association would be. I looked at this toy on my desk and told the caller that the title would be "You Can Get Blood Out of a Turnip."

I made the turnip resemble their impossible task of selling safety. I then proceeded to tell them how to use good programming to sell safety, and I concluded my speech by saying that if you use the right tools, the right safety programs, etc. you can do the impossible. Of course, the right tool for extracting blood is a doctor's syringe. See, I inject my syringe into this bloodless turnip and extract blood. This is the only time in my life that I ever received a standing ovation for a lecture and it cost me a buck and a half.

If you are interested in enriching your

mixture, if you want some additional ideas, please drop me a card or telephone me. Use one or all of the ideas, enough so that the audience will receive your safety message. Remember, the purpose of these ideas is to add color, humor and enjoyment to your safety talk. So often, selling safety is a thankless part of your program because the recipient knows it all and he mentally tunes you out.

The ideas expressed here and the ones I'd be happy to send you are audience tested. If used as suggested or as you see

fit, they will make your safety lecture a little unusual. This alone will create an interest in the audience. Some of these ideas, by nature, will bring a chuckle or smile to the faces of those who observe them. This laughter tells you that they are listening. It is not directed at you but at the "gimmick" which emphasizes your point.

See for yourself how an audience's attention will improve when you improve your mixture. Remember, increased attention will mean increased mileage toward your safety goal.

SCHOOL TRANSPORTATION

DRIVER SELECTION IS IMPORTANT

By JOHN B. MURRAY
Specialist, Pupil Transportation, Office of Education,
U. S. Dept. of Health, Education, and Welfare, Washington, D. C.

Each and every morning during this school year, approximately 13 million children across the Nation will be driven to school by one of the more than 160,000 school bus drivers currently employed by our local school districts throughout the country.

Sometime between 7:00 and 8:30 tomorrow morning thousands of yellow school buses from Texas to Minnesota and from Rhode Island to Alaska will begin their daily runs with a school bus driver behind the wheel.

Recognizing the vital role that these 160,000 school bus drivers are to play in delivering their precious cargoes safely to school, it is fair to pose the question—How were these drivers selected for their jobs?

1. Were they selected primarily because they were able to underbid others in the community for the position?
2. Were they selected solely because they may have had important connections with the influential elements in their community, and thus their jobs represent "political plums"?

3. Were they selected primarily as a result of the practice that we hear some communities follow of giving these positions to persons with "strong backs and weak minds" or what is probably worse, people with both "weak backs and weak minds" because the community felt that there was no other type of work they were capable of doing and that the job of driving a school bus would at least give them a steady although meager income and keep them busy?

Yes, to be perfectly frank, probably this fall some drivers in some localities were selected on one of these bases or some similar basis equally as deplorable and not necessarily on their overall qualifications. On the other hand, in all fairness we would also have to concede that the number of

drivers selected solely on such a basis and not on their overall qualifications would represent a relatively small minority, and that driver selection of this type is fast disappearing as states and local districts tighten their policies and standards in regard to school bus driver selection.

Realizing that the lives of children are in jeopardy whenever a careless or incompetent driver gets behind the wheel of a school bus, we can take comfort from the fact that the vast majority of our school bus drivers are selected with reasonable care and in accordance with sound and defensible standards.

After all, our school bus drivers across the nation have established a remarkable safety record over the years and although it is generally conceded that school bus transportation does have an enviable safety record, this fact in and of itself is no guarantee that we can maintain this record without constant vigilance and progress. It is in this sense, then, and in no way critical, that my following remarks on the selection of school bus drivers are directed.

Driving a school bus is more often than not a low paying part-time job requiring only a few hours of work each day. In the majority of the cases it represents a side job; and as a result school bus drivers are usually recruited from a variety of local sources: farmers or ranchers, garage mechanics, gasoline station operators, store clerks, truck drivers, school teachers, barbers, housewives, ministers, and in some states high school students, represent in many cases, the local groups from which many of our school bus drivers are recruited. Usually the individuals secured from these sources possess only those basic qualifications which, in all too many cases, those in positions of authority feel are in themselves sufficient to drive a school bus, (1) sound moral character, and (2) an under-

standing of the elementary rudiments of driving a motor vehicle.

Even today we have those school officials, I am sorry to say, who do not accept the fact that selecting a school bus driver should demand relatively as much time and attention as the selection of any other member of the school staff including the classroom teacher. It would be incomprehensible to most school officials to think of hiring the first person who walked into their office and asked to be hired as a teacher without first checking his credentials, previous experience, and qualifications.

In hiring a school bus driver, however, we are too often guilty of hiring the first available applicant in spite of the fact that we realize no school bus is safe in the hands of a driver who is physically and emotionally unfit, or who fails to follow sound driving practices; and, as a result, school bus drivers are in many cases ill-suited for their responsibility.

There appear to be two major aspects to the problem, apart from the continuing and competent supervision, of providing the best possible school bus drivers, (1) the recruitment and selection of qualified people; and (2) providing adequate training programs specifically designed to prepare these people for the job to be done. Although recruitment, selection, supervision, and training are in a sense inseparable, I will attempt in as far as possible to confine myself to school bus driver selection in as much as other speakers on the program are scheduled to speak to us on recruitment and school bus driver training programs.

Securing responsible and qualified drivers is not necessarily a new problem in the field of school transportation. Even before the advent of motorized transportation in this country when horse-drawn carriages and wagons were the conveyances commonly used to transport pupils to school, both the personal qualities of the driver and his control of the pupils being transported as well as his skill in handling his team were matters of concern and as such received attention in certain localities.

You will recognize, I am sure, this concern and also agree that the following comments taken from a report by O. J. Kern, superintendent of Winnebago County, Illinois, schools at the turn of the century

has a certain familiar ring. In this report Mr. Kern describes his visit to several newly centralized schools in North Eastern, Ohio.

"So we drove on to North Madison, in Madison Township, where three wagons are used. On our way there we saw the first wagon. We stopped at the farmhouse and talked with the driver. He carried all the children from one district, about twenty in number. His route was five miles long. That is to say, starting at the first home to pick up a child until he arrived at the central school was five miles. Then he drove back home after delivering the children, thus covering ten miles in the morning. Of course he traveled the same ground after school, thus making 20 miles in all. He got \$1.50 a day for his work. We asked him if he made any money at it. He said he did, as he was all the time and labor of himself and team. We asked him if he had any trouble with the children and replied none. He said he was employed by the township board of education, who put him under bond to be careful with the children; to have a safe team; to provide a suitable wagon, covered and provided with curtains, and containing soap-stones and lap robes for the severest weather. We asked what objections the parents along the route had to the new plan. His reply was that the only objection was on the part of two or three at the beginning of the route, as they had to get their children ready somewhat earlier than they used to when they went to the district school. Of course the children had to be ready when the wagon came. He aimed to start at 7:30 and arrive at the building not later than 8:15. Thus there were no children tardy; none came with wet feet or clothing; the attendance was greatly increased and much more regular. The driver believed the movement had come to stay; that the people would not consent to go back to the old way."

Kern goes on to describe school transportation during that period at another school district he visited on this trip:

"The wagons are provided with curtains, lap robes, soapstones etc. for severe weather. The board of education exercises as much care in the selection of drivers as they do in teachers. The contract for each route is let out to the lowest responsible bidder, who is under bond to fulfill his obligations. The drivers are required to have children on the school grounds at 8:15 a.m., which does away with tardiness, and to leave for home at 3:15 p.m. The wagons call at every farmhouse where there are school children. The children thus stepping into the wagons at the roadside find no tramping through snow and mud and the attendance is much increased and far more regular. With the children under the control of a responsible driver, there is no opportunity for vicious conversation or the terroring of the little ones by some bully as they trudge homeward through the snow and mud from the district school."

This account of pupil transportation in Ohio at the turn of the century would indicate that many of our current problems in school transportation such as securing

well-qualified drivers are by no means new ones, but rather in one form or another have been with us for over 70 years.

The seriousness of the problem of securing well-qualified school bus drivers has been compounded in recent years, however, as a result of two developments. (1) The rapid growth of school transportation in this country (for example, in 1923 approximately 800,000 pupils were transported in the United States as against about 7 million in 1950 and more than 13 million this year with an estimated 15 million by 1965), and (2) the increased complexity of our transportation technology today, along with the side effects of this technological development in terms of the complexity of the vehicle itself, increased speeds, and our innumerable and varied traffic and highway problems.

There is no doubt about it—the job of driving a school bus today calls for physical, mental, and emotional capabilities of the very highest order. In order to secure qualified school bus drivers possessing these capabilities, it is necessary as an initial step to (1) establish adequate standards that all drivers are required to meet prior to employment, and (2) rigidly adhere to these standards.

The major responsibility for selecting drivers rests, of course, as it should upon the local school authorities. It is conceded, however, that the states have a major responsibility in exercising a reasonable degree of leadership, authority, and control in this area, and that adequate general standards and regulations must be promulgated by the states, preferably through the state education agency, to guide local school boards in this important function. It is recognized, of course, that local initiative should be constantly encouraged to exceed state requirements whenever possible.

The fact that school bus drivers in all of the states are now required to meet at least some standards indicates that the states do recognize this responsibility. Although there are wide variations between the states, both as to the specific items covered and the extent these items are covered in state standards, there does appear to be a definite trend to require that drivers meet more rigid standards.

The following excerpt taken from a recent

report by the Georgia State Department of Education points out the immediate result this has had in one state.

"In 1959, the State Board of Education tightened up its policies regarding physical examinations. The Board ruled that drivers over 65 could not be employed; nor could a driver with a physical handicap. These newer and more stringent regulations were adopted in order to insure greater safety for the 428,079 Georgia children who get on 1,927 school buses each day to ride to school and home again. When the new regulations were put into effect and more rigid tests required, 322 previously employed drivers failed because of such physical defects as missing limbs, eye or ear handicaps, heart ailments or other disabilities. As a result of the rigid new requirements, school bus accidents in Georgia involving the drivers' judgment were reduced from 28 per cent to 18 per cent."

Generally speaking the standards for school bus drivers in a majority of the states include the following elements: age, physical condition, experience, and character, among others.

Age Requirements

Minimum Age. In 1960, 16 states¹ required their school bus drivers to be at least 21. One state, Rhode Island, required drivers to be at least 25, while in South Dakota, a 15 year old could legally drive a school bus.

In 10 states,² 16 year olds could legally drive a school bus, 5 states³ allowed 17 year olds to drive school buses, and 15 states⁴ allowed 18 year olds to be employed as drivers. One state⁵ required school bus drivers to be at least 19, while Hawaii required all school bus drivers to be at least 20.

Maximum Age. In regard to maximum age requirements, the 1960 survey indicated that 39 states have no specific maximum age limit for school bus drivers. One state⁶

1. Arizona, Delaware, Illinois, Indiana, Maryland, Massachusetts, Michigan, Missouri, New Jersey, New York, Ohio, Pennsylvania, Tennessee, Utah, West Virginia, and Wisconsin.
2. Alabama, Iowa, Kansas, Maine, Nebraska, Nevada, North Carolina, Oklahoma, South Carolina, and Virginia.
3. Arkansas, Colorado, Florida, Mississippi, and Texas.
4. Alaska, California, Connecticut, Georgia, Idaho, Kentucky, Louisiana, Minnesota, New Hampshire, New Mexico, North Dakota, Oregon, Vermont, Washington, and Wyoming.
5. Montana.
6. Delaware.

sets the maximum age limit for drivers at 70, 4⁷ at 65, and 3⁸ at 60.

For all new drivers, Tennessee has an age limit of 55. Virginia requires annual physical and licensing examinations for all drivers over 65 and West Virginia requires a semiannual physical examination for all drivers over 50, also persons who have reached their 51st birthday and have not previously driven a school bus may not be employed in West Virginia.

As we all know, this problem of realistically fixing age limits for school bus drivers is a most difficult one indeed. There are two opposing points of view in regard to the minimum age requirement. There are those on the one hand that support the view that every driver should be at least 21 and some would say 25. While according to others, the employment of minors as bus drivers is fully justified on the basis that pupil drivers, if carefully selected and trained are fully as capable as the average adult driver. The safety records established by pupil drivers in such states as North Carolina tend to give support to this point of view.

On the other hand those who advocate that every school bus driver should be at least 21 contend that: (1) adult drivers are more likely to maintain higher standards of pupil behavior, and (2) driving a school bus requires a "sense of responsibility or degree of maturity" which is seldom possessed by pupil drivers.

Setting definite maximum age limits also presents a problem. It is known, of course, that with advancing years (1) driving skills can decline, (2) sight and hearing can deteriorate, (3) reaction time can decrease, while (4) coordination, general health, and physical stamina are more likely to decline.

Apparently the important question is not always how old a particular driver may be, but rather how safe and reliable he may be. Safety and reliability, however, do not necessarily correlate with age, and it is generally agreed that the periodic physical examinations should be required more often of the older driver.

In spite of the conflicting opinions which

7. Iowa, Louisiana, Maryland, and New Mexico.
8. North Carolina, North Dakota, and Wisconsin.

exist in regard to minimum and maximum age limits for school bus drivers, it appears that two conclusions can be advanced: (1) state minimum and maximum age limits for school bus drivers are essential; and (2) in those states not bound by statutory provisions in this area, state departments of education should exert leadership in setting up reasonable requirements.

I would like to say, at this point, that I am not at all sure that it is wise for the states to attempt to set forth by statute a comprehensive detailed set of standards for school bus drivers. It may be a far sounder policy for the states to enact broad general statutory provisions which in turn place upon the state education agency the responsibility for developing rules and regulations asserting that these rules and regulations will, in fact, have force and effect of law governing all phases of school transportation including the qualifications for school bus drivers.

I hope you will keep this distinction in mind as I discuss various requirements for school bus drivers and the possibility of strengthening these requirements in certain areas.

Physical Requirement

A majority of the states at the present time require school bus drivers to meet specific physical standards and to undergo a physical examination in order to operate a school bus. As would be expected, however, there are wider variations among the various states in regard to the kind and extent of these physical requirements.

In a number of states the physical qualifications are written in very general terms, while in others the physical requirements may be limited to a single item such as requiring all drivers to submit to a tuberculosis test or an eye examination. States desiring to strengthen their physical requirements for school bus drivers would do well to consider at least the following physical requirements as an absolute minimum for all school bus drivers.

A complete annual physical examination by a physician approved by the local school authorities on the basis of a standardized state form, developed by the state education agency with the advice of state medical authorities, and in cooperation with other appropriate state agencies.

This annual physical examination for school bus drivers should be based on adequate minimum state standards and should at least include such items as: (1) an acceptable degree of sight and hearing, (2) the physical strength necessary to handle a school bus with ease, (3) possession and the full and normal use of both hands, both arms, both feet, and both legs, (4) freedom from any communicable disease, and (5) freedom from mental, nervous, organic, or functional disease likely to interfere with safe driving, such as epilepsy, tuberculosis, paralysis, insanity, diabetes, abnormal blood pressure, and heart ailments.

In addition to this compulsory annual physical examination, the local school authorities may wish, and should be encouraged, to require additional examinations during the year as the need may arise.

Character

Most of the states, either by statute or by regulation, appear to support the premise that since transported pupils will spend considerable time each day under the jurisdiction of a bus driver, his character and personal habits should be carefully assessed prior to employment.

Generally speaking, state requirements specify that individuals employed as school bus drivers are (1) to be of good moral character and reputation, and (2) to abstain from the use of profanity, narcotics, and alcoholic beverages. I am not sure a general requirement of this type in itself, without a prescribed procedure that local school officials may follow in determining whether an applicant's character measures up to the state requirement, is sufficient.

The recommendations of the 1959 National School Transportation Conference on the selection, instruction, and supervision of school bus drivers support this point of view. The Conference recommended that "states should require that prospective school bus drivers be selected on the basis of a specific character standard," and local school authorities should apply this standard in employing school bus drivers.

Among the elements that should be considered in setting a character standard are: (1) reliability and dependability, (2) initiative, self-reliance, and leadership, (3) ability to get along with others, (4) freedom from use of undesirable language, (5) personal

habits of cleanliness, (6) moral conduct above reproach, (7) honesty, (8) freedom from addiction to narcotics or habit-forming drugs, and (9) freedom from addiction to alcoholic beverages or liquors.

The Conference also suggested that valuable information about a prospective school bus driver may be obtained by checking court records, personal references, credit bureaus, and state and federal fingerprinting records.

In regard to driver selection at the local level, I believe the point should be continually stressed that:

(1) A properly developed application form can serve as a valuable tool in the selection process.

(2) Personal references or other information of this type which can provide clues to the applicant's personal habits and past work record can be of considerable help as a first step in driver selection.

(3) A thorough investigation of drivers before they are hired is not only extremely important—it is essential.

(4) Finally, a personal interview can prove to be extremely helpful in crystallizing the accuracy and validity of the data collected on a particular applicant and in evaluating his overall desirability as an employee.

Experience

There are also wide variations among the states in regard to experience requirements for school bus drivers. A number of the states simply specify that drivers must file evidence of experience, must hold an operator's or chauffeur's license, or have a satisfactory driving record. Often the state indicates a specific number of years of satisfactory driving experience which may be necessary in order to qualify. A few states have no specific experience requirements at all.

One might question, of course, whether or not the mere experience of driving an automobile, in and of itself, qualifies an individual to drive a school bus. There appears to be considerable merit in the procedure followed by a number of states of specifying that prior to employment (1) new drivers be given a performance test in a school bus, and (2) the applicant's driving record be free of serious traffic violations

and accidents due to negligence. If we firmly believe driving a school bus requires special skills and information, then the answer is, of course, on-the-job experience and training for new drivers prior to assignment.

I would like to touch very briefly on only two of a number of other important considerations in school bus driver selection.

(1) Few school employees are in as unique a position as the school bus driver to influence the community's confidence and respect in its school system. A school bus driver's personal conduct and daily performance as observed by the pupils, parents, and the taxpayers of the community can have a serious impact one way or another on the school's public relations in the community.

(2) A school bus driver can have either a positive or negative influence on the young minds which are under his charge for a considerable portion of the school day: his attitude toward promptness, the manner in which he drives his bus, his respect for laws and regulations during the daily run, the manner in which he handles discipline, his personal habits of speech and dress, his self-control and emotional stability, all can have considerable, immediate, and perhaps even a lasting influence on the attitudes and behavior patterns in this particular age group.

As Walter M. Gordon, head of one of the nation's largest school bus operations with 42,000 riders, Baltimore County, Maryland, so aptly and humorously put it:

"What we are looking for in a school bus driver is a paragon, a diplomat, a public relations man, a nursemaid, a Prussian general for discipline. He must be able to keep both eyes on the road, watch for traffic situations with considerably more care than the average motorist, and at the same time control 30 or more squirming, yelling, energetic, hell-bent kids who are behind his back."

And I might add, we want his services for only a few hours per day at a salary often in no way commensurate with his responsibility.

A report by G. I. Fletcher, an agent for the Massachusetts State Board of Education in 1906, on the quality of the drivers in that state in 1898 might well be used, with certain modification, to sum up the situation as it exists today in regard to the quality of our school bus drivers across the Nation.

"Nearly all of the drivers are reported to be trustworthy. Some are said to be as good as let one get. Some are of doubtful qualifications. All committees and superintendents regard trustworthiness and fitness as the driver as of the highest importance. One committee says: 'Only such persons should be employed as we would trust with the care of our own children.' A few committees say that they have to watch drivers of conveyances and hold them in strict account. Some complain that children are not under proper control in the vehicles; but, upon the whole, there seems to be a good degree of satisfaction with such vehicles and drivers as have been employed."

A HYPOTHESIS ON LICENSING THE SCHOOL BUS DRIVER

By THEODORE KOLE

Senior Research Associate, Executive Asst.
Drivers Safety Service, Inc., New York City

From its beginnings in 1840 in one school district in Massachusetts, transportation for students to and from school has grown into the massive enterprise of today. A 1960 publication reports that although only one in every four students relies upon school sponsored transportation, there are nearly 11 million young people riding school buses each day.

Elaboration on the need for safety in school bus programs is certainly unnecessary. There is no question but that the prevention of accidents should be a high priority goal. However, it would appear that adequate measures are not being taken toward this end. As clear evidence of this, national statistics with only 42 states reporting in 1960, concerning school bus accidents,

show more than 2000 injured and 177 killed in a total of 8900 accidents. In Illinois for example, the average accident rate per vehicle in 1958 was greater for school buses than for all other commercial vehicles!

Recognizing the extensiveness of school bus programs throughout the country, and with the evidence of a great number of accidents and injuries occurring, it is clear there is a need for a concerted effort toward maximizing safety within these programs. However, it would appear that in most instances, greater attention is paid to the mechanical condition of the vehicle than to the driving skills of the operator. Federal and state laws exist pertaining to the physical characteristics of the vehicle. Only limited regulations exist concerning the adequacy of the driver.

The annual cost in 1959 of operating the many school bus systems in the nation was over 400 million dollars. The separate school bus systems, functioning within the unit of the school district, are, in most cases, maintained and financed by the local board of education in cooperation with various state agencies. In fulfilling their responsibility of adequately maintaining these programs, several states have established screening, training, and refresher programs for their drivers. There is a noticeable lack of any such preventive measures in the majority of states, however.

Corrective or punitive measures taken against drivers after the occurrence of accidents do serve as a form of preventive action against future accidents. However, it is the thesis of this paper that the more positive approach of taking preventive measures prior to any traffic offenses or accidents represents a far superior method. Thus, the general hypothesis is that a strict and comprehensive licensing examination will reduce school bus accidents.

Hiring and Screening

As was true in the case of national statistics on the number and severity of accidents in which school buses were involved, information concerning the screening and training procedures for school bus drivers, as they exist in the various states, is quite difficult to obtain. Those states which now have, or which are presently establishing extensive programs in this area do report on their efforts and findings. However, the majority

of states in which programs of wide scope do not exist, report limited data concerning the procedures they employ.

The hours for school bus drivers are typically not those of the usual nine to five working day. They are shorter and are divided over the day according to the arrival and dismissal time of the schools. The salaries paid to these drivers must be expected to be concomitant with these limited hours. It is safe to assume that few adults could support themselves and their families on school bus driver salaries. To supplement the salary, the driver may either be employed in some additional capacity by the school district, or he may hold another part-time job. In any case, due to the nature of the job and its obvious disadvantages, a large proportion of school bus driver applicants tend to be retired persons, students, housewives, or persons seeking only short-term employment. These applicants are not likely to be the best safety risks.

One problem which is highlighted by these conditions is that a good many of the older persons who have been retired from full-time employment and who now serve as school bus drivers are no longer in their physical prime. Unfortunately, attention becomes focused upon this issue only on the occasions when tragedy occurs as a result of the sudden physical incapacitation of the driver. While the question of physical fitness is especially pertinent with reference to the older driver, it is also of serious importance for all drivers. Illinois, for instance, requires not only a doctor's confirmation of the applicant's physical fitness but also yearly examination during the term of employment.

Part of the screening procedures in both New York and Oregon include careful physical examinations. Of course these examinations are usually designed only to detect gross physical deficiencies such as a serious heart condition which would make the individual a risk on the road. Such check-ups in all probability, seldom determine those psychophysical capacities of a driver (reaction time, depth perception, and field of vision) which are equally important to the safety of the vehicle and its passengers.

As one way of meeting this salient problem of the lack of qualified and physically fit drivers, North Carolina has inaugurated a program of hiring and training students

as drivers. At present, over 90 per cent of the school bus drivers in the state are high school students. The training program for the prospective drivers include 12 hours of classroom work as well as a minimum of six hours of actual road training. This instruction is beyond the ten hours of training required for all driver education students in the state. Such a program as this has obvious benefits in providing the opportunity for close supervision of drivers, quick availability of substitute drivers, and greater selectivity in the hiring of personnel.

Initiated by a safety specialist for a local General Electric plant transportation system, another program involving student participation rather than student drivers, was instituted in the school districts in at least one county in Indiana. Two or more students on each bus are trained to provide assistance to the driver in emergencies. This precaution is, of course, taken to avert the disasters which can occur when the driver is unable to handle or maintain discipline with all of his passengers, or to maintain control of this vehicle in a critical situation or when he becomes physically incapacitated.

West Virginia focuses upon the technical ability of the driver and submits each of its applicants to a six hour training program. This is followed by a written examination and an on-the-road test of the applicant's skill in handling the bus. All training and examinations are supervised by the state police force.

In-Service Training and Testing

In Michigan, the in-service training program consists of a 12-hour intensive instruction program held for all school bus drivers in the state. Small subsistence money are paid to those drivers in attendance for the two day program. The instructors for the training sessions, each of whom have been trained in highway safety measures, are brought in from several of the colleges and universities in the state.

A somewhat similar program has been established in New Mexico. It is reported that each year 700 to 800 drivers attend the Annual School Bus Drivers' Institute for training in safety techniques. Refresher courses of the same nature are also carried on during the year in areas where accidents or violations are reported.

A program in Oregon was instituted by the State Department of Education in cooperation with the Division of Motor Vehicles. The essentials of this program are similar to the elements noted above. Oregon requires special school bus driver license. A team of trained inspectors review safe methods of school bus operation and traffic laws and regulations with the drivers. Satisfactory fulfillment of the training sessions as well as certification of physical fitness are required before the license is granted by the state.

As evidence of the efficiency of a screening program, after all school bus drivers in Georgia were tested, the rate of accidents due to errors on the part of the driver were reported to be "cut in half." Furthermore a total of 252 drivers were disqualified from operating school buses as a result of the tests.

There have been numerous reports in the past several years which contain recommendations for national and/or local school bus driver screening, training, and supervision programs. Most of these include mandatory yearly physical examinations as well as some form of training for the driver in safety precautions to be taken on the road. A recent report recommends, beyond the physical qualifications, requirements for high standards of moral character, emotional stability, knowledge of traffic laws and regulations, skill requirements in the handling of the school bus, and experience in driving. Although such a program would indeed be of great value, careful research must precede its establishment. New Jersey, continually active in the general field of accident prevention, is now in the process of doing such research and establishing such a program.

New Jersey Program

In building a comprehensive program in highway safety, the state of New Jersey recognized the need for rehabilitative (corrective and preventive) supplements to its punitive (law enforcement) measures. In 1952, the first Accident Prevention Clinic was established with Drivers Safety Service acting as technical consultants. Since then, the program has grown to comprise eight clinics located throughout the state. The multiple purposes of these clinics include determining those psychophysical and psy-

chological characteristics of the driver which tend to be related to accident involvement, informing the driver of whatever psychophysical deficiencies exist, advising him of how to compensate for or correct limitations, and imparting to him through counseling, more positive attitudes toward law enforcement, traffic regulations, and safety precautions.

In general, drivers who had more than two reportable accidents or who have accumulated a given number of violation points, or who have been convicted of driving while intoxicated, are required by the state to participate in the program. Each subject is given a thorough psychophysical examination, including tests of visual acuity, field of vision, reaction time, depth perception, night vision, color vision, and glare recovery.

Two psychological examinations are also administered to each subject, although at present, the results of these tests are used for research purposes only. Based upon a comparison between the subjects' scores on each of the psychophysical tests and minimum standards which have been established as the basic requirements for safe driving, recommendations are made to each driver as to what he should do to compensate for whatever deficiencies may exist. This processing, including an initial interview and a final counseling session, usually takes about two hours. In cases of extreme psychophysical inadequacies, the driver is referred back to one of the state licensing centers for re-examination and possible action on suspension of his license unless corrective steps can be taken.

Of the 28,834 drivers processed by the Accident Prevention Clinics from September 1952 through June 30, 1959, only 2,469 have continued to reoffend; that is, be involved in either accidents or violations. This represents reoffenses for only 8.5 per cent of the total group of subjects. As a further check on the efficiency of the Accident Prevention Clinics, research is currently underway to determine the reoffense rate of a control group of drivers, who, though "eligible" for action, were not exposed to Accident Prevention Clinic processing.

New Jersey has had a limited examination program for school bus drivers for some years. Until November, 1960, the following procedure was used in school bus

driver licensing in New Jersey: Together with the initial application form, the subject submitted a medical report stating that his physical condition was satisfactory. He also had to satisfactorily complete a test measuring his knowledge of traffic laws. Visual acuity and other psychophysical tests were then administered to the applicant (Porto-Clinic). The final step was a road test on which the driver had to demonstrate his skill in operating a school bus.

In November 1960, however, Drivers Safety Service was asked to cooperate in setting up a new testing program for school bus drivers. At present therefore, applicants are required to go through the complete Accident Prevention Clinic processing. Any subject who falls below the established minimum standards on any three psychophysical examinations is unlikely to be granted a license.

One of the basic problems in establishing a research program within such a practical setting is meeting the needs of the various agencies connected with the program. The Division of Motor Vehicles and the Department of Education, both agreed on the need for psychophysical test minimums as part of the criteria for school bus drivers. However, although comprehensive recommendations have been prepared by Drivers Safety Service, no standard has, as yet, been set on the psychological or emotional qualifications of these applicants. There is now, in progress, a psychological test program as part of the school bus driver screening.

The tests currently used in the program were originally developed by Drivers Safety Service for use in a rehabilitation program which is supported, in part, by a Public Health Grant [RG-6296 (R1)]. The program concerns itself with the rehabilitation of that 8.5 per cent who continued to reoffend following their Accident Prevention Clinic processing. The results of these test administrations to school bus drivers will be used initially for research purposes. As indicated, no applicant is currently denied a license on the basis of these psychological tests.

Table I indicates the extent of yearly accidents, injuries, and death in school buses since 1953. The information has been assembled in such a manner that individual bits of information can become meaningful. For example, Column Three (number of ac-

School Transportation Section

Year	No. of States Reporting	No. of Accidents	Per Cent of Increase	No. of Injuries	Per Cent of Increase	No. Killed	Per Cent of Increase
1953	30	2,941		701		4	
1954	34	4,316	47.77	983	40.22	8	100
1955	36	5,144	18.36	1,304	32.87	18	125
1956	38	5,809	12.95	1,295	0.81	5	-72.22
1957	37	5,953	2.47	1,171	9.07	7	40.0
1958	40	7,186	20.71	1,580	34.92	29	314.28
1959	39	7,152	-1.47	2,039	29.64	13	82.73
1960	42	8,906	24.55	2,067	1.32	19	-64.15

idents) shows a steady climb in accidents—1960 has almost three times the number of reported accidents as 1953. The number of injuries has also increased at the same rate for this period.

Although it is obvious from the above table that the number of accidents and injuries has increased, the number of people killed each year has fluctuated, so that no pattern is discernable. This is hardly any consolation to those families affected by this tragedy.

We note from this table that:

1. There are still no uniform or complete statistics available on school bus accidents.

2. The number of deaths and injuries incurred in school bus accidents does not follow any pattern other than a steady increase—thus suggesting that more intensive research efforts are needed with an emphasis on the vehicle operator.

The following table compares accident and injuries of New Jersey and national statistics. No tabular presentation is needed for the number killed during this period since school bus deaths in New Jersey for this same period totaled only three. What is particularly interesting in this table is that the number of school bus accidents and injuries have increased at approximately the same rate as the national figures.

TABLE II
A Comparison of National and New Jersey School Bus Accidents and Injuries

Year	No. in N. J.	ACCIDENTS		No. in N. J.	INJURIES	
		Per Cent of Increase	National		Per Cent of Increase	National
1963	44	2.22		23	53.08	
1954	54	21.72	47.77	23	0	40.22
1955	54	3.57	18.36	33	43.47	34.61
1956	56	77.77	12.92	41	84.84	0.81
1957	73	23.55	2.47	58	45.90	9.07
1958	101	38.33	20.71	69	22.47	54.55
1959	78	22.77	0.47	34	50.72	28.64
1960	129	65.38	24.55	103	202.94	1.32

In terms of percents, it would seem that New Jersey statistics are even more erratic than the national figures. The above comparison will only become meaningful when the licensees under the new program have had sufficient driving exposure to allow for meaningful statistics. Since the new licensing program has gone into effect, the school bus drivers who were processed under this system have had a total of four school bus accidents and only one private car accident, while at the same time, these same drivers have been ticketed for only five moving violations, with none of these

on a school bus. Thus, it seems likely that some aspect of clinic processing is having the desired effect. It would also appear the bulk of the school bus accidents are being contributed to by the drivers who received school bus licenses before the new procedure was put into effect.

One cannot yet draw any final conclusions since sufficient time has not elapsed for these newly licensed drivers to have had sufficient exposure. However, we hope that they will follow a pattern similar to other Accident Prevention Clinic processed subjects.

TABLE III
An Age Comparison of the Accidents and Violations of Three Groups of Drivers

Age	Per Cent of Sample			Per Cent of Violations			Per Cent of Accidents		
	New Jersey	Accid. Prev. Clinic	School Bus Drivers	New Jersey	Accid. Prev. Clinic	School Bus Drivers	New Jersey	Accid. Prev. Clinic	School Bus Drivers
17	1.8	0	0	3.7	0	0	2.9	0	0
18	1.8	2.2	0	2.2	0.7	0	4.8	1.7	0
19	1.8	4.8	0	2.8	2.2	0	4.8	4.2	0
20-24	8.7	17.0	13.7	13.0	15.2	18.97	18.2	25.9	36.09
25-34	23.3	34.6	32.4	26.9	43.4	43.97	27.6	34.7	36.15
35-44	28.1	32.2	30.2	23.0	28	21.12	30.9	22.9	36
45-54	19.4	10.1	17.1	15.2	6.8	12.14	12.9	5.9	11.34
55-64	11.4	6.3	6.0	8.7	2.9	2.64	6.2	3.9	2.4
65 plus	6.1	1.8	1.6	2.5	1.2	1.4	2.0	.8	.4

Table III is designed to show the accident and violation behavior, in terms of age, of three groups of New Jersey drivers. Columns two, five and eight represent a sample of 503,144 drivers selected randomly from the total population of two and one-half million licensed drivers in New Jersey. Columns three, six and nine represent 1,304 drivers—a sample of the 30,000 Accident Prevention Clinic processed subjects. Columns four, seven and ten deal with the total number of new school bus drivers processed up to October of this year.

No results are recorded for the "under 20" age group—the minimum age for a school bus license in New Jersey is age 21. It is interesting to note that the age range 20-34 of school bus drivers has more accidents and violations than either Accident Prevention Clinic subjects or a sample of all New Jersey Drivers. These facts suggest that:

1. Drivers between the ages of 20-34 ought to be excluded from operating school buses, or

2. More detailed attention should be paid to the past accident and violation history of all applicants, especially 20-34 year olds.

It should be noted that the records recorded for the school bus driver population are for their pre-processing behavior—that is before they received a school bus driver's permit.

The next table presents the pre-licensing records of the newly processed school bus drivers and their post-processing behavior. Table IV indicates, with limitations, a decrease in both accidents and violations. However, we should not be misled by these re-

sults. The time interval between their processing date and the search of their records for post-processing behavior has not been long enough to draw any positive conclusions.

TABLE IV
The Accident and Violation Records of School Bus Drivers, Pre- and Post-Processing
N = 322

ACCIDENTS		Post-Processing	
Pre-Processing	46	Post-Processing	8
VIOLATIONS		Post-Processing	
Pre-Processing	144	Post-Processing	15

The following four tables compare by per cent of failure, three groups of drivers, on various psychophysical tests. In Tables V (A, B, C, and D) the New Jersey or control group were accident and violation free for a period of three years, before being processed. The Accident Prevention Clinic subjects are a sample of those usually processed for accident involvement. The school bus driver group represents the total number processed, to date.

Each table may be read in the same manner. For example, in Table V A, for subjects aged 58 plus, the controls and school bus drivers had no visual acuity failures, whereas ten per cent of the Accident Prevention Clinic subjects failed on left eye acuity.

The four tables provide some interesting data concerning New Jersey school bus drivers. In terms of visual acuity, field of vision and complex reaction time, the school bus drivers have fewer failures than either of the other two groups. Day depth perception is the one area they fall below the controls and "accident repeaters."

TABLE V A
A Comparison, by Per Cent of Failure, on Visual Acuity, of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	0	0	0	0	0
26-34	0	3.12	0	0	3.12	0
35-44	0	1.58	1.25	1.58	3.17	2.5
45-54	0	3.03	0	1.51	4.54	1.44
55-64	0	3.22	2.43	3.22	4.06	0
58 plus	0	10	0	0	2.33	0

TABLE V B
A Comparison, by Per Cent of Failure, of the Field of Vision of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	0	0	0	0	0
26-34	1.56	1.56	0	1.56	3.12	0
35-44	.79	1.19	0	1.58	4.24	0
45-54	1.51	4.92	0	1.51	6.43	0
55-64	0	15.22	0	0	18.39	0
58 plus	3.22	12.66	9.09	3.22	11.66	0

TABLE V C
A Comparison, by Per Cent of Failure, of the Complex Reaction Time of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	0	0	0	0	0
26-34	4.6	10.15	2.56	4.6	10.15	2.56
35-44	7.92	12.30	0	7.92	12.30	0
45-54	9.09	16.66	1.44	9.09	16.66	1.44
55-64	17.74	24.19	0	17.74	24.19	0
58 plus	42.33	46.66	16.66	42.33	46.66	16.66

TABLE V D
A Comparison, by Per Cent of Failure, of the Day Depth Perception of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	37.5	36.28	0	37.5	36.28
26-34	3.12	34.5	44.87	3.12	34.5	44.87
35-44	7.9	43.65	51.25	7.9	43.65	51.25
45-54	9.09	43.18	42.30	9.09	43.18	42.30
55-64	29.02	38.70	53.17	29.02	38.70	53.17
58 plus	13.33	66.66	54.55	13.33	66.66	54.55

What we may be able to say, if the school bus driver offenses at an expected rate, is that their psychophysical characteristics, excluding depth perception, are not necessarily related to their driving behavior. So far, of the over 320 school bus drivers tested and screened, only one has been denied the license on the basis of his failure to meet minimum psychophysical requirements. Therefore, it may be that criteria are either

too low or that only basic psychophysical capabilities are, in fact, necessary.

However, it is more likely a matter of previous screening. Under the new procedure, an applicant has had at least two screenings before receiving his clinic processing. All applicants must first have gone through the usual driver licensing screening and received an operators license. When he or she applies for a school bus driver

permut, he is given a second screening and receives a provisional license for one month; only then does he get the full Accident Prevention Clinic processing.

Conclusions and Hypotheses for Continued Research

It has been generally accepted that there is need for more stringent licensing procedures for school bus drivers. Obviously, if we can prevent applicants who are the greatest risks from operating school buses our accident, injury and death figures should improve. It is also obvious that, in many cases, psychophysical test results give useful information concerning this group of drivers. The need for a high degree of physical fitness is certainly needed. What makes this all the more meaningful, however, is that even with limited pre-licensing counseling, violations and accidents tend to decrease. Thus, we have some basis or logic for *Hypothesis Number One*:

driver who learns about his psychophysical capabilities and is counseled on the compensatory behavior for any defect tends to have fewer accidents and violations.

As indicated earlier, a start in psychological testing in this area has been made. As yet the number of applicants who have taken these tests is too small for any, even preliminary, analysis. Yet, there is considerable evidence from other studies, that measurement of the psychological and emotional components of a driver provide the best hope for identifying "safety risks." In addition, those applicants who are emotionally disturbed should be screened out since they are operating in an extremely sensitive area. Therefore, *Hypothesis Number Two*:

The inclusion of standardized or custom-built psychological instruments in a school bus licensing program has merit, in terms of identifying accident "risks," as well as emotionally unstable applicants.

Although these two hypotheses may seem rather general, their testing holds the key toward reducing school bus accidents.

While the New Jersey research is still in its early stages, it is hoped that studies can be soon initiated to test the above hypotheses and resolve a variety of problems complicated to deal with in this preliminary paper.

A STRAIGHT LINE ON SAFE DRIVER AWARDS AND INCENTIVES

By E. J. SLINGERLAND
Safety Director, Seattle Transit System, Seattle, Wash.

I think it is safe to assume that every one of us works because he gets paid for it—and no one who works for wages is likely to admit to any other reason. It might seem contradictory, then, to talk about safe driver awards as an incentive for employees when we have already admitted that it is money that talks. Those of you who have tried to sell your management on a driver award program will undoubtedly have met with this argument. What I have been asked to do is discuss some of the criticisms of incentive awards, to see if they are really valid.

When we first suggested a program of driver awards for our operators, we were

met almost instantly with the question "Why should we give a driver a medal for doing the job we hired him to do in the first place?" That may sound like a fairly reasonable argument, but I don't think it will stand much scrutiny. While it is true that when we hire a driver, we make every effort to hire one who will be safe, very few companies can boast that all their drivers are perfect. The latest edition of *Accident Facts* verifies this imperfection by recording over 2,000,000 accidents in 1960 involving commercial vehicles.

So I think that we all recognize that while we might have had high hopes, some of our drivers turn out less than perfect, and will

be involved in accidents. We also know that Tom, the driver who has one or two minor accidents each year, costs us more money, yet draws the same wages as George, who has a perfect record. Is there any reason why we shouldn't publicly recognize George's excellent performance, and at the same time provide an incentive for Tom to improve his record? Though we are all working for money, there are none of us who don't appreciate recognition of a job well done. In the motor transport industry, I believe there is no better recognition than that provided by a safe driver award.

Other critics of our program said "What good is a safe driver award? Only the good drivers will get them, and they won't have any effect on the driver who has the accidents and really needs the help." I wonder if this same critic would refuse to buy fire insurance because when the salesman called, his house wasn't on fire? The insurance is the same. Actually, one of the recommendations of a program such as the Council provides is the fact that the benefits reach every driver, good or not so good.

Even the good drivers need a reminder now and then that they are good because they put forth the necessary effort, and not because of luck. Each month we send a letter and booklet or other material to the driver's home, where not only he, but his family as well, reads it. I'm sure that in many cases, the driver's wife has just as much influence on his driving as his company supervisors. One driver told me that after he read the driver-letter, he forwarded it to his son at college, where it was posted on the fraternity bulletin board.

There is another way that the benefits of our program reach nearly every driver. With very few exceptions, the man who has a permanent place on our payroll takes a certain amount of pride in being a good driver. No matter what we're doing, there's a certain competitive spirit that makes us want to be a little bit better than the fellow next to us. If that fellow happens to be wearing a safe driver pin or a shoulder patch, and I'm not, I'm likely to try a little bit harder to get one too. It's possible that I'd never admit it to anyone, but the competition is still there.

This brings up another criticism of incentive awards. Many opponents insist that

incentives for safe driving records, whether they may be in the form of additional pay, merchandise, or a lapel pin, will increase the number of "blind" or "no-report" accidents. I agree that there could be a tendency toward this, but it has been no particular problem to us. Our operators are well aware that while we can possibly excuse an accident, failure to report one is a serious offense which will result in disciplinary action. Last year less than two per cent of our traffic accidents were blind reports.

Some people have told me that an incentive award program requires too much in the way of records—that all I'm doing is making more work for myself. But there is another way of looking at it. No matter what your safety program is, to be effective, it must be based on complete and accurate records. Whether you certify a driver for an award makes very little difference in the amount of work involved; and for any extra work there might be, you are repaid by having available a complete record of each driver's performance. This is essential for any program that produces results in accident prevention.

Of course, the \$64 question, (if such a term can be used) is the one asked by the boss: "How much will it cost?" Unless we are prepared to show that we can save more than the program will cost, we don't stand much chance of selling it. It's easy to calculate the direct expenses, and not much more difficult to add up the indirect costs. There will be the cost per driver in purchasing the material, whether we are giving prizes or shoulder patches. There is the mailing expense if you enter a program that includes such material for the operator.

Some companies pay their drivers for attendance at safety meetings, so these direct expenses would vary according to individual plans, and can usually be figured quite accurately. It is a little more difficult to calculate the money that is saved by such a program. Who can accurately determine the cost of an accident that didn't happen? The best that can be done here is an educated guess, based on your own previous record and the experience of others who have gone into an incentive program. Possibly a few of the facts concerning our own experience in Seattle might be appropriate.

Before we decided to try an award program, we had what we thought was a pretty fair record. Our traffic accident rate was a little better than the national average for comparable properties, and our ratio of claims expense to total revenue had been quite favorable. Our accident frequency rate was more or less stationary, but the cost of accidents was rising rapidly, due to the inflation of claims. In one year alone we had to set aside over \$425,000 for injuries and damages. We felt that if we could reduce our accident costs by as little as one per cent we would save money, as the incentive program that we were considering would cost only about half that amount.

I wish that I could report that immediately after signing up for the Council's driver award program that our accident rate started down, but unfortunately it didn't happen quite that way. It took some time for the program to show effects, and even some of our operators didn't like it at first. However, it wasn't long until even those drivers were showing more enthusiasm for the plan, which they indicated in several ways. More drivers came in to check their records, and ask when their next award was due. Management also took a closer look at these driving records, and we were able to give more attention to the drivers who really needed it. The operators also began to show more concern over their accidents, coming in more frequently to discuss those that were charged preventable. We were always ready to go over these reports with them, using the opportunity to point out the reasons they were considered preventable.

In this way we found the driver award program gave us an excellent opportunity to talk about defensive driving and it seemed

to go over better than when we had to ask the driver to come in.

The driver awards are, of course, only one part of our safety program. We continue to put a great deal of emphasis on training and re-checking. When an operator seems to require it, he is given an additional training period in an effort to help him eliminate any poor driving techniques he may have developed. It is not possible, nor would it be accurate, to say that the incentive awards are solely responsible for the fact that last year we enjoyed the lowest traffic accident rate in the history of our company. Certainly a good portion of the credit for this record, and for the resulting reduction in accident costs is due to this program. It would be hard to find anyone in authority in our company who would not agree that our annual cost of less than \$2000 for the incentive program has not been saved many times over.

In 1960, our cost for injuries and damage was only 40 per cent as high as in 1957, and over the four-year period, the savings were in the neighborhood of half a million dollars. We are not alone in our experience, either. A local trucking concern which introduced an incentive award program reported a 25 per cent reduction in accidents by the second year, and a number of other commercial vehicle operators have made similar reports to our local safety council.

Certainly no one contends that a safe driver award program is a gimmick that will do away with accidents forever, but you will find an increasing number of people who believe that it should be made a part of any well rounded safety program.

NEW DIMENSIONS IN SCHOOL BUS FLEET SAFETY

By SGT. P. A. ZEISSE

Fleet Coordinator, Texas Dept. of Public Safety, Austin, Tex.

An Index on School Bus Patrols

What are the advantages of a school bus patrol?

1. Student training in leadership.
2. Welfare of students on the bus.
3. Assistance to driver in maintaining schedule.
4. Assistance to driver during emergencies.
5. Aid to driver in controlling students at loading stops to prevent accidents.

We are concerned here with advantage (3), which is related directly to our major topic, fleet safety. We shall not evaluate the other advantages.

How is advantage (3) related to the precautions involved at a loading stop?

1. Bus driver seeing distance from point of loading stop.
2. Other driver seeing distance to point of loading stop.
3. Loading stop flashing signal given over 300 feet from point of slowing for a stop.
4. Stop light signal and turn indicators at least 300 feet from point of stop.
5. Stopping bus at least four feet off the pavement or main-traveled portion of roadway.
6. Bus driver sets parking brakes.
7. Bus doors are opened only after bus comes to a complete stop.
8. Driver checks traffic in both directions. (Patrol aid.)
9. Driver signals for students to cross roadway from either direction. (Patrol aid.)
10. Students enter roadway only after receiving signal from driver. (Patrol aid.)
11. Students cross roadway at a brisk walk in a path at right angles to and near the bus. (Patrol aid.)
12. After all students have crossed and bus door is closed, driver turns off loading stop flashing signal and uses turn indicators to aid in entering traffic again.

A study of Texas school bus accident reports 1960 indicates a need of several of the preceding precautions.

We shall look at data related to

1. Students crossing roadway at loading stops.
2. Buses stopping in roadway and on shoulder.
3. Accidents a bus patrol can help prevent.

Note that we are being guided exclusively by what we find in accident reports. This review is an illustration of how schools should proceed in their fleet safety program.

Texas School Bus Fleet Accidents—1960
255 total accidents involving school bus operation.

182 accidents involving school bus loading stops in some way (71 per cent of total).

143 accidents involving school bus stopped (79 per cent of the 182 accidents and 56 per cent of the total).

41 accidents involving school bus stopped on shoulder (29 per cent of the 143 accidents). 17 injury accidents, including six injuries to students crossing roadway (36 per cent of 47 injury accidents involving bus at loading stop).

24/41 non-injury accidents.
86 accidents involving school bus stopped partially or completely in roadway (60 per cent of the 143 accidents).

30 injury accidents (12 injuries, including two deaths, to students crossing roadway) (64 per cent of the 47 injury accidents involving bus at loading stop).

56/86 non-injury accidents.

16/143 accidents not known whether bus on shoulder or roadway (11 per cent of the 143 accidents).

39/182 accidents involving stops where bus was not stopped.

73/255 accidents involving all other bus operations (29 per cent of total).

time, in light of the four general objectives of safety, adequacy, efficiency, and economy; (2) to determine the needs of the district regarding routing of pupil transportation, being guided by the previously mentioned objectives; and (3) to propose a definite routing plan for pupil transportation that would contribute to the safe, efficient, and economical organization of the school district.

The data for these surveys are drawn from such sources as: the office of the county board of education, county highway department, files of the superintendent or local executive head, building principals, and bus drivers. These data are collected by the superintendent, or the local executive head or their designated assistant, and each district is responsible for the accuracy of its own data.

The information collected and procedure for these surveys involve securing detailed maps of the school district, trip sheets or bus time schedules of the present system, definition of attendance areas, equipment inventory, and school board policy for transportation, if any exists. The existing bus routes are plotted on the map, the school sites are located, boundaries are defined, and students are located along the routes by use of colored map pins, coded to the vertical organization of the school system.

The services of our department are given to the route reorganization process, which involves inspection of roads, route construction, mileage measurement, location of pick-up points, shake-down runs, and driver and/or board of education conferences.

After the survey has been completed, a very detailed report is filed with the local board of education, the county superintendent and one copy is retained by our department. This report contains a complete analysis of the routes of the system in use and those of the plan proposed as a result of the survey. The report also contains a comparison of these two routing plans, plus conclusions drawn from the survey and recommendations for improvement.

Since September, 1960, we have completed some twenty odd surveys in Ohio schools. Most of these have been in districts that have had recent consolidations of rural territory. Although, the local board of education is not obligated to follow the recom-

mendations of our surveys, we have been quite well pleased with the number of districts that have indicated their intention to adopt our proposals this school year. A follow-up of these districts should give some indication of the success of our efforts next year and aid in evaluation of our methods.

You may be interested in the results of these surveys, and I will now present the most numerous conclusions consistently drawn from our studies.

1. The complete lack of board of education policy on school bus routing contributes to the inefficient and uneconomical organization of the present transportation system. This lack of policy also makes the administration of the system difficult and inadequate to meet the needs of the future.

2. The number of buses used in many districts at the present is excessive, and due to the reorganization of the school district, it should be possible to reduce the number by several methods that will be mentioned later.

3. The amount of backtracking on school bus routes can be reduced by proper routing at a considerable savings to the board of education.

4. The number of side spurs to the main bus routes should be reduced in order to save travel time and cost. This would extend the range of the bus and contribute to the safety of all pupils by eliminating some turn-arounds and pick-up stops.

5. The number of pick-up stops should be reduced. This would decrease travel time, extend the range of the bus, and reduce operational cost of fuel and maintenance.

6. Single-trip routing should be eliminated, and double or multi-trip routing used wherever possible to decrease operational cost of drivers and equipment. This would increase the efficiency of equipment used and decrease the number of buses needed.

7. The exclusive use of loop routes limits the range of the buses. They can only pick up pupils within an area limited by one-half the travel time of the route, since they must pick up pupils during the whole travel time. A shunting route does not pick up on the way out, therefore, it saves travel time and can range farther from school. Not all situations lend themselves to both types of

routes mentioned, and it should be remembered that the loop route can reduce dead-head mileage and should be used wherever possible.

8. Unsafe turn-arounds and stops should be eliminated.

9. The length of routes should be equalized as much as possible to properly utilize drivers and equipment. This may also eliminate some routes altogether, thereby, reducing the number of buses needed.

10. Overloading and underloading could be prevented by constant route revision.

11. Proper assignment of pupils to school and bus route can prevent overloading and underloading, and help equalize length of routes.

12. Small-capacity buses necessitate short routes that are expensive because the number of buses needed increases. When purchasing new buses, larger buses should be considered.

13. When planning routes, dead-head mileage should be eliminated except in cases where shoestring routes are needed to extend the range of the bus for scheduling purposes.

14. Travel time on the bus should be equalized for all routes as much as possible. This time should not exceed over one hour for high school pupils and forty-five minutes for elementary students.

15. The long elementary school day caused by transporting the high school and elementary pupils on the same bus should be eliminated. When transporting high school pupils in a different building than the elementary site, dual routing should be used. This decreases the number of buses and drivers needed, and increases the efficiency of equipment.

16. The traditional routing practices and restrictions of the old system should be ignored. New route planning should consider the school district as a whole, and routes and pupil assignment should be made for efficiency of operation.

17. Route revision should be made constantly, and administrator-bus driver conferences should be held periodically.

18. Express routes should be used where possible, especially for high school students. This would decrease travel time, eliminate

pick-up stops, and extend the range of the bus.

19. Feeder cars should be used in areas where the regular route would be too long or an extra route would be underloaded. The feeder car could eliminate unsafe turn-arounds, and long side spurs. The feeder car would also be an aid in scheduling.

20. The average number of pupils transported by a bus in a day should be increased to reduce per pupil cost.

21. Average trips per bus per day should be increased to eliminate the low average mentioned above.

22. Average one-way trip should be lengthened by eliminating excessive stops, side spurs, and turn-arounds.

23. Travel time should be decreased for elementary students and increased for high school students in some cases.

24. Average daily mileage of the buses should be increased to give a lower per mile cost and per pupil cost because of the use of less buses.

25. The extreme range in the composition of the bus load, travel time, and pick-up stops contributes to discipline problems for the drivers and principals and safety hazards for the students.

26. The extreme range in the bus load, stops, and daily mileage contributes to the inefficient use of equipment and driver's time.

27. The use of more buses than needed requires more capital outlay for new bus purchase during the depreciation period of the fleet.

28. The use of more drivers than necessary requires more supervision and salary outlay each year.

29. Maintenance costs should be spread over the smallest fleet necessary.

We do not intend to generalize upon these conclusions at this time, but we believe that another year of such investigation will point the way in which school bus routing should move in the future.

It may be interesting to you to know that in every survey conducted to date, our cost estimates have indicated that a decrease in either the per pupil cost or the per mile cost or both may be expected, as a result of route reorganization. Coupled with this

reduced operational estimate, is another cost reduction in capital outlay for bus purchase because of a reduction in fleet size. The estimated savings in annual operating cost have been as high as \$20,000 in one instance, and the capital outlay savings in this case was estimated at \$50,000.

More important than cost have been the indications of improvement in safety such as reduction in stops for a given age group, trip, or bus. A reduction in side spurs and turn-a-rounds improves safety, as does the separation of age groups, decreased travel time, and elimination of waiting periods in many cases.

The administrative changes made possible in many cases indicate a better organization of the school day, the curriculum and staff time.

If, after such limited study of the routing situation in only one state, I were asked to state the most urgent needs of school bus routing today, I would suggest the following areas as most important:

Boards of education should consider, write and adopt policy to guide the administration of pupil transportation. This policy should at least be concerned with the following basic questions:

1. The maximum travel time for high school and elementary pupils on school buses.
2. The maximum speed at which buses will be permitted to operate.
3. The maximum time that transported pupils arrive at school before it opens or wait for a bus after school is dismissed.
4. How far normal pupils must live from school in order to be entitled to transportation.
5. The type of physically handicapped pupils entitled to transportation.

6. How far pupils are required to walk to the main bus line from side roads.

7. Whether the bus will stop in front of each pupil's home on the main route, or only at spaced stops, limited in number by a required minimum distance between stops. It is not suggested that the policies are all-inclusive or that they meet all the needs of all districts. They are presented as essential statements for providing safe, economical, and adequate service.

Boards of education should provide for supervision of pupil transportation in the person of someone other than the head administrator. The problems of pupil transportation today require more time than the head administrator can devote to the job.

Boards of education should adopt the dual routing system for pupil transportation. The high school pupils are transported on separate routes from the elementary pupils. This procedure will free the elementary school from the restrictions of the high school schedule. Dual routing also will reduce the number of buses needed because some of them can be used for more than one route. This is a simple matter of scheduling the start of the high school first in the morning and elementary school last; this is a matter of board policy.

Boards of education should provide for a public information program to show the need for change in the transportation system. This program should be started long before the actual change is put into effect to avoid public opposition to quick change.

In the final analysis, let us not lose sight of the fact that the purpose of safety, efficiency, and economy in transportation is to make available the better educational program which, after all, is the basis of our existence.

AN OLD AXIOM — SCHOOL BUS ACCIDENT SUMMARY — 1960

By DOUGLAS M. FERGUSSON
Superintendent of Safety—Personal Lines,
Nationwide Mutual Insurance Co., Columbus, Ohio

I'm happy to appear here before you again. It's always a pleasure to talk to the leaders in the field of school transportation safety—even when I have to discuss the statistics of our business.

Statistics is never a popular subject—unless they refer to something "vital" and especially interesting, like 38-24-36.

Sir Thomas Browne, an English author of the 17th century, must have had something "vital" in mind when he wrote: "I have often admired . . . the secret magic of numbers."

More to the majority viewpoint, I think, was one of Sir Thomas's compatriots—a bloke named Shakespeare—who noted in his play, "Much Ado About Nothing," that "comparisons are odorous."

The statistics I'm going to review here today may not be as interesting as 38-24-36, but they're every bit as "vital." They pertain to the safe transportation of our "most important cargo"—our school children.

To get into my subject, I cite an excerpt from a report of the 99th Annual Convention of the National Education Association last June. Meeting in Atlantic City, 10,000 N.E.A. members adopted a resolution on the protection of children. That resolution said:

Safety of school children is among the prime concerns of all educators. Yet, despite continuing efforts of school and community groups to prevent accidents and fires, adequate safety remains a serious problem. The National Education Association urges all members of the education profession to continue to use and to expand the day-to-day opportunities for teaching the principles and practices of safe living which are pertinent to their fields of instruction. The N.E.A. calls upon school boards, teaching staffs, and administrators to intensify their efforts to provide physical settings which protect children, to give meaning to the principles of safety, and to enhance the development of safe behavior.

N.E.A. convention resolutions supplement the N.E.A. platform in two ways: (1) by directing the Association's officers and staff

to take specific actions, and (2) by stating the position of the N.E.A. rank-and-file on matters which are educational in nature, national in scope, and of current importance to the teaching profession.

Two things about this particular N.E.A. policy statement are apparent: (1) its scope is greater than the interest of this group here today, and (2) the need for safely transporting an increasing number of children to and from school is the herculean task challenged by the resolution.

Many people, it seems, no longer believe that they can influence actions in their sections of the world. This apathy—this tendency to "let George do it"—may be due to the great international power struggle and the war threats it involves; it may be due to the mighty scientific advances which are announced almost daily; or it may be caused by the world's population explosion and a feeling that one or two people don't count for much anymore.

But whatever the reason for this lack of "go-power," it's up to us—we in this room—to fight it, overcome it, and to pursue the problems of safe transportation with renewed faith and conviction.

We are the leaders—and the manner and methods by which we lead will largely determine the strength and character of those who will follow us, of how many will follow us, and of how good a job we'll all eventually do.

So it's up to us—you and me—to make school transportation safer.

But as I mentioned in this same setting one year ago, we'll see more darkness before we see daylight. With families migrating en masse to suburban homes and with the resulting increase in consolidated school districts, the problems inherent in school transportation have assumed gigantic proportions—and these problems will continue to get worse, instead of better, unless the trends of recent years are reversed.

This is the challenge I throw to you now.

Never before have America's school transportation facilities so badly needed the active support and guidance that you can provide. Your demonstrated leadership and experience are absolutely necessary, if the success we all hope for is ever to be realized. That's why I challenge each and everyone of you—in harmony with our colleagues who are absent today—to assume active roles in promoting a safe school transportation system.

Now accident statistics, by themselves, aren't worth much. They're sometimes nice to know, and they may even be nice to look at—but they do not become meaningful unless they are related to a common denominator or inter-related to themselves. For my purposes today, I'm going to inter-relate some statistics through successive years. By doing this, I think I can chart a trend—a trend that should alarm you as much as it has alarmed me.

First, let's look at the progress that's been made in recent years in securing annual school bus statistics from the various states in the U.S.A. In 1953, such data was furnished by 30 states; last year, 48 reported. That's an encouraging increase . . . but before we become sore from mutual back-slapping, allow me to insert a somber note.

Forty-eight states reported last year. That's a fact. But a number of them still do not separate their school bus accidents from the total reported for all bus accidents. In other words, any accident or fatality involving a passenger-carrying vehicle is recorded in some states. Thus, we safety people don't get all of the information we should to help us plan our attack against accidents. So (if you haven't already done it), I suggest that you acquaint yourself with your state's reporting format and—if it does not conform to procedures recommended by the National Safety Council—I urge you to launch a campaign to bring about adoption of the Safety Council's recommended reporting in your state.

Now, to more accurately measure the size of our school bus safety problems, let's use the reports from the individual states and see how much of an increase there's been in the number of school buses in operation. In 1953, 30 states had 80,000

school buses running. Last year, the number in 50 states was 176,471. I think you'll agree from this comparison that the size of our school bus operation is challenging enough for anyone.

Looking at another angle of our problems, how is the migration to suburbia proceeding? Well, in 1953 five million pupils were transported to and from schools daily. And by 1960—only eight years later—the number had skyrocketed to nearly 12½ million.

Turning to a third area to get the pulse of a rising tide of urgency, let's examine the accident involvement rate of school buses. The figure stood at 2,941 in 1953—and at 8,908 in 1960.

At this point, some of you may be thinking that these advances in numbers transported and accident involvements are not too bad when compared with the increase in school bus usage.

I ask you, though, to please withhold judgment until I make some additional analyses. Because again—this time in the area of school bus accident involvement—some states do not delineate between school buses and public carriers in their annual safety reports. And I don't mean to minimize the tragedy of commercial bus accidents when I indict those states which fail to attach sufficient importance to school bus mishaps to warrant separate accident-reporting data.

When we have accidents, of course, we can anticipate personal injuries. That's as sure as summer and winter, day and night, or flies at a picnic. Statistically, 701 students were hurt in school bus accidents in 1953, and the number had almost tripled by 1960, when 2,067 pupils were injured.

I admit that we might be inclined to look favorably upon these injury figures as they relate to previous data, but again I warn you that such a conclusion will be premature and possibly erroneous.

As long as we have an increasing number of school buses in operation, an increasing number of school children-riders, and an increasing number of injury-producing accidents, we must also expect more fatalities. In 1953, 13 boys and girls were killed while engaged in activities incidental to riding on school buses. In 1960, the number of dead was 50—or approximately four times what it was eight years previously.

My research indicates that previous speakers have given separate treatment to student fatalities which occur on buses and to those which take place while students are going to or from school buses. This separation of information has led to an idea that injuries and deaths occurring while pupils are boarding or dismounting somehow differ from those which take place while the loaded bus is actually moving and transporting its young charges.

I, personally, cannot agree—either with the arbitrary separation of reports of accidents on and accidents off our school buses or with the conclusion that such separation seems to support.

For reasons beyond the intended limits of my presentation, I submit that injuries and fatalities occurring both on and off school buses should be reported together as part of the buses' total operation. I strongly believe this—and I'm exercising the prerogatives of that belief in presenting this accident summary material to you today.

If we now draw the component parts of our problems into one picture, we see what I believe to be a significant, shocking truth. In the period between 1952 and 1961, inclusive, the number of states submitting school bus statistics (but still with some discrepancy), has increased 60 per cent; the number of pupils transported has increased 150 per cent; the number of buses operated has increased 119 per cent; the

number of school bus accidents has increased 203 per cent, and the number of pupils killed has increased 285 per cent.

Now, to those people who have lost confidence in their ability to influence actions in their parts of the world, I ask—what would this school bus safety problem have looked like if every school board could have prevented only one accident or only one injury? How would it look if every state had been able to prevent only one fatality? You know the answers to those questions. But you have to get the questions and the answers to others—and then take them and help us act to solve all of the problems.

Since my assignment is to review the reported school bus statistics for 1960, I can't conclude without going through some more figures. But since you have the same state-by-state data as I (and if you don't, you can get it from the National Safety Council), I'll spare you the agony of a more lengthy report.

Guided by the ancient adage that "die mind can absorb only what the seat can endure," I'm cutting short my part of the program with a tabulation of school bus facts by region. I hope these figures—when compared with the statistics of your state and your neighboring states—will be of interest and value.

In making my tabulation, I have divided the United States into 8 regions.

Region	Number of Buses	Number of Accidents	Number of Pupils Transported Daily	Number of Injuries	Number of Fatalities
NEW ENGLAND (Me., N.H., Vt., Mass., R.I., Conn.)	8,351	162	642,543	67	0
MIDDLE ATLANTIC (N.Y., Pa., N.J.)	22,659	1,049	1,871,182	276	7
EAST NORTH CENTRAL (Ohio, Ind., Mich., Ill., Wis.)	32,422	1,079	2,303,890	145	6
WEST NORTH CENTRAL (N.D., S.D., Neb., Kan., Minn., Ia., Mo.)	23,544	1,076	1,941,235	358	2
SOUTH ATLANTIC (Del., Md., W.Va., Va., N.C.)	30,768	2,635	2,452,917	592	14
EAST SOUTH CENTRAL (Ky., Tenn., Miss., Ark.)	18,096	740	1,350,254	160	16
WEST SOUTH CENTRAL (Okla., Tex., Ark., La.)	19,882	414	1,131,316	126	4
MOUNTAIN (Mont., Idaho, Wyo., Nev., Utah, Colo., Ariz., N.M.)	8,808	247	427,948	93	0
PACIFIC (Ore., Wash., Calif.)	12,650	1,186	1,178,190	148	1
CONTINENTAL U.S.	176,471	8,908	12,280,474	2,067	50

In closing, let me say that the picture I've tried to present here today is not a pretty one. I deliberately refrained from using "honey-coated" words or phrases in my presentation with the hope that my words would arouse you—and that you, in turn, would arouse your neighbors and the people of your communities—and that finally all of the citizens and officials of our nation would be awakened—before it is too late.

Active leadership is needed now! Progress is not automatic. The world grows better—not because people wish that it can—but because they know that it can and pitch in and take steps so it can be made better. And we've all got to push and shove and make it better if we're ever going to have the safest transportation possible for school children—"our most priceless cargo."

PUTTING THE RIGHT ANGLE INTO DRIVER SAFETY MEETINGS

By HOWARD R. CHEEK

Supvr. of Transportation, Board of Education of Harford County, Bel Air, Md.

Good safety meetings do not just happen. As a matter of fact, there are far too many school districts in the United States where safety meetings for bus drivers are nonexistent. There are far too many school districts which do not have an organized safety program of any kind in the area of pupil transportation. This is true, not because the administrators in these districts are not concerned about the safe transportation of their pupils, but because this problem gets lost in the multiplicity of problems which cross their desks daily. It is true because they are understaffed and overworked. It is a situation which will continue to exist until the problem is put in its proper perspective and corrective action is taken.

The prevention of accidents is primary among safety considerations and it is my hope that it will not take a series of tragic bus accidents across the nation to impress the people that proper supervision of the bus operation is a vital necessity.

This is exactly what happened in the state in which I live, Maryland. The schools in Maryland are organized on a county system. Since there are 23 counties and Baltimore City, which is a separate political subdivision, in the state, there are only 24 school systems. Up until two years ago, some of the county Boards of Education had appointed supervisors of transportation

and some had not. No state aid was made available to help toward the payment of the salary of such a person, and many counties felt that they could not afford such a "luxury."

This situation existed for a number of years, until one morning a train hit a school bus which had stalled on the tracks. Seven high school pupils were killed. Several committees investigated the circumstances surrounding this accident, one of which was appointed by the Governor.

As a result, the Attorney General ruled that expenditures for adequate supervision of school transportation was a legitimate expenditure of state funds. The state Department of Education recommended that each county Board of Education appoint a full-time supervisor of transportation, and one assistant supervisor for each 100 buses in use in the particular county. A full-time state supervisor of transportation was appointed.

A full summer session, yielding six semester hours of credit in the field of pupil transportation, was offered last summer by the University of Maryland. Mr. Wesley Pickle of Tennessee and Mr. Mike Haggerty of Minnesota were obtained as instructors for the two courses offered. I feel that a giant step forward has been taken to assure the safest possible transportation of the school children of Maryland. I deeply

regret, however, that this step was not taken five years ago, and that it had to be purchased with the lives of seven children.

A great deal of time must be spent by someone in planning, organizing, and conducting training programs and safety meetings for bus drivers in school districts from one end of our country to the other. It is just as necessary in Oregon as it is in Virginia. The lives of the pupils in small school districts are just as precious as the lives of pupils in large districts. The first step that must be taken in many school districts is the delegation of the responsibility for pupil transportation to a specific person. The person to whom the responsibility is assigned must have a realistic amount of time to devote to this area.

In my opinion, safety meetings cannot be considered except as a part of the overall safety program for bus drivers. The person whose responsibility this program is must clearly understand what his objectives are and what part the safety meeting plays in meeting these objectives.

Let us consider a total safety program for a few moments. What are our concerns? What do we hope to accomplish? How are we going to go about achieving our objectives?

We are concerned, of course, with the safe transportation of pupils to and from school. That is our objective. We are told by the people who investigate accidents and compile statistics that over 90 per cent of all accidents are the result of driver error. We are, therefore, concerned with the elimination of driving errors by our bus drivers.

I think it axiomatic that the person responsible for the transportation of pupils must select bus drivers with great care. You do not hire someone to drive a school bus whose driving record is loaded with traffic violations.

After the driver is hired, he must be impressed with his responsibility and the urgent need for safe driving at all times. After the first impression, he must be constantly reminded. He must be made "safety conscious." We must change the "it can't happen to me" attitude which all drivers have. The driver must realize that, unless proper precautions are constantly observed, it can happen to him. He must also realize

that whatever happens to him also happens to everyone that is on his bus and who is dependent upon his driving. In essence, we must develop and constantly re-enforce a desirable safety attitude.

The safety meeting is one means of developing and enforcing this attitude. It is not the only means. There are many other things which can be done which will help to achieve this objective.

A safety meeting, however, should not be planned and conducted to develop this desirable attitude. The attitude of which I speak will be developed as a result of the total safety program, which should have a cumulative effect upon the driver.

Safety meetings should be specific in nature, and should treat one topic in detail. It is essential that drivers understand the need for the presentation of the particular topic covered in the meeting. The driver must be properly motivated if he is going to derive any lasting benefit from the meeting.

For instance, suppose a review of your accident reports indicates that several accidents involving school buses have occurred at intersections. Here is a specific problem, which presently exists in your school district, which can effectively be made the topic of a good safety meeting. A presentation of the problem, indicating that 15 per cent, or 20 per cent, or whatever the percentage actually is, of the accidents involving school buses so far this year have occurred at intersections should convince drivers that intersections are dangerous places.

Once the driver has accepted the fact that a dangerous situation does actually exist, he is ready to pay close attention to learning some techniques which will help him to stay out of trouble at intersections. Do not attempt to cover "tail gating" or adjusting to changing weather conditions at the same meeting. These are appropriate subjects for safety meetings on their own. Stick to the one topic which has been selected for presentation and do a good job on that topic.

A poor presentation on the selected topic, or the presentation of a topic which bus drivers do not consider important, can be detrimental to your entire safety program. Bus drivers who attend safety meetings

are attending at a time when they would ordinarily be doing something else. Housewives would be home taking care of their domestic obligations. Service station attendants would be working at their primary job. If they regard safety meetings as important, informative, and helpful they will willingly attend. If they do not, they will not. A poorly organized and conducted safety meeting can be worse than no safety meeting at all.

In organizing safety meetings, careful consideration should be given to the physical arrangements. The time and the place of the meeting should be carefully selected, as these factors will, in part, determine how many of your drivers will be able to attend. Some school districts obtain excellent results by having safety meetings in the evening. I find that, in my own situation, it is best to schedule safety meetings immediately after the morning bus runs, and to schedule them at schools where the majority of the drivers finish their morning runs.

This means that a good number of the drivers scheduled to attend this particular meeting are automatically at the meeting place at the appointed time. It requires less effort for them to stay and attend than it would if they had to make a special trip from their homes at some other time. There is also the advantage of having the educational facilities of the school, such as film projectors, motion picture machines, tape recorders, etc., immediately available for use in the meeting. The environment is an educational one and will have some impact upon the drivers.

Careful consideration should be given to which drivers and how many of them attend any given meeting. The meeting will be much more effective if drivers freely participate in an expression of views and/or an exchange of ideas. This will not occur if the number of drivers at the meeting is too large, or if the drivers do not know each other.

In systems which require a large number of drivers, it will be necessary to hold the same meeting a number of times. These meetings should be held in different geographical areas of the system, and should be planned to include not more than about 30 drivers. From the discussions which oc-

cur during the meeting, the conductor of the meeting can often spot misconceptions which drivers have. This will sometimes indicate the need for a meeting devoted specifically to correcting an expressed misconception!

One of the major problems which must be faced in the establishment of a series of safety meetings is that of driver attendance. Bus drivers are just like any other kind of driver, in that they consider themselves considerably better than the average. Many of them have been driving school buses for some period of time, and will not have been involved in an accident of any kind. They consider themselves to be safe drivers, and there is a certain amount of resentment generated when they are asked to attend a safety meeting. The "what can they teach me about driving" attitude must be faced and overcome if safety meetings are going to play an important part in the total safety program.

How do we attack the problem of driver attendance? One way is to make it compulsory. I am sure that this is not the best way. The old adage that "you can drive a horse to water but you can't make him drink" applies to this situation. I think that compulsory in-service training may have some benefits, but I think they are very limited.

Drivers must see that the safety meetings are going to be of some benefit to them if they are to attend willingly. Your job is to make them want to come.

One method of applying gentle pressure in this direction is establishing attendance at safety meetings as one of the requirements for obtaining safe driver awards. This means that drivers who attend safety meetings are recognized on a higher level than those who do not. Drivers like to receive safe driving pins in recognition of the good job they have done. This technique will help to get them to the meetings originally. Whether they return or not depends upon their impression of the actual meetings. If they are helpful, interesting, and informative, they will come back.

The supervisor of transportation in one of the counties of Maryland recently informed me that he had solved the problem of driver attendance. I was rather skeptical, until he explained his problem

and solution. He had been interested in having all bus drivers trained in rudimentary first aid. He was able to obtain a qualified instructor from the regular teaching staff of the county. She was 22 years old, red headed, and had very complimentary measurements. The meetings were held in the evening, and he reported that, not only did the drivers show up, but he sometimes had considerable difficulty getting them to leave. I think his first step in organizing a safety meeting now is to train the red head so that she can be the instructor.

In planning safety meetings, please do not overlook the wealth of expert assistance which is immediately available to you. Be sure, however, that the person that you ask to help you is really qualified in the area in which you need help.

I have never been refused help from people who are knowledgeable in areas which I wish to cover in safety meetings. People throughout the country are concerned with safety on school buses, and will contribute whatever they can toward furthering it if they are asked to do so.

Insurance companies have field safety engineers who are experts in the field. They are more than willing to help, not only from a humanitarian viewpoint, but also because reduced accidents means better business for their employers.

State police are available everywhere and are anxious to help. The American Red Cross welcomes the opportunity to work with drivers in the area of first aid. Safety engineers employed by the government and by private industry have much to offer and are willing to help.

These human resources exist in nearly all communities throughout the country. Not to make use of their talents is a great waste.

Care should be exercised by the person who is responsible for safe transportation, however, that personal contact with bus drivers is not lost. Even when the problem to which the meeting is devoted is being discussed and treated by an appropriate resource person, the supervisor of transportation, if that be his title, should be in attendance at the meeting to introduce the resource person. He should remain throughout the meeting and help to get the discussion and exchange of ideas started.

He should be available after the meeting to talk with the one or two drivers who always have some question which they wish to direct to the supervisor. His presence indicates that the entire school system endorses and approves of the meeting and the concept of an organized safety program. Just as it is hard to visualize an effective faculty meeting without the principal, or an effective board meeting without the president of the board, it is hard to visualize an effective safety meeting without the person responsible for safe transportation in attendance.

There are two cautions to be observed in conducting safety meetings. The person conducting the meeting must realize that he is presenting the topic to a very heterogeneous group. In the group he will have housewives, farmers, retired army officers, service station attendants, and men who work the night shift at a local industrial firm. He will be confronted with educational levels ranging from completion of the third or fourth grade through graduation from college. The members of the group will have vastly different backgrounds. All of these factors must be recognized, and the material must be presented in such a way that it is understandable to everyone. It is always good to use visual aids as much as possible. Such aids might include motion pictures, film strips, overhead projector, and the use of flannel boards or magnetic boards. The last two are particularly valuable for setting up actual and hypothetical traffic situations. Remember that you are after understanding. More understanding will result if the presentation is on a level which is easily understandable by those making up the group. It is not necessary to impress them with our scholarship.

The second caution to be observed concerns the length of the meeting. When the objective of the meeting has been accomplished, stop! Just because the meeting is scheduled to last one hour is not sufficient reason to drag it out. When the appropriate understandings have been developed, everything else is superfluous. Interest will wane quickly, and drivers, when they are finally dismissed, will leave with a bad taste in their mouths. There is nothing sacred about one hour. A good 40-minute meeting is more to be desired than a half dozen poor one-hour ones. As I have stated before, drivers

will not willingly return to be subjected to poorly planned and conducted meetings.

In brief summary, the following must receive careful consideration in organizing and conducting effective safety meetings:

1. Some one person must be delegated the responsibility for school bus safety. This person must have sufficient time to devote to doing this job.
2. Time and place should be selected carefully so that it is easy for drivers to attend.
3. Number of drivers attending each meeting should be controlled so that meetings are not too large.
4. The safety meeting must be specific in nature. The objectives must be clearly defined.
5. The drivers who attend the meeting must be convinced that the topic of the meeting is an important one—one in which they are interested.
6. The presentation must be informative,

interesting, and geared to a level that is readily understood by the members of the group. Human resources in the community should be utilized.

7. Visual and auditory aids should be employed wherever possible.

8. The meeting should be adjourned when the objectives of the meeting have been accomplished.

9. Drivers who regularly attend safety meetings should be rewarded on a higher level than those who do not.

I would again urge that school districts across the nation take the necessary steps to improve the safe operation of their transportation system. I do not mean to imply that travel by school bus is presently extremely hazardous. It is far from it. I do think, however, that increased safety and increased economy can be realized if qualified, trained personnel are appointed to administer this phase of the school program. Do not wait until the horse has been stolen. The time to act is now.

ENCOMPASSING CONTRACT BUS OPERATORS IN THE TRAINING PROGRAM

By BENJAMIN W. NELSON

Supvr. of Transportation, Board of Education of Worcester County, Snow Hill, Md.

In the technological age in which we are living much attention has been focused upon the school system and imploring eyes are watching all of the supporting services which are linked to the total program.

Since transportation is one of the supporting services and we are involved in this endeavor, it is essential that the major purpose of pupil transportation services be defined:

1. To provide educational opportunities for all children regardless of the distance they may live from an appropriate school center of the proper grade level.

2. To provide educational experiences for children above that which might be obtained in a classroom situation.

With the listing of purpose, one needs to add the objectives that have been proven

necessary in the development of any satisfactory program of pupil transportation service. They are as follows:

1. Safety

The first objective is to provide maximum safety for all pupils to be transported and in so doing, the following items should be observed by the Board of Education:

- a. Provide adequate and safe bus equipment.
- b. Select drivers who are capable of operating large vehicles.
- c. Make a thorough study of transportation routes in order to eliminate unnecessary hazards in operation.
- d. Provide for the adequate supervision of drivers and the maintenance of equipment.

2. Economy

The second objective is to provide transportation services at a low cost. In order to maintain a program of pupil transportation within the available funds, it is necessary for a school system to make constant studies and revisions in order to achieve the best service from the funds available for this purpose.

3. Adequacy

The third objective in the operation of a pupil transportation program is based on adequacy of service. In an effort to provide adequate services for all eligible children within a school system, board of education should consider the following items:

- a. A sufficient number of buses to provide transportation services on a system-wide basis for all children within a reasonable time limit.
- b. Provide express type transportation services for children living in remote areas. This arrangement for services should be made to eliminate the necessity of children being required to remain on a school bus beyond the limit of one and one-half hours.

4. Efficiency

A fourth objective requires efficiency in operation. Since the efficient operation of a transportation program depends upon the placement of responsibility, it is necessary that the following factors be given careful attention prior to and during the school term by all responsible persons connected with the program:

- a. Observance of time schedules on a pre-planned basis in order to eliminate inconveniences to those students meeting or waiting for school buses.
- b. Selection of appropriate bus stops so as to minimize the danger of accidents on heavily traveled highways.
- c. Provide a sufficient number of buses to prevent overcrowding and lengthy routes.
- d. Employ capable drivers within the communities to be served.
- e. Maintain adequate maintenance facilities to insure minimum expense and maximum safety in operation.

In order to insure that the philosophy and goals of a transportation program may be realized, it is essential that clearly defined policies be passed by the Board of Education.

It is felt by many that the following should be covered:

1. The general philosophy of the transportation program should be stated.

2. A detailed spelling out of operating procedures is required.

3. Consideration must be given to the type and capacity of the buses to be used.

4. There should be plans for routing and scheduling buses.

5. A specific declaration relating to pupil privileges and responsibilities is necessary.

6. Duties of various personnel must be defined.

7. A realistic system is needed for replacing buses in service.

8. A program of maintenance and repair is needed to keep buses in satisfactory operating condition.

9. Outline procedures for the transportation of pupils for field trips and extra curricular functions are required.

10. Proper training of contract drivers is necessary.

Recognizing the importance of the driver in the total transportation program and the objectives previously stated, our Board of Education put into effect a Pre-Service Driver Training Program.

At the present time the Board of Education will not employ any individual to operate a school bus unless he has successfully completed the program consisting of fifty hours of work.

The course consists of actual classroom work, with tests, plus supervised driver training and then the final check out, by the State Police in a bus over a pre-determined route, taking into account the skills learned in the training program.

Enclosed is an outline of the material covered in the course.

Pre-Service Course for Bus Drivers, 1960-61

I. Content of course

A. Transportation

1. Importance of training program
2. Importance of transportation in school system

B. Responsibilities and regulations of school bus operation

1. State and county responsibilities for transportation

2. Contractor
3. Driver
4. School bus law
5. School Board regulations
- C. The school bus
 1. Bus care and maintenance
 - a. Driver's daily checks
 - b. Emergency equipment
 2. Bus housekeeping
 - D. School bus operation—policies and procedures
 1. Schedule
 2. Loading and unloading
 3. Railroad crossings
 4. Stops and blinkers
 5. Pupil discipline
 - a. Types of bus problems
 - b. The Principal and bus discipline
 - c. Discipline on the bus
 - d. School bus rules
 - e. The Supervisor and bus discipline
 6. Bus drills
 - a. Front door
 - b. Back door
 - c. Two door
 - E. Public relations
 1. What and why
 2. Who and how
 - F. Fire prevention
 1. Causes of vehicle fire
 2. Use of extinguisher
 - G. Driving skills
 1. Individual alertness test
 - a. Person rides in another bus and observes correct and incorrect skills displayed.
 - b. Behind wheel test for each person over a prescribed route checking skills of performance
 2. Written tests
 - A. Traffic and driving knowledge
 - B. Psycho-physical tests
 - C. Essay test on materials covered
- H. Accidents and how to prevent them
 - a. Types of accidents
 - b. What to do in case an accident happens
- I. First aid
 - a. The first aid kit
 - b. What first aid should a driver use in his situation

A HEXAGONAL PROBLEM — SCHOOL BUS SELECTION

By M. R. LIECHTY

Engineering Consultant, International Harvester Co., Chicago

The selection of school bus vehicles is truly a six-sided problem. And even more than a hexagon, we might call it a revolving hexagon. As the six sides of this hexagon, we have selected (1) vehicle life and dependability, (2) vehicle repairs and replacement, (3) maintenance and operating expense, (4) spare units, (5) purchase price, and (6) vehicle application. And when we say that it is a revolving hexagon, you will notice that as your application of vehicles to the intended service is improved, your operating expense will be reduced. You will find that as the dependability of your vehicles rises you will re-

quire fewer spare units. You will find that as you spend more money on the original purchase price for better equipment, you will usually spend less money on repairs and breakdowns. Let's look at each of these items a little bit closer.

1. Safety

As a representative of the School Bus Chassis Committee of the Automobile Manufacturers Association, I can tell you with confidence that the chassis industry feels that we have come a long way up the safety curve, insofar as new vehicles are concerned. There are always things which

can be done. We constantly strive in the direction of added safety and some of the suggestions which we can make at the present time are these:

(a) *Power.* For many years school buses were built with barely enough power to drag the vehicle from its loading source to the school and back home. While other vehicles have been increasing in the power and performance areas, school buses have long been inadequately powered to keep in step with traffic. The new power formula, which was adopted by the national minimum standards for school buses in Lawrence, Kansas, in 1959, is now coming into full play.

It is a good formula for a minimum power standard. Vehicles which meet these standards will have better acceleration than older buses and, in turn, will tend to help keep traffic moving, especially in congested areas and on high-speed highways. This power standard is a good minimum, but it does not preclude the chance that there are applications which need even more power for proper ability to accelerate and maneuver in traffic.

(b) *The driver's position.* We in the chassis industry feel that the driver's position, visibility, and driving attitude, has a tremendous impact on the safety of the school bus operation. We are not satisfied with the driver's physical position in the present day conventional school bus. Too often, while the driver can see well enough to operate the bus satisfactorily, he does not have the superb vision which he should have if we are to achieve maximum safety.

We, the chassis people, and our school bus technical committee are actively exchanging ideas with the engineers of the body manufacturers through their association, in order to improve on and eliminate this particular problem. We have already offered and are actively engaged in selling transit type units with the driver mounted in the front part of the bus where he has an excellent view, not only of the road ahead, but also of the pupils who are entering the bus itself.

(c) *Brakes.* It would be improper to talk about vehicle safety and not mention brakes, but it is our opinion that the single largest improvement in brakes is in the area of maintenance rather than with new equip-

ment. There are new things being offered, such as the parking brake, which is spring applied and air released and actuates the rear truck brakes when the air is lost on an air brake equipped vehicle, but the majority of school buses are still using hydraulic brakes.

There is a new split-system on hydraulic brakes which will be offered in the near future by various manufacturers to enable the operator to bring the vehicle to a stop on those occasions where a failure with the present system might cause a complete loss of braking. But the best safety factor in any brake system is still good maintenance—preventative maintenance, prior to failure.

(d) *Weight distribution.* When you select a new bus you should consider weight distribution, which is an important factor in achieving good vehicle balance and stability, but normally we in the industry do this for you by offering only those wheelbases on only those passenger sizes which result in satisfactory distribution.

(e) *Seating capacity.* We are sure you will agree, that in making new vehicle purchases, it is necessary to plan a seat for each youngster and at least 10 per cent more if it is economically possible. Natural population growth often forces some routes to pick up more pupils than can be properly seated, but in making any plans for new vehicle selection you will most certainly want to provide enough seats to accommodate all of the pupils and a few extras.

And, one more thing on accidents—we have attempted, for years and years, to avoid school bus accidents by stopping all traffic. In reality, traffic in this day and age on high-speed highways is safest while it is moving uninterrupted. It is our belief that the eventual long range goal in school bus safety must include a program where the school bus does not interrupt high-speed traffic. This may necessitate pull-off areas on congested routes and other new ways of loading and unloading which will allow traffic to move uninterrupted in both ways.

We think it is imperative that plans be started now to keep the school children completely off high-speed multi-lane highways. The very act of stopping traffic, in many instances, directly contributes to the accident. Today's school bus is much like

the Sunday driver—not a menace of himself, but breeding congestion, ill will, and discontent, all of which are safety menaces.

Now, what are the six sides of this problem?

Vehicle Life and Dependability

Certainly if you have any pride in your transportation organization you must have an excellent degree of dependability. Your buses must maintain accurate time schedules to allow a high degree of conformity on the route and thereby enable Mammy to have Johnny on the corner without making it necessary to wait for long periods of time in adverse weather. It is wonderful, for our purpose, that when we select a unit adequate to do the job in a dependable manner, that we normally also get longer life as an added bonus. There is no better bargain in school transportation than an extra year of dependable service built into a school bus.

Spare Units

Across our rotating hexagon, as life and dependability of the selected vehicles go up, the number of spare units you need to maintain rigid schedules will go down. This is a natural reaction.

Application

But dependability is also very closely related to the application of the vehicle in the intended service. Buses have been getting bigger and bigger for good reason. The population of the various areas has been increasing so as to enable the average school bus route to fill a larger bus in the same time. It is rarely practical to buy a school bus which cannot be loaded in one hour. Consequently, we expect that for many years stabilized communities will cause a sizable demand for 48 and 54 passenger units, but the areas where the population is increasing most rapidly are areas of dense population. In these fast growing densely populated areas, it is natural that we should lean more toward the 60 and 66 passenger units.

Using today's methods, the 66 passenger unit is the longest bus which we can build in a conventional type unit and still stay within the overall length limit of 35 feet. Since this bus will be operated in congested areas, and since it requires 256 inches of

wheelbase to properly distribute the load, it is too cumbersome to maneuver properly in congested areas. Further, in congested areas we can fill a bus of even larger size in a short time and this is where we recommend the transit type unit which can accommodate another row of seats. The transit type unit with the engine in the front, and capable of hauling 72 seated pupils, has only a 208-inch wheelbase of the conventional 66 passenger unit. This shorter wheelbase results in much better maneuverability and the driver is "up front" where he can see.

With the engine mounted in the front, the transit type bus needs a beefed-up front axle and front suspension system to carry the extra load, which is suspended ahead of the front axle. The aisle entrance way is less than ideal because of the engine cover which uses up a large portion of the floor area in the front of the chassis. The forward control unit does retain an innate identity with normal truck parts. The engine, transmission, radiator, and shift controls are all in positions similar to normal truck operation, allowing a high degree of standardization with other parts and a reasonable purchase price.

To gain the ultimate in application for congested areas, we suggest the pusher bus with the engine mounted in the rear; this bus includes the advantages of short wheelbase, ideal driver location, flat front floor with unlimited aisle room, and ideal load distribution with the 1/3-2/3 front to back load distribution ratio, which allows each tire to carry its proportionate part of the load.

The price goes up a bit because it is designed as a bus instead of a truck, but the application is ideal. In visiting with school bus people over the years, we have often been faced with the question of compromises between a truck chassis and a bus chassis and have been asked to build a vehicle specifically for bus service. The pusher bus unit is such a unit and is designed from the ground up to haul young people.

Other applications, which we must recognize in order to complete the job of getting the pupils to school, are cases which transport the physically handicapped, requiring special driver attention, and many areas are hauling small loads over long distances.

In still other applications, it is ideal to use small vehicles for feeder buses to congregate more pupils in pick-up areas where the larger units can pick them up fast and then make multiple trips to the school. For such an application, a small vehicle, such as the *Treefall*, is gaining popularity and serves a very important purpose. Directly across our hexagon is maintenance and operating expense.

Maintenance and Operating Expense

When it is possible through good application to use five large units instead of six smaller units, then you can save one driver, the housing and greasing expense, and the driver's supervision that goes along with each separate unit. If the six units should be 60 passenger units and the five units should be 72 passenger units, it would result in exactly the same seating area. It is easy to see that when our application is improved, maintenance and operating expenses will go down. But when we talk about the proper application reducing maintenance expense, let us not talk about shoddy maintenance. We sincerely believe in preventative maintenance in school buses, to tear down and inspect, repair and replace all parts before they have a chance to fail in operation.

Other things enter heavily into the particular application and should be considered when making the school bus selection. Such things as cold climate where additional heater capacity is needed. And even time zones such as an area which uses daylight saving time, might use headlights, clearance lights and other lamps sufficiently to warrant buying larger generators. So the selection of the proper equipment to fit the particular application is directly related to the maintenance and operating expense. And what else must be remembered? Repairs and vehicle replacement.

Repairs and Vehicle Replacement

Maintenance and operating expenses are very closely related to repair expenses. For instance, in making recommendations for the national minimum standards, it was the consensus of that group, that a 12-volt 35-amp low-speed cut-in generator was a satisfactory minimum to be used on school buses nationally. The statement has often been made and we repeat it here, that so

often the minimum becomes the maximum. People who select school bus chassis are too often inclined to select components without sufficient analysis, especially on technical capacity of items such as generators.

This can result in a vehicle with inadequate electrical capacity to replace the current drawn from the battery. When this happens, it can only mean trouble. A battery is exactly like a checking account—you cannot draw out more than you put into it. In order to avoid dead batteries, many states are now setting a minimum of 12-volt 30-amp low-speed cut-in generators, and even this size is not adequate for all applications. Always compare your generator capacity with the expected current draw.

The wide-spread use of heavier axles, bigger brakes, larger and more powerful engines, in the same application, will reduce the expense of costly repairs and substantially lengthen the vehicle life.

Purchase Price

And to get back to our hexagon—it is not surprising to see that when you take the definite steps to buy adequate components, reduce repairs, and lengthen vehicle life, then the purchase price goes up. Now the purchase price is very important in the vehicle selection and often is the one outstanding factor which is used in determining what the final selection of vehicle should be. We all know that the purchase price is important, but I contend that the price does not warrant the attention which it receives in making a school bus selection because the best is often cheapest in the long run. But price has been over-emphasized to an extent where our hexagon is out of balance. Prices go too low, repairs go up too high and vehicles are replaced more frequently than necessary.

The transportation industry has concentrated its last ten years in large part to the problems centering on economy of operation—cost per mile of units hauled. In coping with this problem, many facets are involved but I would like to make it appear simple by comparing two typical truck users.

The individual, who owns and drives his own vehicle, often faces his biggest obstacle in purchasing new equipment. He must keep the price low because of the money required to finance the deal and

makes his payments out of proceeds earned by the vehicle. Price is important to him, so he buys a highly stressed vehicle and squeezes out every drop of revenue it can produce. It puts him in business but he is not getting a low cost per mile.

The larger operator or company which has better access to capital funds needed to finance the purchase of ideal equipment, is buying more expensive, low stressed equipment. These operators are rewarded with more dependability, longer life per vehicle, less repair expense, and lower cost per mile of units hauled.

Most school buses have long been in the category of high stressed equipment with short vehicle life because of the emphasis on purchase price. I am happy to see bus users taking a good look at the over-all expense of operation and, therefore, leaning farther over to the side of low-stressed long life equipment as an ideal long range way of reducing the cost per mile per pupil hauled.

So there you have it—a six-sided problem of selecting a school bus, but all revolving around safety and written bid specifications; we must never compromise on safety, and we will always have written bid specifications because most buses are owned by public schools—in fact, our last accurate figures indicated that 64 per cent of all school buses are owned by public schools, 10 per cent by private schools, with the remaining 25 per cent by contract haulers.

I am sure that the 25 per cent of the buses which are owned by contract haulers are selected with all the factors which we have discussed here, carefully considered in the vehicle selection. I am confident that the 10 per cent owned by the private schools are carefully selected, based on all six-sides of the hexagon, but very often the 64 per cent which are selected by the public schools, are selected with the purchase price as the prime factor. When the purchase price is the prime factor in school bus selection, an age-old proverb comes into play; namely, that nothing is so bad but that someone else can make it a little worse and sell it a little cheaper.

I am sure that the transportation officials who buy all of their buses on written bid specifications and low bid realize this and

consequently spend almost 100 per cent of their time, which should be devoted to the vehicle selection, to writing bid specifications. It is, consequently, important that we give it some consideration when we talk about selecting a school bus.

On the one side of the ledger we have the people who actually make their vehicle selection based on good and bad experience, and then write their bid specifications so that the vehicle which they have selected will comply and other vehicles will not comply. This gets the job done in a sense, but we could not, in all fairness, contend that this is free and open competition.

Other people tend to set their own arbitrary standards of brake lining area, engine cubic inches and other physical dimensions, which enable the user to select vehicles with components which have previously been found necessary to satisfy his requirements. This also gets the job done in a sense, but this method has some bad side effects which we in the industry do not like. We know that a larger brake will last longer in a school bus operation, but if you buy brakes on their size alone then you destroy the initiative of the engineer who is constantly striving to build a longer life brake in the same size.

We know that an engine with a larger cubic displacement will last longer, but when you start buying engines on size alone, then you destroy the initiative of the industry to build more efficient engines and to build more engine life into engines which are of adequate size and power to do the job. When you specify clutches by diameter because you desire longer clutch life, then you give no credit to the countless number of people who are working on better linings in the same diameter and tremendous strides are being made in this area.

But, generally, when you buy school bus vehicles on price alone, then you are assuming that all of the vehicles offered are exactly equal and you destroy the incentive of individual companies to build more quality and longer life into their specific bus. You must recognize the differences if quality is to be an incentive to the manufacturer.

So it is the recommendation of the chassis industry that written specifications be based

on performance standards rather than physical dimensions. Tell us what you want this vehicle to do and how you want it to react so that we can take the resources which we possess, our efficient staffs of engineers and testing personnel, to build you the vehicle to do the job which you want it to do. Tell us what you expect by way of vehicle performance and vehicle life. Tell us what problems you are encountering which need to be solved and let us help you with them.

When you write bid specifications, take the time to investigate your specific needs

and write specifications which will result in the quality of merchandise that is required in your application. And when you make your selection from those offered, pick the units that are most economical in the long run, buses that will add to the dependability of your time tables and add to your vehicle life, that will reduce repairs, cut down your operating expenses and eliminate accidents.

Let the local chassis people help you with written bid specifications so that this six-sided figure will become balanced and revolve the way it should—around safety.

THE APEX IN SCHOOL BUS MAINTENANCE

By JOHN M. PARSONS

Supervisor of Transportation, Ohio Dept. of Education, Columbus, Ohio

Pupil transportation in the U. S. today is a big business. It is big in size, big in cost, and a big operation to administer. In many schools across the Nation, pupil transportation is the big problem of school boards and school administrators, and—this problem is still growing.

A few short years ago pupil transportation was a small auxiliary service to be tacked onto the school budget and to be administered easily by spending a few hours with several bus drivers. Today the cost of pupil transportation is a major item in the school budget, and administrators spend many hours struggling with the problems that accompany this growth.

Pupil transportation is no longer an auxiliary service, but a necessary and important part of the total education program. Transportation is essential for the operation of most school systems today. The school bus has also become an extension of the classroom in many school systems. The use of school buses for educational trips such as field trips, county and state testing programs, county vocational schools, etc., is increasing.

School transportation is being used not only to transport pupils to and from school, but to extend the educational horizon, to help attain the American ideal that every

child, regardless of where he lives, or his physical handicaps, has the right to an adequate educational opportunity.

School transportation can be expensive, and it is becoming more so in an increasing amount annually. Many factors are helping to increase the cost of pupil transportation today. School district reorganization and consolidation have expanded this service to a vast number of students who now attend schools in areas far from their homes. The migration of large masses of city people to the suburbs has increased the number of students to be transported.

Mechanization of the farm has reduced farm population resulting in more sparsely populated farm areas. This, in turn, has caused an increase in the size of rural school attendance areas. The steady increase in our population, coupled with the fact that students attend school more years than in the past has added to the burden of pupil transportation.

School districts in the past have been typically small in area and population, because school districts were small the need for pupil transportation did not create any urgent fiscal consideration by school boards.

School boards were able to operate their pupil transportation program with a small fleet involving very little capital or opera-

total outlay. These small fleets were usually maintained by local garages and since most schools had small fleets their yearly maintenance cost would be very minor in comparison to other component parts of the school budget.

For instance one district in Ohio ten years ago had a fleet of two school buses. The total operational expenses for the two buses for an average year was \$2,400. Today this district by consolidation inherited 30 additional school buses. The average operational cost ten years ago per bus was \$1,200. Considering the present average operational cost in Ohio for each individual bus at \$2,100 the total operational cost for this district with 22 buses would be \$46,200, not a small item anymore for school boards to consider.

Also, to be considered by school boards is the capital outlay needed to transport all eligible students. Replacing 22 buses at one time would cost a school board approximately \$132,000. Therefore, it is of the utmost importance, due to increasing operational cost and capital outlay, for a district to establish a safe, efficient and economical maintenance program that will insure maximum longevity for their school bus fleet.

I. Developing a Summer Maintenance Program

It is of the utmost importance for school districts to establish a maintenance program, not only for economy and efficiency but also for the safety of our students transported. A maintenance staff dedicated and responsible for a safe operation is the apex of a safe, economical, and efficient maintenance program. We in Ohio feel that during the summer months is the critical period and at this time a maintenance foundation for school buses needs to be established.

In other words, this is the time when mechanics can do a superb preventative maintenance analysis and have the necessary time to make proper repairs. If this foundation is not built strong enough during the summer months, then a maintenance problem is created for the coming school year.

In Ohio our summer issue of the *Pupil Transportation News Letter* is devoted entirely to maintenance. The following are some of the helpful hints and preventative maintenance tips we call "trouble shooting"

that are used to guide mechanics in their preventative maintenance program.

Low Oil Pressure can indicate clogged oil pump, worn main bearings, worn rings or loose lines—small leaks are not too difficult to spot, and it has been estimated that an oil leak of one drop every 30 ft. will account for a gallon of oil in about 400 miles of driving.

Valves which do not seat properly, or do not have clearances adjusted properly can often be detected by sound, and of course, can always be detected by the compression test.

Cylinder Head and Block: A defective head gasket or a warped head or block will result in loss of compression. Cracks in the head or block may be indicated by water on the spark plugs or in the oil pan, and may result in loss of compression, water in the fuel mixture or improper lubrication.

Engine Mountings: Visual inspection can be made to see if they are very loose. If the mountings are not kept tight, damage can be done to the clutch and/or drive line parts.

Clutch: In those buses equipped with a conventional transmission, power is transmitted through a clutch. Improper adjustment, i.e., no pedal free travel, will cause a slipping clutch which, of course, can be quite expensive. Improper driving habits, such as driving with the foot on the clutch, can lead to the same result. A dragging clutch is most likely caused by too much pedal free travel and natural wear must be compensated for by adjustment of pedal linkage.

Transmission Noise: Noise which seems to come from the transmission, may be caused by another assembly such as the axle, propeller shaft, universal joint, or clutch. Transmission noise may also result from the use of improper or insufficient lubrication, or from poor driving practices. Of course, if the gears are worn or broken, or the bearings on the shafts are bad, replacement is required. This is expensive.

Propeller Shafts and Universal Joints: Excessive noise or vibration can be caused by lack of lubrication; also if propeller shafts are not assembled with universal joints in the same plane, vibration will result. Worn universal joint bearings or journals or a sprung propeller shaft will cause vibration and noise.

Axles: An unusual noise is usually the first indication of improper functioning of axle driving parts. Noises which seem to come from the axles may be caused by the transmission or tires. If there is a continuous axle noise, drive the vehicle on soft ground. If the noise ceases, it has been caused by the tires and not the axle. If the noise continues on soft ground, it is caused by worn or improperly adjusted wheel bearings, worn or improperly adjusted differential gears and bearings, or insufficient lubrication in the differential. If the axle noise is heard in drive only, or in coast only, this is an indication that the differential pinion and ring gear are out of adjustment or excessively worn.

Wheels, Hubs and Tires: 1. Excessive or unequal tire wear—unequal tire pressure may be responsible. Inflate all tires to the recommended correct pressure. 2. Front wheel misalignment will cause unequal tire wear. Check and correct. 3. Bent wheels or damaged wheel bearings will cause uneven tire wear. Replace if necessary. Hard steering may be caused by under-inflated tires, steering gear in need of adjustment, or lubricant, front wheels out of alignment or wheel bearings in need of adjustment.

Steering System: Proper operation of the steering system is closely related to other units in the vehicle. Steering difficulties may involve such factors as front axle alignment, front spring suspension, tire inflation, wheel and tire mounting, wheel bearing adjustments, frame alignment and brake adjustment.

Springs: Break of spring leaves is usually the result of overloading the vehicle or driving at excessive speeds over rough routes. The bus carries a plate giving the manufacturer's recommended gross vehicle weight. This recommendation should be followed, or if this is not possible, allowances should be made when driving the vehicle. Loose or missing rebound clips, or loose U-bolts can also cause spring failure. Frozen shackles, due to lack of lubrication, will also cause spring failure, and also cause springs to break.

Shock Absorbers: Where furnished, are an important part of the suspension system with the springs. They should be checked and filled or replaced when they do not serve their function of damping out rebound.

Brakes: Today's modern buses subject their brakes to terrific stresses. Therefore, it is imperative that brakes be kept in adjustment. If linings are allowed to wear too long, or if shoe contact is not true on the face of the brake drums, wear will be far more rapid and brake drums can become egg-shaped or out-of-round. To correct this wearing is far more expensive than the routine inspection. Tightening of connections, slack adjusters and the like and relining—should be part of your standard preventative maintenance program.

Body Maintenance: During the summer all school bus bodies should be checked for rust spots, deteriorating flooring and seats, emergency door operation, replacement of glass, body attachment to chassis frame, first aid kit, all warning devices and lights, fire extinguishers, flares, pots, etc.

Summer months are an ideal time for mechanics to touch up all rust spots or repaint portions of body. Older buses should be repainted. This will add longer life for the body, and will eliminate need to replace a school bus because of body deterioration.

A preventative maintenance summer inspection check sheet should be available for the mechanics and all buses should be checked thoroughly during the summer. We mail a check sheet to all schools early in the spring as a reminder to the maintenance staff that a preventative maintenance program should be a complete and thorough analysis and repair of the school bus chassis and body.

II. Developing a Preventative Maintenance Program

Preventative maintenance is the necessary apex for a successful and economical school bus operation. An efficient and effective preventative maintenance program is the key for dependability; in fact, it is essential that school bus fleets maintain a dependable service. School administrators depend upon the pupil transportation staff for an operation that will deliver the students to school daily and on schedule.

Commercial bus fleets are adequately maintained, not only because road failures must be kept to an irreducible minimum, but because preventative maintenance is the cheapest way to maintain a bus fleet. Railways and airlines practice rigid preventative

maintenance to avoid mechanical failures during scheduled operation and to reduce total operating expenses. School buses must also be maintained properly if reliable and low operation costs are to be achieved. Safety of bus equipment is almost wholly dependent on preventative maintenance because even the finest bus becomes unsafe if proper inspections and preventative services are not provided.

Preventative maintenance differs from regular repair or replacement maintenance. In comparison, a preventative maintenance analysis or inspection is similar to an annual physical examination. Doctors evaluate and analyze the working parts of the human body to ascertain the need for a preventative medicinal program before the body has a serious major breakdown. This preventative program for human beings tends to extend the length of our life expectancy.

It is imperative to have a staff trained in proper methods and procedures for diagnosing trouble. Just as a doctor is trained for diagnosing human sickness so should the maintenance staff be trained in diagnosing mechanical sickness. A superb preventative maintenance program will extend the longevity, prevent major breakdown, and provide a safe, efficient and economical school bus fleet.

Developing and administering a good program of preventative maintenance for school buses is a cooperative undertaking that begins with the top level policy-forming officials and runs throughout the entire organization. Failure to place maintenance on a policy-forming level is a mistake that often results in inadequate care for school buses. A good maintenance program must be planned and executed at the level of organization responsible for the transportation system.

III. Developing a Dedicated Maintenance Staff.

Developing a basic fundamental attitude and dedication toward preventative maintenance is one of the most difficult things to

accomplish. The development of a proper attitude by the maintenance staff is one of the basic goals that needs to be achieved if a good program of preventative maintenance is to be established. The maintenance staff should constantly be looking for new methods of improvement and dedicate themselves to perfection.

This is often difficult to develop since looking for work to do and its perfection is a concept not always easily acceptable.

The men who drive and service buses must fully believe that every bolt and screw has a definite function to perform, and unless each is in its place, the bus is not complete. Maintenance cannot effectively function where drivers and servicemen do not value the little things that do not immediately impair bus functions. A driver who is genuinely concerned when he knows that the slightest thing is wrong with a bus has a good maintenance attitude. He simply cannot let minor ailments go without attention.

A maintenance staff dedicated to an efficient and safe program of preventative maintenance needs to have many qualifications, but basically they should be dedicated to the following fundamental requirements:

1. Knowledge of all parts of a school bus, and especially the correct function and location of each part.

2. A pride or satisfaction in good workmanship. A good maintenance attitude can be satisfied only by doing things the right way all the time.

This kind of attitude toward preventative maintenance can be developed only through long and careful training. The need for careful attention to small details and the need for exact workmanship must be emphasized by school administrators, training and supervisory personnel, and by everyone having anything to do with school bus operations. Without this emphasis, it is impossible to develop a preventative maintenance program sufficient to insure long, dependable service, and economical operation.

OFFICERS OF THE MOTOR TRANSPORT CONFERENCE NATIONAL SAFETY COUNCIL 1961-62

Vice President for Motor Transport—MARK ROBESON, Vice President, Yellow Transit Freight Lines, Inc., Kansas City, Mo.

Chairman Motor Transport Conference—F. S. LAKE, Director of Safety, Interstate Motor Freight System, Inc., Grand Rapids, Mich.

Vice Chairman Motor Transport Conference—W. G. MCINTOSH, Manager, Engineering Department, Hartford Accident & Indemnity Company, New York, N. Y.

Immediate Past General Chairman Motor Transport Conference—A. J. NAQUIN, Safety Counselor, New Orleans Public Service, Inc., New Orleans, La.

Chairman Commercial Vehicle Section—A. S. LOMBARDI, Director, Safety and Personnel, Western Truck Lines, Ltd., Los Angeles, Calif.

Vice Chairman Commercial Vehicle Section—J. W. LUMPKIN, Manager, Safety Division, R. E. A. Express, Inc., New York, N. Y.

Chairman Transit Section—J. M. BUSBY, Jr., Safety Superintendent of Transportation, Memphis Transit Company, Memphis, Tenn.

Vice Chairman Transit Section—LEE MITCHELL, Director of Safety, Cincinnati Transit Company, Cincinnati, Ohio.

Chairman School Transportation Section Organizing Committee—BILL LEMON, Director of School Bus Safety, New Mexico State Department of Education, Santa Fe, N. M.

Standing Committee Chairmen—Awards—ELMER R. SCHUELMANN, Superintendent, Transportation and Safety, United Motor Coach Company, Des Plaines, Ill.; *Conference Membership*—KARL SCHULZE, Supervising Safety Engineer, Standard Oil Company of California, Western Operations, Inc., San Francisco, Calif.; *Medical Advisory*—HAROLD A. BRANDALONE, M.D., Chairman, Committee on Standards for Motor Vehicle Drivers, Industrial Medical Association, New York, N. Y.; *National Fleet Safety Contest*—HAROLD R. HOSEA, Director of Research, National Association of Motor Bus Owners, Washington, D. C.; *Nominating*—J. P. HIGHTOWER, Assistant Vice President, Chicago Express, Inc., Cleveland, Ohio; *Program*—J. A. DE PEW, Director of Safety and Personnel, Dohrn Transfer Company, Rock Island, Ill.; *Publications*—R. N. PARRICH, Safety Consultant, American-Gas Association, New York, N. Y.; *Research*—E. J. EMOND, Director of Automotive Safety, Armour and Company, Chicago, Ill.; *Selection and Training*—L. F. FURLEY, Superintendent, Transportation and Safety, Toronto Star, Limited, Toronto, Ont., Canada.

Members At Large—E. G. COX, Chief, Section of Motor Carrier Safety, Interstate Commerce Commission, Washington, D. C.; C. E. EMERENBERGER, Manager, Sales Operating Department, Standard Brands, Inc., New York, N. Y.; DOUGLAS M. FRACASSO, Field Safety Specialist, Nationwide Insurance, Columbus, Ohio; P. J. FANNING, Director, Bureau of Personnel and Safety, San Francisco Public Utilities Commission, San Francisco, Calif.; H. K. HALABOOKS, Director, Accident Prevention Division, National Automobile Transporters Association, Washington, D. C.; A. L. HAUCK, Director, Safety and Public Relations, Transportation Underwriters, Inc., Indianapolis, Ind.; G. D. SONTHEIMER, Director, Department of Safety, American Trucking Associations, Inc., Washington, D. C.

Staff Secretary—A. C. FINCH, Manager, Motor Transport Department, National Safety Council, Chicago, Ill.

OFFICERS OF THE

COMMERCIAL VEHICLE SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—A. S. LOMBAARD, Director of Safety and Personnel, Western Truck Lines, Ltd., Los Angeles, Calif.

Vice Chairman—J. W. LUMPKIN, Manager, Safety Division, R E A Express, Inc., New York, N. Y.

Secretary—H. T. WALTON, Director of Safety, McLean Trucking Company, Winston-Salem, N. C.

Immediate Past General Chairman—J. A. DE PEW, Director of Safety and Personnel, Dohrn Transfer Company, Rock Island, Ill.

Standing Committee Chairmen—Program—J. W. JACOBSON, Director, Accident Control Division, F. J. Boutell Driveway Company, Inc., Flint, Mich.; *Content*—RICHARD O. OLSON, Safety and Personnel Director, Dan Dugan Oil Transport Company, Sioux Falls, S. D.; *Driver Award*—BERRY L. WHEAT, Safety Director, Eastern Express, Inc., Terre Haute, Ind.; *Membership*—W. A. DUFFY, Director, Safety and Personnel, The Davidson Transfer and Storage Company, Baltimore, Md.

Regional Chairmen—Central—EUGENE A. HATFIELD, Safety Director, Coca-Cola Bottling Company, St. Louis, Mo.; *Eastern*—NORMAN J. PSYCHOLOGICAL ACCIDENTS — THE INDUSTRIAL PHYSICIAN'S VIEWPOINT

By D. J. KILLIAN, M.D.
 Medical Director, Texas Division
 Dow Chemical Co., Freeport, Texas

Throughout the years that I have treated occupational injuries it has become increasingly apparent that the vast majority of the accidents were not due to mechanical failure of equipment, or faulty protective devices, but due to the human failure of not doing the proper thing at the proper time. When I was a neophyte in this field, I logically assumed that such was due to day dreaming or perhaps just a chance, but as my appreciation of the human psychological mechanism became more acute I began to realize that there was something far deeper and more basic in many of these accidents. This human understanding has progressed until at the present time I am firmly convinced that a significant number of our occupational injuries are due to basic psychological mechanisms, the patterns of which are just as real as the mechanical equipment that we use.

It is time that the folks who work in the field of safety develop an increased awareness of this and, also, realize that many of these psychological mechanisms must have their protective devices just as certain machinery has to have its protective devices. Today through the presentations on this panel I hope that you will develop this increased awareness of the necessity to understand people and recognize certain emotional danger signals if you expect to make a real impact in the field of safety.

I do not intend to bombard you with a barrage of psychological gobbledegook, but I would like to point out to you some fundamental facts about everyone's personality and illustrate how certain psychological mechanisms may have a bearing upon certain accidents. In all of our minds we have certain areas which we must understand before we can begin to comprehend this problem of the psychological influence of the human mind on industrial accidents. It is a well recognized fact that the human mind can be divided into three

parts: the conscious, the preconscious and the unconscious mind.

The conscious portion is the part that does our everyday thinking. It is the part that I am using at this time in presenting this speech to you.

The preconscious is the area of the mind which we do not ordinarily use, but from which facts can be brought up to the conscious mind rather easily.

On the other hand the unconscious mind is the deeper, inner reserves, which is composed of material not immediately available to our conscious thinking, but is composed of stored experiences and conflicts that have occurred throughout our whole lives. The influence of each of these areas is extremely important to the man on the job, but the thing that should be extremely enlightening to all of you is that fundamentally our lives are governed, moulded and influenced by our unconscious thought processes.

Let me illustrate it in this manner. When one learns to drive a car he consciously thinks about taking his foot from the accelerator and applying the brakes during this training period. After awhile this becomes automatic and now when one approaches the stop sign this particular act does not enter one's conscious mind at all. It is in the preconscious area where it can be easily recalled if one puts his mind to it.

If the brain did not function in this manner, our lives would be completely occupied by all sorts of irrelevant thought processes everytime we did something. These things must function at a lower level and on an automatic basis in order that we may devote our conscious thinking to the important things. The unconscious mind, deep within the inner recesses of our thought processes and can only be brought out by certain psychiatric techniques that we cannot concern ourselves with today.

There is one fact that I feel is extremely important, that I have discovered from experience. It is that people who work in safety, as well as members of supervision, have a difficult time accepting the concept that the unconscious mind can really influence an individual's actions to the extent that it will produce serious accidents and disabling injuries.

When one mentions psychological causes of accidents most of the people think in terms of the man who is consciously trying to hurt himself to gain a certain advantage, or that a man is preoccupied by his emotional problems and he does not realize that danger is creeping upon him. If one just considers these aspects of psychologically motivated accidents he is indeed missing the boat on the vast majority of cases. Let us take a few examples to try to drive across the point.

Case number one. This case involved a man who was working on an extruder press in which the equipment was well guarded in a manner that made it virtually impossible for the man to get his hand in the extrusion mechanism and throw the switch at the same time. However, early on Monday morning this happened and the man was brought to the medical department with a seriously crushed hand. During his anguish and state of semi-shock he confided in the industrial physician that he really did not much care what happened to him since he had been having marital difficulty and his wife had run away two days before with another man. At no time after this revelation would he again discuss this situation. The wife was located, however, and within a short time she was at the bedside of the victim crying and feeling a great deal of remorse towards the injury.

Now what did this accident accomplish for this man? Obviously it served the purpose of getting his wife back (at least temporarily), and I think one should really ask himself the question, "Was this really a mechanical accident of a psychologically-induced accident?" When the accident reviewing committee made a study of this particular situation they reported with their analytical, conscious, thinking that they could not understand how this individual could override the guarding mechanism and have this happen.

The question that all of you are probably wondering about is, "Did this man do this deliberately?" To this I would like to add my unqualified "no" he did not! Preservation of life and avoidance of pain and injury is a powerful instinct, and this man's unconscious mind was fundamentally driving him to this solution of his problem. How many times we see highway accidents where there is no logical explanation of why it occurred and it is a matter of statistics that mechanical failure of the equipment plays a minor role in the overall problem. The problem is people and most of these problems involve psychological mechanisms which cannot be understood by the conscious portions of our mind.

Now, let us look at another case and perhaps we can more clearly bring out some other of these unconscious underlying factors that are so important. This man was working in an area where they were temporarily short handed, and his foreman asked him to roll a 400 pound drum out of the aisle. This normally was not the employee's job and he conveniently forgot the order for several hours. Later the foreman again reminded him that the drum in this area was a safety hazard and should be moved. Again the individual chose to ignore this command, and a short while later the foreman became rather disgusted with this turn of events and sternly commanded that the man had better get the drum moved, or else! The employee then went out, seized the drum, and with a tremendous strain which was conceived in anger and executed with hate, moved the drum out of the aisle and, in the process, produced a severe lumbosacral strain in his lower back.

The man was disabled over a year and intensive investigation revealed no evidence of a ruptured disc or any physical disability which would account for the prolonged loss of time from the job. Many months after the original injury, I got into the act as his physician and found out that at one time he and his foreman had been hourly employees, vying for the same job as foreman and that the other fellow eventually got. In my discussion with him he literally exploded resentment towards this man when given the opportunity.

This incident that I pointed out to you reminded me of a little child who deliberately threw himself down and tried to sustain an injury and thereby punish his parents who were the symbols of authority to him. This man's back pain (which I am convinced was a simple muscular strain) became a symbol of the festering resentment that he had towards this figure of authority. The eventual outcome was that the more his back could bother and disable him the more he could blame his foreman for what had happened.

This type of thing is happening all the time in industry. Many times the industrial physicians are not treating an organic injury, but are treating a serious interpersonal relationship between a worker and the chain of authority above him. We have to recognize this and do our best to deal with it effectively. I also feel very strongly that you who deal with safety should likewise recognize it and do your best to deal with it effectively.

I have presented this approach of the consideration of the psychologically motivated aspect of occupational injury to many people in management and invariably I have received the same reaction, which I think is a very healthy one, and I am sure all of you in the audience will be asking the same question. "So there are underlying psychological reasons which truly can be on an unconscious basis for many of these things, but just what good is your talk doing? It is one thing to tell us why something happens, but it is a horse of a different color to say what you are going to do about it. After all, we cannot all be psychologists, or psychiatrists, or physicians, and how can we as supervisors and safety people hope to prevent psychologically-motivated accidents?"

My answer to this is, first of all, there needs to be an awareness all the way up and down the line of management that this business of the psychologically-moti-

vated accident is a very real thing. Secondly, there needs to be training so that these people understand how certain emotional conflicts can express themselves in various physical ways of having accidents. With this should come skill in recognition and assigning people to sublimate many of these emotional conflicts into constructive channels.

Let me give you an example. Each of us has the very primitive emotion of aggression and the skillful supervisor should direct the individual who manifests signs of over-aggression into some form of activity which will be useful in allowing that man to work off his aggression. For example, if he is an outside worker he might be given an ax to clear shrubbery from the edge of a road so that he can work off his aggression by wielding the ax against the trees and shrubbery. This will go a long way towards preventing him from wielding a venomous tongue against his fellow employees or his supervision. It may prevent him from an unsafe act, because his hostility may seek expression in mentally unhealthy channels to punish his boss.

Do not lost time accidents really do a very effective job of punishing the boss? People must be taught that everyone in supervision should be an emotional first aid station and allow the employee to ventilate his problems, and to recognize that when this becomes insufficient he should refer the man on to those who have the special training to deal with these problem cases. The days of the old hard nosed sergeant are over and experience has shown that management gets more productivity, fewer accidents and a healthier and happier worker, when he is dealt with in an environment of understanding, sympathy and genuine concern for the employee. People in safety work can help a great deal by promoting this philosophy and pointing out to management the important factors that we have discussed here.

THE OCCUPATIONAL NURSE'S ROLE IN THE DIRECTION AND REFERRAL OF EMOTIONAL PROBLEMS

By ANNE KLOIBER, R.N.
Supervising Nurse, Pabst Brewing Co., Milwaukee, Wis.

How many times have you heard said, "don't pay any attention to him—he hasn't got all his marbles?" Or, how many times have you discussed an occupational injury or disease with the foreman or supervisor only to have him inject in the conversation—somewhere, "that guy's nuts—he doesn't keep his mind on his work—something's bothering him."

Yes, that is precisely the point! SOMETHING is bothering him! And, it's up to us, as occupational nurses, to steer him in the right direction so that he receives proper help.

We nurses in industry, of course, shouldn't have to wait until an injury occurs or until the man's apparent emotional problem is brought to light by the foreman or supervisor. We should, because of our personal knowledge of people at work, be able to detect certain signs and signals which should alert us to action. For this reason, it is vitally important that the nurse maintain a professional, yet warm, relationship with all employees so that they will come to her willingly with their ailments and injuries. Through her adequate medical records, the nurse will then be able to see patterns of behavior which perhaps even medical people outside of the plant could not detect.

It might be well at this time to add that these people with problems—these people who are "different"—not only call attention to themselves in the Medical Department. They are known to Personnel, the Credit Union, and in other areas of the plant as being in one jam after another. It seems almost as if they're enveloped in trouble.

One can't help but wonder if these situations—these difficulties they create, aren't actually S.O.S.—signals for help. What a pity then if, we, who are in a position, at least to, give them some guidance, close our eyes and ears to these situations—perhaps give them something for their nerves, or offer them another job or a few rationed words of reassurance—just to satisfy our conscience.

This problem, as you are all aware, is not confined to industry alone. All one needs is to look about him—be it in a super market, church, school, or what have you. Emotional outbursts of all kinds are visible almost daily in society at large.

Dr. Gerald Gordon of the DuPont Co., in his paper on "Industry's Problem Children," states:

"People are not either sane or insane in the same sense that a woman is or is not pregnant. Whereas it is impossible to be a little bit pregnant, it is quite commonplace to be a little bit crazy. Some degree of mental illness is present in all of us, normal people, inasmuch as we all suffer from it, we find it difficult to see in others, and all but impossible to see in ourselves.

"The diagnosis of mental illness may be made early from apparently trivial and unrelated signs and symptoms if we are willing to be realistic and objective, even about ourselves. Dr. Dersheimer once wrote that 'industry constitutes one of the most realistic situations existing in our modern world. As such, it is the testing ground on which the strength and weaknesses developed by the early training of individuals become clearly apparent.'

"It is, therefore, in industry where many of the earliest signs of failure or mental illness may be seen. This situation gives management and supervision an opportunity, found almost nowhere else, to do a real job of mental hygiene which will benefit the employee no less than industry."

In keeping with the fast pace we have set for ourselves today, with the result, of course, that there is really never enough time for everything we would like to do, I suppose we feel justified in effecting a job transfer for someone who can't get along in a certain department or where a specific problem exists. But we cannot keep shrugging off these responsibilities in this manner—we must face these issues squarely and give them the time that they truly deserve.

Let me tell you of a problem which existed in our plant recently. This problem, I am happy to say, was resolved with the patient coming out as the victor—one of those "happy-ending stories." This young man has no vision in one eye as the result of a childhood injury. Needless to say, he protects his remaining good eye more than one would do normally. Because of his low seniority, he is occasionally placed in a transfer pool to areas where caustic solutions are used for cleaning. Protective equipment is issued this man, as is to all employees. However, when this transfer arrangement first started, this man would be in the Medical Department constantly with one caustic burn after another—his self-diagnosed caustic burns. Actually, most of the time they weren't burns at all.

During every visit he would beg us for a transfer to another department where this hazard was not present, but the doctor and I both felt that we would try to help him face the problem and not run away from it. We knew that if we gave in to him this one time, we would set off a chain of transfer requests. At any rate, the course was slow and at times quite stormy. There were two or three times when the foreman called us and shouted, "get this guy out of my department—he's getting everyone jumpy."

But we hung on a while longer and were victorious. We tried to educate him as to the proper equipment to wear. We tried to instill in him a respect not only for caustic soda, but for all harmful chemicals. We spelled out to him the proper first-aid measures in the event he did come in contact with them in spite of his caution.

Recently, he came in to see us, and thanked us for making a man out of him. His foreman has told us that he has become a more industrious and safe worker. Not only are we thankful that he's not running to the Medical Department three or four times a day with apparent chemical burns, but more important, we are glad that he faced up to the problem and did something about it.

Happy endings such as this are not always possible. We shall continue to have the overly fearful worker or, conversely, the careless worker—the guy who says, "I can take a bath in the stuff," but who continues

to be a threat because of his deep ulcerations from strong solutions. We shall have to realize that lack of attention to the inanimate things about us often involves us in accidents and that this lack of attention is usually conditioned by our mood or preoccupation with other things at that time.

We shall have to stop using that expression, "he's just accident prone," and, instead, learn to appreciate that accidents to a large extent are the result of the person being unable to cope with the situation in which he is placed. We shall have to realize that our physiological well-being can go up or down like a thermometer, that everyone has regular periods of exhilaration and depression—that it's just not women with "estrogen imbalance."

It is suggested that the nurse include in her history, following an occupational injury, the mood the person was in prior to the incident. She might even go a step farther by asking this same question of the foreman or supervisor. At least it might alert him to the fact that maybe this business of emotions isn't just something you read in a book.

In going back over our more serious and disabling injuries of the past year or so, we came up with the following moods or things employees were thinking about just prior to the time of the accident:

One man, who sustained very serious caustic soda burns to 30 per cent of his body, including his eyes, admitted to the doctor that he and his wife were having marital difficulties—that on the morning of the accident, they had an unpleasant scene which was witnessed by their youngest child, who apparently was the apple of his eye. He admitted to the doctor that this argument had left him nervous and jumpy—and that he just wasn't thinking when he dumped the water into the powder instead of vice-versa.

Another man who sustained a traumatic thumb amputation said afterward that he found he was in an ornery mood from the time he got up in the morning—you know, one of those days when everything goes wrong! Still another man claimed the foreman was nagging him constantly on the morning of the accident.

Is there little wonder then that these people become highly vulnerable to accident

prone? An industrial nurse recognizes the fact that tension and conflict among workers, or between workers and foremen, often causes a rise in accident frequency. Her knowledge of industrial health counseling in such instances can be used most effectively.

While we're touching on the subject of counseling, let me say here that industrial nurses can make themselves responsible to a certain degree for teaching health to the employees. Nothing can replace an intelligently administered health program. Work habits of the employees are influenced by their mental processes and by the help or hindrance offered to them, be it in their homes or at work. It is helpful to the nurse to observe not only how the employee behaves under unusual circumstances but to observe his customary everyday behavior.

Management, of course, also must share in this responsibility. Management should know the physical capacities of the worker, his home situation and his personality traits. Pre-placement physical examinations are a must, as well as routine annual re-examinations. Matching up the job requirements with the individual so that a happy medium is reached is another of management's responsibilities.

A NEW CONCEPT OF ACCIDENTS

By SANFORD G. ROGG, M.D.

Medical Division, E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

There can be no questioning of the fact that, as long as we remain human beings, we will become involved in accidents. Obviously the more we understand the multiple factors involved in accidents, the better prepared we will be to prevent the avoidable ones.

There has been an increasing awareness regarding the fact that our continuing nationally high accident rate is a reflection of personal rather than machine failure. Certainly the engineers who design machinery and in particular, those whose task it is to pay attention to safety features

I would also like to stress the importance of confidentiality of medical information. While it is generally accepted that management must know of existing physical capacities and limitations so that proper job placement can be effected, there is no special reason why all the details have to be spelled out. If the examining physician interprets his findings into a physical capacities appraisal and sends this to management, this should be sufficient. One of the most tested attributes of the industrial nurse is her ability to maintain confidences. If she is to do well as a counselor, this must continue to be of prime importance.

In summation, then, I would like to offer that nurses, because of their personal knowledge of people at work, because of their background fortified with courses in psychology and counseling, and because of their thorough medical records, are able to see patterns of behavior and emotional problems which can then be referred to the proper people for care.

Having the psychiatrist in mind, did you hear about the two psychiatrists who met on the street? One said, "Hello, there! And how are you today?" After which they parted and the other one said, "Hm, I wonder what he meant by that."

and operational control, have all done an extremely competent job.

As a matter of fact, they have done their work so well, that the continuing high accident rates we see quoted yearly throughout our country, can in no sense be called a responsibility of poor design features. At the same time, it would be foolish to inter by any means that continuing effort on the part of design engineers would be unrewarding. The fact to be emphasized is that even if we designed to theoretical perfection, we undoubtedly would still have well over 80 per cent of our accidents occurring.

TABLE I
Leading Causes of Death by Age Groups
U. S. Dept. Health, Education & Welfare

AGE	Accidents	Heart Disease	Cancer
1-4	Accidents		
5-14	Accidents		
15-24	Accidents		
25-34	Accidents	Heart Disease	Cancer
35-44	Accidents	Heart Disease	Cancer
45-54	Accidents	Heart Disease	Cancer

Table I, while contributing no new knowledge on the subject, does emphasize the place that accidents hold as a cause of death in our country.

Without becoming too involved in figures, the National Safety Council's statistics list approximately 40,000 people killed in automobile accidents, 14,000 in industrial accidents, 27,000 in home accidents, and 10,000 public deaths. We can define public deaths to include train accidents, airplane accidents, public fires, etc. or whatever else might happen to a person in a public situation. To this, add an untold number of injuries, possibly running as high as 24 million of the type that brings itself to the attention of a physician or limits a person's activities for at least one day.

Perhaps the question arises as to why the medical profession is becoming so concerned about safety. Certainly any condition that kills about 97,000 people a year and leaves over 400,000 with permanent residual injuries, varying from the minor to the most severe type, should of necessity command the attention of the profession that has the responsibility of caring for these people.

In my opinion, most of the problem is to be found in the emotional status or even in its broader aspects, the personality of people who become involved in accidents. And to digress for a moment, we can define personality in the sense that it is being used here by labeling it as consisting of the habitual patterns of temperament, intelligence, desires and behavior that distinguish us as individuals. We can readily appreciate the problem, in that it is difficult to delve into and obtain an understanding of these factors. This can be easily understood if we realize that we are dealing with personal motivations and conflicts of thought, wishes and desires of people, combined with all the frustrating situations with which they are confronted.

It should be emphasized that there is no

desire to leave the reader with the implication that the problem of accidents is a narrow concept, a psychiatric one, in that mentally ill people who require treatment are the ones who become involved in accidents. It would be much better and more easily understood, if all of us were to acknowledge that we are liable to accident situations at various times throughout our lives.

What is overlooked in a good deal of the work that is being done, is the fundamental factor that looms as most important in all of our dealings with people. This is, that although we like to think of man as an intelligent, rational, coherently reasoning and consistently logical individual, man in reality is predominantly guided by motives and feelings of which he is most often unaware. These logical powers only serve as a means of allowing the individual to reach goals that are created by more deeply placed emotions. This in turn could lead us to realize how we must look at, and deal with, these feelings if we are to be successful in our safety endeavors.

We must realize that becoming involved in an accident is basically the same as any other condition about which people become involved in difficulties. These individuals could just as well solve their problems by developing stomach ulcers, severe headaches, spastic colitis or the numerous other entities that are diagnosed as psychogenic illnesses. The accident-involved person is, in a very unsuitable, and from the viewpoint of our society, in a totally unsatisfactory way, solving the emotional problem by becoming involved in an accident situation.

It appears suitable and advisable to go a little further at the present time and state that the emotions we are discussing arise from the whole life of the individual, the twenty-four hours of each day that he lives, and by no means only the eight hours that he spends in gainful employment.

We have all heard the expression many times over, that so and so tends to take his work home with him. Well, we can reverse this and state that everybody tends to take his home to work with him.

My interest in the factors producing accidents was aroused while discussing one with a safety engineer. He was describ-

ing an accident that had just occurred and in the course of the conversation said "I just don't know what happened. This man has been doing the job for years and knows it perfectly well. As a matter of fact, in the usual course of events, we checked over everything, the switch controlling the machine, and the machine itself, and they were in perfect operating condition; still, the man became involved in an accident that resulted in the amputation of his finger."

After this discussion my thinking went along the lines of what could have involved the man in this accident, and broadening things a bit began to wonder what could be going on in the mind of a person just prior to his having an accident.

By accident, we are referring of course to the common garden variety where the individual alone is responsible. Technically we could call this a "personal accident" with the primary cause to be found in the individual in contrast to the "impersonal accident" with the primary cause in the environment. It is possible to be even more precise here and state that this study was not directed towards an exploration of the basic personalities of these individuals, many such studies have been done and the literature is replete with articles describing the personalities of people who become involved in accidents. Attention was focused on the thinking occurring in a person's mind prior to becoming involved in an accident and by prior is meant half an hour, a minute, or even moments before the event happened.

After becoming interested, it was considered advisable to have reference to what had been written by others on this subject and the literature was searched. This led to the conclusion that very little had previously been done where a trained person sat down with someone involved in an accident and tried to find out what thought processes were going on in the mind of this person just prior to the occurrence of the accident. This was somewhat surprising and indicates a field that has been badly neglected. One thing learned however, was the increasing awareness that we are neglecting a very important phase of accident prevention by omitting the study of the influence of human behavior and moods in causing accidents.

To investigate this matter, a procedure was set up whereby the men who were working in a large plant and had been involved in an accident would be seen by me. The sampling was a non-directed one, the men being picked on a consecutive basis by the receptionist. The attitudes of the men were mainly cooperative. They spoke freely and at times gave more information than was being looked for.

It was felt that to interview someone whose accident had occurred more than three days past would be a useless procedure in that many things would start fading from the individual's mind. Human nature being what it is, when things start to fade from one's mind, the person then tends to supply facts that he actually thinks would fit the situation. It is not meant by this to imply that the individual would deliberately construct misinformation. It is a matter of knowledge that as our memory fades and we are asked to recall an incident that has occurred in the past, a good deal of the information that we bring to recall in information of a type that we ourselves have formulated. The technical term for this would be retrospective falsification.

An excellent article, "Accident Statistics and The Concept of Accident-Prone," by Arbous and Kerrick,¹ states that it is conceivable that with our present instruments of analysis, we may yet succeed in pinning down the personal factor in accident-causation in terms of some strict definition, but this may involve so many restrictions in a mathematical sense that the concept will bear little relation to the real factors in everyday industrial life. The above comments do not constitute a denial of the usefulness of statistical procedures in investigations of this type, nor is it suggested that the research worker can ever dispense with them altogether. The conclusions indicate rather the limitations of these techniques and emphasize the fact that statistics can never do your thinking for you.

The above considerations may well lead one into a state of despondency and frustrated resignation, were it not for the fact that a different approach to the problem seems possible. This approach may not enable us to analyze accident liability in terms of universal principles, laws of dis-

tribution, etc. with reference to human behavior in general, but it may well enable us to reduce the incidence of accidents in our community by enhancing our knowledge of the mechanisms at work causing individuals to have accidents. And surely this is the ultimate objective of all this work.

Before getting into the actual cases seen, it appears pertinent to mention the work of Vinales,² who emphasizes the fact that another limitation of the statistical viewpoint in accident prevention is the emphasis upon isolated aspects of the individual personality, in contrast with the concern, in the clinical approach, for the total relationship. The clinical approach recognizes that there are many different causes of accidents and that they may combine in different patterns in different individuals.

Several things became apparent after the procedure of interviewing was started and led to the realization that my thinking was not in agreement with much that had been previously written about accidents.

The first concept with which there was disagreement was that of a man being "an accident-prone individual." The initial studies on which this was formulated were done in England in 1919.³ The term itself (i.e., accident-prone) was coined in 1939 by Farmer & Chambers.⁴ For various reasons, one of which undoubtedly was the fact that the concept of "accident-proneness" relieved or lifted the burden of responsibility from where it belonged, this idea immediately attracted attention. Other workers in this field, then began to formulate lists of traits that could be found in these "accident-prone" people. Somehow it was presumed, that armed with such a list of traits, one could then more suitably place or even avoid hiring a person falling into this category.

The obvious fallacy of this type of reasoning is that all of us have accidents, whether at home, at the office, at the plant, on the road, or anywhere, and throughout our lives probably will have many times more than one accident. It seems that there are times when all of us are in a state of increased susceptibility to having an accident without it necessarily being a life-long pattern of behavior. Therefore, the type of personality of the accident involved in-

dividual, as wide as the range of our entire population.

Of the people seen, only those with sub-major injuries were considered. It was found that the employees having accidents were mainly experienced men. It seems that the younger plant population is helped by the elasticity of youth in dealing with their problems. They also are more attentive to work hazards and still have "open-ears" at safety meetings. Since no control groups on considerations of hazard exposure could be statistically validated, it would be foolish to attempt to read too much into this.

TABLE II
Comparisons Between Injury Group and Plant as a Whole

	Injury Group	Plant
Average Age	45	44
Average Length of Service	18	17
Average No. Dispensary Visits per Year (Excluding Injuries)	14	2.3
No. Minor Injuries per 100 Person-Years	67	25
No. Previous Major and Sub-Major Injuries per 100 Person-Years	1.6	0.9

From a review of Table II one might be tempted to hypothesize regarding the number of minor injuries in the injury group as compared to the whole plant. Arbous & Kerrick,¹ in their admirable statistical study, strongly conclude that "minor accidents do not enable us to make any prediction with relation to major accidents."

Many people feel that once the accident train is set in motion, there is no real difference between a major and a minor accident and that the resulting injury was the one chance element in the situation. A mathematical example might demonstrate some of the hazards involved in the deductions obtained from collected statistics.

For example, in studying accidents that result in sub-major injuries (a sub-major can be defined as a type of resultant injury that renders the person unable to continue his regular type of work, and a major injury is one that results in loss of time from one's work) it would seem that there are two liabilities to be considered: (a) the liability of the individual to have an accident, and (b) the liability of this event to cause subsequent injury—resulting in its being recorded. It is conceivable that if the injury were not chance determined, the following results may be obtained as illustrated in Table III.

TABLE III
—Represents unplanned events without injury.
(a) —Represents unplanned events with sub-major or major injury.
In the case of two individuals, the results will might be:
Individual X had a, a, a, (a) a, a, a, a = 1 reported sub-major or major accident.
Individual Y had - (a), (a), (a) = 3 reported sub-major or major accidents.

In the records Y would obviously be considered more accident prone than X, but this would not be a reflection of his proneness to unplanned events (near accidents) since Y has only 4, whereas X has 8. It would rather be a reflection of the liability of such events as he had, to result in injury. This may well be determined by factors beyond his control and the study of (e)'s would give little indication of the individual's susceptibility to (e)'s.

Another deterrent factor bearing on Table III is the inability to equate exposure hazards between the injured group and the plant as a whole.

Returning back to Table II it can be seen that there is a valid statistically significant difference between the average number of dispensary visits per year for the injury group and the rest of the plant. Possibly the people having injuries are settling their emotional problems via this route while the plant group is discharging its emotional problems via psychogenic symptomatology.

TABLE IV
Accidents with Demonstrable Psychological Factors of Recent Origin

Psychological problem of recent origin	Number	Per Cent
No evidence of emotional disturbance	12	44.4
Subtotal	27	100.0
Non-assignable, multi-party responsibility	8	
Not cooperative	2	
Total	35	

Roughly 70 per cent of the psychologically disturbing factors were job-connected, 30 per cent non-job connected.

Table IV might on a clinical basis substantiate my hypothesis. It is, however, a fundamental piece of knowledge that it is never possible in any science to prove a hypothesis.

It may be informative and interesting to transcribe the notes made after interviewing three people who had been involved in accidents.

Case No. 1 a male employee age 21 with two years of employment as a driver for a parcel delivery concern. He sustained a severe twisting injury of his right ankle that required the use of crutches and kept him from regular work for five weeks. The safety bulletin listed the following description.

"This injury was sustained during normal operating conditions. The weather was clear and cold. The concrete surface was level and dry and free of any foreign body. The truck running board was clean and dry, with all door attachments in excellent condition. The injured stated that he looked before stepping down and noticed nothing out of the ordinary." This man in talking to me said that he realized as he was getting off the truck he was headed to go around the front of it. Realizing this, it then became necessary for him to turn so that he would be facing towards the rear and be able to walk around the back of the truck. The sudden shutting of his body after it had already established the direction in which it was going resulted in the accident.

He went on to talk very freely and stated that he was hit by a truck as a child at about nine years of age and ever since that time he has been afraid to walk in front of any vehicle even to the present moment. Even now if a car or truck is parked at the curb with no one in it, he still will not walk in front of this vehicle but will walk an extra fifty feet if necessary, in order to go behind it. He says at any time he absolutely cannot avoid walking in front of a truck or car, the picture of his being hit by the heavy truck when he was a youngster still comes to mind. "Several times a year," he continued, "I still have nightmares where I wake up screaming and soaked with sweat, dreaming that the truck was coming down the street and about to run over me again. All that I know is that I still can't get over the fear of walking in front of any car or truck."

Case No. 2. This case that I am going to describe, is I feel, an interesting one although it did not actually result in an accident in which somebody was hurt, but very nearly did and would have created an extremely serious situation had the accident itself actually occurred. The man in question was sent to the plant medical building because of an acutely upset condition following the incident. His job is to put an alloy

into a chemical process. He has been doing this for two years and is a first-class operator. In the past four weeks he has had a new helper. This helper and he evidently were extremely incompatible. He feels that this man was negligent and had a careless attitude towards his work. The operator had spoken with his foreman twice asking for a new helper, giving the above reasons for his request. He told his foreman that sooner or later such carelessness would lead to an accident.

No action had been taken up until the day in question. The morning of the incident, he was particularly annoyed by his helper. In violation of all operating rules he dropped his charge of pellets into an agitator following routine procedure except for the very serious omission of not checking to make sure that the agitator was cleared of its previous charge. Fortunately (and in no way could the man know this) the agitator happened to be clear at that time. If not, a violent explosion would have occurred. When the man realized what he had done, he began to suffer an acute panic reaction and his foreman sent him to the medical building. The man was able to pinpoint his thinking when talking to me—"I was so mad with the helper, I knew something would go wrong. I tried to get rid of him but they wouldn't transfer him. I guess the strain was too much for me waiting for him to do something wrong so I went ahead and did it myself."

Case No. 3, a 36 year old man with sixteen years of service fractured a finger while working on a machine. This was the man's first recorded accident in all of his years on the plant. He had worked a double shift the previous day. He said he was asked to do this a few hours before quitting time. He and his wife had made arrangements to go out that evening, this of course entailed the usual difficulties of baby sitters, etc. Although he very much wanted to say "No" to supervision's request, he has always been too compliant an individual to be able to voice his own feelings and therefore, said he would do the extra work. As far as supervision was concerned, their request was routine with this man, since he was usually asked first when there was some extra work available. The next day the man was thinking about the previous evening and was pretty much "burnt up inside" about what

had happened. In addition to his normal resentment he had experienced a difficult situation with his wife when he explained to her that they were not going out. As a matter of fact, he stated his wife was "as boiling mad as he had ever seen her." While dealing with these feelings of extreme resentment, the man suffered an injury.

One of the things that can be seen here is that in the cases quoted we have a fairly clear idea of what was going on in an individual's mind just prior to his becoming involved in an accident. As to how this might be of any benefit in helping us to prevent accidents in the future, several implications can be drawn. First, we should learn all that we possibly can about the fact that such motivations exist in an individual. By this I do not wish to imply that all safety engineers should become amateur psychologists but they must at least have some basic idea of the facts of how human behavior and emotions at times may influence our susceptibility to accidents.

To this end safety educational material could perhaps be reviewed, to emphasize this fact. The advertising industry in the past ten or so years has been doing a good job in some respects with what is called motivation research. Perhaps orienting our safety education somewhat in that direction might be fruitful. In our study of accidents we should try to find out from the people involved how they felt about the accident at that particular time, so that we may learn something about the problems and distractions that have diverted the individual's attention from the safety hazard. By doing this, we may also get some hints about what things distract and disturb people and also some idea of how we may be alert to similar problems in others. Perhaps with a better understanding of the human factors involved in accidents, we can make safety education even more effective.

After a recent talk which I gave to a group of safety men and supervisors, someone in the audience asked me a question—"What would you do with a man who continually and knowingly violates established safety procedures? He insists that he will do the job in the way that he desires." I gave the question back to the audience for an answer and several members stated—"I would fire him." The man who originally raised the question sadly said—"I can't, we both work for the Government."

Another interesting facet of human behavior here is that the employee himself, the individual who stands most to lose through an accident, is the last one to accept the fact that safety is as much a part of doing his job as any other area of performance. Of course, a safe worker will aid management, but openly and directly the safe employee will primarily benefit himself. Be that as it may, and this cannot be too strongly emphasized, we can certainly see that there has been a tendency to be tolerant towards the continued irresponsible actions of people involved in accidents.

We also must realize that stronger demands for an adult standard of behavior will be necessary. Our society as a whole must insist on adherence to effective lines of behavior in regards to safety. Certainly it does not make sense to lightly gloss over the irresponsible, the immature, the careless and negligent individuals who cause accidents. It is a rather grim prospect that the irresponsible actions of people who refuse to follow our rules are yearly causing increases in our national statistics of people who are killed and injured. It appears that the least we should do is to learn more about the factors leading to people becoming involved in accidents, so that we can be in a position to work out ways for lowering the frequency of accidents that can be avoided.

My feeling is that the medical profession must assume more responsibilities in developing these effective ways to help in accident prevention. Since I am firmly convinced and feel that most of us who deal with safety agree that the emotional factors are the cause of the greater part of accidents, our approach must become more meaningful and must consider the emotional life of the people concerned in order to effect any changes.

CLINICAL OBSERVATIONS ON THE CUTANEOUS EFFECTS ASSOCIATED WITH CURING EPOXY RESINS

By DONALD J. BIRMINGHAM, M.D.
Medical Director, Chief, Dermatology Section
Occupational Health, Research & Training Facility
U. S. Public Health Service, Cincinnati, O.

Occupational dermatitis occurring from the manufacture of plastics was observed shortly after the industry began. Phenol, urea, formaldehyde, and hexamethylenetetramine were among the chemicals first used in making synthetic resins, and they became well-known dermatitis producers. Later, almost every new plastic, such as styrene, alkyd, melamine, acrylic, and polyvinyl, became associated with outbreaks of dermatoses in the respective industries.

About six years ago, the epoxy or epoxide resins were introduced to American industry, and since that time we have had an opportunity to observe many cases of contact dermatitis due to the handling of these resins and their amine hardeners. This is a problem not only in our industry, but one which has been similarly noted in Great Britain, the Netherlands, and Switzerland, where much of the epoxy development took place.

The epoxies have become commonplace in a large cross section of United States manufacturing because of their excellent strength, adhesion, chemical resistance, and dielectric properties. They are widely used in electrical equipment manufacture for enclosing transformers, condensers, and other components; in automobile plants for tool and die castings; in painting for surface coatings; in aircraft and other plants for adhesive purposes. Their versatility points to even greater application.

Some epoxy resins are irritants, or sensitizers, or both, but the major problem in handling these materials occurs from the di- or triamine curing agents which are, for the most part, irritants and sensitizers. The workman contacts the epoxy resin and the hardener while mixing the weighed or recommended amounts of these basic ingredients. In small plants, several workmen may mix their own batch of resins and hardeners, and thus it becomes difficult to control contact with the basic ingredients.

After the resin and hardener have been mixed, the material can be cast into a mold or it can be brushed onto a form. Sometimes the mixture is successively alternated with layers of Fiberglas cloth to construct the mold or form. Molding is generally done with rollers, brushes, or similar tools, but on occasion it is done by hand. As a rule, the resin becomes deposited on the tools which are subsequently dipped into acetone or other ketone solvents for cleaning purposes. At the same time, the workman frequently uses the solvent to remove the resin from his skin. Finally, after the molding or casting has been done, the laminates are tooled. The epoxy-Fiberglas structure may be sanded, drilled, sawed, and painted.

In these successive operations, several hazards occur, namely:

1. Mixing the resin with the hardener, wherein contact may be made with the basic components or their vapors.
2. Molding: Some workers mold the material while wearing gloves; others use no protection whatsoever. Rarely are the face and neck protected.
3. Solvents: Cleansing the tools in solvents and at the same time removing the resin from the gloves or the skin constitutes a distinct hazard. The resin tends to concentrate in the solvent container, and a workman washing resin from his skin in this fashion unwittingly deposits a film of resin upon the skin.
4. Tooling: Grinding, drilling, or sanding the cast or molded laminates creates a hazard of contact with minute spicules of Fiberglas. A mechanical dermatitis can occur when slugs of glass become imbedded in the exposed surfaces of the skin. This is not an allergic dermatitis; it is simply a foreign-body reaction giving rise to irritation, itching, scratching, and, frequently, secondary infection. In Great Britain, it has been sug-

gested that the tooling operations may also depolymerize the resin, in which instance, the workmen would be contacting resin decomposition products largely of unknown composition.

Many of the uncured epoxy resins can be handled without ill effect, but those of the lower molecular weights have irritant properties. On the other hand, almost all of the amines are irritants and sometimes sensitizers. Their high pH (13-14) damages the keratin or at least severely weakens this protective layer of the skin. At the same time, surface lipid is readily removed. Further insult occurs from contact with the ketenes. The additional alkaline effect of most industrial cleansers, along with the amines and solvents, leads to marked redness and dryness of the skin. A dermatosis of varying degree usually results. There have been complaints that contact with the fumes has caused not only a dermatitis of the face, eyelids, and neck, but also asthmatic symptoms from breathing the amine-contaminated air. Several years ago, Dornel reported this problem among men working with amines.

From the case histories collected during numerous surveys involving these operations and from reviewing the experience of others in Europe, it is evident that the major cutaneous effects are produced by contact with the liquid stage of the low molecular weight resins, or the hardener, or with a mixture of these before polymerization or curing is complete. As a general rule, the completely polymerized product is inert upon the skin.

The onset of dermatitis generally occurs within three weeks from the beginning of employment, but it may be seen earlier in workmen already sensitized or among those who are careless in handling the mixtures. Most of the workmen continue to work by using protective devices, but some who have become highly allergic must change employment.

We have concluded that the best method of controlling dermatitis from epoxy resins is to introduce the best preventive practices possible. Outbreaks of dermatitis can be averted by following a few basic rules: (a) thorough education of management, supervisors, and workmen about the hazards; (b) adequate ventilation to control the Fiberglass particulates and the epoxy dusts and vapors;

(c) personal cleanliness through appropriate industrial cleansers, protective clothing, and, where needed, protective creams. To elaborate further, the following recommendations have been found to be reasonably effective:

1. All supervisors and workmen should be instructed thoroughly about the hazards of these operations and the importance of avoiding contact.
2. The mixing, molding, curing, and tooling of the resins should be done in an isolated area of the plant, to avoid contamination of other areas and employees.
3. Batch mixing of the resin and hardener should be done under a ventilated hood to control the escape of vapors. Only a few workers should be permitted to do the batch mixing.
4. During molding operations, skin contact can be avoided by wearing protective sleeves and cotton-lined rubber gloves. Clean uniforms should be furnished and changed each day if necessary.
5. Acetone or related solvents are not to be used to cleanse the skin.
6. Tables, machinery, tools, floors, walls, and windows must be kept free of the Fiberglass spicules and resinous dusts. The tables can be kept clean by using disposable heavy paper.
7. Clean-up rags should be replaced by disposable paper towels.
8. Grinding, sawing, drilling, or polishing the molded laminates should be done under ventilated hoods which remove all dusts from the breathing area and minimize the problem of skin contact.
9. Accidental spills of the resin or catalyst should be washed from the sites contacted as soon as possible by using mild soaps in warm water dispensed at conveniently located wash stations.
10. Neutral or acid soaps should be used in preference to alkaline, powdered, or abrasive cleansing agents.
11. Water-soluble skin-protective gels which are neutral in their pH provide some help in protecting against the action of the solvents.

To summarize, after the introduction of epoxy resins into American industry, a large number of cases of contact dermatitis have occurred. Many of the basic epoxy resins

can be handled without offending the skin, but most of the amines used as hardeners have an irritant or sensitizing effect. It is possible to avert contact dermatitis while working with epoxy resins by educating management, supervisory personnel, and the

workmen about the hazards associated with these materials; by introducing vapor and dust control measures, and by employing personal protective devices, notably protective gloves and adequate washing facilities and cleansing agents.

ENGINEERING CONTROL OF PLASTIC MATERIALS

By GEORGE E. TUBICH

District Eng., Michigan State Health Dept., Lansing, Mich.

Plastics, in one form or another, now have become an integral part of our way of living, from the plastic-cased clock which wakes us up in the morning to the plastic tooth brush we use when we go to bed. The growth of the plastic industry has been phenomenal; so much so, in fact, that virtually every industry has been affected by the unique properties of these man-made materials, and the future appears limitless. New machines and materials are being developed every day by our engineers and scientists. At the June, 1961, plastic show it was commented that if the industry continues to increase over the next 2½ years as it has in the 2½ years since the last show, it will be possible to look forward to countless new products and new uses for plastics which are not even dreamed of today.

A great deal of time and effort has been given to some of the relatively new plas-

tics such as toluene diisocyanates, epoxies, polystyrene-fiberglass, and dextrin. The new materials, however, are not receiving all of the attention. New uses of the long developed plastics such as phenol and urea-formaldehyde, furfuryl and polyvinyl chloride attach new significance to these materials. Both the new and old compounds have important uses and are of importance to industrial health in terms of health hazards.

Numerous papers have been written about the ability of plastic materials to produce dermatitis along with recommended methods of alleviating the problem, therefore this discussion will cover the other potentially hazardous characteristics of plastics. When the term plastic or a given plastic is mentioned the engineering control measures for stabilizers, catalysts, fillers, hardeners, parting materials and similar compounds are also taken into consideration.

Toxicology of Synthetic Resins

No discussion of these properties is complete without reference to the excellent compilations by Wilson and McCormick.¹ The following summary is provided for convenience and is quoted from the above reference. The original text should be consulted for complete details.

Acrylic Resins. Methyl methacrylate vapors have some systemic effects on the brain cortex and on the blood pressure, resulting in lowering. The acrylic resins themselves appear to be substances which can be used successfully as bone replacements, artificial eyes, and other prosthetic appliances. When placed in certain regions of the human body, however, they should be kept under observation because tumor formation, tissue reaction, and sepsis have been reported.

Alkyd Resins. The alkyd resins are capable of causing occasional mild cases of dermatitis.

Amino (Urea and Melamine) Resins. The amino resins (urea and melamine) can in certain combinations, particularly melamine formaldehyde compound, pyrolyze into hydrogen cyanide and carbon monoxide. Urea-formaldehyde-ethylene glycol resins can safely be used as food-wrapping material. The aminoplasts may be very toxic. Dermatitis has resulted in workers handling these resins.

Cellulose Plastic Materials. Cellulose plastics can be used safely externally; they only rarely produce dermatitis. Internal use may be hazardous. There is some occupational risk in the manufacture of cellulose acetate.

Coumarone-Indene Resins. A relatively non-toxic variety of resins. The hypersensitive person can acquire a dermatitis from handling these materials.

Epoxyes. The epoxy resins are relatively inert chemically and are resistant to heat. Severe skin irritation can occur in their manufacture and use. They must be handled with care. The curing agents with these resins appear to be the primary cause of the skin irritant effects.

Fluorocarbons. The fluorocarbons are extremely resistant to corrosive agents and solvents. The end-products are inert and non-toxic, but toxic decomposition products may be produced. Inhalation of Teflon dust may cause an effect resembling "metal-fume fever." Irritation of the mucous membrane and pulmonary edema can occur from inhaling the decomposition products.

Nylon. Nylon is a perfectly safe material. The fashionable women of the world have proved this by wearing nylon hose. In spite of its widespread use, only occasional cases of proved contact dermatitis have been reported. Nylon can be implanted in the human body with little or no tissue reaction.

Phenolic Resins. The phenolics as finished laminates are inert and non-toxic. They can be used safely as external prosthetic appliances. Many workers exposed to these resins during manufacturing processes have developed severe dermatoses.

Polyethylene. Polyethylene is a perfectly safe, non-toxic, inert material. It can be used as a surgical repair material, both in and out of the body. Occasional tissue reaction can occur, probably only in the sensitive person.

Polyester Resins. The polyester resins are relatively inert, non-toxic materials. Virtually no one appears to be allergic to them.

Silicones. The silicones are practically physiologically inert and non-toxic. They may cause a transitory conjunctival irritation when introduced into the eye but no corneal damage. Silicones are non-sensitizing and non-irritating.

Polystyrene. Polystyrene presents no health hazard from oral ingestion or in contact, being inert and non-toxic. In its manufacture some hazards are encountered, especially from ethylbenzene. Dermatitis can occur.

Vinyl Resins. The vinyl resins are used for a variety of purposes. Polyvinyl pyrrolidone (PVP) is non-toxic and can be used in the human body. Polyvinyl chloride (PVC) has been stored with little reaction in the chest cavity. Some slight skin irritations have been observed in workers manufacturing PVC.

Polyurethanes. The polyurethanes are a relatively new class of polymers. The finished polymers are inert chemically and present no toxic hazards. During manufacture severe industrial health hazards occur because of the use of isocyanates. These compounds can be lethal and in small amounts are very irritating to mucous membranes, producing an asthmatic type effect. Great care must be taken in their use. Close medical supervision of workers is desirable.

Case Histories

Epoxy resins are truly wonder materials and an answer to the plastic technologists' and product designers' dreams because of their excellent range of properties and applications. Epoxy fabrication procedures including resin application by brush or spray, compounding and finishing, all require ventilation control. Any attempt to make a complete list of the applications of this versatile resin is futile because of new uses listed almost daily. However, a few are mentioned here to show its wide range and point out some problem areas.

One of its major uses is in conjunction with fiberglass. The fiberglass can be used as a cloth or mat, or in specially designed spray guns that shred or chop the glass filaments and apply the resin simultaneously. In either of these applications good ventilation is required to control the solvent vapor and irritating effect of the fiberglass. Control measures are required at the mixing of the resin, and at the spraying, brush or roller application to reduce the amount of contaminant in the worker's breathing zone.

Upon curing of the product certain secondary operations of sawing, milling, grinding, and sanding may be required. Since these operations generate heat it is believed that vapor can be regenerated and set up

new exposures. Similarly, these operations produce dust. The literature indicates that fiberglass dust upon inhalation, has little if any effect. However, some of the fillers such as silica flour or lead can produce disabling effects and therefore require ventilation.

An example of regeneration and dust is cited by Joyner² who reports an episode in which six laborers developed upper respiratory irritation from inhaling emanated dust and/or vapor during destructive removal of epoxy resin-concrete. Secondary infection occurred in three of the patients. A mild nephrotoxic action was thought to be observed in all six patients. The offending agent was not conclusively identified but is thought to have been xylene, amine salts, or other unknown resin decomposition products.

Other uses of epoxy are in paints and require the conventional ventilation provided for any spray painting operation; an additive for tile and terrazzo flooring requires general ventilation for solvent vapor control; solvent vapor control is also needed at operations of encapsulation of electrical and electronic components in the resin, and in automobile body repair shops. In an instance where adequate ventilation is not or cannot be easily provided, personnel protective equipment approved by the U. S. Bureau of Mines for solvent vapor or dust should be provided.

The polyester resin utilizes styrene to dissolve the resin and facilitate mixing and application. Many of the problems and controls mentioned for epoxy resins are equally applicable to this resin and vice versa. Application of the resin to fiberglass cloth requires ventilation.

In some instances the scope and extent of these operations may present problems with respect to providing local exhaust ventilation. In these cases dilution ventilation should be considered. The following example is of design value when the observed conditions are considered.

In a process of room curing at 76° F. and curing time of one hour, the solvent loss of styrene is five grams per square foot of surface area per hour, (5 gr/sq.ft./hr). When these factors are taken into consideration, the calculation of the amount of solvent liberated and exhaust air required

to reduce the styrene concentration to a safe limit is easily made.

In both the epoxy and polyester resins the mixing, handling and storage of the catalyst should be done with care to avoid fire and explosions. An example is methyl ethyl ketone peroxide which is a strong oxidizing agent, and therefore should be stored carefully to guard against spontaneous combustion when this material comes in contact with organic substances. The mixing of benzoyl peroxide and tricresyl phosphate with a wooden paddle resulted in an explosion that severely burned an employee about the face and arms. Since this operation was previously carried out many times in the same manner without dire consequences, it was felt that the paddle was contaminated by some such material as cobalt naphenate.

Polyurethanes, at the present time, are finding the widest use in the form of foam. Foams are made by metering and mixing the correct amount of toluene diisocyanate (TDI) and other required ingredients. The mixture is deposited in a mold, allowed to foam, jell and partially cure. The foam may be stripped from the mold within a short time and then is allowed to cure fully at room temperature or at elevated temperatures in an oven. Toluene diisocyanate can be given off during the mixing, foaming and curing procedure or at any stage before being consumed by the chemical reaction. During these steps the TDI liberated can be irritating to the skin, eyes, and respiratory tract which can cause, in some people, an asthmatic reaction. This contaminant can be controlled by providing ventilation at the various steps involved.

Adequate facilities should be provided for decontamination of work areas in case of accidental spills of TDI. These should include adequate floor drainage, hoses, mops, and buckets. An adequate supply of decontaminants consisting of aqueous 5 per cent ammonia containing 10 per cent isopropyl alcohol or a water solution of sodium carbonate should be kept on hand. An oil absorbent can be used since it is helpful in drying up the spill. The contaminated absorbent then must be removed quickly to a ventilated location and/or treated with one of the decontaminating solutions.

Polyvinyl chloride mixed with powdered lead creates a serious health hazard. Con-

tral for this is achieved by providing exhaust ventilation at the blender and providing the operator with an air supplied helmet. Good housekeeping was also instituted to remove accumulated dust deposits.

Delrin acetal resin liberates decomposition products largely consisting of formaldehyde when above normal operating temperatures are encountered in injection molding and extrusion work. Should excessive temperatures be encountered the heat should be turned off, injection pressure reduced, and the overheated melt allowed to drop in a bucket of water. This procedure cools the cylinder and reduces the amount of fume. The area should be cleared until some means of ventilation has removed the contaminants.

Phenol and urea-formaldehydes have been the stand-bys of the plastic industry. New formulations and uses are continually being introduced. Plastic problems are generally not encountered in foundries; however, these materials are now integral parts of foundry operations.

Sand is mixed with 3-6 per cent of an alcohol solution of phenol formaldehyde in a muller. Heated air is passed into the muller to drive off the alcohol and deposit the resin on the sand particle. This results in a serious explosion hazard. The application of exhaust ventilation, 4-5 times over normal requirements, reduces this hazard. The resin coated sand is transferred to the molding machine and here irritating amounts of phenol, ammonia, and aldehydes are liberated. Ventilation controls these irritating gases. During pouring of these molds significant amounts of carbon monoxide and the above-mentioned irritating gases are given off. Ventilation is required to control these gases.

Urea-formaldehyde modified with furfuryl alcohol is used as a new core binder. The mixing and molding operations release formaldehyde and require ventilation.

Plastic coating of metal parts is a relatively new development. The metal part is heated to the required temperature and dipped into a tank of plastic powder which fuses to the heated metal part. Almost any pure resin or mixture of resin, plasticizers and stabilizers are involved. The literature is fragmentary on the health problems of

plastic dust. A case is cited of irritation to the upper respiratory system from polymerized polyvinyl chloride dust.

Ventilation is provided for the plastic coating operation to recover the fine powder because of its high cost and to improve housekeeping. This also aids in alleviating the dust explosion problem which is common to many fine plastic powders.

Thermal Decomposition of Plastics

Fears are frequently expressed that plastics involved in fires will yield combustion products which are more toxic than those usually occurring with wood or other common combustible materials.

Some of these fears are based on cases reported as follows: Upon exposing "teflon" to temperatures over 450° F. the decomposition products cause a temporary flu-like condition referred to as "polymer fume fever". A fire at a plant handling epoxy resins resulted in two employees being hospitalized for two weeks. It was theorized that the disability may have been due to decomposition products of epoxy resins. It has been previously mentioned that exposure to epoxy concrete dust has produced ill effects. A report from England indicates some of the decomposition products may include depolymerized resin, free amines, and other intermediates.

A review of the published literature shows that, in a majority of fires, the principal toxic combustion product is carbon monoxide, and although other lethal gases might also be present, the volume of carbon monoxide would be so much greater that it would constitute the major hazard.

A hazard certainly exists when plastics are involved in fires and fears of additional gases involved must not be minimized nor obscure the realization of the hazards of carbon monoxide. It also points to the real conclusion of the need for further study of pyrolysis and/or combustion products to determine the effect of specific contaminants, combination of decomposition products, and brief exposure to high concentrations.

Flammable Liquids

The use of flammable liquids in plastic processing and fabrication plants has rapidly increased in recent years and constitutes one of the major health and fire hazards

in plastic plants. The commonplace use of many flammable liquids has caused some operators to discard the health and safety aspects of the problem and to become complacent. This has resulted in an ever-increasing number of harmful solvent exposures and fires with consequent loss of life and property.

Not all flammable liquids vaporize at the same rate nor is the same proportion of air required for ignition and burning of the vapor-air mixture. These characteristics and others are used to determine the degree of hazard of flammable liquids. Some of the more important factors which are taken into consideration include flash point, ignition temperature, explosion range, vapor density, solubility in water, toxicity, specific gravity and diffusion.

Flash Point. The lowest temperature at which a flammable liquid gives off vapors in sufficient quantity to form a flammable mixture of vapor and air immediately above the liquid surface is termed a "flash point."

Explosive Range. Vapors of flammable liquids burn or explode when the proportions of vapors and air are within certain limits. There is a lower and an upper explosive limit for each liquid. The vapor-air mixtures that lie between these two limits is called the explosive range.

Ignition Temperature. Ignition temperature is the minimum temperature required to initiate or cause sustained combustion.

Vapor Density. Vapors of almost all solvents are heavier than air and they may flow long distances along the ground to a point of ignition and then flash back. The relative weight of a vapor as compared to that of an equivalent volume of air is termed vapor density. The heavier vapors tend to resist dispersion and remain in the low spots.

Solubility in Water. The water solubility of a flammable liquid is an important factor in selecting a good fire extinguishing system. Certain foam extinguishing agents are effective on petroleum fires, but ineffective against alcohols and water soluble solvents. Special alcohol resistant foams are available for these materials.

Toxicity. The vapors of most flammable liquids are harmful if breathed in quantity for an extended time. Certain of these materials break down in fires to form toxic

and irritating products of combustion which impede the work of firemen and make extinguishment more difficult.

Specific Gravity. The specific gravity of a liquid is a ratio of the weight of a given volume of the material to the weight of an equal volume of water. Most flammable liquids are lighter than water and will float if not soluble in the water. If burning, a fire will spread.

Diffusion. The vapors of flammable liquids tend to diffuse in air in the same way that a drop of ink in a glass of water diffuses through the water so that it all becomes colored. The lighter vapors will diffuse faster than the heavier.

Control Measures

1. **Engineering.** The substances used in the formulation, mixing, lay-up, and curing of resin fabrications present serious hazards to health and plant operation. The locations for these operations should be ventilated to exhaust dangerous vapors from the working atmosphere and discharge them far enough away from the building of origin to prevent their contaminating the fresh air intake.

Because of the dermatitis possibilities, every precaution must be taken to prevent spills and drips. Disposable paper, replaced as needed, should be used to cover bench and floor surfaces likely to become contaminated.

Meticulous plant care and constant employee supervision should be maintained to guard against the two chief dangers in plant operations:

1. Skin contact with the reactants.
 2. Exposure to their vapors and dust.
- B. **Personal Protective Equipment.** To prevent personal contact, the following items should be used by employees for the exposures indicated:
1. **Full face shields,** or preferably, gas-tight chemical safety goggles and organic fume and vapor respirators, to protect the eyes and face. These are especially necessary for employees working with caustic amine curing agents that are toxic and volatile, such as triethylene tetramine.
 2. **Gloves** (rubber or plastic) — to be worn whenever skin contact with the resins or their fabricating or curing agents is

likely. When soiled, the gloves should be discarded, or washed in acetone or methyl ethyl ketone (toxic, volatile and flammable) followed by soap and water. They should never be removed from their place of use without being cleaned, or placed where unauthorized people may handle them.

3. **Protective clothing**—coveralls and plastic aprons and sleeves, to protect employees repeatedly or continuously working in contaminated areas. Coveralls should be changed at least twice weekly, or whenever so contaminated that irritating substances are likely to contact a worker's skin.

4. **Protective creams**—of a suitable type, to be used by those subject to occasional and unpredictable contamination.

5. **Placement of Workers.** Toxic substances affect some individuals more than others. Susceptible workers are often injured by concentrations easily tolerated by the average person. As the hypersensitive cannot be identified until symptoms develop, all employees should follow the safety precautions outlined. The dermatitis resulting from the uncured resins and their modifiers may sensitize the individual, making him more susceptible to dermatitis. Such employees should be removed from the exposure until they have completely recovered from this condition. Subsequent contact with the causative substance should be limited to what can be tolerated without a recurrence. Hypersensitive individuals should be removed from the exposure.

6. **Training and Education of Workers.** Much of the success of protecting workers engaged in resin formulation depends on their knowledge and understanding of the hazards involved. The following points should be especially emphasized:

1. A continuous flow of fresh air should be maintained in work rooms.

2. Workers should keep themselves and their equipment clean.

3. Mild soap, or a skin detergent, and water should be used for washing. Organic solvents, such as acetone or other ketones, alcohols, benzene, gasoline, kerosene, and toluene, should be avoided, as they are more or less toxic, and may increase susceptibility to dermatitis by removing skin fats and moisture. If they have been used previously for cleaning equipment and

thus contain dissolved epoxy resins or their curing agents, there is even greater danger of dermatitis and sensitivity toward it due to the fine film of resin which such contaminated solvents spread over the skin area.

4. Skin roughness and dryness should be corrected by the use of satisfactory ointments.

5. Open cuts, abrasions, or skin areas already irritated (as from fiber-glass "mechanical itch") should be kept from contacting any of the materials already mentioned as likely to cause irritation.

6. Fingernails should be kept short and clean.

7. Hands, especially if contaminated with the irritating substances referred to, should be kept away from the face and other parts of the body.

8. Suitable rubber or plastic gloves should be used.

9. Irritating substances should be washed off gloves while they are still on the hands, the wash water being kept from touching the hands.

10. Talcum powder or, for those allergic thereto, baby or cornstarch powder, should be used on the hands to facilitate putting on and taking off the gloves, and to alleviate the irritation of excessive perspiration under the gloves. People allergic to the gloves can wear light cotton gloves underneath.

11. Powder and gloves should be kept on clean paper, changed at least once every shift to prevent contamination.

12. A minimum of protective clothing, such as coveralls and plastic aprons and sleeves, should be worn to prevent heat rash while nevertheless providing adequate protection.

13. Showers should be taken before changing to street clothing.

14. Any sanding or grinding operations producing resin dust should be well exhausted.

All employees should understand that anyone can develop dermatitis and that everyone should follow these precautions. Each should understand that once he develops a skin rash, he is more likely to get it again. Each operator should take special care to prevent others from developing

dermatitis because of contact with plant equipment, hand rails, door knobs, valves and switches that he has been too careless to keep clean.

Personal cleanliness is a prime requisite for all employed in the curing and fabrication of resins. They should make every effort to:

1. Avoid direct contact with the uncured resins or their curing agents.

2. Remove them as quickly as possible from any skin or body part contacted.

3. Leave no possible sources of contamination for others.

4. **Storage.** The solvents and curing agents are volatile, flammable liquids and should be handled with the following precautions:

1. They should be stored and handled in safety cans, approved by Underwriters' Laboratories.

2. The area where they are used should be cool, well ventilated, and isolated from open flames, oxidizing agents, and other fire hazards.

3. A flammable-gas indicator or explosimeter should be employed for checking questionable air concentrations.

4. A sign reading: "DANGER—FIRE HAZARD, FLAMMABLE SOLVENTS" should be prominently displayed.

5. Approved fire extinguishers should be readily available to fight fires.

6. **First Aid.** Facilities for immediate care of any accidental skin or eye contact should be readily available. The following measures are suggested:

1. Eye contamination—The eye should be immediately washed with copious quantities of clean water for ten minutes. All cases should be referred to a physician immediately.

2. Skin contact—Affected areas should be cleaned thoroughly with soap and water. Fresh acetone or methyl ethyl ketone may be used only if necessary, and then in small amounts, as these are toxic and flammable, as noted under Personal Protective Equipment. Solvents used previously to clean

tools or equipment should not be applied to the skin. Clothing wetted from spilled solvents or curing agents should be replaced immediately. If the affected person is not sensitive to ethyl alcohol, a light application of it may give relief.

7. **Waste Disposal.** Every care should be taken to keep all contaminated gloves and clothing, waste paper, rags, etc. in special isolated plant areas reserved for that purpose, with every previously indicated precaution being taken for storage and handling.

Contaminated clothing, equipment or waste should not be permitted to come into contact with such items as handrails, door knobs, valves and switches that employees are likely to touch with the bare hands. All materials contaminated with uncured resins or their curing or processing agents, that are to be discarded, should be disposed of as quickly as possible.

THE MAN MOST LIKELY . . .

By MAX E. STANSBURY

Dir., Labor Relations Div., Continental Pipe Line Co., Houston, Tex.

Every once in a while I am forced to give up time when I might be shooting pool to attend a meeting and listen to a so-called "message" from some speaker or other. When I make that sacrifice, I like to think that the speaker knows what he is talking about.

On the assumption that you would feel the same way about it, when I was asked to talk to you, I started casting about for a subject on which I could appear qualified to speak. A quick review of my personal history gave me the answer.

I used to be in the land department of my company and lasted only about five years. Then I was in the legal department for about three years. Currently, I'm having my troubles in the industrial relations department. Having thus been tried and found wanting in three high fields of endeavor, I feel that I can qualify as an expert on the subject of how to be a failure. I am even willing to put my neck out a little bit and attempt to tell you how to be an outstanding failure as distinguished from the ordinary or run-of-the-mill failure.

The reason there are so few truly colossal failures is that many of the persons striving toward the goal lack concentration and direction. They are like the famous Leacock character who leaped into the saddle and galloped off in all directions. The man who succeeds as a complete failure will choose the road that best suits his type and will steadily canter toward that goal.

I have picked out five excellent routes to outstanding failure and have named them after streets and highways. They are the "Toll Road," the "Corduroy Road," the "Freeway," the "Dead End Street," and the "High Road." Any one of them offers opportunity for the man who wants to really make a mark in the failure field.

One of the most scenic routes to failure we will characterize as the "Toll Road."

In this group you will have men-of-distinction for company. This is where you will find the boy-wonder presidents, the

meteoric-rise veeeps, the ball-of-fire geniuses in most any line.

Now it will take you longer if you choose the "Toll Road" because you first must be a success before you can fail.

In my school of thought, success, compared with failure, is easy to achieve since every psychologist, conference leader, and after-dinner speaker is full of foolproof advice on how to climb the ladder of success. So by following all this advice on human relations, you will undoubtedly be a great success in a relatively short time. Having done so, you then proceed to throw it away in a mental, physical, or emotional breakdown.

Gone are the days when an ordinary ulcer or a cardiac condition could qualify you as a "Toll Road" failure. Modern medicine patches you up, and within a few short months you are back on the job. You have to do better than just ulcers or a mere heart attack in this modern age if you are to be acclaimed as a failure. I suggest a complete nervous breakdown.

Suppose everyone recognizes you as an able fellow, doing an excellent job. That makes it pretty tough to be a failure. But under the Stansbury System, you're not hopelessly doomed to a life of success. In those circumstances it is a good idea to begin thinking of yourself as indispensable and infallible. Skip lunch. You are too busy to eat. Fill your briefcase, your desk, and your mind with reams of work details. Refuse to allocate any work to assistants or subordinates. They can't do it right anyway!

Let yourself be a little miffed because the committee adopts Bill's suggestion rather than yours. Let yourself be envious because it's at Dick's desk that the big boss usually stops for a bit of chit-chat when he is visiting the salt mines.

Hate or envy, for any reason, can really use up a lot of emotional energy. And with your efforts devoted to hate and envy, you will be well on the way toward an emotional blowup that will take you out of the picture.

It will help if you will develop a thin skin and take everything personally. Learn to feel that every departmental instruction and every company bulletin is actually directed right at and against you. You can reach the point where if one of your company's brass hats says "Good morning" to you as you enter the plant, you can spend the rest of the day fretting about whether he meant something by that remark.

With only a little effort you can read flights into actions or remarks where no flights were meant. These you can nurse into really important cases of self-pity—in such an extent that you can become a hypochondriac always in search of a cure for an imaginary illness.

One of the most helpful devices in your struggle upward in the failure field is to run from making decisions. If you really put your mind to it, you can reach a situation where you can never finish any task because you are busy rationalizing, postponing, seeking, and fussing to find the perfect solution. Keep your finger on every tiny detail. Insist on personally handling everything that comes along so that you can overload your brain with unnecessary stimuli.

Then, as part of an over-all campaign, on any job or project you undertake, set your sights so high that you can't hope for full accomplishment. Using this method, even though you have done a pretty good job, you are left with dissatisfaction and frustration which gnaw on your nerves and emotions. Another advantage is that you can waste a great deal of time in self-pity and self-condemnation, and you won't have time to go out and accomplish another pretty good job that satisfies everyone but you.

Work like a dog on every job and neglect your health, your family relationship, and your friends so that there will be no rest for your body, for your nerves, or emotions. Only then can you assure yourself that you are really on your way along the "Toll Road" of failure.

Maybe some of you are unwilling to spend the time necessary to become a success before achieving failure. Then the "Toll Road" is not for you.

I offer others.

The "Corduroy Road" to failure is one

reserved for the rough, tough, lie-man type. If you are ill-mannered, talk too loud and too long, the "Corduroy Road" is the one for you.

It is a rugged road and requires constant affirmative action. You must drop any cultural qualities that you have. A liking for music, literature, art—that stuff's for sissies. For you, the three B's are beef, brawn, and booze. Any attempt to engage you in conversation about anything except sports—or maybe women—brings from you nothing but derision.

In voicing your opinions, you will be very decided and positive in your views. You are required to take it as a personal affront if anyone suggests views contrary to yours. In that case, you can disagree, good and loud, perhaps making a few reflections on the other man's intelligence or motives.

This is a particularly handy approach to use on people you have just met. Right away they can mark you down as a man they want nothing further to do with, and you are therefore well along the "Corduroy Road" to failure, unhandicapped by any new friends.

One of your biggest assets in your travel along the "Corduroy Road" to failure is to be a heavy drinker, but beware of this course if all you do is slide under the table. As a result of your drinking, be bellicose and antagonistic. The happy drunk, the weeping drunk, people will tolerate, even forgive. But the drunk who wades in there swinging his marked himself as a first-class heel that no one wants around.

Drunk or sober, be quick to anger. Frequent violent outbursts of temper are valuable in causing people to avoid you.

At the first sign of adversity, let go completely! Spend valuable time giving associates and subordinates large pieces of your mind. This will make people think you'd be much happier and less bothersome in a nice quiet sanitarium, weaving bright rugs. As an excuse, you can blame the necessity to relieve nervous tension, or the rapid pace of your job. You can always comfort yourself with the thought that most great persons are temperamental.

Now, in contrast with the "Corduroy Road" traveler—rough, rugged—is the smoother, urbane "Freeway" fellow.

The "Freeway" is another road to outstanding failure. On the "Freeway" you can spend your time on the job dreaming about a promotion, transfer, or a higher paying job with another company. Or, you can devote your thoughts to entering a business for yourself. For instance, try to think up a product that costs a dime, sells for a dollar, and is habit-forming.

Don't regard your job as a reason for living, but only as a means for earning a living. You must watch yourself so that you don't develop an interest in your work so that you actually enjoy it at times. That might be fatal to your hopes for failure.

Be very open in expressing your dissatisfaction with your pay, the conditions under which you have to work, the boss' ability and his feeling toward you. Never fail to criticize the company's general policies or practices, whether they are generally regarded as good or not. And while you are at it, don't display any loyalty to your employer or company. Attack the quality of the company product, and don't go out of your way to use it yourself or to recommend it to your acquaintances.

And, always oppose the best interests of your industry or your company. A good gimmick along this line for fellows in the oil business is the depletion allowance. I've been talking in generalities—let me give a detailed case history of how a "Freeway" failure can go to work.

The depletion allowance is a 27½ per cent deduction which our country's income tax laws allow for people and for companies in the oil-finding business. Similar allowances are made in mining and in other businesses where there is a big risk to the investor who puts up the money, and when the production makes it a "wasting asset"—that is, once you take it out it's gone and irreplaceable except by new discovery. You deplete the product by producing it.

That depletion allowance is of paramount importance to oil company employees. Only because of it can your company justify huge expenditures, such as are being made offshore of Louisiana to search for more oil—oil that forms the backbone of our national security. Those huge expenditures are the stake in a tremendous crap game. Lose enough and your company is out of the game and you're out of work. The de-

pletion allowance is the little edge that lessens the nearly 10-1 odds against winning.

The depletion allowance is not very well understood by the general public, and it has been represented by its enemies as a tax "loophole." Yet practically everyone understands that depreciation on a plant or piece of machinery that produces a product is an allowable and justifiable income tax deduction. The depletion allowance for oil produced is the equivalent of depreciation on a plant. Because you're in the oil business, your friends outside the industry will want your views on the depletion allowance.

As a man on his way along the "Freeway" route to failure, you should influence your friends to believe that the depletion allowance is tax evasion by the big-money boys, that it shouldn't be allowed for the oil industry. By so doing, you can really sabotage your company and your industry; and since your objective is success as a failure, you have thus struck a telling blow for yourself.

It helps in crushing down the "Freeway road" to failure if you can find a bright young engineer or scientist who will confide his ideas to you. Then you can contrive to encounter the plant manager and can modestly start out something like this, "I know so little about these things, and undoubtedly you have thought of it first, but it seems to me . . ." and then expound, as your very own, the pilfered idea. Enough scheming of this kind and pretty soon all your associates and superiors make every effort not to impede your progress along the "Freeway" road to failure.

And be careful what you read. It might veer you from your objective of being a failure. For instance, take this quotation from Lawrence Appley, president of the American Management Association:

"If one foreman is motivated by a wish to be of service and sees his job as an opportunity for service, he has an influence that is farther-reaching than he himself may realize. For if he helps one person who works for him to be a better worker and a better citizen, that one person will be a more constructive influence in his own family, among his friends, and in the community in which he lives. Multiply that by 15 or 20 individuals

in the foreman's department and we can see that he is rendering a far greater service than would seem to lie within the boundaries of his job.

"At the same time, such a foreman is attaining the results for his company that are most to be desired, and he is destined to progress to greater and greater management responsibilities."

You had better watch that kind of stuff. First thing you know you'll be thinking it's sound and logical. Then you'll believe it and start practicing it. If you do, brother, you're a dead duck so far as being a successful failure.

"Now," you may ask, "what if I'm not the 'Toll Road' type . . . or not rugged enough for the 'Corduroy Road' . . . and can't qualify for the 'Freeway' . . . what do I do then?"

That's a good question. It encourages me to discuss the "Dead End" and "High Road" routes to failure.

To make the grade as a failure in the "Dead End Street" class, it is not enough to be just a procrastinator. This is a big help, but it has to go deeper.

Instead of letting letters, reports, and memos just clutter up your desk top without your taking any action, put them in your desk drawer and forget them!

After two or three crises—with the causes found in your desk—you'll be marked as a man who will go far as a failure.

On the "Dead End" road to failure, you must always stand on your dignity and sit on your prerogatives. Protocol, the amenities, and the red tape must always be observed.

There is no room in you for levity, hearty laughter, camaraderie, or just plain friendliness. If anyone encroaches just one tiny bit on your prerogatives, or sticks his nose in your field of endeavor, see that the whippersnapper is properly and swiftly put in his place. If you are violently jealous of what you are sure are your very own rights, your very own business, then you can keep practically everyone from helping you.

It is a nice touch to be a stickler for the rules, regardless of the circumstances. This is particularly helpful in human relations or in dealing with people. In any written rule or law, there will be found

flaws that work injustices in certain circumstances. Be sure that you insist upon the application of the letter of the law in those cases.

A further refinement of the "Dead End Street" approach is to check every possible angle on every problem, regardless of its importance. You can really have a field day on some minor type of problem while you seek everybody's opinion as to the solution and make surveys to see what other companies have done in similar circumstances.

A word of caution here. The process of checking other people's opinions and industry practices can be a valuable tool on an important problem. If you slip and go through the process on a problem that really deserves that attention, you're liable to wind up with a feather in your cap instead of making progress along the "Dead End Street" to failure.

However, even in the case of such a mistake, you can sometimes redeem yourself and make the situation an aid to your campaign for failure. For instance, having mistakenly assembled all the pertinent facts on a problem that warranted the effort and the time, write a report so long-winded and so disorganized that your busy boss will discard it in disgust. Or leave out some essential, such as the estimate of the cost, so management has to reenter it back to you.

Little refinements like those are the mark of a man entitled to travel the "Dead End" road to failure.

Probably the most exciting road to failure is the "High Road." This category is the "Living It Up" school of failure. For those who really qualify, it leaves many pleasurable and erotic memories.

As a modest beginning, you can live beyond your means. No piddling efforts like buying cars, houses, and television sets on time will do, however. Be big about it. On a Chevrolet income, go in debt for a Cadillac. That will, in turn, lead to other mismanagement of your funds and finally, on a stack of unpaid bills, you can climb to success as a failure.

Go in heavily for expensive partying and debauchery that leaves you all hung over on the job. Being thus unable to perform will act as insurance that nobody will want you around the job.

Above all, involve yourself with many, many women. For almost any man even one woman is sometimes a strain. But for the man who wants to be a "High Road" failure, it's a case of gritting your teeth in determination and making the necessary sacrifice by carrying on with at least two. And it's not enough that you have a clandestine girl friend. It's almost axiomatic that nobody cares particularly about your private affairs. It's only when you flaunt your indiscretions in their faces that the decent people become disgusted with you.

See to it that your girl friends call your office frequently, or that your wife is so disturbed that she seeks help from your associates. Or take your little playmate to social affairs where your friends and acquaintances are put on the spot by having to accept or reject her.

Getting involved in newspaper scandals or being named as the "other man" in divorce proceedings is needlessly dramatic, even though it might be effective.

You can be every bit as effective, and possibly more obnoxious, just by making a few passes at the wives of fellow employees. Then you will quickly achieve the status of a "High Road" failure.

Now those are my five basic roads to achieving outstanding failure. You can have combinations, clover-leaves, detours and by-passes, but the fundamental routes will always be there:

1. The Toll Road
2. The Corduroy Road
3. The Freeway
4. The Dead End Street
5. The High Road

Somebody could well ask now what road I took in qualifying myself to speak so authoritatively on failure. I must admit that I didn't practice what I've been preaching.

I followed none of those routes. If you'll permit me a Texas brag: I'm a natural. I didn't have to work at failure in any of the ways I've outlined for you.

Some of us who think we have an inferiority complex find out that we're mistaken. We don't have an inferiority "complex"; we're just plain inferior. That puts us in what we might call the "Parking Lot" class of failures—no effort, no striving; just plain natural aptitude.

Less than one per cent of you can qualify as "Parking Lotters," however. Most of you will have to work at it through the routes I've been telling you about, but let me pass on a tip for those of you who might want to try to belong to this inner-circle group.

Somebody asks you to make a talk like this one. Without shame you steal ideas, words, sentences, stories, examples from sources such as Lloyd Thanhouse of Continental Oil Company, from Kiplinger and Fortune magazines, from the Reader's Digest, from Shepherd Mead's book "How to Succeed in Business Without Really Trying," and from Jim Whetsell of one of Conoco's smaller competitors—The Texas Company. Mix them all together—and your "original" talk is all written.

Thus, the "Parking Lot" failure spares himself the painful process of thinking. And does a "Parking Lotter" give any credit or acknowledge any sources of his material? Heck, no! You can't be a failure by being fair to people. They'll be twice as mad at you if you let them discover your perfidy for themselves.

In all of the routes to failure, and even in the "Parking Lot" method, your attitude is the most important single factor. You can't be just casually interested if you are to reach your goal. Only when you find that your mind is constantly occupied with thoughts of failure can you say that you've achieved the proper attitude. When you're first pointed toward failure, it's all right to think about it on a part-time basis. But if you aspire to be a real resounding flop, you must develop a full-time attitude.

It is sort of like the lady who called the desk of her apartment hotel to complain that someone was banging away at a piano in the suite next to hers. The clerk explained that the piano was being played by Liberace, who was practicing for his concert that evening. The lady immediately called several of her friends to come in a hurry to her apartment. They listened with attention and appreciation to sparkling piano music by Liberace. The sounds from the next suite were the same. Only the lady's attitude had changed.

Gentlemen, watch your attitude. You, too, can learn to fail. Work at it, and I'll guarantee that ex-friends and former co-workers will vote for you as "The Man Most Likely to Fail."

Environmental Health

The meeting place for the three disciplines, industrial hygiene, safety and medicine, is their common interest in a healthy environment.

Man's external environment has three major components:

1. The *biological* component, including the living things of the plant and animal kingdoms—ranging from the food upon which life depends to those micro-organisms responsible for disease.

2. The *physical* component, encompassing the nonliving things and physical forces affecting man—such as water, air, food, chemicals, heat, light, and other radiations.

3. The *social* component including a complex interplay of factors and conditions—cultural values, customs, attitudes; economic status; social and political organization; and ability to support facilities and services.

It should be remembered that most of the total of man's external environment is found outside of industry. However, the primary responsibilities and therefore the opportunities of the occupational health team stem from the job environment of the worker. A review of the chief biological, physical and chemical agents which on occasion may form a hazard will show many areas of concern to the industrial hygienist, to the safety supervisor as well as to the physician.

Biological agents (infectious diseases: bacterial infections, rickettsial infections, virus infections, protozoan infections, fungal infections; parasitic diseases: venoms and animal toxins.)

Physical agents (abnormal temperature and humidity; abnormal barometric pressure; motion, acceleration, and gravity; vibration, noise, and ultrasound; radiant energy: light, ultraviolet, infrared; electricity; ionizing radiations.)

Chemical agents (dusts; gases and fumes; metals; acids and alkalis; solvents; other organic compounds.)

Accident Prevention

The disciplines of industrial hygiene, safety and medicine have a considerable stake in motivating workers for accident prevention. Safety devices, safety committees and various educational efforts have not and cannot do for the individual the

things he must do for himself. Human failure is still the chief cause of accidents.

Psychologists insist that accidents are not chance happenings but follow specific patterns of human behavior. The directing force arises from a strong emotional base. In this behavior the psychologist identifies a hostile component, expressed either outwardly or inwardly. Much needs to be learned about how to handle this hostility. The victim cannot wish it away; he usually is unaware of its existence. We who are dedicated to preventing human failure in industry must take time to look into the psychological problems of the people who have the accidents and who will continue to have them until their aggressiveness is redirected.

One method of help advocated by many is that of providing a channel of communication through which a person can express feelings of insecurity, doubts, anger, fears, to a friendly and interested listener. Call this emotional catharsis, non-directive counseling, or by any title that is preferred, the process represents hope for accident prevention. The opportunity for counseling comes to all members of the occupational health team. It is essential to be alert and not miss the opportunity when it presents itself.

The medical department can assist in selling safety, the safety group can back up the industrial hygiene activities and so goes the reciprocity cycle. Taking time and trouble to work safely annoys many people. Emphasis needs to come repeatedly and from several sources before some recalcitrants accept the necessity to do the job the right way in order to retain the job.

Slowly we are gaining knowledge of the relationship of impaired function of the human "machine" to the accident potential in people. The relationship is still blurred and inexact, partly through the remarkable ability of man to "compensate" for his deficiencies and to reduce his exposure to accidents through various and ingenious devices. In spite of the lack of sharpness in the correlation of many physical and some mental states with accident frequency, there are contributions which the physician can make toward accident prevention.

The individual should not undertake work which exceeds his physical capacity. The

organic diseases, impairments in function, reductions in motor and sensory responses which clearly predispose to accidental injuries afford the physician an opportunity to help. This may result in better job placement, engineering modifications, or reduction in one's physical efforts.

Things seen and reported by a plant physician can give leads to safer operations and reduce the number of injuries. This example was related by an engineer: "There were a series of first aid cases involving shoulder injuries. The minor injury reports were complete in detail and Dr. T. M. noticed that all cases involved the same shoulder. They were strains involving the same muscles, and responded well to heat and rest. Dr. T. M. went into the matter more thoroughly. He had noticed that all the men affected worked in the same house. He took time to make a trip to the scene of that operation and found that every one of the strains occurred as the men were attempting to lift a heavy lid on a dope bin that had a tendency to stick. Dr. T. M. recommended to the plant management that air cylinders be installed to raise the dope

bin lids. The suggestion was accepted and those particular minor injuries ceased."

The challenges to the health and safety team are many and varied. New processes, new material, new equipment come into industry at a rate which taxes the ingenuity of hygienists, safety engineers and physicians. Our common interest is that of keeping healthy, able workers on the job. The diversity of training and experience which this triumvirate brings to the task is a potential source of strength. That strength can be realized by our continuing recognition of the contribution each discipline can make through co-ordination of efforts and support of one another. The results are healthier workers and better places to work.

THE CONSUMING DANGER OF ASSUMING

By KRAUS EARHART

Safety Supervisor, Employee & Public Relations Dept.
Texaco Inc., Houston, Tex.

When Mr. Quincy V. Tuma asked me to speak on the subject, "the consuming danger of assuming," I couldn't say no.

Today, there is so much to know about so many things. Certainly one can't know it all, even though many would have you believe they do. A passage from the Scriptures gives appropriate emphasis to this opinion. It is from I Corinthians 8:2:

"And if any man think that he knoweth anything, he knoweth nothing yet as he ought to know."

I would advise you that if you must tell all you know, be sure to know all you tell. It is said that half of the problems of the human race are due to the lack of business knowledge—knowledge of what is

their business and what is none of their business.

That which is our business we should know well for it affects the well-being of our fellow men. We have a responsibility to know our business well in order that we may clearly and factually communicate with and pass information on to others so there will be no assumptions concerning accident prevention. We should objectively think things through.

A cartoon with drastic assumption appeared back in 1830 and showed the dire disasters which would befall the American people if steam power were to be used in the factories. It even went so far as to suggest that mothers have no more chil-

since proposed use of steam would do away with any possibility of jobs for them.

Around about the time I arrived upon the American scene (some years after 1830), there were many people in and out of government circles who were assuming and even predicting that the U. S. Patent Office would have to close down for lack of applications. A lot of other good and presumed knowledgeable people of that period had the feeling that they had gone about as far in their knowledge of the world as it was possible to go.

Times have changed considerably and times keep changing. Today, practically all literate people recognize that much more knowledge is available to those who make the effort to acquire it.

Opportunities today are more plentiful than ever before. Each new thing that is discovered in the world does not cut down but one the sum of discoveries to be made. Rather, it opens up a whole new vista of discovery and development in a new direction.

With more knowledge comes more progress. Sometimes, progress represents the substitution of a complicated nuisance for a simple nuisance.

For instance, we have better engines today. A little over 40 years ago, it took only 100 horsepower to keep a combat plane in the air. Today, it takes 250 horsepower to carry a 115-pound female down to the "drive-in" grocery in the next block.

We have faster cars and better roads to travel on. The old-time narrow trails where two cars could barely pass without colliding are fast being replaced with six and eight-lane highways where a half-dozen or more cars can collide at one time.

Progress of real significance was indicated a few years ago by Professor Walter S. Buckingham, Georgia School of Technology, when he made the statement,

"If properly understood, applied, developed, and controlled, automation together with atomic energy may provide the means for eliminating poverty for the first time in the history of the world."

Arnold Toynbee, eminent British historian, said not long ago:

"The Twentieth Century may be considered as the first age in history in which people have thought it practical to make the benefits of civilization available for the whole human race."

That, too, would be progress of great significance.

However, it appears that most of the great nations are giving most effort to strengthening their military posture. If World War III does come, it will be unique in that it will never be mentioned in history books.

You may think that it was a wisecrack for my talk to be titled, "The Consuming Danger of Assuming." Well, why the danger? Who's assuming? The danger results from too many people mistaking "looking for seeing," "listening for hearing," "observation for understanding" and "opinion for thinking."

In the present age of mental and moral confusion, we are in somewhat of a 20th Century Babel in which a *sea of paper, an avalanche of words, and a thunder cone of sound* are too often substituted for a rational exchange of meaning between human beings.

In your discussions of and for safety.

Just how do you rate?

Do you assume and prate.

Or do you really communicate?

Take another look at the title, "The Consuming Danger of Assuming," and think about "eating" instead of "consuming" and you may come up with a realistic assumption that it isn't what you eat but what eats you that is dangerous and gets you into trouble. Why are so many people inclined to assume worries about things over which they have no control and can do nothing about? That sort of thing eats you. Ask your psychiatrist. It's too bad that we can't do what it is said the Government does with its problems: just subsidize them.

Another scriptural passage which I think is timely is from I Corinthians 14:9:

"Except ye utter by the tongue words easy to be understood, how shall it be known what is spoken? For ye shall speak into the air."

Some other wise words were spoken by St. Ambrose in the 4th Century. He said:

"The wise man, before he speaks, will consider well what he speaks, to whom he speaks, and where and when."

Right now, I am sure that you will agree with me that it is a good policy to say what you mean, stick to the facts, and mean what you say, and make sure that you are understood by those to whom you speak. Being misunderstood can be serious.

Assuming something and jumping to a conclusion is very unwise and may break up a friendship of long standing. Sometimes it just doesn't pay to assume that you know the whole story. When you tell something, tell the whole story and be factual—not hypothetical. Facts are hard to come by, but they have the solidity of diamonds. We tend to be beguiled by what is paraded as fact.

Many adults make the mistake of not considering children and youth as people or as individuals. It works both ways, for most youngsters assume that a lot of their elders are "way out" or "squares." It is a source of joy and satisfaction when parents and their offspring come to a meeting of the minds and have proper recognition for each other. The difference between genius and stupidity must be that genius has its limitations.

A statement I heard recently provoked me a bit. It was:

"There's been so much said about selling safety: why should anyone want to buy safety when he can have all he wants for free?"

There's a brilliant assumption. Safety isn't free—certainly, not in Texaco and not in many other well-managed outfits with which I am familiar. It takes a sound, well-planned program which is nurtured on a continued basis. Just because a group of employees or a department or company has been safe, or compiled a good record over a long period of time, it's a big mistake to assume that someone won't get hurt later on.

Many years ago, I began to think seriously about the consuming danger of assuming and down through the years many tragic events have occurred to keep me aware of the fallacy of assuming—for instance:

(1) The West Central Texas rancher who for many months drove his car across the T & P Railroad tracks each day at the same crossing and at the same time.

He never saw any trains and he assumed there would never be trains at that time, but one day the "Morning Flyer" was several hours late and met the rancher and his car "head-on" at the crossing.

(2) The Indiana father who assumed that his pistol was out of reach and well hidden but his four year old son got possession of the car keys to unlock the car trunk and remove the weapon from a locked box. The fantastic and tragic feat performed by this young gunman should dwell heavily in the minds of all parents for he critically shot three other youngsters. (This story emphatically illustrates to what length our modern youngsters will go to obtain fascinating "play-pretties.")

(3) The Alabama school bus driver who assumed that the bus brakes had been repaired just because he had reported the poor condition of the brakes. Four youngsters, including two of his nephews, were killed when the bus collided with a train.

And so, on and on—countless thousands of similar tragedies occur and too many times because people are prone to assume and come up with wrong assumptions.

The trusting statistician, 6' 4" tall, assumed he could wade across a river which had an average depth of three feet. Although he drowned, it is possible that he learned, but too late, that averages are a mathematical fiction or assumption to which the real world seldom conforms.

Words form the link of communication between people. They can bring understanding or misunderstanding, according to how they are interpreted or used.

Words are tools to be thoughtfully chosen and carefully used. Good words can be poorly used and may, perhap, unintentionally convey a wrong meaning—like the signs:

in a Government office—"Executives Without Secretaries May Take Advantage of Stenographers in the Typists' Pool."

in a library—"Only Low Conversation Permitted Here."

on cemetery gate—"No Digging or Planting Here."

at hospital ward entrance—"Maternity Ward—No Children Allowed!"

Connotations of terms vary with the experience of the individual. The sentence,

"He picked up a ham on the way home," would have three decidedly different meanings to: 1) a connoisseur of food, 2) a little theater devotee, or 3) an amateur radio operator. And then, don't forget that "Ham" was also the name of the chimpanzee sent for a ride into outer space. This "Ham" was aeronautically simulated. Simulated is to assume the appearance of something without the reality. In this case, "Ham" substituted for man.

Much of what we say depends upon the one to whom we say it and his readiness to assimilate it. People who jump to conclusions or make quick assumptions are usually the most vocal and when given a chance to speak, they always seem to have so many unexpressed thoughts—you know the type, I'm sure.

Like many others, I have long been concerned about the huge amount of wastefulness coming from the expenditure of words beyond the income of ideas. I am tolerant of people who disagree with me. After all, they have a right to their ridiculous opinions. One thing that displeases me very much is the way some narrow-minded people try to impose their thinking upon others.

Did it ever occur to you that prejudice is a great timesaver? It enables you to form opinions without bothering to get the facts.

I listened with much interest to Professor Arthur Secord at the National Safety Congress a few years ago when he posed the question:

"How can we be more sure when we say something to other persons that they will hear what we think we said?"

His answer caused me to conclude that what we say is never important. The important thing is, what did the person, or persons, hear? What did they think we said? Do the words we use mean the same thing to the people to whom we speak that they mean to us? We must speak the other fellow's language. We make a great mistake in assuming that words mean. Words don't mean—only speakers do.

Many years ago, I heard an astute speaker say that listeners should be advised in these words, "Don't keep your attention on my words. Never mind what the words mean. What do I mean?"

It makes little difference how simply one speaks if, when speaking, listeners assume something different from what is said or interpret the words in their way rather than those of the speaker. The use of the right words at the right time is important.

For instance, in management's discussion with employees, we know it is much more important to say "earnings" instead of "profits," and "employee benefits" instead of "hidden wages," etc.

Many safety people labor the idea that they should have management support when their real need is for management action, direction, and participation.

Some of us are guilty of serious misuse of other words in our business, such as:

"Fireproof" instead of "Fire Resistant,"

"Inflammable" instead of "Flammable,"

"Accident Prevention" instead of "Injury Prevention,"

"Lost-time Accident" instead of "Disabling Injury,"

"Carelessness" instead of the specific cause.

There are many others—too many to detail here.

It is pretty well indicated to me that we should say what we mean and mean what we say. We definitely should prefer the familiar word to the far-fetched, the concrete word to the abstract, the single word to the circumlocution, the short word to the long and the Saxon word to the romance.

We must realize that our listeners are going to make interpretations of what we tell them. Sometimes it may coincide with or slightly resemble our meaning. Once a person knows the "why of a do" or the "why of a do not," better performance generally results, but until they do, look out! Tell him why. Tell him why not.

Misunderstanding is not always a matter of stupidity on the part of the listener. If the pupil hasn't learned, then the teacher hasn't taught. And don't forget that hindsight explains the mistake or the accident that foresight would have prevented.

Misunderstanding and assuming can sometimes be amusing without danger.

The big "boss" was attempting to fix a door in his home when he found it did not hang properly. He called to his son to get him a "screwdriver."

After what seemed an unusually long time, the boy came into the room and with apology, said: "Gee, Dad, I've got the orange juice, but I can't find the vodka."

Another instance of assumption involved a good-looking young lady. She went into a sporting goods store and ordered all the equipment necessary for a baseball game, including a baseball, a bat, a catcher's mitt, and a catcher's mask.

The salesman asked, "Are you sure you want all these?"

The girl answered, "Yes, I do. My boss said if I'd play ball with him we'd get along fine."

Most of you people here in this audience know how to either 1) draw a triangle, 2) open a pack of cigarettes or 3) tie an underwriter's knot—but can you lucidly tell me how to do any one of them? Think about it. The answer is probably "no," but perhaps you can tell and show me how to do each one. Perhaps we should do more showing with our telling.

Incidentally, not only do we not hear and interpret things alike, we also rarely see things exactly alike. Can you properly describe an elephant to a person who has never seen one? Can you describe an automobile accident in the same way as several others who may have seen the accident from the same vantage point? We have a tendency to see things not as they are but as we are.

Words are not things. Words represent things, but are not identical with them, and hence must not be confused with them. Words sometimes misrepresent things, too.

Some people use words to express thought, some to conceal thought, and others use words instead of thought. The use of words is no assurance of thought behind them.

Sometimes what you are speaks so loud people can't hear what you say. Words are in many, many cases very unnecessary to convey a feeling of disrespect, distrust, of hate, or even love . . . your attitude shows.

The right words, undergirded and backed up by proper precept and example are real musts for anyone whose life affects that of another—parent, relative, minister, teacher, manager, supervisor, safety engineer, etc. This is especially true in a behavior or action situation when the "tell and show" method applies. It is basic to an element of philosophy which was established some 2,000 years ago—the Golden Rule—and it is wrapped up in just eleven short words:

"Do unto others as you would have them do unto you."

Sometimes when you have a few spare moments, try to think of some other basic principle that would cure all of the world's ills faster than the Golden Rule put into action. And, remember, there is gold in the Golden Rule for the man who does not estimate others by the rule of gold.

Words, words, words—words are so important. The manner in which we use words can be a decisive factor in:

1) whether we make real lives for ourselves or just make livings.

2) whether we are part of the answer or a part of today's problems, and,

3) whether we are to be guilty or innocent of compounding "The Consuming Danger of Assuming."

Thus far I have used about 4,000 words, which should suffice; therefore, I hastily conclude with the few challenging words of this short poem:

Life itself can't give you joy
Unless you really will it,
Life just gives you time and space
It's up to you to fill it.

EMPLOYER—INSURANCE CARRIER COOPERATION IN ACCIDENT PREVENTION

By R. C. CARSON

Supvr., Engineering & Loss Control Div., The Travelers Insurance Co.,
Houston, Tex.

I should like first to establish or state what our common points of interest are. In other words, what it is that motivates us or what it is that makes it necessary, desirable or advantageous for an employer and his insurance carrier to establish a high order of cooperation. The answer is very simple and compelling; we have a common problem, the control of preventable accidents.

In some cases the employer may be self-insured. In other cases or localities, the employer or certain of the personnel may organize, own and operate an insurance company in which the employer's interests are insured. However, it would appear that most employers have found it simpler and less expensive to use an outside insurance carrier. So, again let me stress that we do have a very real common interest.

As an example of one area where improved cooperation would oftentimes help, let us think for a moment on the subject of better and more complete interchange, or exchange, of knowledge and information. Many times, an employee in a plant or industry can get, or knows, pertinent facts surrounding the cause or causes of a mishap, and these facts are only in part made known to the insurance carrier's safety representative. Employees of industry should be instructed over and over that when disaster strikes the insurance carrier is virtually standing in the company's shoes.

On the other hand, when the insurance carrier's safety representative discovers or uncovers pertinent facts surrounding the possible cause of a mishap, he should not be guilty of holding back the presentation against that time or place that could result in what he might feel would be personal aggrandizement. In view of our common interest, all parties concerned should freely and without reservation exchange or interchange any and all information that could possibly lead to a quicker or more accurate solution to our common problem, the control of preventable accidents.

Perhaps, in many cases improved and longer lasting cooperation would result if a proper first contact or introduction were made. The next time you insurance carrier supervisors assign a new safety representative to an account, or the next time your company safety supervisors assign a new man to a plant or to a department, try giving this matter of the first contact or introduction a lot of thought. When the assignment is decided on, don't just send the man out to whom it is assigned, take him. In other words, go with him.

Prior to the time of this first visit, make a definite appointment with management's top supervisor in the unit to which the new man is to be assigned, whether it be a department, a plant or a section of pipeline. If at all possible, arrange to have this top supervisor's boss present for at least a part of this first meeting. Introduce the newly assigned safety representative, reiterate to management, even though you have likely done it many times before, that the newly assigned man's purpose and function will be to offer assistance in any way that he properly can toward realizing a more efficient and smoothly running operation.

You can make good use of this opportunity to outline to management some of the background features of the newly assigned man and some of the other reasons that cause you to feel that he is particularly fitted and eminently qualified for the assignment. A proper introduction will go a long way toward establishing a friendly and cooperative relationship.

Perhaps in some instances a more cooperative atmosphere could be created or be made to prevail if the man in the industrial plant knew more about the reasons behind some of the information the insurance company safety representative may be trying to develop. If at times it may appear that the insurance company safety representative is straying a little far afield from what might be thought of as his proper sphere of activity, please

remember that he too serves several masters. It is true, and properly so, that his primary function is to serve those whom his company insures, but he also in many instances is asked to act as an information gathering agent. This information may be in connection with ascertaining whether or not the industrial operation is properly classified, the classification in this instance having to do with the type of operation being conducted; and it is therefore the classification that establishes the rate upon which compensation insurance is based.

The insurance company safety representative may be trying in some instances to develop information relative to a possible exposure contingency about which the industrial plant employee may not be aware. In any event, line supervisors should remember that whether the safety representative be from the insurance carrier or from their own safety section, his purpose is to help you work toward a more efficient operation. So whether any suggestions he might make would appear to be items of benefit to the line supervisor or items of benefit to the local safety section, as long as compliance would result in a more efficient operation, the suggestion is of benefit in all in the control of preventable accidents.

There are different kinds, or types, or forms, of cooperation that exist between an employer of workmen and his insurance carrier. These differences are due to the differences in the size and complexities of industrial organizations and to the development, or lack of it, in connection with their accident control efforts.

First, let us consider the company that has little or no accident prevention provision. We can all think of a company that falls in this category; it is usually a small or medium-sized company that has grown in all departments, save accident control. They may have been lucky and have not felt the need for accident control, when all of a sudden it is apparent that the tide has turned and all become aware of the awful realization that luck runs and works both ways.

For this company, the formulation of accident control techniques takes on the aspect of a "crash program." In a case like this, the insurance company safety representative has no trouble getting cooperation, his problem of greatest concern lies in guiding it. It

is a natural development for the insured to want and expect things to happen too fast. The tendency is to lose sight of the fact that the sorry state of affairs did not come about overnight and it cannot be cured overnight. Correction of the difficulty lies in the establishment and purposeful execution of a basic accident control program with all the speed consistent with what is attainable from a practical standpoint.

Any one now faced with a similar problem in any of his plants or departments should remember that the solution is going to call for the utmost in patience, understanding and hard work between the insurance safety representative, the company safety director and the line supervisor. Again, let me stress that the problem was not compounded overnight, and a workable solution will only be delayed through any show of tempers or any efforts on the part of any of the participants to "pin the monkey on someone else's back."

At the other end of the scale is the industrial concern with an adequate staff of competent accident control personnel. This is the type of company that we insurance company safety representatives are prone to think of as being "self sustaining." And they actually in many cases don't need much help. However, to be of help to a company like this, the insurance company safety representative must be capable of work of a high order, and he must play his proper role, that of an advisor and helper in any way that he can be of assistance in furthering the formal program of the insured company. Any industrial concern, though, however large, is not so big but that they cannot use another pair of eyes and another pair of legs.

In any consideration or study of the subject of cooperation between the employer and his insurance carrier, I think we should spend a little time in the area of safety meetings. Many words have been spoken and many people have expressed their views as to who should properly participate in safety meetings, who should be responsible for conducting safety meetings, what the relative functions of the various participants should be, etc. As far as the insurance company safety representative is concerned, I think his proper role can be easily and clearly set forth and described.

He should give understanding and patient

guidance to those who can't or don't know how to hold safety meetings and he should freely give advisory help to those who have and hold regularly scheduled safety meetings. In many small companies or in companies of some size that are for the first time trying to set up a safety organization, the word too often seems to get around to the effect that the insurance company safety representative is going to conduct our safety meetings. An insurance company safety representative has no more right or prerogative to conduct your safety meetings than he would to take over the administrative functions of any other phase of your business.

Safety meetings should be conducted under the guidance of the local or line supervisor, with the local supervisor looking to top management and his own company safety section for help, and both looking to the insurance company safety representative for advisory assistance. Personally, I think it quite proper and in good taste to invite the insurance company safety representative to your safety meetings as a guest and on occasion to invite him as a guest speaker. The insurance company safety representative should welcome such opportunities to thus be of constructive assistance.

There are certain personnel alignments and "chains of command" within companies that tend to either facilitate or hinder good cooperative work in the field of accident control. In my opinion, the placing of safety activities, or accident control, under the insurance department is not usually a very good set-up. Effective accident control must provide for a means of determining and identifying causes and potential causes of accidents, and then a means for formulating recommended suggestions for measures to correct these causes; and an insurance department is simply not normally geared to function in this area.

A personnel arrangement that seeks to cast people in the dual role of accident prevention representatives and claim adjusters is another that in my opinion is not a good combination. Under such an arrangement, no one could give adequate and satisfactory attention to one without neglecting the other.

For an example of still another undesirable combination, in my opinion, the placing of accident control under an operations department is not good and is even in the

same category as the bank examiner allowing the teller to audit his own books.

Accident prevention departments appear to have a natural affinity toward personnel departments, and such an arrangement seems to work quite well unless one man is saddled with the dual role of trying to act as personnel director and also accident prevention chief.

Not all companies are large enough to have all the departments just mentioned in a clearly defined arrangement, but regardless of company size, someone has to serve in the offices just mentioned, and no company gets small enough that accident control can just be turned over to the insurance carrier. In other words, a good safety record cannot just be bought. It must be brought about through good basic planning and good supervision, just as is true with any other successfully executed operational phase of the company's business.

The insurance company safety representative should make good use of the many opportunities he has of engendering cooperation through selling local or plant supervision on the fine work being done by their own accident prevention departments. He is in an excellent position to cite some specific examples where safety suggestions have resulted in improved production efficiency. He can in good taste point out many of the things done by plant safety departments to help supervision and how and in what ways many of them have lowered the costs of accidents.

The insurance company safety representative should stress at every opportunity that good accident prevention work and the attendant low accident costs do not indicate any lack of need for further accident prevention work or that a good record should ever be a valid reason for a slackening of efforts in this area. A good accident record and low costs indicate that somebody has done some good work to bring about this happy state of affairs; and once this state is attained, it should be a continuingly profitable situation to keep it that way.

I should now like to discuss some of the things which we might term "do's and don'ts." As I have indicated earlier, most anyone is more inclined to feel cooperative if he knows a little more about the reasons

behind the activities of the other fellow. The visits which an insurance company safety representative makes to your plant or operation are usually of the periodic or regularly scheduled type, but he at times may visit you as a result of a special request. When he comes as a result of a special request, he is usually seeking information of a specific rather than a general nature.

Whatever the reason for his visit, you local or line supervisors and your company will get the maximum benefit from his visit only if you give him enough time and assistance to make a thorough and comprehensive survey. As for insurance company safety representatives, at all times, they should try to make appointments in advance, to make their surveys on a day and at a time of day that causes the local supervisor the least inconvenience.

Another item that I should like to touch

on briefly is in the "don't" department, and it is directed at local and line supervisors. When an insurance company safety representative or a man from the company's own safety section presents a recommendation for the correction of a potentially serious or hazardous exposure, please don't procrastinate in effecting compliance, on the grounds that the exposure has caused few or no injuries. After a given exposure has resulted in a man being seriously injured or killed, no one argues then as to whether or not the corrective measure should be applied, but for the injured it is then too late.

One more item, and again it is a "don't" and again directed at local or line supervisors. A safety representative does not necessarily have to be an expert in the operational field of the company's business or activity. He must be, and is, an expert in the field of accident prevention.

DATA PROCESSING OF ACCIDENT RECORDS

By E. W. MILES

Safety Representative, The Ohio Oil Co., Findlay, Ohio

The Ohio Oil Company's operations are wide-spread and varying. And conducting an effective safety program for such a company is a herculean task. Yet, Ohio Oil's safety department is doing just that by applying the same principles of management to its safety efforts as apply to all other vital operations. In doing so, the basic responsibility and authority for safety matters rests first with the line supervisor. And, it naturally follows that the record keeping begins with them.

As in any other business operation, the value of record keeping is wholly dependent upon efficient, accurate and complete reporting. The final analysis is no better than the accurate and comprehensive basic information provided concerning any specific mishap.

The Ohio Oil method was conceived and tailored to its specific situation and business. It may not apply to all companies. But for Ohio Oil, it has proven to be an efficient and successful method.

Ohio Oil Accident Reporting Procedure

Reporting and investigating accidents is a fact-finding job which entails accumulating and analyzing the pertinent data, and giving consideration to the reasons for the accident. While cost determination is important, the basic reason for an accident investigation is to find the cause so prompt corrective action can be taken.

With this in mind, the Ohio Oil method includes three initial forms which make up the "case record file."

1. Form 2126, Notification of Accident,
2. Form 2473, Accident And Safety Report, and
3. Form 2109, Accident and Safety Investigation.

Form 2126—Notification Of Accident

Form 2126, Notification Of Accident, is prepared immediately by the supervisor of the injured employee and forwarded to the safety department in the company's general offices. This form alerts the safety depart-

ment that an accident has occurred and that a claim will result. Its primary purpose is to expedite immediate investigation of the accident and to keep the safety department posted on current accidents and costs which may accumulate prior to receipt of the Accident and Safety Report. It should be noted that this report is confined to factual information only. It does not contain opinions or recommendations.

Form 2473—Accident And Safety Report

Following "notification of the accident," the foreman prepares Form 2473, Accident And Safety Report. This form contains all the information from Form 2126 and additional information concerning the circumstances surrounding the accident, such as the equipment involved, the unsafe physical condition which gave rise to the mishap, any personal factors which contributed to the accident, and safe practices which were violated. It further includes steps taken to prevent the injury and both the injured's and the supervisor's recommendation to prevent recurrence. This form outlines the factors which led to the accident and sets the stage for a more complete investigation.

Form 2109—Accident And Safety Investigation

Every accident is thoroughly investigated to determine its contributing and immediate causes and to provide the base for prompt corrective action. At Ohio Oil, this is accomplished by Form 2109, Accident And Safety Investigation. This form takes up where the Accident And Safety Report leaves off. It is concerned entirely with detailed descriptions of the accident, its causes, and the corrective steps which have been, or will be, taken to prevent further mishaps.

Form 2126, Notification Of Accident, and Form 2473, Accident And Safety Report, are prepared by the supervisors. Form 2109, Accident And Safety Investigation, is prepared by the division safety engineer in cooperation with the supervisor. All the aforementioned reports are forwarded to the general offices in Findlay, Ohio.

Data Processing Of The Reports

When the forms are received by the headquarters safety department, they are closely

reviewed for completeness and accuracy. Then the information from the Accident And Safety Report (Form 2473) is transcribed to IBM cards in a series of codes and fed into the data processing equipment for storage. This provides the initial record of the accident and includes everything except the following incomplete and variable factors

1. severity of the accident,
2. days lost,
3. medical, sick benefits and compensation, and
4. whether the accident case is final or pending.

These variable factors are brought up-to-date monthly by Form 1262—Safety Department Monthly Report Of Accidents, and forwarded to the general offices.

The safety department accumulates these reports and quarterly revises the data processing file by issuing a corrected IBM card.

At the completion of each quarter, an IBM run is made listing all accidents occurring during the quarter, and any pending accident cases requiring payment during the same period. The runs are distributed by the safety department to each safety engineer and each employee relations supervisor. At the completion of the second, third and fourth quarters, cumulative runs are distributed.

This modern system of reporting and recording of accident information is designed to provide a complete, accurate record. Each step, or recording form, overlaps its predecessor to carry the total report or investigation a step further—until the completion of a final record in the safety data processing system.

This system not only provides a ready reference for quick, efficient accident analysis, but it provides a permanent record of accident statistics.

It must be realized that this is a brief description of Ohio Oil's handling of accident reports. If further information is desired, please contact the Safety Department, The Ohio Oil Company, 539 South Main Street, Findlay, Ohio.

DATA PROCESSING OF ACCIDENT RECORDS

Participants: J. U. PARKER, Chief Safety Engineer, Humble Oil Refining Co., Houston;
DR. G. H. COLLINGS, JR., Medical Director, American Oil Co., Chicago;
E. W. MILES, Safety Representative, The Ohio Oil Co., Findlay, Ohio;
H. GENE MILLER, Manager, Research and Statistics Dept., National Safety Council, Chicago;
C. P. VORHES, Coordinator of Safety, Jones & Laughlin Steel Corp., Pittsburgh, Pa.

Dr. Collings listed three requirements necessary before data processing of accident records can be considered a viable tool for accident prevention: (1) a large number of reports—on the order of 2,000 per year (2) ready access to data processing equipment (3) medical reporting at a quite sophisticated level. Gathering the type of data required for reliable statistical inference to aid prevention can only be accomplished if immediate reporting at the point of injury allows for direct key punch transcription. The step necessary for combining the supervisor's report of the injury with the point of injury report was elucidated by Dr. Collings' slide presentation.

Mr. Miles demonstrated, through a slide presentation, a set of four report forms—cross-coded for key sort—which can provide comprehensive, detailed accident information: (1) Accident Record report form—which details medical information (2) Notification of Accident form—which serves frequency computation needs (3) Accident and Safety Report—made out by the supervisor (4) Accident and Safety Investigation Report—made out by a qualified safety engineer. Analysis of data contained in these forms can pinpoint accident trouble spots and go far toward explanation of their causes.

Mr. Vorhes spoke to the problem of the availability of data processing equipment. Through the use of both hand punch and machine punch key sort cards, reporting can be accomplished in all desired locations. The method of hand punching can be easily taught to the employees who must report accident in areas remote from the machine punch equipment. If, however, the number of employees in the remote areas become sufficiently large, it may be necessary to make a machine installation.

Mr. Vorhes also discussed the need for a reporting manual or guide to programming for data process equipment. As yet a comprehensive guide for coding accident factors has not been developed. The question of the agency or agencies best suited to develop such a guide might be answered by members of the National Safety Council, the U. S. Public Health Service, and the U. S. Department of Labor.

Mr. Miller gave a brief history of the evolution of machine data processing at the National Safety Council. He noted that the key sort function was once accomplished entirely by hand. Today, work requiring man-months of labor has been reduced to man-hours. In 1962, NSC will acquire the programming capabilities of the IBM 1401 system.

Perhaps the major difficulty with data processing of accident forms was stated by Mr. Miller. The difficulty lies in fitting the accident to the form. In setting parameters and limiting the number of variables to be handled, the form must necessarily lose not only the flavor but a significant percentage of the information that can be found in a foreman's narrative of the accident.

In the open discussion, Mr. Parker observed that the justification of data process techniques must always reside in specific goals for accident prevention. Dr. Collings capped the discussion by pointing out that mere collection, storage, and retrieval capability of data contributes nothing to accident prevention. Until questions leading to a suitable array of the data are put, the implications of the data must remain unknown. Dr. Collings cited the array which connected the cause of typhoid to a contaminated water supply. The distribution of victims with respect to a particular well gave the needed clue.

GAUGING FOREMAN EFFORT

By E. M. McCracken, Jr.

Supvr., Employee Communications, Area Personnel and Industrial Relations,
Pacific Coast Area, Exploration & Production, Shell Oil Co., Los Angeles, Calif.

By "gauging" I mean measuring or "assessing"; by "foreman" I mean a first line supervisor who has an assigned crew or gang. In other words, what I intend to talk about is how we are measuring the effort which the first line supervisor makes toward accident prevention.

I am assuming at this point that we agree the foreman plays an important role in an accident prevention program. It is recognized that there are differences in the degree or amount of responsibility which the foreman assumes in various companies and in addition, there may be differences in the amount of responsibility he may assume within a specific company. As a general rule, a foreman in field or scattered operations—such as exploration, production or pipeline—must, by necessity, shoulder a greater load than the foreman working within the confines of a large plant. In many plant situations, specialists such as safety engineers, nurses, etc. are more readily available to give expert assistance than they are in scattered operations.

But regardless of these variations, I think it is generally agreed that the first line foreman does play a significant part in any accident prevention program. To state this in another way: the first line supervisor has more influence on the actions of the people who work for him than any other person, and since a large percentage of accidents and accidental injuries are attributed to "human failure," the foreman is thus the key-stone in every work environment. Let me not belabor the point.

Because of this key position which the foreman occupies, it follows that there should be an accurate assessment of the kind of a job he does.

I am not suggesting that the logic to this conclusion is original. However it is important that we agree on these two points:

1. The foreman plays a key role in accident prevention, and
2. There should be some means of measuring his effectiveness.

In preparing for this session I anticipated little difficulty on the road to agreement thus far. There may be some of you who will not be so quick to agree with the route which I choose to follow from this point.

A widely-used method or perhaps one should say a "standard" method of measuring accident experience is by frequency rate and severity rate. This is a convenient method and one which can easily be used for comparative purposes. I have no quarrel with the use of frequency and severity rates for assessing the effectiveness of an accident prevention program within a company, or a plant, or a division within a company. But accident frequency rates and severity rates do not measure an individual foreman's performance with any degree of validity. This is true because they can only indicate those foremen who have had more injuries per man hours worked. Let me hasten to add that I think this to be important—but frequency rates and severity rates, while they suggest that remedial action be taken, do not in themselves suggest what kind of remedial action should be taken.

In my company, in addition to frequency and severity rates, we analyze accidents and injuries to determine trends. I'm sure that each of you do pretty much the same. We code each report so that in a few minutes time our computers can tell us the number of accidents in each of many designated classifications: by injured's length of service, his age, occupation, supervisor, part of body injured, type of injury, time of day, work location, etc. Past experience does indicate weaknesses and such information is invaluable in the overall planning of an accident prevention program.

In this sense, we are planning future activities based on past experience. Would it not be more desirable to detect the cracks in our armor in advance? This is what we have been attempting. We have been directing a new effort toward uncovering weaknesses before they can produce accidental

injuries. And I should like to tell you about this.

In January 1960 our accident prevention program was what we considered to be a well-rounded one for exploration and production activities. Our organization included an area chief safety engineer and his assistant located in Los Angeles, with safety engineers located in each division headquarters. The program included on-the-job safety meetings, fire demonstrations, first aid training, posters, signs, protective clothing, safe work practices and procedures, etc. In spite of these efforts, the frequency rate had begun to creep higher in 1957 and this steady rise had continued.

After thorough studies and many discussions we concluded that we could expect a definite improvement in accident prevention if operating supervisors at all levels would give closer attention to those factors which influence safe work practices and procedures. This added effort was to be in addition to our existing program. In other words we considered it to be a supplement to—not a substitute for—other accident prevention activities.

With this general end in view we drew these specific objectives:

1. To continuously remind operating management that the primary responsibility for preventing accidents is theirs.
2. To provide operating management with a means of measuring the performance of individual supervisors in most of the areas which affect safety.
3. To encourage operating managers to help supervisors to improve performance in areas where weaknesses are found.
4. To motivate supervisors to do a more comprehensive job of supervising for safety.

A fifth objective which we did not publicize but which is nonetheless important:

To convince employees that management is interested in preventing injuries, and not just in a good "record."

Our next step was to design an approach which would accomplish these objectives. Here I shall describe as briefly as possible the mechanics of the program which we developed, which we call our supervisor safety

assessment program. (I should like to emphasize that the philosophy of this program is the thought which I want to leave with you today. This philosophy is applicable in any company. While these mechanics are important they may not be adaptable to your operations. I am describing them only because they may clarify the philosophy.)

1. Present a safety trophy in each production division and in our gas department to the foreman or assistant plant superintendent considered to have done the best job based on the following:
 - A. Job Instruction and Planning
 - B. Foreman's Personal Rating Sheet
 - C. Housekeeping
 - D. Condition of Tools and Equipment
 - E. Effectiveness of Safety Meetings
 - F. Crew Knowledge of Safety

In addition, individual awards will be presented to the crew members of each winning foreman.

2. Awards shall be presented annually. Competition period extends from July 1 to June 30.
3. Each foreman shall be rated quarterly in two of the categories listed. The final quarter ratings will be made in those two categories which most need improvement according to earlier rating.
4. Only foremen who have operating crews or gangs will be rated.
5. Ratings shall be completed by the division safety engineer and the next two higher levels of supervision above the foreman level. In no case do first line supervisors rate either themselves or their contemporaries.
6. Division winners will be selected on the basis of the total number of points.
7. Awards will be presented at the annual safety dinner in each division.

Here are some questions which I have taken at random from questionnaires used to determine crew knowledge of safety. We believe that imparting this knowledge is part of a foreman's job and therefore it is not unreasonable on our part to ask for a measurement. These are typical questions and you can see what we are trying to determine.

(Fire Protection)

1. Of the following types of extinguishers, which would you *not* use on an electrical fire? Why?

A—Dry chemical
B—Foam
C—Carbon Dioxide (CO₂)
D—Water

2. What is the best type of fire extinguisher to use on an oil or gasoline fire? Why?

A—Water
B—Carbon Dioxide (CO₂)
C—Soda and acid
D—Dry chemical

(First Aid)

3. Why are puncture wounds dangerous?
4. Burns are classified according to severity. Please describe each of these classifications.

First degree
Second degree
Third degree

(Gasoline Plants)

5. Where are the smoking areas in this gasoline plant?
6. What are the emergency signals for fire in this plant?

(Production)

7. Where are the "kill switches" on this well servicing machine?
8. When a gas engine is down, what is the first thing to check before starting?

9. If a compressor engine is down, what is the first thing to check before starting?

(Drilling)

10. When charging or recharging a blow-out preventer accumulator or slush

pump pulsation dampener, what gas should be used? Why?

11. When raising a mast is it best to connect the weight indicator before or after the mast is raised? Why?

12. A series 900 blowout preventer assembly is rated to operate up to the following working pressure

2000 psi 3000 psi 4000 psi 5000 psi

This safety assessment program for supervisors completed its first full year last June 30. It is too early to attribute any improvement in our accident record to this, although there has been improvement.

We do believe that it is accomplishing its objectives. We are convinced that this in turn will reduce the frequency and severity of accidents and injuries.

It has most certainly involved operating management from division managers to foremen. It has provided information about specific weaknesses which division managers can use as a basis for discussion with individual foremen. District superintendents and district foremen with an assist from our training section have been coaching foremen in those areas where they need strengthening.

To sum up our philosophy of this program for you once again:

- (1) We believe that work done properly and correctly is also done safely;

- (2) We believe the foreman has more influence on the actions and performance of his crew members than anyone else;

- (3) We believe that improving the performance of the foreman will result in improved performance in his crew—and thus fewer accidents and fewer injuries.

Based on our experience thus far—we think this program—or system—of "gauging foreman effort" will be most rewarding in terms of fewer accidents and fewer injuries.

THE PERSONAL FACTOR IN ACCIDENT PREVENTION

By HOWARD C. KLOPP

Dean, Fenger Junior College & Bogan Junior College, Chicago

I. Introductory remarks

- A. Personal factors concerned primarily—the psychology

1. Psychology—study of the individual
2. Sociology—individual in groups and situations

II. Consideration of the personal factors

- A. Concern of National Safety Council

1. Build the equipment with the human factor in mind

- a. Man-machine concept as a system; i.e., Franklin Taylor—psychology of design of machines, "Man as organic data transmission and processing link, between machine and control of a machine"

- b. With hazards taken out keeping in mind man's physical characteristics.

2. Use of safety devices when hazards can't or not taken out of machines in manufacturing processes.

- a. Personal factors, attitudes toward such devices help or hinder productivity, forgetfulness or distraction, learning safe procedures

3. Increase safety through people

- a. Safety education and training
b. "Why" people have accidents.
c. Personalities involved

B. Functional approach by psychologist

1. A re-examination of the accident processes concept
Alexander Mints & Milton A. Blum

"We have pointed out that in many instances the portion of accident records attributable to

differences in all forms of accident liability is relatively small as compared to the residual variance attributable to the operation of factors, which are not predictable in terms of either the constant characteristics of people or the previous accident records. The expression 'chance factors' or unpredictable should not be misunderstood. They are not unpredictable in terms of changing features of the life situation."

2. Purposeful behavior of man
a. Need directed and goal oriented
b. Needs of people in industry—or anywhere

- (1) Belonging
(2) Achievement and recognition
(3) Knowledge
(4) "Anticipation attention"

3. Job of psychologist, safety director, foreman

- a. Understand human beings
b. Predict human behavior
c. Control human behavior

C. Application to the industrial situation

1. Willard Kerr—complementary theories of safety psychology

- a. Accident proneness—15 per cent
(1) Environmental factors—heat, ventilation, congestion, etc.

- b. Goals freedom alertness—30-40 per cent

- (1) Freedom to set reasonably attainable goals is accompanied typically by high quality work performance—more alert to hazards

Past General Chairmen—G. B. BLACK, Sun Oil Co., Philadelphia, Pa.; PAUL CLABORNE, Pan American Petroleum Corp., Houston, Tex.; PARKER C. FOLSE, Mobil International, New York, N. Y.; C. D. ATTAWAY, Chief Safety Engr., Thiokol Chemical Corp., Marshall, Tex.; D. M. FARRELL, Butte Pipe Line Co.; D. A. KLEMM, Pan American Petroleum Corp.; W. I. KENT, (Retired); J. HOWARD MYERS, The Atlantic Refining Co.; J. L. RISINGER, (Retired); H. T. MARKER, Phillips Petroleum Co.; WALTER BOON, Sun Oil Co., Marcus Hook, Pa.; C. A. MILLER, (Retired); J. H. BROWN, Tide Water Associated Oil Co.; H. W. BOGGS, Sinclair Oil and Gas Co.; A. W. BREELAND, Lone Star Gas Co.; R. B. ROOPER, (Retired); GERALD O. LOCKWOOD, Continental Casualty Co.; GEORGE F. PRUNING, Consultant

*Past General Chairman

PLAN NOW --

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

**See the Latest in Safety Equipment
At the Greatly Expanded Congress Exhibit Hall**

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

improving, as much as possible (i.e., EM-
 PLOYEE SAFETY ATTITUDES).

We are certain that you realize the importance of and emphasis which should be placed upon this subject.

*List of Equipment and Materials
 Needed:*

- 1.—One set of 38 . . . 35 mm slides
- 2.—35 mm slide projector
 - a.—automatic . . . with remote control from your position as "leader" . . . will eliminate necessity for someone else to change slides.
 - b.—the projector "slide tray" may not hold all 38 slides.
- If two (2) trays are required, it is suggested that slides #1 through #18 be placed in one tray; and, slides #19 through #38 be placed in the second tray.
- 3.—Projection Screen
- 4.—Chart Pads—(50 sheets in each pad)
- 5.—Chart Pad Holders
 - a.—"Set-up"—same as in Discussion Leadership Training
- 6.—Handouts
 - a.—one set of 3 handouts for each participant
- 7.—Leader's Manual
- 8.—Illuminated Podium or Table Lectern
- 9.— . . . check the "Physical Setting" page
- 10.—
- 11.—
- 12.—

Opening The Session

Introduction of Discussion Leader by a Member of Management. When no management representative is available or all members of the group are not acquainted with you, introduce yourself. Welcome members of the group and begin with:

I. Introduction.

All of you certainly realize that Mr. . . . approves of our meeting with you for a discussion regarding attitudes of human beings and how such attitudes are related to a subject, in which all of us are and should be interested—Safety!

Not all of this material is original with us. We are indebted to: The State of Ohio . . . "Trade and Industrial Service" . . .

and "Management Information" . . . which is published by The Elliott Service Company, 30 North Mac Quessen Parkway, Mt. Vernon, New York.

We'll have some suggestions, later on in this meeting, regarding what we can do about some of our problems pertaining to the safety attitudes of human beings.

(show slide #1 . . . "pardon me! is your slip (attitude) showing!")

II. The title of our discussion is "Pardon me! Is your slip showing?" Our title is a take-off of an old saying . . . with which some of you may be familiar. The story is told about a man who was present at a very formal party. He noticed that a lady's "slip" was hanging below her dress. Since he was a man who was always interested in helping others . . . with their problems, he went up to her and said:

(show slide #2 . . . "pardon me madam! your slip is showing.")

"Pardon me, madam! Your slip is showing."

So we are going to begin by talking about a subject, with which you are all certainly familiar:

Waste!

Now, that's a quick switch, isn't it? We are not sure that all of us would have the same understanding of what an attitude is or what we mean by attitudes, but, certainly, we all know something about wastefulness.

Don't be too concerned, now, how this all applies in a discussion pertaining to safety. We'll tie the two together later on in our meeting.

III. "Waste, Incorporated."

Let's think of waste as being a corporation . . . a big business organization.

Mr. F. W. Stein, vice president, manufacturing, of the Standard Register Company, is quoted as saying:

"Unless we put waste, incorporated, high on the list of our competitors, we are failing to recognize an evil that can decay our business."

Are you helping to keep a tough competitor in business?

Fortunately, wastefulness is not formally incorporated. If it were, we might see advertisements like this . . . on the business opportunity pages . . . of our newspapers.

(show slide #3 . . . waste, inc.—beats all competition—losses guaranteed)

(pause . . . allow time . . . for reading)

Yes, Waste, Incorporated, beats all competition and losses are guaranteed.

(show slide #4 . . . door of Waste, Inc.)

(pause . . . allow time . . . for reading)

How does "Waste, Incorporated" get a toe-hold? What keeps this tough competitor in business? Come with me. Through this company's door. Let's visit some of the departments supervised by the officers and listen-in on some of the conversations.

We'll learn of some typical reactions and attitudes that enable "Waste, Incorporated" to survive within our companies.

(show slide #5 . . . Waste, Inc.—what's a minute here or there?)

"What's a Minute Here or There?" It doesn't seem like much but time costs money, more money than ever before.

Have you ever heard someone say something like that?

Minutes here and there soon add up to hours and dollars everywhere. The multiplication of small wastes, maintenance wastes, wasted materials, supplies, power, parts, tools and waste of time, soon means major bills—and "new business" for Waste, Incorporated.

Let's move on into another department.

(show slide #6 . . . Waste, Inc.—Some waste is normal)

"Some waste is normal." Have you ever heard something like that?

This, too, can be a dangerous assumption. Many of us are resigned to accepting a minimum waste level, and after all this is like declaring a guaranteed minimum dividend to "Waste, Incorporated."

Over in the next department another person is talking. Let's go over there and listen in.

(show slide #7 . . . Waste, Inc.—I don't waste much. They must be talking about somebody else.)

Yes, the directors of "Waste, Incorporated" like to hear this kind of talk:

"Oh, I don't waste much. They must be talking about somebody else."

The directors know that if every one of our employees wait for the next man to do something about waste reduction, Waste, Incorporated, will be in business for a long, long, time.

Let's ask some of the men . . . what they are going to do about it? One of the men replies:

(show slide #8 . . . let's reduce waste) "Let's reduce waste . . . Let's do something about it."

(show slide #9 . . . let's reduce waste—starting tomorrow)

"Starting tomorrow."

Why do we wait 'till tomorrow? Special peak loads, pressures, breakdowns, bottlenecks and many other things are excuses, not reasons. The only way to drive "Waste, Incorporated" into bankruptcy is to tackle waste reduction today . . . tomorrow . . . every day!

Pardon me, gentlemen! Was this man's slip showing?

(show slide #10 . . . Waste, Inc.—prosper)

"Waste, Incorporated prospers" where there is neglect, procrastination, indifference, carelessness, inability and irresponsibility.

Remember? These are the "officers" of our competitor's organization.

Any member of management from the first line supervisor up to the president or, as a matter of fact, any employee who wants to put our competitor ("Waste, Incorporated") out of business must translate his own savings attitude into positive employee attitudes and actions on the job.

Mr. Stein, of Standard Register Company, concluded his remarks with:

"As our company continues to grow, Waste, Incorporated, become a more imposing adversary. To meet the growth challenge of tomorrow, we must practice waste reduction today!"

(show slide #11 . . . Waste, Inc.—closed—out of business)

Yes, if we practice waste reduction today, tomorrow and every day, Waste, Incorporated, will soon be closed . . . out of business.

Pardon me, gentlemen! . . . is your slip showing?

IV. How to get opinions and feelings.

We mentioned earlier that we would point out some things we could do. Are we interested in solving our problems with people

whose attitudes help keep our "Waste, Incorporated" competitor or any of our other competitors in business?

If we are, let's begin by getting the facts! . . . And be sure we have the whole story. Let's find the real cause of his behavior.

We can help solve such problems by learning more about the individual so let's talk with him. Let's get his opinions and feelings.

If, when talking to another person, you want to get his opinions and feelings about a problem, our suggestions are:

(show slide #12 . . . how to get . . . no. 1—don't argue)

1. Don't argue!

Many times, in talking with "problem" individuals, what they say will present an opportunity for you to "disagree" start an argument. Is anything satisfactorily settled by arguing?

Our first tip, then, is if you want to get opinions and feelings of other people, don't argue! Keep in mind that you are trying to get his opinions and feelings, learn more about him, so let him tell you.

(show slide #13 . . . how to get . . . no. 2—encourage him to talk . . .)

2. Encourage him to talk about what is important to him.

You may have to vary your approaches during your talk. The more you already know about the individual the better you can vary your approaches. If you can get him to talk about what is important to him (rather than what seems, at the moment, important to you), you will soon discover that he is telling you some of his opinions and feelings, and you are learning more about him. After all . . . That is why you are talking with him.

(show slide #14 . . . how to get . . . no. 3—don't interrupt)

3. Don't interrupt! Let him talk. Once you get him talking, you may want to interrupt and make a "speech." Our third suggestion is:

When he is telling you his opinions and feelings, don't interrupt.

(show slide #15 . . . how to get . . . no. 4—don't jump to conclusions)

4. Don't jump to conclusions!

When someone is talking to you, have you ever (during the conversation) made a

"quick decision" and seconds or minutes later learned that you "decided" without all the facts? Hear him out! Don't jump to conclusions!

(show slide #16 . . . how to get . . . no. 5—don't do all the talking)

5. Don't do all the talking.

Keep in mind that you are trying to learn more about him. We human beings have a tendency to want to tell others about ourselves. In this case he will follow this tendency, so don't do all the talking.

(show slide #17 . . . how to get . . . no. 6—listen)

Our last . . . but certainly not the least important suggestion is:

6. Listen!

In order of importance, possibly, this "tip" should have come first. Why? Because if we don't listen, we won't learn of his opinions and feelings. We won't learn more about him as he talks to us.

We, as discussion leaders are always wondering if we are communicating with you, if you as participants, are listening and if you are listening, what are you hearing and learning?

Psychologists tell us that, among other things peculiar to human beings, we have tendencies to hear only the things we want to hear.

You might say that hearing is done with the ears while listening is done with the mind.

There is a big difference between "Let's sit-back and hear what he has to say" and "Let's sit-up and listen!"

So if you want to get opinions and feelings, learn more about other people, we suggest that you "sit-up."

(show slide #18 . . . stop . . . look . . . and listen)

STOP . . . LOOK . . . AND . . . LISTEN!

(turn off projector.)

(it is at this point in the meeting that you lead "group discussions" pertaining to problems in "Getting Opinions and Feelings" of others; this discussion should be planned and conducted along lines of training received in "Discussion Leadership.")

(use "chart pads" for listing the title, "direct" objectives, and headings for the

charts on which you list participants' contributions during the discussion.

(after you have summarized participants' contributions at the conclusion of the discussions, briefly thank group for their contributions and participation in the discussions.)

(a 10 minute "break" is suggested at this time; during break . . . change slide tray if necessary.)

(after "break" . . . turn on the projector and continue. . .)

1'. Introduction.

(show slide #19 . . . pardon me! is your ship (attitude) showing?)

Before we discuss some of the things we can do after we get opinions and feelings, we want to talk about another tough competitor of ours. Thousands upon thousands of words have been spoken and written about safety with all its implications.

With this group we don't believe it necessary or essential to quote some V.I.P.'s philosophy of safety.

11. "U.N. Safe, Incorporated."

So let's think of this tough competitor as also being incorporated—a big business!

It is also fortunate that this competitor is not formally organized. If it were, we would see advertisements like this . . . in the newspapers.

(show slide #20—U.N. Safe, Inc.—beats all competition—losses guaranteed)

(pause . . . allow time . . . for reading)

Yes, here again, we have a competitor that beats all competition and guarantees losses.

Did you notice that this advertisement included human beings?

How does the "Un-Safe" corporation get a foothold? What keeps this competitor in business?

(show slide #21 . . . door of U.N. Safe, Inc.)

(pause . . . allow time . . . for reading)

OK, Come with me, again. Let's open this competitor's door and visit some of their departments. Remember these departments are also supervised by the officers.

Let's listen and we'll learn of some typical reactions and attitudes in this corporation.

(show slide #22 . . . U.N. Safe, Inc.—hurry-up . . . we've only got a minute)

"Hurry-up! We've only got a minute."

Why? Why did he only have a minute? Is this a case of the old "Put-it-Off" attitude showing? Did he pay attention to some instructions given "X" minutes before? Or is the old "who cares?" ship showing? Just why is he in a hurry?

We know that time does cost money. But there are many, yes, many more things in this old world of ours more valuable to human beings (dollarwise or otherwise) than being in a hurry.

Have you ever heard "better late than never," "haste makes waste," "slow down . . . it's later than you think?"

"Pardon me, gentlemen! Is this man's ship showing?"

Let's move into another department and listen.

(show slide #23 . . . U.N. Safe, Inc.—some risk is normal)

"Some risk is normal."

Yes, this, too, is a dangerous assumption. Have you ever heard someone say, "I know this is risky business but, after all, it's all in a day's work"? Have you ever heard someone say "It's just one of those things"?

How about being around tomorrow to do the work? Yes, to do some other things we like to do.

Again many of us are resigned to accepting the products of the "Un-Safe" corporation without giving much thought to the consequences.

This, too, helps build greater profits for "U. N. Safe, Incorporated."

Let's visit another department.

(show slide #24 . . . U. N. Safe, Inc.—I don't take chances. They must be talking about somebody else)

"Ah, I don't take chances. They must be talking about somebody else."

This is sweet music to the ears of the directors of "U. N. Safe, Incorporated."

More business for their corporation.

Remember? Losses are guaranteed by this competitor of ours. Losses in human

being hours of work, materials, equipment and many other things, including life, liberty, and the pursuit of happiness.

Let's move on into another department and hear some more about this competitor of ours.

(show slide #25 . . . U. N. Safe, Inc. —let's be safe)

"Let's be safe." Yes Sireeeeee! Let's do something about it.

(show slide #26 . . . U. N. Safe, Inc. —let's be safe—starting tomorrow)

Yes, you guessed right!—starting tomorrow!

Pardon me, gentlemen! Is this man's slip showing, too?

Again, the why's: Why don't we start today? Why don't we start right now?

Many of the answers are not good reasons at all—peak loads, other things to do, don't have time, stoppages, breakdowns, and many other things are excuses, not reasons.

(show slide #27 . . . U. N. Safe, Inc. —U. N. Safe, Inc. prospers)

Yes, the U. N. Safe Corporation prospers too, where there is inattention, haste, chance taking, fatigue, excitability and ignorance.

Remember! These are the officers in charge of production at "UN-Safe, Incorporated."

All of us who want to put "UN-Safe, Incorporated" out of business must, in some way or other, translate our own safety feelings—attitudes—to other people. We must do something to develop positive actions and "attitudes" (like our own) in other people. Get them to:

(show slide #28 . . . stop — think — safety)

Stop and think and act safety—now!—Today — tomorrow — every day — and everywhere. If we can, then a sign will go up on the "UN-Safe" corporation's door, too.

(show slide #29 . . . U. N. Safe, Inc. —closed)—out of business)

Closed! . . . Out of business!

Dr. Earle S. Hannaford, safety engineer of American Telephone and Telegraph Company, has said:

"Eighty-five to ninety per cent of industrial accidents are due to human failure, caused by emotional or mental problems."

Dr. Hannaford advises to watch for these

symptoms—errors in work, changes in everyday behavior, changes in routine habits, increases in near-accidents, poor safety attitudes and safety program fatigue.

VII. Factors that determine the kind of a job an employee is doing

Before we point out some additional things we can do about some of our problems pertaining to attitudes of human beings, we want to discuss some factors that determine the kind of a job an employee is doing. What are the important things that make an employee valuable or worthless?

For clarity, we can group them under three general headings—knowledge, skill and attitude.

Knowledge is the knowing how; skill is the ability to do, and attitude is the wanting to do.

Attitude is the way an employee feels about something, may be considered as a control valve—on output—on his actions.

For example: A person may know how to, and be able to do, a thing very well, but just doesn't want to do it.

When we encounter a safety attitude problem with an employee, let's check first that he has knowledge and the skill to do what is required.

If he doesn't have the knowledge or skill to do the job, it is clearly a problem of education and training.

If he has these then it's our job to go to work on his attitude. A sufficiently strong attitude will result in action!—and we hope good actions!

VIII. Now, let's take a look at some of the important considerations, in developing attitudes in those people we supervise.

(show slide #30 . . . important consideration no. 1)

1. Attitude, to be developed, must be consistent with employee's goals and the total situation.

An employee's personal "goals" would be what he is working toward to fulfill his desires—his needs—things an employee believes he must have for a successful living.

(these were discussed in our Understanding Human Behavior course)

The total situation refers to the employee's background, native endowment,

financial status, health and others, including the job itself.

(these were discussed in our Understanding Human Behavior course)

(show slide #31 . . . important consideration no. 2)

2. Employee must be led to recognize that he is actually involved in the problem.

We may have to spend some time personally going over a situation with an employee to help him see that this problem is his problem.

(show slide #32 . . . important consideration no. 3)

3. Employee must freely accept an attitude. We can't force it on him from outside.

Have you ever heard of someone telling someone else:

"You better change your attitude . . . or else!"

How would you feel . . . if you were the one being told?

(show slide #33 . . . important consideration no. 4)

4. Facts alone won't change anyone's attitude. The way one feels about the facts is more important.

So when presenting facts to your employees, the employees should appear to discover the facts for themselves; then they are their facts.

(show slide #34 . . . important consideration no. 5)

5. Attitude to be developed will be strengthened if any action proposed seems to get the employee closer to his goal.

(show slide #35 . . . important consideration no. 6)

6. Employee will not accept a new attitude if he feels he is being attacked.

(show slide #36 . . . important consideration no. 7)

7. Changing a person's attitude takes time.

We can't do it over-night. Don't expect miracles to happen. The small, but numerous positive impressions that we make on the employee are the things that count.

For some time, experts in the field of human relations have emphasized the im-

portance of sensitiveness—sensitiveness on the part of the supervisor to his employee. You see, there's a lot more to being a good leader than just knowing in general what makes people tick, or how to shape attitudes.

The most sensitive supervisor is one who is sensitive to the real needs of his employees. It is only when we understand the whole person, his individual traits, his joys and his sorrows, his drives and his goals, that we can supply the kind of leadership that pays off in higher productivity and a safer, healthier, happier existence for everyone concerned.

(turn off projector)

(it is at this point . . . in the meeting that you lead "group discussion" pertaining to problems in "developing attitudes." this discussion should also be planned and conducted along lines of training received in "discussion leadership.")

(use chart pads for the same purposes as indicated for your first "group discussions." after you have summarized participants' contributions at the conclusion of the discussions, briefly thank members of the group for their contributions and participation in the discussion.)

(start projector . . . show slide #37 . . . pardon me; is your slip (attitude) showing? . . . and continue with:—)

At the conclusion of our meeting today, we have a set of three handouts we want you to take with you. They will serve to remind you of the important points we have been discussing:

1. How to get opinions and feelings
2. A check list which will help you gauge your own listening habits . . . and
3. Important considerations in developing better employee safety attitudes.

1X. We want to close our meeting today by—

1. Asking a question . . .

2. Answering the question . . . and

3. Offering another suggestion.

The question:—Pardon me, gentlemen! Is your slip showing?

The answer:—Your slip (attitude . . . regarding the importance of safety) is showing. How much? . . . We don't know.

Our suggestion:—Don't let anyone talk you into covering it up.

(show slide #38... let 'er hang...)
Let 'er hang! The farther down, the better!

Thank you, again.

(distribute sets of handouts)

(important instructions... to discussion leader: (it is expected that you will prepare complete "minutes" (report) of both group discussions... and forward one copy of each "group" discussion... through proper channels... to our Safety Director.

HANDOUT NO. 2

Few virtues are more prized and less practiced than good listening. This check list, though by no means complete, will help you gauge your own listening habits. Try to answer each question objectively.

LISTENER'S QUIZ

When taking part in an interview or group conference, do you:

	Usually	Sometimes	Seldom
1. Prepare yourself physically by sitting facing the speaker, and making sure that you can hear?..	()	()	()
2. Watch the speaker as well as listen to him?....	()	()	()
3. Decide from the speaker's appearance and delivery whether or not what he has to say is worth while?	()	()	()
4. Listen primarily for ideas and underlying feelings?	()	()	()
5. Determine your own bias, if any, and try to allow for it?	()	()	()
6. Keep your mind on what the speaker is saying?	()	()	()
7. Interrupt immediately if you hear a statement you feel is wrong?	()	()	()
8. Make sure before answering that you've taken in the other person's point of view?	()	()	()
9. Try to have the last word?	()	()	()
10. Make a conscious effort to evaluate the logic and credibility of what you hear?	()	()	()

WHAT'S YOUR SCORE?

Score yourself as follows: Questions 1, 2, 4, 5, 6, 8, 10: Ten points for "usually," 5 for "sometimes," 0 for "seldom." Questions 3, 7, 9: Zero for "usually," 5 points

for "sometimes," 10 for "seldom."
IF YOUR SCORE is below 70, you need training; 70-85, you listen well but could improve; 90 or above, you're an excellent listener.

From: "The Management Review," a publication of the American Management Association, Inc.)

HANDOUT NO. 1 HUMAN RELATIONS HOW TO GET OPINIONS AND FEELINGS

1. Don't argue
2. Encourage him to talk about what is important... to him
3. Don't interrupt
4. Don't jump to conclusions
5. Don't do all the talking yourself
6. Listen

(From the Trade and Industrial Education Service—State of Ohio—Course in Human Relations Training)

HANDOUT NO. 3 UNDERSTANDING HUMAN BEHAVIOR

Important considerations in developing attitudes:

1. Attitude to be developed must be consistent with employee's goals and the total situation.
2. Employee must be led to recognize that he is actively involved in the problem.
3. Employee must freely accept an attitude.

4. Facts alone won't change anyone's attitude—the way one feels about the facts is more important.
5. Attitude to be developed will be strengthened if any action proposed seems to get the employee closer to his goals.
6. Employee will not accept a new attitude if he feels he is being attacked.
7. Changing a person's attitude takes time.

FIRE FIGHTING NEAR LIVE ELECTRICAL APPARATUS

By G. W. N. FITZGERALD
Supervising Eng., Electrical Testing, Research Div.
The Hydro-Electric Power Commission, Toronto, Ont., Canada

Tests have been made to determine the limit of safe approach to live electrical equipment with fire hose streams. Tests were made with various nozzles at pressures from 30 to 100 psi. Results indicate that spray or fog stream nozzles may be used with safety up to the limit of safe working space. Solid stream tips up to 5/8-inch can be used, providing a reasonable distance is maintained from the electrical circuit. Solid stream tips above 5/8-inch may be hazardous if used on live electrical circuits.

One hazard encountered in fighting fires is the possibility of accidental contact of the fire hose stream with live electrical circuits or live electrical apparatus. Since a solid column of water is a conductor of electricity, the column must be long enough to limit the current to a low value. If this value increases beyond safe limits it may create a hazard to the operator of the fire hose line.

The resistance of the water column will decrease as the size of the column increases, and it is necessary, for the same measure of safety, to maintain a greater distance from electrical apparatus with larger hose streams. The electrical resistance of the water stream will increase very materially

if the water column breaks up into separate droplets. Thus it should be safe to approach closer to live electrical apparatus with spray stream nozzles.

In order to determine the limit of safe approach to live electrical circuits and apparatus, under varying conditions of fire fighting, tests were made during which fire hose streams were played on a metal target that could be energized from a test transformer at a power frequency of 60 cycles per second. These tests were made with the co-operation of the Fire Services Division, Office of the Fire Marshal, Ontario. The Fire Services Division supplied a pumper, equipment and personnel during the tests.

Test voltages ranged from those encountered in domestic and industrial service to the highest transmission voltages encountered at power stations.

Various types and sizes of nozzles were tested, at water pressures varying from 30 to 100 pounds per square inch, at the nozzle.

The specific resistance of water samples from various parts of the Province of Ontario was examined to determine the range of resistance to be found in water from various parts of the province.

In order to determine what types of nozzles were to be tested, it was necessary to consider the types of fires that might be encountered in or near electrical apparatus.

First, class A fires where live electrical circuits might be adjacent to the outside of buildings, or within the buildings.

Second, class B and C fires in electrical equipment. In these cases, equipment failure may result in a flammable liquid fire and adjacent electrical circuits may still be energized.

For the first case, solid streams may be employed to pour a large quantity of water on the fire or to obtain a long reach of the fire stream.

A standard 2½-inch shut off was used with replaceable tips in sizes from ½ inch to 1½ inch.

Also to consider plant installations where permanent hose lines are usually 1½ inches, combination off-log-solid stream nozzles were used. These have a ¾-inch tip for the solid stream position.

In the second case, spray or fog stream patterns are generally more effective in blanketing the fire without the danger of spreading the fire as might happen if solid streams were used. The spray stream pattern was used on the combination nozzles and tests were also made with a 2½-inch adjustable nozzle and a 1½-inch Poweron Nozzle.

The tests were conducted to allow a maximum current of three milliamperes in the fire hose stream. This value is generally considered to be at the lower threshold of feeling for most normal people. In addition, tests previously made to determine the safe approach of fire hose streams to live electrical equipment have used the same maximum value of safe current.

The nozzles were mounted on an adjustable platform on a rubber-tired truck or on the boom of a sky-worker vehicle. Between the end of the hose and the nozzle, a pressure gauge adapter was inserted, so that pressures at the nozzle could be measured.

An insulated conductor was rigidly attached to the nozzle and connected through a milliammeter to the grounded side of the test transformer.

The nozzle was positioned at a fixed dis-

tance from the target and, with various tips and water pressures, the voltage was raised until the current of three milliamperes was flowing down the hose stream, through the nozzle to ground.

The tests were made using Toronto city water which has an electrical resistance of 1800 ohms per cubic inch at 8.5°C.

Solid stream patterns maintain a fairly solid water column up to the limit of a good stream. Beyond this point the water column begins to break up into showers of spray. The limit of a good stream may be decreased by wind conditions, but all results were plotted considering the maximum reach of the stream in still air.

With most nozzles a slight "necking" and "crossover" of the water stream occurs between 10 and 20 feet from the nozzle, depending on the size of the tip and the pressure. Thus, up to this point the water column decreases in size slightly, then increases. Beyond the "crossover," for all solid stream patterns up to the limit of a good stream, the water column conducts current which increases with pressure at the nozzle, and which also increases with the size of the tip used.

For tests on low voltages a minimum approach of five feet was used. The results of these tests indicate that for all tips below 1½ inch the current was less than the safe limit of three milliamperes. With a 1½-inch tip at 30 psi, the limit of three milliamperes was reached at a distance of five feet.

Tests at voltages above 600 volts were made at distances from 5 to 30 feet. With the smaller tips the solid stream began to break up before the 30-foot distance with increasing resistance in the hose stream and thus a lower current.

Graphs showing the distances at which a current of three milliamperes was reached for various tip sizes and pressures are reproduced in Figures 1 to 4.

The pressure at the nozzle materially affects the approach distance with most tips. With tips over ¾ inch and pressures of 100 psi, approach to or contact with live electrical apparatus may be hazardous.

In most cases the stream from combination nozzles was not as good as with a straight tip of the same size. There appeared to be some difference in good stream distances with different nozzles of the same

Figure 1

Figure 2

Figure 3

Figure 4

type. Considering that a well designed combination nozzle will have the same effectiveness as a straight nozzle of the same size, safe distances for a $\frac{3}{4}$ -inch straight tip should be used for all $\frac{3}{4}$ -inch nozzles.

Because the water column of a 3/8-inch tip begins to break up into showers of spray at a distance of about 20 feet from the nozzle at 100 psi, it is safe to use a 3/8-inch tip on live electrical apparatus provided a reasonable distance is maintained.

In order to consider the effect of low resistance water on the hose stream, calculations were made to consider the use of 600-ohm water in place of Toronto city water at 1800 ohms per inch cube. From a survey of water resistances from various locations in Ontario, it is considered that the minimum resistance of water used for fire fighting would be 600 ohms per cubic inch.

The curve shown with "dash" lines in Figure 3 is plotted based on 600-ohm water, and Table I shows the minimum approach distances for various circuit voltages.

TABLE I
Limit of Safe Approach to Live Electrical
Apparatus
¾ Inch Solid Stream Pattern
100 PSI—Water Resistance 600 Ohms
per Cubic Inch

Volts to Ground	Circuit Voltage	Minimum Safe Distance in Feet
2,400	4,160	18
4,800	8,320	20
7,200	12,480	22
9,600	16,640	23
14,400	24,960	25
18,000	27,600	25
25,000	44,000	30
66,500	118,000	30
130,000	230,000	30

Because the spray or fog stream patterns project separate droplets of water, the resistance of the water stream is greatly increased.

Consequently quite close approach to the target was possible with complete safety. Spray nozzles are safe to use within three feet of 65,000 volts to ground (equivalent to a 115,000-volt circuit).

However such close approach should not be considered for hand held hose lines. Considering the limits of safe approach to live electrical circuits for trained electrical utility personnel, a table of safe approach for use with spray or fog streams is set out in Table II.

Public Utilities Industry

TABLE II
Limit of Safe Approach to Live Electrical
Apparatus
Spray or Fog Stream Nozzles

Volts to Ground	Circuit Voltage	Minimum Safe Distance in Feet
2,400	4,150	4
4,800	8,320	4
8,000	12,500	4
10,000	13,500	4
14,000	24,800	4
16,000	27,600	4
25,000	44,000	6
55,500	115,000	8
130,000	230,000	14

With a minimum distance of five feet from nozzle to electrical contact no hazard should exist for all solid stream tips up to 1½ inch at 100 psi.

In summary, with high voltage circuits:

(a) Solid stream tips up to $\frac{1}{4}$ inch may be used with care, provided distances are maintained as shown in Table I.

(b) Solid stream tips above $\frac{3}{4}$ inch should not be used near live electrical equipment.

(c) Spray or fog streams may be used up to the limit of safe working space on all voltages of electrical equipment; see Table II.

ELECTRICAL RUBBER GLOVES IN THE PRIMARY AREA

By E. A. SHULTZ
Vice President-Operations, Illinois Power Company
Decatur, Illinois

My assignment is to tell why we use electrical rubber gloves in the primary area. In carrying out this assignment I hope no one gets the impression that I am arguing with any of my distinguished colleagues on this panel. I am certainly not trying to sell you on the idea that the way Illinois Power Company does things is the only right and safe way.

There are many instances where a lineman should put on rubber gloves before he leaves the ground. Some work must be done from platforms. With the developments being made in insulated aerial baskets, and with their singular characteristics to prevent serious falls, I believe we all will find increased use of aerial baskets. However, most of us will be doing a lot of work from poles for several years. My philosophy of getting line work done from poles safely includes the use of rubber gloves when within reach of energized primary conductors, that is 2300 volts to ground and 4160 volts phase to phase. So I will confine my discussion to that area, what we believe in, what we do, and why.

That linemen wear electrical rubber gloves when working on energized primary conductors is a part of their craftsmanship that is not too old. It is only during the past 40 years that electrical gloves have come into use as personal protective equipment. One of our executives, now retired, has told me of working on energized 2300 volt-wires regularly. His only insulation was the rubber gloves he used. When electrical rubber gloves were introduced, linemen bought their own and used them as barriers between the conductor and their hands. So they have always been known as personal protective equipment.

From all the summaries of questionnaires that I can find, it appears that at least 80 per cent of all electric utilities believe about as we do. Because electrical rubber gloves are personal protective equipment, the use of them, like other lineman tools is much

more a matter of determination out on the job than one to be determined by rigid operating rules.

I want to quote for you what our safety manual says on the wearing of rubber gloves. It is not extensive. It has been changed very little during the past 15 years. "Employees shall put on rubber gloves with leather protectors before entering any areas where there are live conductors carrying 400 to 5000 volts. The rubber gloves shall be kept on until employees have left such live areas."

"Employees will be expected to wear rubber gloves to do many jobs in which the voltage is below 400 volts, where there are such conditions as: damp weather; excessive perspiration; substandard or close construction; unusual strain or body position (a slip is more apt to occur); or wet equipment."

The wearing of rubber sleeves is optional to the foreman and his men.

Now, as safety rules, those are not very specific. We make no attempt to define the primary area in any greater detail.

Perhaps I should explain that our whole safety program is built around the line organization and that includes delegating responsibility for safety out to the foreman on the job. We don't do much in the way of large group safety meetings but we do stress tailboard conferences.

There are two good reasons why our rules on electrical rubber gloves are so written.

1. The rules are short and understandable, whether linemen work up on poles or on the ground. Guiding pole butts, manipulating hydraulic booms, or tending wire reels while standing on the ground are just as hazardous as tying in conductors to insulators. On all of them electrical rubber gloves may have to be worn.

2. Whether men are doing electrical work in power stations, sub-stations, on towers or poles, the rules are the same. All of our men doing this work belong to the same

craft union, so the rules should be consistent. If we attempted to spell out more detail on the wearing of rubber gloves, the various situations would be endless.

I have already mentioned that I consider electrical rubber gloves to be personal protective equipment. By personal, I mean something pertaining to the individual lineman just as are his climbers and body belt. Rubber gloves are not necessarily furnished by the lineman now. Neither are other personal items. Practices vary among companies.

Electrical rubber gloves are personal protective equipment because they are a barrier between his hands and live primary conductors. They insulate him from the live wires.

A lineman air tests his gloves because they are intended to protect him. He carries them with him, just as he does other personal tools. Gloves are inspected and tested periodically in the laboratory, but a lineman still gives them a going over just before he uses them.

I am drawing a distinction here between gloves and the other protective devices that the crew tools or crew equipment. Some of the crew usually maintains them or directs the caring for them.

I repeat again. We expect a lineman to use judgment when to use his rubber gloves and we expect him to choose the proper size that he carries. He is a craftsman.

If he doesn't come to us as a journeyman, he goes through the long standing training procedure of apprenticeship. The proper use of rubber gloves is a part of apprenticeship training. We try to emphasize the positive approach to protection, the exercise of good judgment, and above all the necessity for the lineman to think for himself. We know that when he goes up a pole, each job will have some variations more or less from every other one. So the thinking for himself is pretty important. He must think about what he is doing, what the hazards are and why, in order to do his job properly and safely.

We have not refused to consider ground-to-ground rules. There have been several well prepared papers by capable men that have endorsed the ground-to-ground rules. We have weighed the proposals in terms of

our own operation. We conclude by leaving our practices as they are. Here are some of the reasons why:

1. Each year more of our primary lines become 7200 volts to ground. We have always used 10,000 volt rubber gloves and our limit of 5000 volts came into being when we had very little 7200 V. We serve a lot of small communities and rural lines, but any time we work 7200-12,500 volt energized, we have always done it with hot sticks and without rubber gloves.

Now any one crew can finish a 4160 volt job and move directly to a 12,500 volt job.

It would hardly be logical for us to tell men to wear rubber gloves ground-to-ground on the first job, then tell them they don't need gloves to climb on the second job.

That leads me to the second reason.

2. I don't like to see men encumbered as they climb and descend poles below the primary zone. I believe the rubber gloves and leather protectors increase the hazards of slips and falls. I realize that men can and do climb with gloves but it seems to me that so doing, as a general rule, introduces an unnecessary hazard. There is also greater likelihood of unknowingly puncturing rubber gloves on nails, tacks or barbed wire in the lower parts of the pole. Ordinarily these items are very few up in the primary zone.

3. The third reason ties in with our emphasis on tailboard conferences. If safety can be discussed with more meaning out on the job, it can be considered with still more clarity up at the beginning of primary zone. When a lineman stops just below the primary zone to put on his rubber gloves, he has a chance to observe the whole pole top close up and to plan his moves and work. The conditions observed from this point can be quite different than they are from the ground. The forced stop, when there is work to be done in the primary zone, can be one of the most important steps in safe work on the pole. It develops the habit to stop and look things over.

4. I have quoted from our rules that we expect men at times to wear rubber gloves when working on secondaries. I believe our practices wherein men must exercise judgment and they routinely stop part way up the pole, gain greater use of rubber gloves when working on secondaries than if we tried to spell it out in detail.

Throughout this discussion, I mentioned rubber sleeves just once. I have not yet mentioned other protective equipment—rubber blankets, line hose, insulator hoods, and so on. Our rules pertaining to the use of such equipment are in the same vein; there are a minimum of directives.

I should mention too, that our continuing investigations and analyses of accidents and near accidents do not indicate that we would improve safety by more specific rules on the use of gloves and other equipment.

In summary, I want to repeat:

1. Our line work requires craftsmen, not automatons. Our rules on the use of electrical rubber gloves are in line with craftsmanship training and encourage thinking.

2. Electrical rubber gloves are personal protective equipment. Our rules recognize that they are to be treated as such, just as are other pieces of personal equipment.

3. When a man has a definite reason for a stop part way up a pole at a good observation spot, it becomes habit for him to observe and plan on-the-spot means to accomplish his job safely.

GROUND-TO-GROUND USE OF RUBBER GLOVES

By L. C. MEYER

Electric System Specialist, Employer Mutuals of Wausau

If every job went the way it was supposed to go, there would be no accidents. If men acted like machines and could be counted on to always perform their work in the prescribed manner, again the result, no accidents.

But men are not machines and some jobs do go wrong—sometimes the unexpected occurs and another accident results. If we keep in mind that an accident is the clue to something going wrong, then we can proceed with the premise that hand contact electric shock accidents are of great concern in the electric utility industry. They are of great concern because of their high frequency in comparison to other parts of the body involved.

Putting it more bluntly, there exists a need for a better procedure of getting rubber protective equipment on the hands of the men before contact is made with energized equipment. Current accident reports continually emphasize this need.

The problem resolves itself into one word—"HOW." How can we get rubber gloves on the hands in time to prevent the accident? What method or procedure offers the fewer loop holes, the least chance of human error, and the greatest consistency of compliance?

It is my sincere conviction that "rubber gloves from the ground up" or "gloves—

ground to ground," (the two terms are synonymous), provide the best solution to the problem.

Let me discuss the various procedures that are being followed, pointing out the advantages of each.

First, there are some few utilities that still follow the policy of permitting the men to decide for themselves when and where rubber protective equipment is needed. Perhaps they have rules covering this but these are so completely disregarded that the rule might as well not exist. The men themselves operate on the theory that "they can take care of themselves" and believe that they know, by training and experience, when they should wear their gloves.

At first glance, this appears reasonable because it seems that an experienced lineman would know, if anyone did, the disastrous effect of contact with high voltage. All too frequently one of these systems has a rude awakening and expresses surprise that it had to happen on their system. Why should they be surprised, all they had to do was look and they would have seen it coming. The only unknown was "when."

The basic reason for these accidents is probably due to the old adage "familiarity breeds contempt." With linemen working near and around energized equipment so often they lose sight of the potential danger

in the nearby equipment and apparently relax their vigilance and care as they proceed with their routine work.

I don't believe I could get much of an argument from any of you on the impracticality of this particular practice.

The next procedure, and this one has a goodly number of advocates, is the policy requiring that protective equipment be put on when the working position is reached but before starting the job. I have no particular quarrel with the procedure, if they could follow it. I am sure that many of the utilities represented here that follow or have followed that practice have had serious hand contact electric shock accidents.

This is explained by a basic principle in safety engineering. If a man will expose himself to danger often enough, sooner or later he will become injured. More specifically, if a lineman without proper protective equipment gets within reaching distance of energized circuits often enough, sooner or later he will make an accidental hand contact. No, he doesn't intend to, but, a climber gaff cutting out, a moment of forgetfulness, a riser wire to the transformer hidden behind the pole, and he becomes another accident statistic before he even gets belted off. Granted that the incident of occurrence is small in relation to the number of times that things go according to plan, I defy you to find a volunteer to be the next victim of such an accident.

Can you pin the blame for such an accident on the foreman or supervisor? I don't think so unless you are looking for an excuse for the accident and not the cause.

If the procedure calls for protective equipment before entering the working or reaching area, then perhaps the foreman or supervisor can be involved. But it seems to me that if you are going to follow that practice you are putting an almost impossible responsibility on supervision. In effect, you're asking them to watch closely every time any man climbs any energized pole.

Looking at this procedure another way, what you are doing if you subscribe to this practice, is drawing a thin invisible line somewhere on every pole. Below, and out of reach, a safe area; above, and within reach, a danger area where gloves are required before entering. Keep in mind that the location of this invisible line will shift

with the circuits and equipment on each pole. Could a transformer case be energized? Could a shock from a secondary cause a fall that could be as permanently disabling as a double amputation? And tell me, what good was that invisible line to the fellow that climbed a new pole, watching his feet so as to miss the knots, and suddenly found that his hands had run out of pole?

Even if a good job of training and education has made everyone conscious of that invisible line, even though supervision is outstanding, isn't there still the chance that some day—perhaps the foreman is checking the work order just as the lineman is climbing up, thinking about a fishing trip or last night's date. As far as time and place are concerned, this man can get into trouble, and I do mean trouble, before he gets his mind back on the job and before anyone can warn or stop him.

We know this can happen because a few years ago I received three accident reports where the work was three or more feet from the nearest phase wire, yet a primary contact was made. The question comes up in those cases—what were these men thinking about? It makes a good question, but very difficult to get a good answer.

I am sure that all of us would admit to having experienced such mental lapses, occasions where our eyes were open but our minds sure weren't, but fortunately we came to in time to avoid injury. Quite often we hear of, or experience such mental lapses in connection with driving. We all do pretty well when driving in heavy traffic but how good are we when we get out on the open road?

But to get back to the practice of requiring rubber gloves before entering the danger area. I would have no particular quarrel with this if a foolproof method of obtaining 100 per cent compliance could be established. I am sure that efforts are being made to improve this procedure but the accident reports indicate there is still a long way to go.

So, let's consider the "ground to ground" practice. In the hundreds of group safety meetings that I have discussed this subject, I have heard every excuse against that practice that was ever dreamed of. Clumsy? Not as much as trying to eat with metal claws instead of hands. Hot? Nowhere near as hot as 12,000 volts, or even 2,300. Slow

production? Developing dexterity while wearing rubber gloves is largely a matter of practice.

Further, consider the time element, the length of time that the rubber gloves would be worn under the "ground to ground" rule. Why don't you do a little checking and try to find the per cent of time that your average lineman actually spends on energized poles on an average day. I am sure you will be surprised at the low percentage figure you come up with.

Possibility of puncture while climbing and not having protection when you get to the working area? Possible but not too probable if the glove protectors are in good shape. In 30 odd years in the utility industry I have only heard of two cases of burns through a faulty glove, and both of these were minor. Besides, daily air tests and regular dielectric tests will detect puncture in most cases before injury can develop. Besides, with the high distribution voltages in use today, gloves are to be worn, according to the National Electric Safety Code, for protection against an accidental contact, not for direct hand manipulation of the energized equipment.

Wearing rubber gloves "ground to ground" has every logical reason for being the solution to the hand contact electric shock accident. It is the most sure way of getting rubber gloves on the lineman's hands before he gets within reaching distance of energized equipment. Besides, it is far better to wear rubber gloves, and not need them, than to need them and not have them.

The reason I favor this practice over the "below the invisible line" method is primarily because of the time element. Assuming the man forgets and starts up a pole without his gloves on—ten seconds will have elapsed before he reaches the danger area, the area where he actually needs them. During that time interval there is a greater opportunity for the man himself to recognize the omission he has made. There is also more opportunity for supervision or

some other crew member to see the omission and to stop him.

There is also the chance, on vertical single phase construction, of the phase becoming dislodged by vibration of a pole being climbed, due possibly to a cracked insulator that was not visible from the ground. With rubber gloves already on, the man at least has a fair chance to catch it or ward it away from his body. Without rubber gloves, you provide the answer.

A normal human characteristic is that of resisting change. That calls for discarding old established habits and developing new ones, and we are all guilty of it. It may appear like a radical change to go to "gloves ground to ground." It probably was for the many utility systems that have already done so. We have no way of knowing how many lives have been saved or how many burns have been prevented by this practice. Periodically I receive an incident report—that is a report of how rubber gloves prevented an accident. They are not as dramatic or tragic as many of the accident reports but much more preferred from my point of view.

In my present position over the past 15 years I have made an intensive study of electric shock accident causes and costs. Bare hand contact is still the most common type, yet the frequency of all shock accidents is less than half of what it was 15 years ago, according to my figures.

Yes, progress is being made, but there is still a lot of room for improvement. My crystal ball is no clearer or better than yours, but I can see the day coming when any electric utility that has not adopted the "ground to ground" rule will be in the small minority. Probably many more lives will be lost before that day comes, many more hands and legs will have been amputated. Yet each one of these accidents will add emphasis to the need for a more positive procedure of obtaining consistent use of rubber protective equipment. And that is where rubber gloves "ground to ground" comes in.

WORKING FROM LINEMEN'S PLATFORM

By H. E. HATFIELD
General Supervisor of Safety
Georgia Power Co., Atlanta, Ga.

The full protection of our linemen is a problem that has been with us for some time, and it is my aim to pass along a few ideas that I fully believe, if adopted, will greatly reduce the frequency and severity of linemen accidents.

By the way of review, and to emphasize the problem, I would like to quote from an address that was presented to the Electric Utilities session of the National Safety Congress on October 21, 1954 by Fred Harman, who at that time was the safety manager, New England Power Service Company, Boston, Mass.

"The fact that, year after year, electric utility linemen suffer the greatest number of fatalities in the industry, about 60 per cent of the total, or about 90 of the average of 150 fatalities per year, based upon recent Edison Electric Institute figures—makes it appropriate that we talk about protection for linemen."

Seven years have passed, many lives were lost in that period and I wonder if we are doing all we can to educate and train our employees to eliminate these tragic accidents?

Progress has been made to be sure; however in 1960 the Edison Electric Institute reported 105 fatalities in our industry; of these 105 cases 49 occurred on poles and when these 49 cases are analyzed they point to a significant fact "Path to Ground." The same is true when we analyze non-fatal electric shock and burn records.

Several factors are always present when these accidents occur, these factors were best expressed by Tom Hughston of the Texas Power and Light Company in a recent talk when he referred to an analysis of electric shock and burn cases as follows:

1. All occurred on simple jobs
2. No one was looking
3. Little or no planning
4. Failure to follow the rules

This analysis indicates to me that we

as supervisors and the workers themselves have a responsibility that must be a co-ordinated effort if we are to improve our safety performance and that criticism without being constructive is not the answer. Line work is inherently hazardous, the wires and devices which linemen work on regularly carry voltages which can kill, but, like other hazardous work, it can be made safe if the protective devices which have been developed are used.

By failure to get full use of protective equipment, isolating linemen from the "Path to Ground" which he does not do for himself, presents a challenge which I believe can be solved. The solution to this problem goes hand in hand with the required voltage increase in our primary distribution lines. This higher voltage in the 15 kv range can be maintained affording the lineman a greater factor of safety than he has had in the past while working on the lower voltages.

It can be worked with rubber gloves, class 2 (15kv), or class 3 (20kv) from an insulating platform, insulated skyworker or insulated ladders; this method will remove the problem of "Path to Ground," place the worker in a position to work with less physical strain and it will be necessary to make two simultaneous mistakes before he could be injured by electric current. The method in detail is as follows:

1. Work the specified voltages with class 2 (15kv) or class 3 (20kv) rubber gloves with 18" cuffs and glove protectors.
2. Workmen insulate themselves from a ground contact by the use of approved insulated safety boards, insulated ladders or insulated baskets supported on insulated booms of sky lift equipment.
3. Workmen must maintain clearance or provide insulation from metallic paths to ground and from other phase conductors.
4. Work on lines of the 15 kv range must be done only during proper weather conditions. Work of this type must not be done during periods of rain, mist, or heavy fog conditions.

5. All work must be done with complete isolation and insulation from paths to ground. This includes the covering of conductors with rubber protective equipment.

The electric utility industry is making progress in the reduction of frequency. The 1961 figures show our rate to be .582, slightly lower than the all industry average of 6.04, however our severity rate is one that should give us much concern with our rate being 1.222 or 210 days lost per mil-

lion man-hours worked, as compared to the all industry average of 729 or 121 days lost per million man-hours worked. I know we can do better.

It is my belief that if this method is followed in detail as has been outlined here today, we will put the lineman in a safer position, afford more physical comfort, remove the possibility of "Path to Ground," and greatly reduce or eliminate the "shock and burn" problem.

AERIAL BASKET UPS AND DOWNS

By BASIL J. LORENZ

Manager of Safety, Northern Indiana Public Service Company
Hammond, Ind.

"Cut down on man-hours needed to perform aerial work." "No rubber protective equipment needed." "Put your employee in a safe insulated work position." "Work energized conductors bare handed." "Save thousands of dollars a year."

These are but a few examples of the promotional material which has greeted us during the past few years as a result of the rather sudden realization regarding the work potential of the aerial basket in the utility industry. Add to this the many, persuasive verbal dissertations on the merit of this type of equipment, and a general picture of a money-saving, fool-proof, accident-free method of working energized overhead lines and equipment is developed. Our operating people, and rightfully so, are really "up" on this when they realize the potential benefits which can be derived from use of the aerial basket.

I wish to make clear at this point, that I am not opposed to the use of the aerial basket. Quite the contrary, I feel that it is an invaluable aid in safely and efficiently performing many and varied job assignments. A survey of 73 companies revealed that from a primary use in tree trimming operations, the aerial basket is now extensively used in distribution line work, transmission line work, substation work, and on street light installation and maintenance.

Much has been said about such advantages, but like any other tool used in our work,

there are certain inherent hazards connected with its operation and use. We cannot be lulled into a position where these are overlooked. The very selling features of the equipment contain suggestions that are contrary to principles of safe practices that we have been advocating for years. The emphasis is placed on what the employee does not have to do and therein lies the challenge to the safety man.

A positive, down to earth approach is needed. Established safety rules, procedures or practices may have to be revised, but they should be established on the basis of what to do not on what you don't have to do.

There are a number of controversial areas relating to the necessary safe practices in the operation of aerial baskets. Variations in construction of booms and baskets make generalization difficult, however, I will attempt to cover a few which in my opinion are of primary importance in realizing the full safety potential in the use of this equipment.

One of the principal areas of "time-saving" is in the use of protective equipment such as line-hose, hoods, blankets, etc. The aerial basket places the worker in such a position that much of the equipment that normally would be covered when working from the pole is now beyond his work area and consequently would not need to be covered. This reversal of what previously would have been normal practice tends to have the

effect of a general relaxation as far as the use of protective equipment is concerned. The worker is apt to apply the same reasoning to the exposures within his work area and neglect to use the necessary protective equipment. If he, himself, or anything that he is handling becomes involved in a direct contact, phase to phase or phase to ground or neutral, the same tragic results will occur even as it did when he worked from the pole and neglected to use protective equipment.

Experience gained from the limited survey mentioned previously, plus individual reports, has already pointed out fatalities and lost time cases due to contact aloft when working from aerial baskets. The solution of course, is the training of your people to realize that the aerial basket is not an insulated cure-all, plus the establishment of positive safe practices in the use of protective equipment in conjunction with the use of the aerial basket.

The concept of an insulated boom and basket can lead to a relaxed attitude by ground personnel in relation to the possibility of receiving an electric shock. The average reaction is to touch freely the truck body regardless of the proximity of the boom or basket to energized conductors or equipment. Experience here again has already produced fatal and other types of injuries due to not following the usual practice of staying clear from any equipment which might possibly contact energized conductors.

One supervisor received a fatal shock as he stood leaning against the truck bed when the supports of the basket contacted an energized conductor on a 12.5 KV circuit. A metal reinforced air hose installed in the field by an unauthorized employee provided the path to ground.

In another case, an employee was removing tools from a bin on the truck when contact was made by the lower non-insulated portion of the boom. He was fortunate in that the results were not as severe as the previous case.

These are outstanding examples of what can happen in the everyday operation of this equipment. Add to this the fact that most of the equipment in use today does not receive an adequate periodic dielectric check and you have the ingredients of a potential accident.

The establishment of a "stay clear" rule, in my opinion, is the best preventative measure regardless of the type of equipment you may have and regardless of the testing procedure you may follow. The innovations, repairs or even contamination which may occur in the field can easily by-pass all insulation and render it useless. Keeping the people on the ground from touching the equipment unless proper precautions are taken is a positive procedure in effectively preventing this type of accident.

"Belting in" to the basket while working aloft is a practice adopted by many companies. A number of objections to this practice can readily come to mind. At first thought it may seem almost ridiculous to tie a man down when he is working in an enclosure that rises at least waist high. Add to this the thought that any means of attachment will be in the way, hinder movement and will probably prove difficult to sell or enforce and the reaction will be to shy away from such a practice.

Here again our limited experience has indicated that serious accidents have occurred which could have been prevented by the practice of "belting in." In one situation, the leveling cable broke causing the basket to tip over throwing two employees some 20 feet to the ground. One employee was killed and the other severely injured. In another case the brackets holding the hydraulic piston broke due to mis-adjustment, causing the basket to tip throwing the employee to the ground.

In still another case, two employees were using a length of pipe anchored at the basket as a boom in lowering a 35-lb. tool. This operation caused the basket to tip throwing both men to the ground. In yet another situation, planks were placed across the rim of the basket and used as a working platform. An employee fell when he stepped on the plank beyond the edge of the basket rim. These are actual cases which point directly to the advantage of establishing "belt-in" rules.

I am sure that all of us can readily visualize a situation where the positioning of the basket puts the object to be worked on just beyond the reach of the employee. The basket cannot be moved any further due to obstructions. What is the next step? The employee, more than likely, will attempt to climb up on the rim of the basket and from

this precarious position attempt to perform the job. It takes no stretch of the imagination to further visualize the step, the fall and the injury.

In my own particular company, we have gone to a nylon lanyard and with the D-ring located in the back of the belt. Our reasoning in adopting this particular combination was predicated on the following:

1. We wished to limit the free fall and by locating the attaching ring or bar at the rear of the basket and having the length of the lanyard only long enough to allow free movement within the confines of the basket, we feel that a foot or so of free fall is all that would be experienced should the basket tip over.

2. This arrangement does not give the employee enough movement to allow him to stand on the rim of the basket.

3. The lanyard and belt have a shock load rating that is at least four times that of our standard lineman's body belt and safety strap.

4. We have an existing practice that the snaps of a safety strap cannot be engaged in the same D-ring of the body belt when belted in. It was felt that the natural tendency would be to use one D-ring only if the standard safety was used to belt in. The use of the lanyard eliminates the possibility of a daily noncompliance with an existing practice and subsequent undermining of its observation in other phases of work.

5. There is also a possible benefit in the event of a fall. With the D-ring located at the back, the initial impact strain is taken by the stomach muscles rather than the back muscles and the possibility of a severe injury may be lessened. The potential here is questionable, however, it may be a factor.

Our experience with this practice has been favorable. There has been no indication that the arrangement has hindered the movements of even two employees in the basket at the same time. The confines of the basket are rather limited and the lanyard and belt does not interfere with movements needed to effectively work from the basket.

The question of whether to allow any movement of the truck while the basket is extended with one or more employees in the basket has plagued many companies. Practically all of the original models and a large

majority of the present ones require the use of outriggers when ascending the basket. Recently, models have been developed which do not require the use of outriggers. It is certainly a tremendous incentive in the pursuit of saving time to consider allowing at least a minimal movement under certain conditions. The lack of any accident experience, at least to my knowledge, due to movement of the truck with boom extended is probably related to the fact that very few companies at present permit movement of the truck under these conditions.

In general, I believe that this approach is good, safe operating procedure. We have only to look back on our experience with aerial ladders. I am sure that many of us here today can recall instances where, in spite of electrical and mechanical safety warning devices, ladders have been sheared off by tree limbs, telephone cables, and many other types of overhead construction. With the ladders, only material damage was involved. With the aerial basket, you have not only the material damage, but also the potential of serious injury to an employee.

There is no question in my mind that the accident experience would follow that of the aerial ladder should free or limited movement of the truck be permitted with the basket extended.

One of the major considerations arising in connection with the use of the aerial basket is concerned with the maximum voltage which can be safely worked with rubber gloves. I shall not endeavor to voice an opinion on what this limit should be, but merely re-emphasize that whatever the voltage decided upon, a careful and thorough study should be made and again a positive set of safe practices should be established.

Time does not permit the exploration of other areas of consideration in the use of aerial baskets. Future developments of this equipment will present future problems. The safety man will be confronted with old and new pieces of equipment, each having operating characteristics of its own. The challenge will be to allow for the new without relaxing the necessary precautionary measures for the old.

In conclusion, one might say that the aerial basket while being a boom to the industry in the assistance of efficient operation, offers a distinct challenge to the safety

people. The very selling points that make the equipment so desirable in operations—mobility, ease of reaching elevated locations, insulation value, reduction of necessary protective equipment, reduction of necessary personnel to do a job—have a tendency to undermine or minimize the safe practices which we have been developing for years. This shift in practice and in the employee's attitude which follows, can have a detrimental effect on the entire safety program.

The safety man should recognize this potential reaction, and when the aerial basket

makes its appearance in his company he should be prepared to make a positive approach in the safe practices to be applied in the operation of the basket. He should be ready to prescribe what has to be followed in the operation and not fall into the trap of letting the idea of what safe practices the employee does not have to follow predominate.

The aerial basket can be one of the best accident prevention tools available if you come "up" with a positive approach and don't let "down" on your safe practices.

THE OHIO FUEL GAS COMPANY'S DRIVER IMPROVEMENT COURSE

By R. G. CLAAR
Safety Dir., The Ohio Fuel Gas Co., Columbus, Ohio

The training we have chosen and are giving to our employees centers around what is perhaps the best known and most talked about driver training in the country today—the Harold L. Smith System of Defensive Driving.

Our program consists of a four-hour session limited to a maximum of ten drivers per session. Since its inception we have trained approximately 1,800 drivers. We begin with a 16-millimeter sound movie entitled "What's your Driver Eye-Q?". This film describes and shows fifteen common traffic situations—situations in which we find ourselves nearly every time we take a vehicle out on the road.

The film is narrated and after the narration, the scene stops for a brief period during which time the participants check either "A," "B," or "C" as the correct answer on a prepared test sheet. The period of time allotted for the decision of the driver is, in most cases, more than the reaction time required if he were facing this situation while actually operating a vehicle on the road.

After the film is finished, a brief discussion follows during which time the participants give their reasons if they do not agree with the stated correct answers in the film. We find that there is never a

decision where all of the participants agree with all of the answers.

The purpose of the film is to stimulate discussion rather than to say if John Doe has all of the correct answers he is an expert driver and if Joe Smith misses seven that he is a poor driver. The test sheets are not graded but disposed of following the discussion.

We have no formal "break" in the session but immediately following the film the drivers are given an examination of vision with the Bausch and Lomb Ortho-Rater and a hearing test with Ambico-Oto-Chek.

When the tests are evaluated, a confidential report of the results is given to each employee in a sealed envelope.

A summary of all tests, noting deficiencies, is then furnished to the department head for a follow-up by the supervisor who urges the necessary correction for employees who are below minimum standards.

This period, with only one employee being tested at a time, offers the instructor the opportunity to guide and continue to stimulate discussion of our own local vehicle-accident problems. What might appear at first glance to be a period of idleness becomes a valuable addition to the effectiveness of the program. Following the testing period, the program continues

with an illustrated lecture based on the Smith System. (We obtained a film strip and Leader's Manual on this system, and from this we wrote the manual for our own use. The film strip was processed into 35-millimeter slides which makes them much more adaptable and permits us to include additional slides pertaining to our driving problems and statistics).

We proceed on the basis that our drivers know *how* to drive. Otherwise, they would be unable to obtain a state driver license. The *how* part of driving consists of manipulating the vehicle, applying the brakes, turning left, turning right, stopping and the many manual skills necessary to control the vehicle.

We also are convinced that our drivers know *what* to do. The *what* part of driving consists of a basic knowledge of traffic rules, observation of the speed limit, granting the right-of-way, consideration for other drivers and, of course, what can be expected from other drivers or how other drivers should operate their vehicles.

Since these first two steps are elementary, we mention them only in passing. The third step, and this is the heart of the Smith System, indicates when to make the necessary moves in traffic to blend with the traffic pattern and avoid conflicts with other vehicles, pedestrians and fixed objects. The *when* part of driving indicates if a driver is expert or mediocre.

The five "Seeing Habits for Expert Driving" are as follows:

1. **Aim High in Steering.**—This allows the driver to set his eye on a target in the center of his lane far enough ahead that he will be able to keep his vehicle in the proper lane without conscious effort. It also relieves him of the probability of over-steering and fighting the steering wheel.

2. **Getting the Big Picture.**—By scanning the total traffic picture ahead and to the sides and to the back, the driver is aware of how his vehicle relates itself to the movement of other vehicles and pedestrians and gives him the opportunity to regulate his speed to conform with the traffic pattern and thus avoid conflict. Conflicts cause accidents.

3. **Keep Your Eyes Moving.**—By scanning the scene ahead, to both sides and the

rear constantly, the driver is aware of the total traffic pattern and does not allow himself to be lulled into a trap which might cause him to have an accident. If his eyes move constantly to the scene ahead, to the left and right and to the rear view mirror, he will avoid a fixed stare which would narrow his vision and cause him to overlook important developments in the traffic pattern.

4. **Make Sure They See You.**—If a driver desires to pass a slower moving vehicle it is to his advantage to give a friendly "beep" of the horn to let the driver ahead know what his intentions are. In a situation where a pedestrian or a youngster on a bicycle or perhaps an animal might suddenly dart into the driver's path, the same courtesy should be observed. In any case, in an uncertain situation the expert driver will take his foot off the accelerator and either apply the brakes or allow his foot to hover over the brakes to touch it if necessary.

The driver who intends to make a turn or a stop will signal his intention well ahead of the maneuver to allow the other driver the necessary time to adjust his speed or direction to conform with the traffic pattern.

5. **Leave Yourself an "Out."**—The driver who observes the other steps consciously may still find himself the victim of another person's poor judgment. However, this need not cause an accident if he has allowed himself a "pace cushion" of at least one car length for each ten miles of speed between his vehicle and the one ahead.

The expert driver who practices this step will unconsciously allow himself a swerving path if the driver ahead makes a sudden change in the operation of his vehicle. He drives in such a way that he can compensate for the change in traffic ahead and he can slow down, sound the horn and pass if safe to do so or go off the road and stop if necessary. In other words, he avoids being boxed-in in a situation which might result in an accident.

We conclude our program by summarizing the five seeing steps in visual form and issue a challenge to the drivers to consciously practice the five seeing habits. The statement is made that the true expert drivers avoid accidents by practicing these habits and we are sure our drivers can do likewise.

We issue two hand-outs at the conclusion of the session. First, a booklet, "The Eyes Have It" which summarizes the Smith System and includes some timely information and advice pertinent to safe driving. The second is a pressure-sensitive label printed red on a white background listing the five seeing habits which the drivers are requested to post in a prominent place in their vehicles. We also make these labels available to the

employees for use in their personal cars on whatever vehicle they are driving, the expert driving habits are called to their attention constantly.

While this is only one of the devices necessary for a successful fleet driving program, we note with satisfaction that in the areas completed in our company there is an encouraging decline in vehicle accident frequency.

MAINTAINING INTEREST IN SAFETY

By FRANK P. MUELLER

Dir. of Safety, The Peoples Gas, Light and Coke Co., Chicago

The importance of employee interest in safety cannot be too strongly stressed, and the accident prevention efforts of any company surely cannot succeed without it. Ways in which this interest can be stimulated and preserved are perhaps as numerous as they are varied. The approach to the problem will not be the same in every case, and what may prove highly effective in one company may be entirely without results in another. Let's consider some of the different approaches to the problem of maintaining employee interest in safety.

1. **Management's Part in the Safety Program.** The statement that top management must be behind a company's safety program if it is to succeed has been worn threadbare. Let's assume for the moment that this is not a problem here. The fact remains that it is equally if not more important that all levels of management and supervision be *all* on safety if the rank and file is to be at all concerned. The average worker has much closer contact with his supervisor or with his foreman than he has with the chairman of the board or with the president of the company. It goes without saying that the interest shown in safety by the first line supervisor will be pretty closely followed by the workers. If the immediate boss is disinterested in safety or indifferent to safe job performance, so, too, will be his men.

2. **Non-Management's Part in the Safety Program.** It is oftentimes a mistaken idea that the accident prevention activities of an

organization should be restricted to the safety section or safety department of the organization. Nothing could be further from the truth. The safety program, if it is to succeed, must involve as many employees as possible. This involvement must mean something more than an indifferent participation on the part of the employees. It must mean the personal interest and enthusiastic support of everyone. This might be accomplished by appointing employees to serve on departmental safety committees, or on inspection committees, or even as safety deputies within the various departments. These committees will usually provide a real service in the interest of safety if given proper recognition. Their findings and recommendations should be made to someone in authority who can take action when and where necessary to correct hazards or unsafe conditions.

3. **Safety Meetings.** Safety meetings provide an excellent way in which to present topics of interest to all employees. Meetings should be held regularly and frequently and should be conducted by someone in the line organization—preferably the first line supervisor. Subject material for discussion might best be provided by the safety section, and the meetings should be diversified enough to stimulate audience interest. Every effort should be made to keep the employees informed of what is happening accident-wise throughout the company. Discussion of accidents and injuries should be encouraged for the purpose of reducing the

possibility of their recurrence. Visual aids, such as films, slides, flip charts, flannelboard presentations, are all helpful and should be used in stimulating interest in the safety meetings.

4. *Incentives and Awards.* There are many incentives that might be used to help maintain interest in safety. Recognition of a job well done is an effective way of motivating people, and this is true in safety as it is in other fields. This may mean the issuance of safety awards to individuals or to departments, such as certificates or plaques. It may mean little more than the personal commendation of the individual or department by an executive of the company. It might mean publicity either in the local house organ or even in some of the local newspapers. People like to be patted on the back for a job well done, and a compliment earned and sincerely given will do much to stimulate interest in the safety program.

5. *The Suggestive System in the Safety Program.* Employees should be encouraged to use their suggestion system as a means of calling attention to existing hazards or to the need for changes in job procedures or working conditions. Suggestions often call attention to situations overlooked by management that might constitute real hazards and require correction.

6. *The Investigation of Accidents.* The more serious accidents should be personally reviewed and investigated by members of management. The purpose of such investi-

gations should, of course, be made clear to the employees involved in the incidents. These reviews are not intended to be fault finding but rather fact finding. They are held primarily for the purpose of learning something from the misadventure and, most importantly, to try to arrive at some conclusion as to how similar incidents can, in the future, be avoided. Such interest manifested by management cannot but help favorably impress the non-management employee and make him want to do everything possible to avoid future involvement in an accident.

7. *Safety Promotional Materials.* There is a great variety of safety promotional materials that can be used effectively in stimulating interest in safety. These include leaflets, booklets, colored posters, questionnaires, and articles of all kinds having to do with safety. Information is available from the National Safety Council, the American Gas Association, and local safety organizations specifically directed toward the establishment of a good safety program in any company, and the maintenance of employee interest in that program.

Surely there is a variety of approaches to the problem of stimulating and preserving interest in safety. It's a job that requires real effort, imagination, and dogged perseverance. Unfortunately, it is a problem that will not solve itself. The results can be really rewarding—a better safety record, which means fewer employees getting hurt. Maintaining interest in safety is important.

YOUR TRIP TO "SUCCESS"

By J. WESLEY SAMMIS
Safety Representative
Philadelphia Electric Co., Philadelphia, Pa.

Are you on dead center?
You are if you have not been wondering about your safety program!
Been around a long time?
Maybe you've maintained the status quo too long!

Ah, you're new at it and puzzled! Puz-

zled because you've inherited a patch-work quilt?

In either case, you are on dead center if you don't think it's time to reappraise your program.

Maybe you think you are tops as a salesman

You can sell yourself . . .

You can sell your program . . .

You can sell your supervisor . . .

You don't need management backing . . .

Well, perhaps a good hard look at your accident program will tell a story.

Let's take a ride. Join me in the Safety-Mobile. Fasten your seat belt, and we'll be off on the road to success. The town whose population is limited only to those who conduct successful safety programs.

To get there we must be alert for the guide posts which will help reduce the detours of poor programming, the cross-roads of indecisiveness and a wrong turn in failure road.

Our car moves over program road but progress is impeded by indecision excruciation. Good back filling and packing with the solid materials of management directives will soon have us on the way again. The crew foreman shows us that the leak was plugged by using just the facts. This plug is manufactured using the raw materials of accident costs, operating and productive efficiency, human benefits, and frequency rates.

The hole filled, we are able, now, to make a right turn into top management highway. As we move along, the side streets of confusion and poor planning whiz by, at legal speed of course. New construction on top management highway suggests that an alternate route will make our journey less hazardous. Thus, we will continue on cooperation road.

A refreshment stand in the oiling, suggests a recommended driving break. Partaking of the elixir of freshness, cooperation road gives pause to review a problem.

A near miss—an accident without an injury—but a solution had to be found. Cooperation was the key to this successful solution. At one of our gas plants, a mobile crane, performing a job done for 20 years without incident, contacted and tore down the overhead lines feeding the plant substation. The lines carried 66KV and, although no one was hurt, presented a problem.

Local Supervision contacted us and asked for recommendations for a solution. Our solution was to bring the lines in underground. Next came the coordination job.

Contacting the Electric T. & D., Engineering and Gas Departments, all details were worked out. These details involved obtaining agreement on several important points. The company being largely electric and with 53,061 miles of overhead transmission lines posed a selling problem. The incident occurred on a gas facility. The cost was computed to be about \$75,000.

Not only was agreement obtained on these points, but, additionally, all future installations for feeding this type substation would be underground. The plan, solution, and allied information was submitted to top management. Little time was wasted in approval since all the facts, agreements, and information was individually available.

Refreshed, it is time to move on. We gear in, slip into traffic.

Shortly, a flashing yellow light ahead indicates a slow down for the sometime speeding traffic on line supervision hesitancy, on the road to safety meeting. Brake quickly! Here comes a stop light runner! The speeding blur, just slow enough to recognize, indicates that "I'll do all the talking" and "I'll be in the vehicle. This is to be expected. These two are a pair when it comes to the matter of going to safety meeting. One will not listen to any suggestion, the other doesn't believe in its importance. The next car comes to a stop; we would expect this. "I know the value" recognizes the importance of observing all the signs, signals and road conditions important to arriving at a good safety meeting.

Entering next to engineering freeway, we have three good lanes upon which to travel: planning, coordination and field survey. This freeway ultimately passes through the towns of good construction, fewer mechanical hazards and mutual understanding.

Leaving the freeway, again we enter management highway, but the gas tank is low. We cannot reach success without more fuel. Employee reaction service station is just the place! Each flowing gallon of tail-board conference, following safework rules, suggesting new safety items, and training indoctrination help give the highest octane for good go power.

Management highway looms large and broad as the side road of regular safety inspection, visual aids, accident analysis are

passed, each contributes to the flow of traffic, but without disruption.

Our seemingly uncomplicated journey nears an end as we approach the town of Success, population unlimited. Towering before us is the peak of Upper Management.

At times it seems to overshadow our destination. The ribbon of concrete stretches before, winding from the base to the summit like a carelessly scattered string, giving cause for concern as to how easy might be the trip.

The stolid traveler, however, can attest to a smooth ride up the slopes. Smooth through careful planning and coordination.

The highway will continue onward. The ever improving roads are made possible by alert, prepared safety men. The alert plan. Planning prevents stagnation and lethargy.

Whether you continue your journey with top management support, and without consequence, can only be determined by how you plan your trip.

STIMULATING EMPLOYEE USE OF PROTECTIVE DEVICES

By WARREN E. FUHRMAN

Safety Dir., Milwaukee Gas Light Co., Milwaukee, Wis.

It amazed me to learn that some gas companies have problems getting employees to use safety protective equipment. I was surprised to learn that many had to utilize incentives, or discipline, to encourage the use of these articles. In Milwaukee we don't have this problem. Our people wouldn't think of using the air hammer without protective glasses, wouldn't think of cutting a pipe without a bonding wire, would never work on live gas without a gas mask, or the fire extinguisher near the ditch.

I'm talking, of course, about Milwaukee, Utopia. Now, let's talk about Milwaukee, Wisconsin.

May I assure you at this point that we have just as many obstinate, unpredictable people in our labor force as you do and it has been a long struggle to win them over to safety awareness.

Each year we have a safety shoe promotion. The local dealer uses a truck display room to bring his products to our employees. The great advantage is that we can in this manner, take the shoes to the employees at his work site wherever it may be in our city.

Expert fitting is a vital part of this program—if the shoe fits—they'll wear it. The inside is as attractive as it can be under the circumstances. This vehicle holds 1100 pair of shoes in sizes from 6 to 15 in all widths

However, in the event that a style or size is not available, it is delivered the next day by special messenger to the employee.

During this drive, the company contributes two dollars and 50 cents toward each pair of shoes, and the dealer discounts another dollar. We also allow the employee to have the cost deducted from his check in two payments. The reduced price is held open for two weeks after the truck visit to enable employees on vacation to participate. At any other time of the year, nothing by the dealer, and the employee must visit the retail store on his own time.

Our safety glass program incorporates both plano glasses and prescription glasses. We provide various types of non-prescription glasses depending on the job. I'm sure these are familiar to you gentlemen. If not, they are all on display at the various booths in the basement of this hotel.

Our prescription safety glass program may be different from yours though, so I will explain it to you. We charge the employee \$9.00 for single vision and \$11.00 for bi-focals. This includes the examination, the fitting and the glasses themselves.

All of our people desiring prescription safety glasses go to an ophthalmologist for the examination. We have decided on an

M.D. because we feel that he is better qualified to find other problems and offer advice or treatment as needed.

When the glasses are ready, the employee is fitted by a dispensing firm. Our purpose here is to eliminate complaints and at the same time, give our people the best of attention. All prescription glasses are furnished in this two-tone frame again to encourage their use off the job also. Any damage incurred on the job is repaired here at no cost to the employee.

We are one of the few companies in the country that demand the use of a hose mask while working on live gas. Our concern in this regard is because of the fire hazard. If a fire should occur in the trench, we want our employee to have his eyes, nose and mouth protected. Perhaps some of you have read of hospital accidents where the anesthetic has burned in the patients lungs killing the patient. We emphasize these cases pointing out that a combustible mixture can be present in the employee's lungs at any time gas is present in the ditch.

We have even gone to the extent of negotiating a clause on gas masks into the labor contract with our union. It states, "Foremen in the distribution, construction and repair departments shall not direct employees to work on live gas on mains or service piping without the employee wearing a gas mask." If you will note, it is written in a negative manner. If the foreman shall not direct them to work without the mask, then they must work with it.

Let me assure you at this point that a paragraph in the labor contract is not the complete answer to getting the employees to wear the mask. We also had to analyze their objections to the equipment and see if we could eliminate those also. Let me give you some of their objections and see how familiar they sound to you. "It's too old in the winter, it's too hot in the summer, it fogs up, it's too bulky. You can't breathe in the damn thing."

Fortunately, one of our superintendents came up with a solution that stopped most of the objections. The answer was a small squirrel cage 12-volt blower installed in the center of the mask case. The motor is one designed to clear the bilge of motor boats of gasoline fumes so it is perfectly safe for natural gas.

This blower keeps enough air supplied to make breathing easy and to eliminate fogging. During the summer it keeps the face cool.

In winter, we reverse the process and keep his face warm by placing the case under the truck heater in the cab. The blower can be equipped to fit in a cigarette lighter or two clips can be used as we do so that it can be connected to all equipment even the air compressors.

The fire extinguisher has become second nature with our construction and repair crews. It is almost automatic the way they take it off the vehicle and place it near the trench. We use the dry chemical extinguisher and I attribute its complete acceptance to its demonstrated performance. At several demonstrations we have had the extinguisher representative work with our employees on very large fires.

In addition, many of our foremen and employees have attended a three-day school at the fire extinguisher's home plant in northern Wisconsin. I can personally vouch for this school as being outstanding. After three days, you have inhaled enough baking soda to keep you sober for the next month.

We also provide what is commercially known as the "Sankey Foot Guard" to all our air compressor operators. This item was made mandatory after a child broke and the hammer dropped on an employee's foot. However, we could only make it mandatory during the summer. When winter arrived, we suddenly found that most of our compressor operators had big feet and the large Sankey guard made would not fit over their overs. So we had to back up on our rule. If anyone here has an answer, I would appreciate hearing it.

One of the items that we have not stressed to any great degree has been safety belts in our vehicles. However, you may have read that Wisconsin just passed a law requiring that all 1962 vehicles must be delivered with two seat belts installed on the front seat. Obviously, if we are going to get these with each new vehicle we purchase, we are also going to promote their use.

In addition to all of the items and methods that I have shown you we use, we also use the ordinary approaches to promote the use of safety equipment—methods such as bullet-

tin boards, posters, slogans, contests, the Wise Owl Club, Golden Shoe Club and so forth.

I was asked in this short address to tell you what we do at our company, not what

we would like to do to promote the use of protective equipment. Maybe next year they will invite me back to tell you what we would like to do. That would take much longer.

THUMBS DOWN ON VIOLATORS

By RICHARD K. AYERS

Managing Dir., Metropolitan Safety Council, Denver, Colo.

Utilities people have been among the finest leadership we have ever had, and the particular service to safety they have rendered over the years, and are now engaged in, can not be questioned.

I was invited to explore some of the principles upon which safety programming can be effectively formulated and perhaps give an example or two of workable programs that can be the basis for your own efforts.

In the midst of this wonderful age in which we live, we are still each concerned with some real down-to-earth problems. The same problems that have been with us ever since man came down from the trees and out of the caves—to develop patterns for more successfully living with each other—*safely!*

I am dubious of my ability to tell you much that is new or remarkable. Perhaps my function can best be to review, if you please, some of the fundamentals, maybe find a new perspective. That could be a worthwhile objective and one I might wish to contribute to.

You may know that I am by profession a public relations consultant and, as such, usually attempt placing everything in a public relations perspective. Perhaps then, my experience as a safety council manager can come into play to tie the thing into one ball of wax.

Let's take a look at the major objectives of industry from a public relations point of view. Any successful enterprise must be concerned (perhaps even more today than ever before) with projecting itself as being good to own and invest in, as being good to work for, as being good to deal with and

buy from and as good to have in the community.

Programs geared to project these purposes form the shareholder relations programs, employee relations programs, customer relations programs, and community relations programs. Taken together they compose the public relations programs for that concern. In broadest terms they might be said to dictate the operations and management policies and interpretations that may be placed on them.

The broad and overlapping spread of the communications industry today, maybe even more than in any other industry, brings every segment of this relationships endeavor into every other segment. Certainly the employees of Bell Telephone are owners and shareholders as well as customers and active members of the community. Owners are found in each segment. Everyone practically is a customer and you reach the entire community with every interest you have.

We can almost safely say that any program that affects the community and its people can affect the communications industry—for either good or bad, depending upon which direction it points.

If it is to reflect good for you it must, in my opinion, be away from the old paternalistic image, perhaps even the materialistic image often held, and be a truly humanistic projection.

I don't think I need dwell on this point with you people. But, let's just say that any program to be properly useful must project your leaders and your industry as truly interested in people. It must project a human concern for owners, employees, customers and the community.

So much just now for your motives and requirements for a program.

Let's consider the safety council movement.

Here, too, we find motives and objectives parallel to those of the industrial community as they relate to helping improve our communities. Here, too, we find the major impact area the local scene, for accidents happen to you and to me and to others, where we live, where we work, where we play, and where we raise our families.

Actually, our objectives are interrelated. They can almost be said to be mutual.

Communications and other utilities have long recognized safety as an appropriate goal for use in every phase of public relations programming and to every segment of their publics. It may well be the one strongest tool! They have accepted the mutuality of objectives with the safety movement and cooperated to the fullest extent. My earlier remarks indicated some of their efforts and many more could be cited. Their use of community programs and backing for effective programs at all levels and in all attacks on accidents.

Since it is necessary for you to be aware of how the safety movement operates if you are to use it effectively, let's review a bit. Likely you already know more about it than can be stated in this short summary.

Let's put it simply, that any good safety council approaches its programming on a four step basis:

- (1) Determine the facts about accidents with all the implications.
- (2) Inventory the resources that are already working against the problems and discover and develop new resources that may be needed.
- (3) Establish effective programming to bring to bear the resources against the problems on a priority basis.
- (4) Continually evaluate and reevaluate programs in the light of ever changing conditions.

You are so familiar with this process it is useless to go into it more deeply. But, now and then, it may pay to review the entire procedure as established by the National Safety Council and made available for local use of councils.

It may be well to point out, here and now, that this process is workable. But, it can be only as effective in your own community as your community leaders will help make it. That, it seems to me, is where you people have always been most generous and willing. You must give substance and leadership, work with the program and use it to the fullest advantage for both yourselves and the community. Likely any success will depend on just how far you and other industry go to make the safety movement vital not only in accomplishing your own objectives through it, but helping it accomplish its own objectives; again, mutuality of purpose and effort!

I said we would take a little look at a specific program that might serve as an example. The one I wish to discuss and demonstrate, I believe embodies the best principles of safety programming. It recognizes a major problem, establishes resources and methods for attacking the problem, and serves as a general emphasis sort of promotion. It should be pointed out, though, that this program must fit into a pattern of well rounded efforts geared to create a climate for safety in every field. This is not just the one or the only program. It is one of a group that fill the needs of a specific place at a specific time. (It might find use for you in your area also since the attack is based on a rather general problem.)

We intend to look at a problem and an approach to a logical solution through a massive program—a program we chose to call "Thumbs Down on Violators."

First, it was apparent from the death rate that we were killing far more people in Denver and the state of Colorado during the first six months of this year than ever before. That was the real problem. But—a close look indicated that at the current rate we would reach a new all time high of terrible proportions before the end of the year unless the trend was reversed or at least slowed down.

Facts were placed on paper. What was happening? What is the cost? What can be done about it?

It was obvious that the accident rate was the direct result of violations of our laws—both man made and those of common sense. It was also obvious that if violations

could be stopped a lot of lives could be saved. We must make traffic crime unpopular. And the traffic safety committee went to work.

The approach to a program was developed after long study. Materials were made available in substantial quantities. They included window cards, posters, bumper stickers, mail inserts, handout flyers, discussion sheets, radio, TV, and newspaper material, house organ material, slides, proof sheets, plates and mats. Everything was tied to that one theme "Thumbs Down on Violators."

The committee appealed to every segment of the community. Letters and followup were directed to employers, association leaders, religious leaders, civic leaders, service clubs, women's clubs, youth groups, farm groups, labor groups, government agencies, media and everyone else we could possibly reach. Every group was contacted and asked to assist and they were also asked to help improve on the program to help make traffic crime unpopular. This has been regularly followed up, too.

A steady flow of material was presented to the press and radio-TV was given material to help keep the pressure on. This is still being kept up.

You may logically ask at this point, "What has happened? Did people flock into this program? Did you get a lot of support from everyone you asked to assist?"

I should like to mention here that a tremendous job was done and it is being done by our committee and pay a deserved tribute to chairman Phil Milstein (President of the Banker's Warehouse Co.), Mrs. Henry McLister (the vice-chairman, and a real working community leader) and the entire committee. They not only have a good program but they are keeping the pressure on and getting results.

Within one week after the appeal was made, a résumé shows that the forward looking people in each segment appealed to were on the ball and working on the program. Cooperation was and has been good from those who always cooperate in such efforts, fair from those who do a bit now and then and not so good from those who rarely cooperate. The heartwarming indicator however is the new

groups and firms which got into the act with this program and now—after some three months—the program is gaining momentum and growing week by week. Let's cite just a few examples.

Clubs gave us help. The Pilot Clubs produced their own stickers and featured the program at their national convention in Denver. The Colorado Jaycees are just now entering the total program in a big way. Federation of Women's Clubs is proposing this as a major effort this winter throughout the state. Others are using the program in mailings, meetings and other ways.

Employers, of course, are the backbone for they go all out to help reach their employees. They take the bull by the horns and add new twists of their own to make it effective. There is one contractor who created graves on each of his paving compactors, with white crosses labeled "Joe the Dragger," "Tom the Speeder," etc., flowers and the works, all backed with the "Thumbs Down on Violators." You can imagine the interest these pieces of equipment create around the area.

Many have used the total program to advantage just as did the Mountain States Telephone & Telegraph Co. Bob Mills had his own bumper stickers printed and distributed, they placed them on company vehicles. They attempted to reach employees and the community as a whole through all their resources and that hits a lot of people!

Some of the labor unions went to work on this. A bakery drivers union is a good example. They bought bumper stickers from us at cost with their own label, secured permission to place them on the trucks of every major bakery in the area, and got the message out.

Many cities officially joined the effort hoping to help make traffic enforcement easier. In Denver, Mayor Batterton cooperated with the erection of the first of 60 death scoreboards being kept up to date with each added death. One city manager (Aurora) placed stickers on all city vehicles. The police chief in Englewood had posters, flyers and stickers distributed and the city mailed 13 thousand cards to homeowners carrying the theme and the message. All over the area city officials cooperated in getting signs up and the word spread.

Media have given the program rather good support and it is expected that as more results are obtained more will be done. Radio-TV is giving good support and the newspapers carry a lot of material. The Denver Post commented editorially and urged all to take the message to heart.

Advertisers have assisted in the program too with use of the material. General Outdoor placed 25 bulletins in strategic spots and helped us keep the message alive. And we could go on and on.

Just one more sample. The religious leaders of many groups have helped in a great measure to call the moral implications of the program to the attention of their parishioners. Many have used sermons and mailings to good advantage as you might know they would.

Now you probably want to know about the results in a more material way. Has it saved lives? None are more aware than we of the danger in accepting figures at this early date. I do believe, however, it can be safely said that it's working!

We do know that accidents are reduced now and that a lot of attention has been paid to traffic crime. Maybe we are just lucky. Maybe it would have happened anyway. Who can ever know?

The facts show that at the end of July we had killed not the 48 predicted for Denver, but just 42. At the end of August we hadn't killed the 49 anticipated, but 45. And at the end of September we hadn't killed 71 but just 49. And in each of these months traffic injuries and fatalities have

been reduced from many previous years! In fact we are at this time just six more than a year ago, while when we started this effort we were 12 behind.

Fatalities in the state have shown similar trends and at the end of September the gap was closing. It was just three more than a year ago.

Sure, that's far too many. But—we haven't stopped our "Thumbs Down on Violators" program and, what's more, I doubt it has really reached its peak. We may actually save a lot of lives in the long term and we intend to keep going until it loses its effectiveness or until someone can come up with a better program!

I want to close by saying that I do believe this is the sort of program that can be developed to meet a real need in a community. One that you can be proud to be associated with and one you can put your teeth into and do something about. I believe it gives you an opportunity to take your rightful place as well as project your own objectives.

Safety and industry can find mutual concerns, institute and prosecute action on a priority basis, and cooperate to do a worthwhile job just as we always have, and likely always will.

And, because of this mutual concern and action—because of what you do—our own communities, our states, our nation and the world, will be safer and better places in which to live, to work, to play, and to raise our families. And, incidentally, those who have participated will have profited.

PUTTING ACROSS YOUR SAFETY MESSAGE — A TOUCH OF GLAMOUR

By FRANK BURROWS

Field Service Dir., Citizens' Traffic Safety Board, Chicago

I hope to impart to you a variety of ideas to advertise good safety tips. This collection of ideas first began to accumulate when I was asked to lecture at Northwestern University Traffic Institute. Since a large part of my work consists of lecturing before all kinds of groups, old and

young, large and small, a need to do something other than just talk safety arose. I discovered that a large part of the audience very often did not receive the message. I began to incorporate little attention getters to hold interest. The audience seemed to receive the safety message more

strongly, and in a sense I became a better communicator for safety.

To understand how an idea, or "gimmick," should be used, one must keep in mind three definitions which when used through all your safety planning will enable you to attain the maximum results. The three definitions are:

1. **Safety**—Doing the "job" the right way. Job is anything a person undertakes to do—standing, sitting in a chair, crossing the street, driving a car, running a machine, peeling potatoes, etc.

2. **Safety Education**—The art of making a man want to do what he ought to do.

3. **Safety Program**—To create an appetite in people who are not hungry.

Keep these definitions in mind. Observe the next ten minutes of my lecture. I am going to demonstrate how I sell safety. . . . (Here a short traffic safety lecture was given in which several visual aids, gimmicks, magic and humorous stories were used as an example of what adding a touch of glamour to a safety message means.)

. . . But I do feel I have "thumbing" important to point out to you. Supposing you're driving your car and you approach an intersection. Now, I'm in the other car approaching the same intersection. This is an unmarked intersection. There are no signs, no signals for either one of us. We are both traveling at the same rate of speed, and we both will arrive at the corner at about the same time.

The only difference is this—you happen to be in the car on my right, and I happen to be in the car on your left. Now, by law, who has the right of way, the car on the right, or the car on the left? (The car on the right.) Well, now, perhaps we are not reading the same law book because in my law book it does not say that the car on the right has the right of way. My law book simply states this—"the motorist on the left," and that's this fellow here, "must yield the right of way to the motorist on the right." It does not say that you have it. It says he must yield it to you.

Now, I may be a little bit stubborn, I may step on the gas, blink my headlights, blow my horn, speed up a little bit. You will slam on your brakes, to avoid an accident, and you may say something to me

as I pass by, besides that isn't my name anyway. But you do not have the right of way by law. It says I must yield it to you, and if I don't yield it to you we know you do not have it, and if by law I'm supposed to yield it actually I do not have it. So you see, neither one of us has the right of way.

What about a traffic light? You have the green light, and I have the red light. Do you have the right of way over me? No you do not. The law simply states that for the red light I must stop and yield the right of way to those of you traveling through on the green, but for the green light the law does not state that you have the right of way. It simply says that you are allowed to go through that intersection if you can do so safely. And if I run through the red light, you don't do so safely.

Of course, I would get the \$10 traffic ticket for running a red light and causing an accident, but what good is a ten dollar ticket going to do you or me if both of us are in the hospital. You see, even with the green light you do not have the right of way by law. And I know a case in court where the man who ran a red light caused the accident and received a ticket, won the case because they proved in court the person traveling through on the green light could have prevented the accident.

Supposing you're traveling on the main street, the through street, a state route, boulevard, or whatever you want to call it. I'm approaching from one of these little side streets, and I have a stop sign . . . by the way, in case some of you have forgotten what this actually says, it says, *Stop On Pedal, not Spin Tires On Pavement*. If it looks to you like I am not going to stop, what do you do?

Well, like nine out of ten of the motorists, you remind me, don't you? Beep . . . beep . . . beep . . . you blow that horn to remind me, look out fella you're supposed to stop for that sign. I'm going first. What happens if I don't stop for that sign? Even then, you do not have the right of way. The law only states that I'm supposed to stop at the sign and yield it to you. It does not say that you have it.

What I'm trying to point out to you is this—out there on our streets and high-

ways, I don't care where you're driving or what you're driving, you never have the right of way by law. Never. The law only explains who is supposed to yield it. It will not say that you have it.

Another example of communicating a safety lesson is . . .

Now, I've never ridden with any of you and I don't know what kind of drivers you are, perhaps you're very good. But supposing you're driving your car on a dry street, you have four good brakes and four good tires. You're traveling at the slow rate of 30 miles per hour, and that isn't very fast. Suddenly, up ahead someone backs out or walks out in front of you and you have to hit the brakes.

Now, in how many feet could you stop your car traveling at 30 miles an hour on a dry street with four good brakes and four good tires? . . . 66? . . . 30? . . . 150? . . . 45? . . . Well, the answer is 88 feet. Eighty-eight feet! Eighty-eight feet it would take you to stop your car traveling at 30 miles per hour.

Let's analyze this. I have a ribbon here one-half inch representing a foot, one-half inch to a foot. The top of my case here will represent the highway. You're traveling at 30 miles an hour, that's 44 feet per second. You come along this highway and right here at the corner of my case you see danger and that (snap) quick, you put your foot on the brake, but you can see by my yellow ribbon here that you will travel 33 feet, the approximate length of two cars parked bumper to bumper, before you can get your foot on the brake.

Then, after you put your foot on the brake it will take another 55 feet to come to a halt, making the total stopping distance from the time you see danger, slap your foot on the brake and stop your car about 88 feet. Now if you're real good, you might stop your car in about 79 or 80 feet, but if you happen to be tuning in the radio, lighting a cigarette, or talking to someone next to you, it might take you 100-some feet. But the average person will take 88 feet to stop his car at 30 miles per hour.

Now, I'm going to double the speed from 30 to 60 miles per hour, twice as fast, to show you what it's like should you be traveling on one of our turnpikes, expressways or out on the open road where you can

travel 60 miles an hour, 88 feet per second. You are traveling 60 miles per hour, as you come along the highway here and right here at the corner you see danger and that (snap) quick you put your foot on the brake.

But if you double the speed from 30 to 60, you will double your reaction distance from two car lengths to four car lengths. Instead of 33 feet you will now go about 66 feet, the approximate length of four cars parked bumper to bumper, before you put your foot on the brake, and ladies and gentlemen I don't care if you have power brakes, I don't care if you throw out an anchor, it will take you another 300 feet to stop your car.

Three hundred feet, that's the length of a football field from goal line to goal line. Three hundred feet, making the total stopping distance in the neighborhood of 366 feet to stop a car that's traveling at 60 miles per hour. You see, when you double the speed you don't double the stopping distance, you multiply it.

This is one of the reasons why we have multiple accidents on our super highways. I don't know what people tell you, but I know what they tell me. They say, "Burrrows, if I do what you say and follow at a safe distance everybody cuts in front of me." "So, a person is allowed to change from one lane to another if he can do so safely." I reply, then they say, "But they keep pushing me back." "Wait a minute," I say, "if you're on a city street, how fast are you going? About 30 miles per hour? Out on a super highway, how fast are you going? About 65 miles an hour? Then kindly explain to me how they push you back when you're traveling straight ahead at 30, 40, 50, or 60 miles an hour?"

I can't figure this out, can you? But I usually turn to them and I say, "Hey, when are you going to fill out that blank?" And they say, "What blank?" And I say, "The one between your ears."

And that is the way I attempt to present the safety message to the people here in our area.

You know, sometimes those of us who have a safety message to sell overlook the obvious. Sometimes we create our own illusions. Our own most trying problems are often the result of self-deception. And too many people selling an intangible safety

message are prone to assume that the doors are locked against them when the difficulty is actually a mental block. Remember Harry Houdini? He was an ingenious entertainer.

Behind Houdini's skill as an illusionist was a profoundly scientific mind and a keen grasp of the application of modern mechanics to intricate physical problems. He matched wits with locksmiths and prison wardens, and never failed to escape within the time limit. But he almost failed on one occasion by overlooking the obvious.

The warden who nearly outwitted Houdini used a simple artifice. He placed Houdini in an "escape-proof" cell and closed the door. Houdini tried all his ingenuity on the lock but could get no action from the mechanism. A few minutes before the deadline, in desperation, he tried the knob or the ponderous door. Presto! It hadn't been locked in the first place.

Ladies and gentlemen, I want you to use gimmicks, humor, or anything else you can think of to add that touch of glamour to your safety message. Let's stop overlooking the obvious. Let's use proven advertising principles. Let's encourage people to at least look at or want to hear what we have to offer.

Let me encourage you to use some of these ideas. You will not only be doing a good deed, selling safety, but you will enjoy it more, and you will be creating an appetite in people who are not hungry by making them want to do what they ought to do—that is, to do every job the right way.

Look at some of the ideas I have here. You could build a whole routine around these gimmick types of glasses, "Goo-goo" glasses—funny to look at, aren't they, Goo-goo glasses—make me look sick, don't they. Open and shut glasses, and what about this pair here that makes me look as if I'm pop-eyed. When I wearing these I could tell you that I want to see what's actually causing accidents. See what you're doing, ladies and gentlemen, you're laughing at what I'm doing and how I look while I have these glasses on. But think, while you're laughing you're listening to my message. This is what you have to do with your safety program. People will enjoy it more, and they will receive more from it.

How about these articles here. I have

a little police badge, a little boy's police cap, his gun, his whistle and his handcuffs. Any one of these items can be tied into a safety message. You can tell the audience while twirling the handcuffs that with their cooperation you can "handcuff" a certain cause of accidents. With the gun you could pretend that you are out "gunning" for crime and that is the thing that causes accidents in a specific field. Blowing your whistle can be tied in with blowing the whistle to stop accidents, and so forth. You could build a whole safety message around dollar bills that come in many shapes and forms—large comic dollar bills, little dollar bills, rubber dollar bills. With a little bit of imagination you could tie in the cause of accidents or stretching your money, stretching money through the prevention of accidents. See what I mean? Let's add a touch of glamour—demonstrate.

Earlier I was able to plant a piece of corn in everyone's pocket or purse. I have developed a little SAFETY SIX PACK in order to help you plant a safety message in everyone's mind. This SIX PACK contains six items which have retention value and are very inexpensive. The six items are:

1. A piece of string—"string along with our message of safety."
2. A kernel of corn—a pocket or change purse reminder of the need for cooperation of the individual in the safety program.
3. A safety pin—to be pinned on one's clothing as a reminder to keep one's guard up against accidents and be safe at all times.
4. A band-aid—to be placed on the back of the hand or dashboard of a car as a reminder that traffic laws or good safety rules practiced will hardly ever result in an injury serious enough to need more than a band-aid for repair.
5. A rubber band—"you must stretch your efforts for safety."
6. A lollipop—"don't let accidents make a 'sucker' out of you." Work hard to "lick" the problem of accidents.

Let me give you an idea of how to think about glamorizing your safety message. See, I have here what's called a "Hypo-Phony." This looks like a regular doctor's syringe, and, as you can see, it looks as if I am drawing blood right out of the air. I saw this article in a drug store. It costs a buck

and a half. I felt I could use it in a safety message, so I purchased it.

Shortly thereafter, I received a telephone call asking me what the title of my lecture to be presented before the Woman's Auxiliary to the American Medical Association would be. I looked at this toy on my desk and told the caller that the title would be *You Can Get Blood Out of a Turnip*. Ladies and gentlemen, I made the turnip resemble their impossible task of selling safety. I then proceeded to tell them how to use good programming to sell safety, and I concluded my speech by saying that if you use the right tools, the right safety programs, etc., you can do the impossible. Of course, the right tool for extracting blood is a doctor's syringe. See, I inject my syringe into this bloodless turnip and extract blood. This is

the only time in my life, ladies and gentlemen, that I ever received a standing ovation for a lecture, and it cost me a buck and a half.

The ideas expressed here are audience tested. If used as suggested, or as you see fit, they will make your safety lecture a little unusual. This alone will create an interest in the audience. Some of these ideas, by nature, will bring a chuckle or smile to the faces of those who observe them. The laughter tells you that they are listening. Please do not be mistaken about the laughter. It is not directed at you but at the "gimmick" which emphasizes your point.

I personally challenge you to use some of these ideas and see how you will improve the communications between you and your audience with a touch of glamour.

THE PRINCIPLES AND PRACTICE OF HEART-LUNG RESUSCITATION

By ARCHER S. GORDON, M.D., Ph.D.

Head, Cardiovascular Surgery Section, Lovelace Clinic and Foundation
Albuquerque, N. M.

What....? Heart-lung resuscitation is an emergency first aid procedure that combines artificial respiration and artificial circulation. The best rescue technique for artificial respiration is mouth-to-mouth resuscitation (MMR). The best rescue technique for artificial circulation is external cardiac resuscitation (ECR). These techniques are most effective when used together.

When....? Heart-lung resuscitation should be started at once in any case where there is absent respiration, heart beat or pulse. Time is crucial—seconds count. Adequate ventilation and circulation must be restored within minutes if resuscitation is to be effective. Don't waste time seeking help or equipment. Begin at once.

Who....? You—or anyone can learn and perform effective heart-lung resuscitation after minimal training. Remember, almost 70% of successful rescues are accomplished by persons at the scene—family, neighbors, friends or passers-by. Don't delay. You can save a life NOW.

Where....? Resuscitation should be performed anywhere a victim is found. Don't waste valuable time moving him—finding special equipment—seeking additional help—getting him out of the water, etc. It is necessary to move him only if gases or fumes are present.

How....? Learn, practice and follow the simple principles and instructions below.

PRINCIPLES

1. *Clear Air Passages.* Effective resuscitation can only be accomplished with unobstructed air passages. Sometimes this maneuver alone is sufficient to allow the victim to resume spontaneous breathing. The air passages can usually be cleared of anatomic obstruction by tilting the head into maximum extension. Obstruction by foreign bodies requires removal by the rescuer's fingers or inversion of the victim.

2. *Inflate Lungs.* Rhythmic inflation of the lungs through the victim's nose or mouth may restore spontaneous breathing if there

is any effective heart beat. Artificial respiration must be started immediately in order to oxygenate blood which is circulated either by spontaneous heart action or external cardiac resuscitation.

3. Compress Heart. Then begin rhythmic External Cardiac Resuscitation and continue it—until a palpable pulse and spontaneous breathing have resumed. Be sure the victim is on a firm support, such as the ground, floor, table or bed board. For adults use both hands to press on the breast-bone; in a child you can use one hand to compress the breast-bone while the other hand is slipped under the back to provide firm support.

Head Tilt Method, Mouth-to-Mouth Resuscitation—Closed Chest Method, External Cardiac Resuscitation

1. Clear Air Passages.

Lift Neck

In an unconscious person, relaxation of the jaw usually results in blockage of the air passages by allowing the tongue to drop backward into the pharynx. When the neck is lifted, the head drops backward into extension. This alone will sometimes clear the air passages and allow a victim to resume spontaneous breathing.

Extend Head

The head should then be tilted into maximum extension. One hand pushes the jaw upward from below; the other hand pushes the crown of the head under from above. When the chin is pointing almost straight upward, the jaw and tongue are drawn forward and the air passages are cleared.

2. Inflate Lungs.

Open your mouth widely. Place it over the mouth OR nose of an adult or large child (the mouth AND nose of a small child), make a tight seal and blow into the air passages until you see the chest rise and feel the lungs expand. Adults require a deep breath from the rescuer; infants and small children only need small puffs of air. Your cheek rests on the victim's mouth and prevents air leakage during mouth to nose breathing. The victim's mouth may be kept open for mouth-to-mouth breathing by drawing down his lower lip, while air leakage from his nose is prevented by

your cheek—or you may pinch off the nostrils with the other hand. Now remove your mouth and take your next breath as you hear and feel him exhale. Reinflate the lungs 10 to 12 times per minute for an adult, at least 20 times per minute for a child.

3. Compress Heart.

Be sure the victim is resting on a firm surface. Place the heel of one hand in the center of the chest over the lower portion of the breastbone and place the other hand on top of it. Rock forward and use the weight of your body to exert pressure vertically downward. This moves the breastbone an inch or two and compresses the heart between it and the spinal column. The pericardial sac which surrounds the heart is non-elastic so this compression propels blood out of the heart into the lungs and the body. When the pressure is released the chest re-expands and the heart refills with blood. The cycle is repeated 60 to 80 times per minute for adults, 80 to 100 times per minute for children.

Cycle

Heart-lung resuscitation is accomplished best by two rescuers who alternate in performing mouth-to-mouth resuscitation and external cardiac resuscitation. A series of five cardiac compressions followed by inflation of the lungs at a rate of about 60 to 80 heart beats and 12 or more breaths per minute provides excellent blood pressure, blood flow and blood oxygen saturation. Faster rates should be used for children.

Two rescuers can also do mouth-to-mouth and external cardiac resuscitation simultaneously instead of alternately. However, in cases where there is liquid or semi-liquid material in the lungs, air passages or stomach (i.e., drowning, pulmonary edema, vomiting, etc.) simultaneous application results in stomach and pulmonary contents being discharged into the face of the rescuer performing direct Mouth-to-Mouth Resuscitation. When chest compression and lung inflation are alternated this is avoided. Better pulmonary ventilation is also provided without any significant sacrifice in the effectiveness of circulation.

In an emergency, a single individual can alternately inflate the lungs and compress the chest. In this case it may be desirable to follow each lung inflation with a series

of eight cardiac compressions, instead of five.

Alternate Method

Silvester Heart-Lung Resuscitation

When a completely manual technique is desired, the Silvester method can be combined with External Cardiac Resuscitation to provide Silvester Heart-Lung Resuscitation. The victim is placed on a firm surface with a towel, block, or some other slight elevation under his shoulders so that his head will drop back into maximum extension. The rescuer kneels at the victim's head, grasps both of his wrists, places them on top of each other in the center of the chest over the lower breast-bone and rocks forward using the weight of his body to deliver a series of cardiac compressions. He then rocks backward raising the victim's arms above his head to produce lung inflation. The complete cycle is then repeated 12 to 15 times per minute.

Adjunctive equipment is not required for effective MMR; is second aid rather than first aid; if used, should have the following characteristics:

Small, compact, light weight—no valves or moving parts—easily cleaned or sterilized—fit all faces and configurations—only extend one inch into mouth—firm bite-block between teeth—flexible, tightly-fitting face piece—can be used with "Head Tilt" method of MMR.

Drainage

If you are unable to inflate the lungs with mouth-to-mouth resuscitation, check for foreign body obstruction by quickly sweeping your fingers through the mouth and throat. If this maneuver does not remove the obstruction, a child should be picked up quickly, inverted over the rescuer's arm and given firm blows over the spine between the shoulder blades until the obstruction is dislodged. When the stomach is distended following submersion or feeding, a child may be similarly inverted for drainage.

exerting pressure on the abdomen with the underneath hand.

An adult with airway obstruction may be rolled up onto his side and his shoulder placed across your knee and thigh for drainage. Firm blows over the spine between the shoulder blades may dislodge a foreign body in the air passages. Pressure exerted with your hand between his navel and ribs will promote the drainage of stomach contents with reduced danger of aspiration into the lungs.

These maneuvers should be performed quickly followed by resumption of heart-lung resuscitation.

Training Aids

Very little training is required if these principles are understood and applied.

You can begin by practicing the principles on each other. A clean handkerchief or cloth (A) may be used between "rescuer" and "victim" for practice or in actual emergencies. It does not interfere with Mouth-to-Mouth Resuscitation. However, if not available in an emergency, don't worry about infections from direct contact when a life is at stake.

You can also practice placing the hands over the breast-bone and exerting moderate pressure. A single operator, or two operators, can practice the 5:1 rhythm of ECR: MMR. It helps to count out loud to synchronize your efforts.

Various manikins and models are available for practice. Some of these closely simulate the feeling of actual lung expansion and chest compression. They allow you to extend the head and inflate the lungs (B) or combine mouth-to-mouth and external cardiac resuscitation for complete heart-lung resuscitation practice (C). Breathe Life Trainers can also be used (D). These jackets are worn by the "victim" and simulate the action of the lungs during mouth-to-mouth resuscitation.

WATER UTILITY SAFETY

In speaking of safety on the reservoirs and lands belonging to a water utility, Mr. H. D. Harman, vice president and general manager of the Gary-Hobart Water Corp., Gary, Ind., said that the ground rules of a water safety program must deal with these areas: the utility and its employees, the customers, the equipment, the quality of the water, and the elevated storage facilities supplementing the reservoirs. He defined a reservoir as any impounded supply of water.

Mr. Harman gave an example of the dangers of having a reservoir near a community, pointing out the pressure exerted by citizens to gain permission to fish in the reservoir, usually followed by extensions to allow row boats, then motor boats, and from there through water-skiing to a full-fledged resort and pollution of the water.

Mr. Harman mentioned that the 10-12 elevated tanks in Gary, located at pumping stations, were a constant safety problem. He said that the greatest dangers were from intrusions by teenagers, and that barbed wire, locked gates, and solid, high foundations were barely enough to prevent them.

Mr. J. C. Vaughn, chief filtration engineer, South District Filtration Plant, Bureau of Water, Chicago, discussed safety at the water treatment plant, and said that the functions of a safety program there should be to eliminate existing hazards, provide protective equipment, and ensure safe-work practices through a safety education program. He said that his plant owned \$30,000 worth of safety equipment.

Mr. Vaughn, in an excellent series of slides, showed the range of safety devices in use at his plant: bulletin boards and suggestion boxes, monthly safety bulletins, chain guards at steep stairways, plastic protectors on pumps and grinders, striped guards on couplings, voltage signs to warn of electrical wires, safety clothing for work with chemicals, washing facilities for acid burns, and gas masks, solvay kits, and other equipment for work with poisonous gases.

Speaking of safety in the storage and distribution of water, Mr. Merrill H. Anderson, safety advisor, City of Duluth, Minn.,

mentioned that Lake Superior was the reservoir for Duluth, and that the pumping station at Lakewood turned over 15.5 million gallons of water per day. He pointed out the attendant problem of obtaining a satisfactory pressure of flow from the distributed water. Another problem arose from the use of cast iron mains, which developed leaks after years of use, probably due to electrolytic deterioration, and necessitated large-scale replacement and even the laying of entire new systems of mains.

Mr. Anderson said that most accidents resulted from misadventures during routine operations, and that unusual or particularly hazardous operations were so carefully attended to that accidents were few and minor.

Mr. Oliver Summers, plant engineer, Indianapolis Water Co., Indianapolis, Ind., discussed the problems of administering a safety program at a water utility. He said that water utilities were somewhat behind in the safety endeavor, but that an encouraging start had been made through the adoption of a safety manual and increased contact with smaller utility plants.

Mr. Summers stressed the need of having top management take an active part in the safety program, by attending safety meetings and by meeting with supervisors. He said that tail-gate sessions were a must in any safety program, and that such sessions should be held with the engineering and meter reading departments, but not necessarily with the office staff. He stressed the role of the supervisor as the main line of safety defense, and the necessity of keeping records.

In a note on automotive safety, Mr. Summers outlined a two-point program for the maintenance of a safety fleet: inspection of vehicles (most important), and the detailed investigation of accidents. He said seat belts were an excellent idea.

In the question-and-answer session that followed, the means of disciplining safety-rule infractions were discussed, and two different solutions were proposed: penalties of suspension or loss of pay, and compulsory attendance at safety training sessions.

OFFICERS OF THE PUBLIC UTILITIES SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—V. L. WISELDOFF, Safety Advisor, Illinois Power Co., Decatur, Ill.

First Vice Chairman—ERROLL DUNBAR, Safety Engr., Potomac Electric Power Co., Washington, D. C.

Second Vice Chairman—PAUL WINDSOR, Safety Dir., Bureau of Safety, Chicago, Ill.

Secretary—T. F. WICKORD, Safety Supvr., Commonwealth Edison Co., Maywood, Ill.

Program Committee—CARL J. LOHMAN (*Chairman*), Safety Dir., General Telephone & Electronics Service Corp., New York, N. Y.; P. W. WATSON (*Vice Chairman—Communications*), Dir. of Safety, General Telephone Co. of Florida, Tampa, Fla.; W. W. WILLIFORD, Plant Supvr., Safety, The Chesapeake & Potomac Telephone Co., Washington, D. C.; J. O. PARKER, Safety Supvr., American Telephone & Telegraph Co., New York, N. Y.; R. R. PHILLIPS (*Vice Chairman—Electric*), Safety Engr., Duquesne Light Co., Pittsburgh, Pa.; C. A. FISCHBACK, Safety Supvr., Southern California Edison Co., Los Angeles, Calif.; M. B. TRAVIS (*Vice Chairman—Gas*), Dir. of Safety, Northern Natural Gas Co., Omaha, Neb.; W. R. LA DUE (*Vice Chairman—Water*), Supt. & Chief Engr., Bureau of Water Supply, Akron, Ohio; H. D. HARMON, Vice Pres. & Asst. Gen. Mgr., Gary-Hobart Water Corp., Gary, Ind.

Technical Publications Committee—E. M. CHASE (*Chairman*), Safety Dir., Central Vermont Public Service Co., Rutland, Vt.; N. W. TEMPLE (*Vice Chairman—Communications*), Plant Safety Supvr., The Pacific Telephone & Telegraph Co., Seattle, Wash.; C. E. HAMMON (*Vice Chairman—Electric*), Safety Dir., Columbus & Southern Ohio Electric Co., Columbus, Ohio; JOHN W. GRONBECK, Safety Mgr., New England Electric System, Boston, Mass.; R. V. HAVERFIELD, Safety Dir., Indiana & Michigan Electric Co., Fort Wayne, Ind.; M. H. MAXWELL, Safety Supvr., The L. E. Myers Co., Clawson, Mich.; R. W. TOMLINSON (*Vice Chairman—Gas*), Safety Dir., Philadelphia Gas Works, Philadelphia, Pa.; C. H. GUM (*Vice Chairman—Water*), Safety Supvr., Department of Electric & Water Utilities, Jacksonville, Fla.

Training Committee—H. C. POTTHAST (*Chairman*), Supvr., Wisconsin Rural Electric Job Training & Safety, Menominee, Wis.; W. L. CURTIS (*Vice Chairman*), Safety & Fire Engr., Accident Prevention Div., The Hydro-Electric Power Commission of Ontario, Toronto, Ont., Canada; J. WESLEY SANMIS, Safety Engr., Philadelphia Electric Co., Philadelphia, Pa.; R. N. PARICH, Safety Mgr., American Gas Association, New York, N. Y.; H. C. MCCHESSNEY, Sr., Safety Rep., The Detroit Edison Co., Detroit, Mich.; V. A. APPELYARD, Exec. Mgr., Chester Municipal Authority, Chester, Pa.; W. J. BRYAN, Safety Engr., Michigan-Wisconsin Pipe Line Co., Detroit, Mich.

Audio-Visual Aids Committee—WARREN D. COLLINS (*Chairman*), Exec. Safety Dir., Orange & Rockland Utilities, Inc., Boston, Mass.; SAMUEL McKNAY, JR. (*Vice Chairman*), Safety Dir., The Bell Telephone Co. of Penn., Philadelphia, Pa.; JAMES SEALY, (*Safety Consultant*) Ebasco Services, Inc., New York, N. Y.; W. W. DUNN, (*Safety Director*), City Utilities of Springfield, Springfield, Mo.; A. E. PIEROWAY, (*Safety Director*), New Brunswick Electric Power Commission, Fredericton, N. B., Canada.

Contests & Awards Committee—ROBERT M. CLARK (*Chairman*), Safety Dir., Atlantic City Electric Co., Atlantic City, N. J.; K. G. CREGAR (*Vice Chairman*), Safety Dir., Metropolitan Edison Co., Reading, Pa.; M. H. INGRAHAM, Safety Dir., Central Main Power Co., Augusta, Maine.

Membership Committee—B. J. LORENZ (Chairman), Mgr. of Safety, Northern Indiana Public Service Co., Hammond, Ind.; E. B. HURST (Vice Chairman), Safety Dir., Virginia Electric & Power Co., Richmond, Va.; S. T. ROMESON, Safety Supv., Carolina Telephone & Telegraph Co., Tarboro, N. C.

Newsletter Committee—CHARLES SCHWEICHAERT (Chairman), Exec. Asst., Hoosier Engineering Co., Columbus, Ohio; D. E. BUCKLEY (Vice Chairman), Safety Dir., East Ohio Gas Co., Cleveland, Ohio; WARREN D. WILT, Safety Engr., City of Detroit, Detroit, Mich.; GEORGE C. SORR, Asst. to Gen. Mgr., Department of Water & Power, Los Angeles, Calif.

Off-The-Job Committee—R. G. CLAAR (Chairman), Safety Dir., The Ohio Fuel Gas Co., Columbus, Ohio; R. F. MILLS (Vice Chairman), Gen. Plant Safety Supv., Mountain States Telephone & Telegraph Co., Denver, Colo.; J. E. ARPEL, Safety Engr., Commonwealth Edison Co., Chicago, Ill.; A. B. SHERRE, Safety Engr., Rural Electrification Administration, U. S. Department of Agriculture, Washington, D. C.; R. E. McELDOWNNEY, Jr., Safety Dir., United Fuel Gas Co., Charleston, W. Va.

*Deceased

PLAN NOW --

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

PULP & PAPER SESSIONS

A NEW CHALLENGE FOR SAFETY

By H. M. GRAY

Vice President, Seairight-Oswego Falls Corp., Fulton, N. Y.

A group of individuals whose working life is devoted to the protection of human life and limb performs a service the importance of which it is difficult or impossible to surpass. We of the Seairight-Oswego Falls Corporation are proud of our record in this important activity. Therefore, we want to support it in any reasonable way in which we find it possible to assist. There is another reason, and that is my own personal deep interest in industrial safety, as well as safety in all other activities of human endeavor.

Perhaps I was fortunate. The first day I worked in industry was during my student days in 1919. That day I was a member of a crew of men whose duty it was to unload manually rather large pieces of limestone from a freight car. These stones were so heavy that the only way I could get them out of the car was to first get them on top of the side of the gondola and then just push them off, which apparently was the practice of the entire group. Before getting one rock out of the car, I was successful in injuring one finger. There wasn't any one concerned as to whether or not I injured fingers, hands or any other thing. It was assumed that each workman would protect himself.

Before the first morning's work was over, one of the more reckless of the group was successful in dropping one of the large rocks on his finger, which at that moment was on the edge of the top of the gondola and he amputated the finger at the second joint. The only comment made by the foreman of the group was, "Get back to work fellows, there are lots of fingers in the world." That comment made a lasting impression on me.

From the beginning of the building of the American industrial empire, the importance of safety was not fully recognized. Management paid a day's wages for a day's work. There was usually an abundance of personnel available and if not, it was not difficult

to recruit from the crowded areas of Europe. These things were not the result of a cruel, heartless and indifferent attitude; they were the result of not recognizing the expense of replacing the trained workmen who would become injured or ill, or the good production practice which resulted from insisting upon safe working rules and all that goes with it. That condition was the product of the time.

With the advent of the compensation laws, and state and government controls, and with the development of enlightened management, safety came into its own as an absolute, indispensable part of the modern day industrial activity.

During the Second World War production pressures were very great. Accident rates rose in some plants to alarming levels in a short period of a few years where industrial safety activity was allowed to slip back or was simply ignored.

In fact our own plants became so busy, and management became so occupied with the sheer pressure of producing things, that to our great horror and sadness, we discovered we had a frequency rate in the 30's, and then that was that. It was decided that never again would that be allowed to occur. If you work at something intelligently, you can influence it for good or bad. In the case of safety, the influence desired was for the good and the objective was a frequency of zero.

Zero frequency was not achieved, but a frequency below two was achieved and an average of about two has been maintained for many years.

Any problem which has a solution can be brought to a favorable decision if sufficient quantity and quality of the proper thought is brought to bear upon the situation. Thus it is with safety.

The objective of excellence in this area was zero frequency, which is not often achieved and may not be achieved. Nevertheless, the end result was most gratifying.

along with all of the concomitant favorable results accruing to the workmen, and the personnel in general.

It was inferred earlier in these comments that management was not as sincerely and deeply interested in safety in the past as it is at the present. Just a word of explanation about that.

I do not want to leave the impression, which I believe would be completely erroneous, that management was unconcerned with human suffering. On the contrary, it has been my experience that American industrial management, at least during my working life, has been deeply concerned about these problems; and the lack of an earlier and more aggressive safety program for plants may be laid at the door of the group foremen, or department heads, or mill managers who seem to have a tendency to read into management's policy things which are not there and were never intended to be tolerated.

Enlightened management has always recognized that no amount of remorse, however sincere, has ever restored life or limb, or healed an injury or alleviated pain.

Anything worth doing is worth doing in a safe manner. One of the most depressing things that management can hear is to learn of an accident and then be told "Well, we were in a hurry." Surely sometimes it is necessary to work faster than at other times. But at no time does management expect the worker to go at a rate which jeopardizes life and limb.

With the competition for labor in the boom periods following World War II, the greatest progress has been made in safety practices in American industries. A good, intelligent, American workman will simply refuse to sell his services to a business where the working conditions are so hazardous that he does not know whether or not he will return home to his family at the end of his working day free of injury.

What are the present challenges which industry must face in its safety program for the future?

1. It seems apparent that there will be unending competition for the service of the skilled worker. The result will be that the skilled worker will demand a safe place in which to work and safe working rules and practices.

Pulp and Paper Sessions

2. Labor is going to cost more each year. This probably will eventually lead to serious conditions such as the pricing of a product out of profitable competition with other equally good or satisfactory products. Since labor will constantly increase in cost, the cost of having labor unable to work because of injury will also increase.

3. For some reason or another which I do not understand, it seems to be increasingly unpopular to want American industry to make a profit. Yet, it is only through the American profit system that we have worked ourselves up to the highest standard of living in the history of the world.

Let me give you a bit of advice. Never work for a company which does not make a profit. Do not plan to continue working for a company which does not make a profit. No employee of a company can for long be more successful than the company for which he works. Now it is certainly easy to understand that good safe working practices rigidly followed and enforced go a long way toward assisting a company in making a profit.

Therefore, if not for humane reasons—and they, of course, are the more important—then for selfish reasons, you in your chosen work in this great pulp and paper industry, which has served us so well, and of which we can be so proud, must plan to constantly work toward a lower number of man hours lost because of accidents.

4. You must to justify your existence in a world which is constantly demanding more and more of all of us, develop an attitude of excellence toward this very important work, that there can be an assurance of continuing quality of product with safety.

5. You cannot as safety directors assume the responsibility of management in this important field, but your first duty is constantly to inform management of their responsibilities in seeing that the proper program is set up and enforced. This will require personal attention by the highest members of management, and it deserves the best attention.

You cannot assume the foreman's responsibility for enforcing safe practices in his group, but you can constantly educate him, to a point where he feels that it is a personal affront if workmen under his supervision get hurt.

6. Take an uncompromised stand. A practice is safe or it isn't safe. If it isn't safe, it should not be allowed to continue.

7. Have constantly before you as your objective in your working-day life a frequency rating of zero. It will not often be achieved, but that should not keep you from trying. What you will achieve as you persevere is the great goal of making the pulp and paper industry the safest industry in business.

Is the pulp and paper industry to be satisfied with a frequency rating of 0.93 and a position of 20th place when it is so easy to get the frequency below two (while we are shooting at zero), and then go from there to lower rates, approaching perfection?

Not only develop and maintain an attitude of excellence toward this important work but also indoctrinate management, the foremen, the rank and file of workmen, so that they display a vigorous attitude of righteous indignation when any injury occurs, however trivial.

You have a good industry in which to demonstrate your ability. You have a rather uniform rate of operation and employment, with a low turnover. You are just as well trained and just as capable as the safety directors in other industries.

All of these things being true, can you think of any reason, other than perhaps a

lack of continuing vigor and perseverance, which keeps your industry at such a high level? You can do in life almost anything within reason that you think you can accomplish. In this your full time work you must recognize but three basic things.

1. Safety is everybody's business.

2. The objective in safety is a frequency of zero.

3. Perhaps this is the most important of all. You must recognize that you are responsible for the program which results in the education of all employees to the fact that safety is everybody's business; and that zero frequency is achieved and maintained at many places, but that it is never the result of a haphazard or undirected program. It is never an accident when such a record is achieved. It is the result of hard work and the everlasting drive of the crusader, of the man dedicated to his mission and willing to put forth the energy and courage to achieve the objective, and to refuse to accept defeat. This I know you can do.

I hope that you may dedicate yourself anew to go back to your place of work after learning more, and carry forth your work to success. You have already done much. Indeed, you have done even great things. Therefore, with that experience in back of you, you are capable of greater achievements.

INCREASED ON-THE-JOB FIRE TRAINING (A must in the Pulp and Paper Industry)

By M. M. "SMOKEY" BATZER

On-the-job Industrial Fire Prevention and Damage Control Trainer, Philadelphia, Pa.

In probably few other industries is the dreaded cry—"Fire!"—feared as much as in the pulp and paper industry.

In the woodlands, a carelessly dropped match or cigarette butt may start a blaze that in a scant few days can wipe out tens of thousands of acres of prime timber and with it perhaps a mill's chances of expansion, if not survival.

In the mill itself, a collection of rags or oily waste may be the springboard for a

fire that will burn the plant to the ground, taking with it millions of dollars in invested capital, years of hard work and the jobs of hundreds of workers.

The pulp and paper industry has recognized this grave danger and thus its fire record, so far, has been a good one.

But this is no reason for your industry to rest on its laurels. Vigilance and on the job training are "musts" if those "small" fires which do occur from time to time

are to be kept from becoming major disasters.

I'd like to tell you a true story to emphasize this point. It happened to me in a Canadian pulp and paper mill.

While we were doing some in-plant fire protection training, I went up to an employee standing on the uncomfortable back-side of a large paper machine, rolling along at usual hoped-for breakneck speed.

"Suppose," I said, "you discovered a fire here on the floor, a fire that was big enough so that you couldn't positively stamp it out with your foot. What would you do?" Know what the reply was? "Well, I guess I'd get the hell out of here. I'm not paid for fighting fires."

That was the unfortunate attitude of this employee. Sure he might have saved his own bacon by getting out of there; but by running, instead of turning in the alarm and bringing portable fire fighting equipment into play, he would have given the fire a big head start and helping hand. That fire—undetected for even a few more minutes—could have endangered the lives of many other employees and burned the mill to the ground.

Now you may very well say: "Ah, SMOKEY, that happened in a practice run, but it wouldn't happen if a real fire were involved."

Want to bet? It happens every day, everywhere and in every industry.

Here's a case almost as bad. It's listed in a Fire Commissioner's Report under the heading: Typical Fires, 1957.

"April 25, Seminary and Classical College, Iowa \$1,170,120. While welders were installing a new metal stairway fire broke out in an unsprinklered shallow roof space of the otherwise completely sprinklered 9,500 sq. ft. 3-story brick, wood-jointed building. Welding sparks were the probable cause."

"The welding crew attacked the fire with several fire extinguishers and the alarm was not transmitted until someone outdoors saw smoke pouring from the building. The fire spread through the unsprinklered parts of the roof space and although sprinklers operated in certain parts of the roof space and in the fifth story to protect these areas,

they had no effect in the unsprinklered areas."

"Hose streams also were unable to reach the fire raging beneath the roof."

Eventually the roof collapsed breaking sprinkler piping in the fifth story and later the bell tower fell in and caused most of the building to collapse."

Don't misunderstand me. Let's give those welders full credit for doing their duty as they saw it. But the critical point is they attacked the fire with hand extinguishers and the alarm wasn't transmitted until someone outdoors saw the smoke. It's a matter of history and record now that by the time smoke was sighted, it was too late. If the alarm had been turned immediately, there's a chance the building might have been saved.

Think that's an isolated case?

Same Report, same year, and I quote:

"May 29, restaurant et al.; loss \$514,530. Four buildings, housing stores and apartments. Originating within a nonfire stopped partition in the first floor restaurant, fire was first discovered when heat ignited papers on the floor adjacent to the partition. Employees attacked the fire with buckets of water but the fire persisted and when it started to spread along the wooden and combustible fireboard interior finish, they fled and notified the fire department."

"Flames were coming from the roof of the 215 foot by 70 foot three-story wooden building when firemen arrived. Fire spread to two wooden buildings on one side and one on the other before sufficient fire apparatus could be assembled to make an effective attack."

Get that? Fire spread to two buildings on one side and one on the other before sufficient fire apparatus could be assembled. It may be a hard, blunt way to put it, but it boils down to hiding while home burns.

I cannot stress too strongly that it is within the first thirty seconds of the life of a fire that the most effective headway can be made, against it—even by people of limited know-how.

Even in industries as fire conscious as yours, few people realize the full extent of the terrible toll that fire, exact from the nation every year.

In 1960, fire claimed the lives of 11,350 men, women and children. That's one life every 47 minutes, 31 times a day. In addition to that number killed, countless thousands of others were seriously injured, many of them to spend months in hospital, many of them unable to work again.

In terms of property loss, last year's toll was \$1.5 billion. That's a good deal more than it cost to build the entire St. Lawrence Seaway, the hydro electric power phases of that great project excepted.

Frightening, isn't it? Fire is a vicious, wanton thief and killer that respects no one.

It is one of the most serious problems that confronts the continued prosperity of the North American economy today. It is a problem that is growing more serious annually. It is one that we are all guilty of doing too little about.

What makes the terrific annual loss of life and property due to fire even more tragic is the fact that virtually all of it could have been prevented through proper care and proper training.

That's why I want to show you what a formidable and frightful enemy fire is. Fire losses are difficult to assess with any accuracy, and they are even harder to predict.

Nevertheless, as far as 1961 fire toll is concerned, I'll stick my neck way out and say this: If fatalities conform to the national ten-year average, more than 11,600 people will be killed by fire in the United States this year. If the pattern of property loss experience established in the last decade is true, then fire losses in 1961 will top the one \$1.5 billion mark by a wide margin.

This will happen—and remember it could happen to you—unless all of us, starting right now, get out and do something about it.

Fire loss figures are apt to be misleading. Virtually every source you look at will give you a different dollar figure for losses sustained in any given year. Claims paid out by fire insurance companies are often taken as a useful yardstick, though bear in mind this presents far from the whole picture.

Some companies are self insurers; some

insure only part of the risk. Frequently, the actual amount of the physical loss exceeds by far the amount of insurance carried. The sad fact is that according to figures compiled by the National Fire Protection Association, the dollar value of fire losses has been increasing more rapidly than the number of fires.

As I said a moment ago, figures are apt to be misleading and they seldom tell the whole story. Fire does not respect statistical averages, which are computed from hindsight information. If you have a fire in your mill, don't be lulled into the security of thinking that the loss is going to be confined to your just, proportional share of the industry average.

Now can you forget about the intangible losses that result from major fires—losses that can't be or aren't measured in direct dollars and cents terms; ones that probably can't be covered by insurance are ones which, none the less, are very 'real' and which have a direct bearing on the well being of the enterprise.

There are many of them. Surveys in the U. S. have disclosed these sobering facts about severe business and industrial fires:

43 per cent of the concerns hit by bad fires were unable to resume operations.

17 per cent of those firms able to furnish financial statements before a fire were unable to do so afterwards.

14 per cent suffered a severe reduction (from 30 per cent to 66 per cent) of their credit rating.

26 per cent, unaffected as to credit rating, nevertheless suffered a severe loss in customer relations.

Just think about that for a moment. If you expose yourself to fire risk and loss, priceless records, plans, documents, and the like which took years to produce and assemble and which are the very life blood of your business may go up in smoke in a very few minutes.

I'm thinking, for example of production and test lab reports. You can't insure the true value of these reports, and you can't buy back the information contained in them for any amount of money. Believe me, if money could reproduce these records, your nearest competitor would have bought himself a set years ago.

Then too consider what happens to your business if a disastrous fire puts you out of operation for an extended period. Have you thought about the good will of customers who depend on you for materials? If they can't get their requirements from you, they'll have to turn to alternative sources of supply—in all probability your competitors.

And once a competitor gets a foothold in your market, it may take you years to get him out again. In fact, you may never be able to regain all of your former markets.

In such a highly competitive industry as pulp and paper, I think you will all agree it is poor business indeed to let fire give your competitor the upper hand in your own markets.

There's another important consideration too—your labor force team. Quite apart from moral and social considerations, if you have to shut down for fire repairs, you'll probably have to lay off a considerable portion of your work force.

As you know, we all have to eat. Once laid off, your workers will probably try to find alternative employment. Will you be able to get them back again once you reopen? It's almost a certainty that part of the work force will be lost to you for good. When you re-open, therefore, you'll have to take on new men and will have the added expense and production set-back of having to train them from scratch.

Bear in mind too that fire insurance companies aren't set up as charitable institutions.

And I'll tell you right now that the last time I made this suggestion, a manager came up to me and said: "Smoke, who are you trying to impress? You should see the premiums we have to pay each year."

Well, that's exactly the point. The insurance principle is very simple. Premiums are collected from the many to cover the losses of the few. If industry has a bad loss record this year, everyone's premiums go up to compensate for it next year. Thus fire costs everybody money. It's a vicious circle, and you can't beat it any other way than by cutting down the fire losses.

And there's much more to the insurance angle than just that. If your plant has a bad fire record, believe me, you are going

to feel it in the size of the insurance premium you pay.

As I said a moment ago, insurance companies aren't charitable institutions. They, like you, are in business to make money. They come in, gauge the risk, and set premiums accordingly.

I'd like to turn for a moment to the moral and social implications of the fire problem. You, as members of the pulp and paper industry are the employers—the "job-givers" to a large number of Americans. As a result, the burden, as well as the responsibility, placed on your shoulders is a very heavy one.

In many smaller communities across the nation one pulp and paper mill is the sole industry—virtually the sole source of employment—and for all intents and purposes, the only reason for the community's economic existence.

On the management of such companies rests the responsibility for the well being of the entire community. If the mill burns down, shareholders are not the only ones to suffer. The death warrant for an entire community may have been signed.

The sad fact is that technology and markets do not stand still in today's fast changing world. If a manufacturing operation is burned down, economic conditions may dictate that it remain closed forever. If it is to be rebuilt, it may have to be rebuilt elsewhere. One need only look at the trend towards establishment of pulp and paper plants in the southern states to find proof of the validity of this argument.

There is also the human element to be considered. In North America, business and industry help look after the employee's welfare in many different ways. Employers contribute to unemployment insurance; many pay part of health, sickness, life insurance, and pension plans. They may even offer a stock purchase plan so that employees can participate to some extent in the profits of the business.

Surely the very life of the employee is no less important than the fringe benefits he received!

I think everyone in this room would do everything in his power to avoid having to call on the wife of an employee—the mother of five children—to tell her that

she has become a widow. Yet each year in the United States, there are dozens of businessmen on whom this sorrowful duty falls.

The real tragedy is that in almost every instance death could have been avoided by proper training, proper precautions, taken at the proper time. This will suffice, I think, to show how great and how far-reaching the economic and social implications of fire loss are.

Let me just add this: some authorities suggest that the indirect losses due to fire are more than five times greater than the actual damage to any property. To the best of my knowledge, no one has yet been able to contradict this statement.

The real problem in industrial fire prevention today is not one of equipment; it is one of training and attitude. Contrary to widespread opinion, there has been nothing radically new in methods of extinguishing fires for many years. Our basic tools have, for the most part, been in use for the past fifty years, or so.

The real deciding factors in whether there will be a fire loss or not are these:

Have fire hazards been recognized and effectively eliminated?

Do plant personnel know—instinctively—what to do if fire breaks out, how to do it, and when to do it?

Has the plant availed itself of all possible fire fighting and fire protections services and facilities that are available to it?

Few people realize the speed with which usually small fires get big and uncontrollable. For example, it is often pointed out that an average fire at the end of two minutes is three times as large as at the end of one minute. At the end of four minutes it can be twenty-five times as large as it was at the end of two minutes. And at the end of ten minutes it may be one hundred times as large or larger than it was at the end of four minutes.

These estimates are conservative. Where combustible vapors of petroleum and similar products are involved, the acceleration rate is much more rapid.

It follows, therefore, that more can be done with less know-how and less equipment in the first thirty seconds than the best trained and equipped fire department

can often accomplish when it arrives on the scene ten or more minutes later. That is why management must accept the challenge of getting the man on the job-level to realize he must deal with a small blaze intelligently and immediately, whether or not this is part of his particular job. If management doesn't succeed in this mission—it is missing the boat.

When dealing with fire protection problems, we often hear the term fireproof. Unfortunately, fireproof is one of the most abused adjectives in the English language.

There are virtually few substances on earth that won't burn under certain conditions. If there were, scientists wouldn't have had to spend so much time and effort trying to devise methods to effect re-entry of space rockets into the earth's atmosphere.

Probably one of the materials that comes to mind most easily as one that supposedly won't burn is water. That's because water is widely used to extinguish fires. However, we need only recall that during World War II many incendiary or fire bombs were dropped by both sides. To fight the resulting fire with water was soon found to be suicidal. The reason: An incendiary bomb, being made out of a material called thermite, burns at about 8,400 degrees Fahrenheit. When water is exposed to a temperature of 8,400 degrees Fahrenheit, it decomposes into its component elements, oxygen and hydrogen. The former supports combustion, and the latter actually readily burns, given the right conditions.

Thus I leave the result of fighting thermite fires with water to your imagination. Like water, supposedly fireproof buildings have a nasty habit of burning when they are not supposed to. I'd like to quote again from a Fire Commissioner's Report: dealing with the destruction of a hardware Company Building at a loss of \$700,000.00.

"Destruction of a noncombustible (steel framing, aluminum siding and roof) with noncombustible contents (hardware, plumbing supplies) probably seemed to be a remote possibility to the owners and may have accounted for their decision not to sprinker the building. As it turned out, the combustible attic floor, stored papers in the attic, office furniture and combustible crates and cartons of stock provided adequate fuel to cause total destruction of the building.

"The fire originated when sparks from a welding torch being used on the roof fell on papers stored in the attic. The fire burned an estimated 30 minutes before employees in the first story discovered it. Public fire fighting was ineffective due to poor water supplies, the nearest hydrant being 2,000 feet away."

In the past few years the march of science has created two or three thousand new, combustible products that didn't even exist a decade ago. All are potential fire hazards, particularly if you don't know them, their properties and behaviour.

To sum up, recognition of fire hazards and in-plant fire prevention and fire fighting training are the keys to lower industrial fire losses.

At your respective companies or plants, if you do nothing else, I urge you to do this:

Make a careful, thorough inspection to see if you can spot any fire hazards.

Eliminate any that you find.

Find out whether you have sufficient fire fighting equipment and, above all, whether what you have actually works.

Find out whether your employees on all levels have sufficient training and know-how to deal effectively and immediately with any fires that may occur.

Satisfy yourself that both your employees and your fellows in management are fire prevention "oriented."

If you haven't established a mutual-aid fire fighting agreement with neighbouring industries, work one out. This is particularly important in small communities with only limited municipal fire fighting resources.

Don't look on plant visits by fire inspectors as the coming of the seven-year plague. On the contrary, make a point of inviting your local fire fighting authorities into the

plant before disaster strikes. If they know the layout and their particular problems, they will be much more effective in dealing with any blaze that may occur.

I cannot impress on you too strongly that you can't take too many precautions and that you can't give your employees too much training. Ocean-going vessels, by law, are required to hold a weekly fire and boat drill. Yet ships still burn!

This is in spite of the fact that they are floating in a sea of water and have much more fire giving equipment built right into them than the average industrial plant.

Recently, Ambrose B. Kelly, general counsel of the Associated Factory Mutual Fire Insurance Co., summed up the fire loss problem very neatly. He said, "... experience in loss prevention indicates that the attitude of management is just as important as good construction and physical protection against loss. A reinforced concrete building fully protected by automatic sprinklers by having a management indifferent to loss, an attitude which is reflected in the attitudes of the employees, is not a good risk.

"Fire starts because of carelessness of employees or because of faulty maintenance, and when it comes there is no plant organization trained and ready to extinguish it promptly and with a minimum loss.

"Automatic sprinklers have proved their worth, but a single shut valve can destroy the effectiveness of the entire system.

"For effective loss prevention, we must have both proper physical conditions and a proper management attitude. Given both... losses can be substantially reduced."

And that is expert opinion. It comes from an insurer who judges you as a fire risk in the dollars and cents you must pay.

As an industrial fire fighting and fire prevention trainer, I can only add one word: "amen."

INFLUENCING BEHAVIOR FOR SAFETY

By GLENN F. GRIFFIN

Training and Safety Consultant, Park Ridge, Ill.

I believe we are not paying as much attention to influencing behavior as we ought to. Behavior is the most important factor in safety or in accidents. When I say that behavior is the most important factor I am not thinking of the outmoded concept that 85 per cent of all accidents result from unsafe acts and only 15 per cent from unsafe conditions. If we could take a few hours and examine a thousand or so accident reports I could convince you that unsafe conditions probably occur just about as often as unsafe acts.

When I say that behavior is the most important factor in accidents or in safety, I have in mind that unsafe conditions are the result of somebody's behavior and that any given unsafe condition is really an unsafe act just one step removed. When you look at it that way it is not a case of 85 per cent due to unsafe acts and 15 per cent due to unsafe conditions but rather 100 per cent due to unsafe acts although not necessarily unsafe acts of the injured persons.

But whether you follow me in all this reasoning or not, I think I could get an affirmative vote to the proposition that most accidents result from the way people act. The thing that worries me is that many of my friends in the safety business tell me that accidents result from unsafe acts of people and in the next breath tell me that after all you can't do much about the way people act.

Now when people say that I know they are just discouraged by some instance of unsafe conduct that seems quite inexplicable because, of course, we can do much to influence the way people act.

Human behavior and how to control it is such a broad subject that I have selected just three factors influencing behavior that seem to me to be very close to the actual point of contact in accident occurrence. They are:

- Knowledge and skill
- Attitudes
- Temporary states, physical, mental and emotional

I can't say which of these is the most important factor; in fact, when we investigate an accident it is often difficult to tell which of the three is predominant. One leads to another. A very simple example is that of a man who is assigned to a job that he does not understand. (A lack of knowledge and skill). Because of this he becomes worried and frustrated. (A temporary state). The continual worry and frustration eventually leads to a feeling that he doesn't like this job and that the whole safety program is a lot of bunk. (An attitude).

If you really want to make a complicated case of it you can say that having arrived at such an attitude he then shuts his ears to further instruction and as a result gets in bad with the boss and as a result of this his attitude gets worse and worse. That can go on endlessly and sometimes it does.

But we have to start somewhere and it seems to me the logical place to start is with the matter of knowledge and skill. Certainly we can't expect that a man will work safely unless he has the required knowledge and skill and certainly we can say that the boss is responsible for seeing that he does have that knowledge and skill. I will have to illustrate the importance of this factor by a negative example.

A man was told to empty a tank of solvent. Having given the order the foreman walked away and the next he heard the man had suffered an injury trying to tip the tank over to empty it. The fact of the man's ignorance then came out when it was disclosed that there was a drain cock on the bottom of the tank.

The obvious remedy for lack of knowledge and skill is instruction, instruction about safety, yes, but mostly just plain simple thorough job instruction. People need to learn how to do the job as it is done in the place where they are working and this includes knowing the names of things, knowing the principles behind the actions, knowing the why as well as the how. It also includes not only knowing but

includes practice under observation until a supervisor knows that the man is going to do it right.

If this kind of an instruction program is going to work it means that the people responsible for instruction know that the amount and kind of instruction varies with different people, that with some people it has to be repeated more often than with others but that with all people it is a never-ending process.

Job instruction has to be done on the job by the responsible man on the job who is the foreman, and here we safety men get our first and biggest alibi, which I am afraid we have used until it has worn pretty thin. That alibi—"the foreman is responsible."

Does this mean that we can leave instruction up to the foreman and that we can blame him for accidents that result from ignorance? Certainly not.

If our job as safety men amounts to anything at all, it is up to us to see that the foreman acquires the necessary knowledge and skill to transmit the necessary knowledge and skill to the people under his supervision.

And so I am giving away what is, perhaps, the most important point of my talk which is that while all the things we are talking about are part of the foreman's job, they are our job, too, and perhaps first.

A foreman has so many things to do! He is being crowded for production, for cost control, for quality control, for work simplification and methods improvement, and the management people who are pushing many of these other activities are not always alert to the important job of influencing the behavior of employees. And yet if we allow the job of influencing behavior to be neglected, the whole operation deteriorates. Controlling the behavior of people is still the most important function of the foreman; in fact, the very reason for his existence.

So it is up to us to see that foremen get training in job instruction. I won't insult your intelligence by telling you how it is done because I think you already know. Call it JIT or call it the Allen Method or call it by any new-fangled name that has been invented, foremen need it and most of them

will not acquire it by absorption. We have to teach that over and above the knowledge and skill needed to do a job, it requires a very special skill to teach the job and we have got to teach people the old JIT maxim that if the student hasn't learned the teacher hasn't taught.

This job of learning and improving instructional methods has to be continuous. If the instruction dies out good practices become neglected, as many of us can attest from observation.

But how to keep teaching the same thing over and over? That is what so many training men and safety men ask me. Don't people get tired of the same thing and just stop listening?

No, people don't get tired of it if we use our imagination and skill in presenting it. Here are just two ideas for keeping instruction alive and keeping it new and interesting:

1. Start a program of getting foremen to work on safe work methods and job breakdowns for the jobs in their departments. Possibly tie this up with accident investigations. Hold some meetings, discuss with them the best methods and have them tell their experiences in teaching.
2. Let foremen learn by teaching others how to instruct. Practical training men know that job instruction is more often done by other people than by the foremen. And yet when job instruction is taught it is usually taught only to the foremen. If this job instruction by other workmen is to be done right, the people who do it have to be taught and the foreman is the one who should do it. This is the best possible instruction for the foreman who, even as you and I, learns best when he tries to teach others.

That's about enough to say about job instruction and I haven't said anything new but if I have started you thinking again about something that you long ago thought was good but that finally fell into disuse it will serve a useful purpose.

Now let's look at attitudes, the way people feel about things. I think when management people talk about attitudes for safety they really think about attitudes for

accidents. A few years ago President Dearborn of the National Safety Council made a speech called, "Seven Deadly Beliefs." In this speech he pointed out that all of us run into danger because we believe such things as these—that accidents are an act of God, that taking chances is necessary in order to get the job done, that safety is for weaklings, that too much safety takes all the fun out of life, that people will think we are afraid if we practice too much safety.

Now that kind of preaching is all right and we need some of it but if we are going to influence people for safety we have to concentrate also on some safe attitudes rather than on unsafe attitudes. I have asked many in groups of safety men to tell me some safe attitudes and I find that it is pretty hard to think them up quickly. This indicates to me that we do concentrate more on the unsafe attitudes than we do on the safe ones. Let me give you a few safe attitudes that I think all of us need to know and teach.

An accident can happen to me at any time when I take a chance.

Accidents can always be prevented.

It is a mark of good sense and skill to work safely.

We can always take time to work safely.

The men I work with will think well of me if I practice safety.

Many other safety attitudes could be added to this list and I would like to suggest to you that if you hold safety meetings you make this the subject of a meeting. Let each man tell you what he thinks is the most important safe attitude and then discuss them.

In order to build safe attitudes among employees, it is necessary for management people to know what they themselves believe about safety. We should have these safe attitudes straight in our own mind if we are going to impart them to somebody else. We have to make a conscious effort to get people to accept these very attitudes.

Now how do we get people to accept attitudes? Consider for a moment how attitudes develop.

Attitudes grow in an environment that is favorable to them. They grow as a result of example. They grow if the safety in-

struction is consistent. They grow if the instruction is backed up by firm supervision. They grow if people have a chance to talk about how accidents can be prevented. They grow if the men themselves have a part in the whole safety effort and if their part is recognized.

Creating the environment, setting the example, giving the instruction and discussing safety with the men is a job for the foreman to do but again who teaches the foreman? We are the specialists. If we don't do it it won't get done.

That is a pretty brief discussion of the development of safety attitudes but possibly just mentioning some of these things will cause you to think about them and if you think about them I'm sure you will know the answers.

Finally let me come to that very troublesome factor in accident occurrence, temporary states, physical, mental and emotional.

This is the toughest of all. In accidents I have observed, in unsafe and harmful conduct that pops up every day, in my own personal life, the bad temper, the forgetfulness, the abstraction due to worry about real and imaginary troubles, the anger at unfair treatment, the lassitude due to fatigue and boredom and ill health, these are the states that I know the least about curing, but we can't pass them up just because they are difficult to handle. We have to do something about them.

I used to tell foremen that the remedy for these temporary states is to be alert and to know when men are troubled and to give them help and advice. I was always pretty satisfied with this solution until I ran into a bunch of foremen who were not properly docile and respectful. In effect what they said to me was, "O yeah? How do we know when a man's got trouble? Maybe he doesn't want us to know. If we do know, what can we do about it? Can we say, 'Don't worry now. It isn't as bad as you think.' How can we say that? Maybe it's worse. And anyway, the man has to work. Pulling him off the job would only add to his troubles."

So I asked these foremen what they thought we should do about these men with troubles. And we talked about it for three or four sessions. Here are the best thoughts that we could come up with.

First, counselling and helping are OK if you get a chance and if it seems called for.

Beyond that, remember that many of the troubles and frustrations are job created. Let's try to keep from causing troubles. Let's always be available when men have gripes or a worry, not to soothe them, but to try to do something about the thing that is bothering them, before it gets to the point of a neurosis.

You know we talk a lot about men who bring troubles to work. Let's think about the fellows who take work troubles home with them. Psychiatrists tell us that much domestic trouble and illness and many off-the-job injuries result from worry about job troubles. We tell the foreman to say good morning when men come to work. Do we think enough about being around to say good night when they leave so that when they go home they won't have that gnawing feeling that maybe the boss is mad at them, or that he has forgotten some complaint or request made during the day.

So much for preventing the troubles, but there is more. We know that everybody has troubles of many sorts and we can't cure them all. But we can teach people well enough and supervise them well enough and develop good enough work habits so that even when a man is disturbed he won't get hurt. That is not too difficult and we can apply it to ourselves as well as to the men who work in the shops.

And we can create safe working conditions so that safeguards will protect the fellow who forgets. Actually, many of the most familiar safety devices and guards are not needed at all when we are fully alert but are there to protect us when we forget.

Again, I say that a very large number of the serious accidents result from temporary states, physical, mental and emotional, and that you and I and our friends and our families are subject to these states just the same as the man on the job. Together, we and all the other management people should give consideration as to how we can prevent these states from resulting in job injuries.

These are just a few of the things that we can do about the three factors we have been discussing:

1. Knowledge and skill.
2. Attitudes.
3. Temporary states.

I am aware that some of you are saying, "Well OK, but that's pretty elementary stuff. He hasn't told us anything new." But listen to this. I have been talking to people about their safety programs and I find that many of them are giving almost no time to activities consciously and specifically aimed at improving behavior. Why?

Here is what they tell me: "Oh, we had some job instruction training once quite a long time ago." I can't refrain, in that connection, from reminding you of the old gentleman in the club who was talking with a member whom he had just met. The member offered him a drink and the old gentleman replied, "No, I tried it once, didn't like it." "Then, how about a smoke?" "No, tried that once, didn't like it." "Like to play cards?" "No, tried it when I was young, didn't like it."

About this time a young man walked in and the old gentleman introduced him as his son. Whereupon the member who had been attempting to cultivate his acquaintance said, "Your only child, I am sure."

Let me assure you that training and job instruction tried once, a long time ago, is not enough. If it is not done continuously it dies, and you and I have seen it die. Another thing that safety men tell me is that they tried a program of having their foremen talk regularly to their men about safety. But the foremen got tired of it, couldn't think of anything new to say and so it just petered out. That is an excellent program.

Some companies with good safety records say that it is the most important part of their whole safety program, having a foreman talk to two or three men every day about safety. But it won't work unless it is kept alive and promoted by some management person, and that ought to be the safety man or the training man. The companies where it works best have occasional meetings with their foremen in which the foremen all exchange experiences and tell about the things that they have been talking about with their men. But it will die just like job instruction training will die if you don't keep pushing it.

The bottom recorder in the operator's station presents the profile of the basis weight as the gauge scans across the sheet. On the return scan the target weight is shown as a straight line. The scale on the recorder shows the position of the slice screws. This enables the machine tender to reference the weight variation to the appropriate slice screws and make the necessary adjustments. Because six to ten profiles per reel are obtained, more uniform profiles result.

The top recorder, on the Operator's Station, presents the averaged basis weight of each scan across the sheet. This is presented as a straight line on the scale that reads in absolute basis weight. The actual weight seen by the gauge is then compared to the target weight. If this weight varies from target more than is desired, a signal is fed to the automatic control, contained in a second electronic console. The control opens or closes the stock valve or stuff gate to make the appropriate correction to basis weight.

Presently, there are more than 150 Accu-Ray Basis Weight Systems on Fourdrinier and cylinder paper making machines. More recently, systems have also been installed on off-machine coaters. More than 177 systems are installed on coaters and gummers. Also, more than 140 systems have been installed on extruders and extruder laminators. Different types of source detector units are designed to do specific measurement jobs.

U-Frames are used in a number of applications, available for sheet widths up to 160 in. Source detector units are designed for the metals industry. One used on high speed steel tandem mills weighs in excess of 2500 pounds, to give you an idea of the ruggedness of design. There also are "O" type brackets.

Another application of the absorption principle of radiation is used in the measurement of fluid, slurry, and in some cases, solids streams. The signal can be fed to a recorder or recorder controller for manual or automatic control of the process.

These composition analyzer systems are being applied today in pulp and paper mills for black liquor, lime and slurry, white liquor, calcium hydroxide slurry, clay slurry and clay-starch slurry measurements. They are also being used to control evaporation, absorption, extraction, drying, mixing, classi-

fication, filtration, size reduction, material handling, and filling operations in industry.

II. Blocking of Radiation

In this case we find level measuring devices in which the mass of liquid or solid material blocks the radiation between the source and detector. This principle can be used for detecting levels in vessels with solid walls, such as steel and concrete, without having any contact with the material within the vessel. By extending the detector, this principle can be used to measure continuously the level of material in a tank or bin.

These level measuring devices are of interest in pulp mills for level measurement in a number of areas. Digester level specifically has received considerable interest. Since this type of measurement system was introduced some three years ago, over 400 devices have been installed.

There are some other interesting applications of this device. Since it can "see" through solid walls, it can be looked at as a sort of gamma radiation photo cell. It can be made to disregard foam, froth, dust, and other gaseous materials. It will average out turbulence and occasional interrupting matter such as agitators and paddles and will be unaffected by them.

There is an installation on a clinker cooler in a cement plant. The source looks through the walls of the cooler and measures the height of the bed of hot cement clinker. This level is controlled to permit the most efficient operation of the cooler.

Another installation uses two level switches on a standpipe feeding powdered coal to a boiler in a power station. The radiation passes through the stream of powdered coal. If the coal bridges the pipe, the radiation is cut off and the switches initiate a shakedown to remove the coal build-up.

The blocking principle can be used to detect the height of fill in cans on a conveying line and the signal is used to control the filling machine. Underfilled or overfilled cans can also be automatically rejected from a conveyor line using a similar system.

Of course, the one outstanding advantage of these systems is that level, density, weight, or thickness can be accurately measured without contacting or without affecting the measured material.

What is involved in the use of radioisotopes? We have discussed why and where radioisotopes should and can be used. Let us turn for a moment to see what radiation really is.

Over simplifying, there are two types of radiation. The first of these is Corpuscular radiation. This type of radiation exhibits the properties of particles such as size, weight and velocity. The flow or movement of electrons is an example of corpuscular radiation.

The second type of radiation is exhibited in wave form. Heat, light, and radio waves are examples. Wave radiation covers the spectrum from alternating current, radio and ultra high frequencies, infra-red, white and ultra-violet light, x-ray and gamma ray, and finally, through the cosmic ray region which possesses the highest frequency and energy level and shortest wave length of all energies in the spectrum.

There are approximately 50 radioactive elements found in nature. Radioactive means that the element is unstable and the atoms are disintegrating or emitting a charged particle from the nucleus. Eventually all radioactive elements reach a stable form. When a half life is mentioned for a radioisotope this means the time required for one half of its energy to be emitted. The half life will vary for every radioisotope from seconds to thousands of years.

Radiation can be found all about us in nature. For example, there is enough Potassium 40 found in the average human body to emit 150,000 beta particles per minute with energies up to 1.5 MEV. Carbon 14 is continuously being formed in the atmosphere by the action of cosmic rays on nitrogen in the air.

Radioactive isotopes are generally referred to today as being artificially created since they are produced from a chemical element not normally radioactive. Bombardment in a reactor rearranges the neutrons and protons in the nucleus of atoms of these elements.

There are various types of radiation being used in industry. These are:

(1) *Alpha radiation:* This is radiation of a helium atom nucleus (helium atom without two electrons). Alpha particles have a large mass and a slow speed. A few inches of air will stop alpha particles.

(2) *Beta radiation:* This radiation consists of high speed particles, electrons, with little mass. Approximately .030" of steel is required to stop these particles.

(3) *Gamma radiation:* This is high energy wave type radiation, and 0.65 inch of steel or 4 inches of water is required to cut this radiation in half. A fourth type is X-radiation, and Bremsstrahlung, both of which exhibit the same properties as gamma radiation. (a) X-radiation is generated by high voltage acceleration of electrons, generated by heating an electron emitter. These electrons are directed to strike a target, generally tungsten, and the X-ray is generated. (b) A similar technique using a beta radiation emitter (electron) and striking a target will produce higher energy radiation called Bremsstrahlung. Except for energy levels and method of generation, these two types are identical.

Let us define terms used in radiation.

Curie: This refers to the quantity or amount of radioactive material present. A curie is defined as the quantity of radioactive material in which 3.7×10^{10} atoms disintegrate in each second of time. This term is analogous to power in electricity.

MEV: Million electron volts. Refers to the energy level of the isotope. This is analogous to voltage in electricity.

Röntgen: A röntgen is an energy measurement difficult to express, however, this can be done practically by defining energy in terms of the specific effect produced in a specific apparatus. The most convenient method is to collect and measure the number of ions, caused by radiation, produced in a given quantity of air. The röntgen is a unit of dose of total energy exchanged. The intensity of a radiation beam is expressed in terms of dose per unit time and the common terms is roentgens per hour, or more commonly, milliroentgens per hour, abbreviated mr/hr. The reading of an ionization survey meter can be in mr/hr and can be used to determine the radiation intensity level around an isotope system.

Dose: Is the quantity of radiation absorbed, per unit of mass, by the body or any portion of the body. Total dose will specify an amount over some period of time. Several units of a dose are in current use, however, the most common is the rem. A. E. C. Regulation 10CFR20 gives infor-

mation to compare this measurement to other units if necessary. A rem is defined as a measure of dose of any ionizing radiation to body tissue in terms of its estimated biological effect relative to a dose of one roentgen of X-rays.

Let's now consider the actual construction of the source itself and its housing in a source-detector unit used in an industrial measurement system. The size of this hermetically sealed unit is about as big around as a nickel and about $\frac{1}{8}$ to $\frac{1}{4}$ inches high. The source is then placed in the source holder assembly with a shutter assembly. The shutter is power activated and spring closed so that in the event of a power failure the shutter will automatically close. It is mounted on a "U" frame, and the access panel contains a lock to prevent unauthorized entry.

An alarm window protecting the source is a printed circuit. Should any one attempt to get into the source from this side the circuit is broken. Once the circuit is broken an alarm horn sounds and the shutter automatically closes. The horn will continue to sound until the window is replaced or power is removed from the gauge.

In the density gauge, the source capsule is sealed in mechanite. The mechanite is welded onto the process pipe, allowing a small air space. This type of gauge has no shutter since it becomes an integral part of the pipe.

In a small radium source unit used for level once again we find the source sealed into the unit. Because of low radiation levels no shutter is required on such a unit.

In a larger source unit used in level devices a center "cannon ball" rotates, focusing the radiation into the solid mechanite, reducing radiation to low levels. The unit can be locked in this position, thereby permitting handling or entry into the area of the measuring beam.

The largest of the source units will take up to 1 curie of Cobalt 60. The weight of this source assembly is approximately 850 pounds.

What must be done to get isotopes into the plant? Uses of radioactive isotopes fall under the jurisdiction of the Atomic Energy Commission. This agency has very actively promoted the use of isotopes and has been extremely helpful to potential users. In or-

der that the safe use of isotopes is assured, certain restrictions and precautions govern the use of isotopes.

Regulations pertaining to radiation devices are contained in A.E.C. Regulations 10CFR20 "Standards for Protection Against Radiation" and 10CFR30 "Licensing of By-product Material." This type of equipment can be obtained under either specific or general license.

Specific licenses are granted by the A.E.C. to cover specific situations such as the distribution of isotope gauges and to cover their use in specific situations or applications.

The Commission has also attempted to encourage the broad use of isotope radiation equipment by setting manufacturer's standards compatible to safety requirements of other manufacturers of industrial equipment. If certain conditions are met by the manufacturer of isotope equipment and other requirements are met by the user, the user can acquire radiokotope systems under a general license covered by 10CFR30, Par 30.21c. This exempts the user from the conditions of 10CFR20 except for those sections dealing with reporting of accidents.

I suspect that some of the above has been confusing. If it has, further studies of the A.E.C. regulations is recommended if you have or contemplate isotopes in your plant. I also suspect that once you are familiar with the subject it will be no more confusing than your electrical or building codes. Whether you are licensed generally or specifically, there are some reporting requirements involved:

1. Theft must be reported as explained in 10CFR20

2. Telephone and telegraph reporting to the A.E.C. on any of the following:

- Exposure of any individual to 25 rems or more of radiation
 - Release of radioactive material, averaged over a 24-hour period, that could exceed 5000 times the stated limits.
 - Loss of one work week due to the operation of facilities
 - Damage to property over \$100,000.
3. 24-hour notification by telephone or telegraph.
- Individual exposure of 3 rems

b. Release of material, averaged over 24 hours, that could exceed 500 times the stated limits.

c. One day loss of facilities

d. Property damage over \$1000.00.

4. 30-Day report

This report is generally necessary with accidents less serious than the above, where individuals have received some excess of permissible radiation levels. This report would contain notes to the above and precautions for the future.

Before leaving the subject, I must mention that most states also have regulations concerning isotopes. It would be well to be knowledgeable in this area also. Another good practice is to inform your plant fire group of the locations of isotopes, or at use town facilities, the town fire marshal should also be informed. The use of radiokotopes does present potential hazards from exposure to radiation fields and contamination by radioactive material. The Atomic Energy Commission governs both areas very closely. Additional safeguards are imposed by the manufacturer of the device, local authorities, and plant safety groups.

Exposure to radiation fields is minimized by the manufacturer of these devices through the construction and location of the source unit. For example, Industrial Nucleonics restricts the maximum radiation field to 5 mR/hr at 12 inches from any surface which is normally accessible to personnel. In most AcumRay equipment, external radiation is far below this figure. Contamination by radioactive material presents the greatest potential hazard with the possible exception of exposure to gaseous sources. Great care is taken to prevent any possible contamination.

If plant safety groups are not directly concerned with plant insurance, you are probably expected to know to what extent and degree the use of isotope equipment could affect your insurance coverage. In general, two distinct types of insurance are involved with the ground rules different for each. These are general liability and fire insurance.

General liability provides third party coverage to property and persons. Industrial Nucleonics Corporation General Liability would cover the claims of our customers. General liability policies have nuclear exclu-

sion clauses but these clauses do not apply to our types of equipment.

The second form, fire insurance, covers loss of property and profits or the loss of the use and occupancy. The nuclear exclusion clause does apply in the case of fire insurance.

Having radiation devices does not void fire insurance, but if you want to be covered for loss caused by radioactive material you would have to pay a surcharge. This surcharge depends on the type of structure covered and other considerations. It would be determined in the same manner as standard fire insurance is determined. For example, the rate would be higher if the type was located in a frame building rather than in a brick or concrete structure.

These devices have been through fires, floods, and explosions and no additional loss has been incurred due to the presence of radioactive material. Because of our rugged construction, as you have seen, we have been able to maintain this record with more than 3,000 installations scattered throughout industry.

Examination of a density gauge after it had been through an explosion and fire in a rocket fuel plant revealed no contamination, even though the source detector unit was badly damaged.

Unfortunately, insurance companies do not yet recognize improved encapsulation techniques, or other safety techniques. In some instances, where a gaseous source is used, common in the paper industry, no contamination hazard is present.

Some of our customers pay the additional surcharge for the added protection in their fire insurance policies. Others do not feel the risk of loss caused by radioactive material contamination is worth the extra charge. In no case has a customer decided not to install the device for insurance reasons, as very little risk is involved.

Before, during and after installation it is extremely important that all personnel coming in contact with the unit be thoroughly instructed in the matter of radiation safety. The manufacturer of the equipment should be properly equipped to give assistance in this area.

What must be done on a continuing basis once isotopes are in the plant? With the radioactive material in the physical and

chemical state described above, the likelihood of failure of the encapsulation is extremely low. If a failure were to occur it is thought that it would be extremely gradual. The initial indication of such failure would be the presence of radioactive material on the external surface of the source carrier. The presence of such radioactive material would be detectable by wiping its surface with a test swab and inspecting the swab for the presence of radioactive material with high-sensitivity radiation detection equipment. The sensitivity of these tests permits detection of the presence of radioactive material in quantities hundreds of times below the amount considered hazardous. Such tests are routinely carried out at six month intervals, either by the gauge supplier or by the user when he has suitable facilities and personnel.

In closing let me compare the safety aspects of a radiation level device with that of conventional methods of tank level control. Suppose the radioactive level device was used to measure level in a 10 foot diameter tank 10 feet high. The device would be used to turn on and off a pump in order to maintain the desired level.

The presently used technique might be a float system. This system would inherently

have more failures than a radiation level device. Therefore, someone would be required to climb into the tank periodically to check and repair the float system. Certainly climbing a ladder is not a great hazard but it is more of a hazard than standing on the ground.

Assume that operating procedures called for cleaning and painting the inside of the tank every three months. Warning signs mounted at the access to the tank would instruct personnel to close the source shutter before entry. With the shutter closed there is no possibility of entering a higher than tolerable radiation field.

There is, of course, always the possibility that a negligent person will ignore the warning. The danger of this is no greater than that of ignoring a warning sign on a 440 volt electrical line. The results of the negligence is a different matter. In the case of radiation received for a limited time, it is unlikely that any damage to the individual would occur. In the case of ignoring a power line warning it is likely the person would be injured, perhaps fatally.

Look upon radiation devices as an extremely useful form of energy offering many industrial benefits. Properly used, they are worth their weight in gold.

SAFETY IS BUILT INTO THE KAMYR CONTINUOUS DIGESTER

By O. A. LAAKSO
Kamyr, Inc., Hudson Falls, N. Y.

There are in operation today a number of distinctly different types of continuous cooking systems, each one custom-designed to handle a particular raw material, utilizing a specific process, producing a particular grade of pulp. This paper deals with the subject of how safety is built into a continuous digester.

On the North American continent the greatest interest today is in kraft cooking, and so we shall in this paper deal with the continuous kraft digester. In order to discuss the safety aspects of the unit, it becomes necessary for us to go into a gen-

eral technical explanation of the principles involved in a continuous digester of this type.

First, let us examine the basic difference between the familiar batch process and the continuous kraft process. In a batch operation a vertical stationary digester shell is filled with chips, along with the required amount of cooking liquor, and spent make-up liquor. The vessel is capped, and steam is applied to the system in order to raise the material to cooking temperature, and is held at temperature for the time required to complete the reaction. Non-condensable gases are

released from the digesting vessel during the rise to temperature, and the pressure in the vessel is approximately equal to the corresponding vapor pressure of steam at the cooking temperature.

In this type of system there is a tendency for overcooking the outside of the chips, and undercooking the center of the chip, due to the fact that impregnation of the wood chip with chemical takes place during the rise to temperature. There is also lack of uniformity between the top and bottom of this vessel due to the fact that the chips at the bottom are getting a partial pressure impregnation, due to the static head of liquid, while the chips at the top of the vessel are barely being washed by the liquor.

This lack of uniformity in the batch digester was the initial basic reason for designing the equipment to conduct the process continuously.

Basically, the typical kraft continuous digesting system consists of the following steps:

1. Metering of the raw chips together with a light presteaming to prepare them for impregnation.
2. Impregnation with cooking liquor at 220°F to 240°F for approximately $\frac{1}{2}$ of an hour.
3. Uniform rise to temperature.
4. Adequate time at temperature with no mechanical action on the chip. This is accomplished by two independent liquor circulation systems, one at 15 psi pressure using the chip chute pump, item 7, which pumps liquor into the chip chute and flushes chips and liquor into the through-type pocket of the feeder when the pocket is in the vertical position. The chips are retained in the pocket by a coarse grid on the casing while the liquor passes through to the suction of the pump and is recirculated.
5. Cooling and washing of the cooked chips prior to discharge.

Referring to the flow sheet, the foregoing steps are achieved as follows:

Item 1 is the surge hopper, which stores chips at the head of the system; the size of this bin varies from mill to mill, depending on what other storage facilities are available, but in general no less than 20 minutes storage is recommended.

Item 2 is the chip meter, which controls the rate of feed to the system. The meter has a five-pocket rotor, and each pocket delivers its entire contents to item 3, a low pressure feeder. This feeder is a steam valve which holds against the 15 psi chip pre-treatment or steaming vessel pressure.

To avoid damaging the chips, the low pressure feeder—which like the chip meter

has a pocketed rotor—rotates at a faster speed and has larger pockets than the chip meter. The rotor, which is tapered, is equipped with an advancing mechanism to provide clearance adjustment in the casing which is necessary due to wear caused by sand and grit entering the system with the wood chips.

The steaming vessel, item 4, not only acts as the chip pretreatment vessel but also serves as the heat recovery system, since the low pressure steam used for pre-steaming comes from the flash tank located at the discharge end of the digester vessel. Release vapors from the steaming vessel can be piped to a condenser for the production of hot water for pulp mill use. The vessel itself is about 5 feet 6 inches in diameter and 24 feet long, and is equipped with a screw conveyor for moving the chips toward the discharge end. The chip level would be less than one foot high, thus providing the maximum steam volume and opportunity for all chips to become equally pretreated.

From the steaming vessel, the chips fall by gravity into the chip chute, item 5, and then are transferred to the 165 psi operating pressure of the digester shell by the high pressure feeder, item 6, which is the heart of the system. This feeder, traveling in the order of four to six rpm, does the difficult job of transferring chips at 15 psi to 165 psi without performing any mechanical action on the chip. This is accomplished by two independent liquor circulation systems, one at 15 psi pressure using the chip chute pump, item 7, which pumps liquor into the chip chute and flushes chips and liquor into the through-type pocket of the feeder when the pocket is in the vertical position. The chips are retained in the pocket by a coarse grid on the casing while the liquor passes through to the suction of the pump and is recirculated.

When the feeder pocket rotates 90 degrees to the horizontal position, the second circulation system using the top circulation pump, item 8, flushes the chips out and on up to the top of the digester shell. This circulation pump derives its suction from the top of the digester vessel, where the liquor is separated from the chips by means of the top separator, item 9, which consists of a cylindrical slotted screen equipped

with a cleaning screw to ensure chips moving down into the digester.

The high pressure feeder has been made a continuous operation by having four through-type pockets at 45 degrees to each other, thus insuring that at all times there will be the equivalent of one full pocket in the filling position. The feeder, also having equal pressures on both sides of the pocket in both the filling and discharge positions is completely balanced and requires a minimum of horsepower to operate.

The rotor of this feeder is tapered to allow for wear, and because of the high pressure in the discharge position, a slight flow of liquor takes place from the high pressure side to the low pressure side, thus providing a seal of lubricant liquor in which the rotor rotates. As the pocket will be filled with liquor in the discharge position, this liquor in turn provides the flushing medium when turned to the vertical position and an excess is built up and carried away to the liquor supply pump, item 10, to be returned to the digester shell, item 12, along with the make-up cooking liquor and the necessary bulking spent liquor. This liquor is pumped to the digester at a hydraulic pressure of 165 psi.

In order to have distinct temperature zones in the digester shell, the liquor is maintained as indicated above at a hydraulic pressure of 165 psi, which is higher than the vapor pressure at the highest temperature in the shell. All boiling has been eliminated, and due to the faster rate of chip flow downward, the rate of heat conduction upward has no effect in maintaining a relatively cool zone at the top of the vessel. In the upper portion of the shell, therefore, impregnation takes place with the active alkali at a temperature of 240°F, and not until the chips are approximately one-third through the vessel are they subjected to the higher temperatures.

The rise in cooking temperature is accomplished by two separate liquor circulation pumps, items 13 and 14, each deriving liquor suction from headers, nozzles and slotted strainer plates located inside the digester shell. You will notice that the inside diameter of the strainer plates is the same as the inside diameter of the digester shell in the penetration zone, the shell increasing in diameter to provide the space required

for the screens without having to reduce the diameter of the chip plug moving down the shell. Heating can be provided by indirect tubular heat exchangers, or direct steam, the heated liquor being returned to the digester by means of two central pipes, one inside the other, each ending at the top of its respective strainer zone.

The upper heating zone will increase the temperature from 240°F to, say, 300°F, the second zone from, say, 290°F to 330°F, the blank space between each zone being a dwell zone or equalization area where the temperatures of each individual chip evens out throughout its mass. No further heating takes place, and the chips are retained at cooking temperature according to a cooking graph until they reach the discharge zone some 90 minutes later. To avoid fibre degradation while still at cooking temperature, it has been found most essential to cool the chip mass in the digester shell prior to discharge, before subjection to the action of the bottom outlet device, item 18, a slowly rotating paddle required to break up the compressed chip mass prior to actual discharge from the shell.

Cooling is performed in a manner similar to the heating mentioned above, by introducing spent black liquor at approximately 180°F from the brown stock washing system through a high pressure pump, item 19, and through a small central pipe inside the two heating zone central pipes, and discharging into the chip mass at the top of two further slotted strainer plate sections. Again, the digester shell diameter is increased to maintain a uniform chip plug diameter. With the addition of the cool liquor, the hot high solids liquor is displaced and extracted through a set of screen plates, nozzles, and a header to a flash tank, item 20, where the hot liquor is flashed at 15 psi and the resultant flash steam going to the pre-steaming vessel, item 4.

Although the one-to-one displacement gives the maximum heat recovery from the system, it does not sufficiently lower the temperature of the chips to a point where degradation cannot occur, so further cooling is added and extracted as above to a second flash tank, item 21, where the liquor flashes at 0 psi. Also, the liquor from the first stage flash tank flows to the second stage flash tank and flashes at 0 psi. This

steam can be piped with the relief from the steaming vessel to a condenser for the production of pulp mill hot water. This system, now referred to as the diffusion-extraction system enables the stock to leave the digester shell at approximately 200°F or less.

This system although installed primarily for uniform cooking with maximum heat recovery, also results in improved brown stock washing. It is obvious that the high solids liquor is being removed from the system before the pulp goes to the washers and can be sent directly to the multi-effect evaporators, thereby reducing the load on the washing system. In effect, we have now introduced a partial washing stage in the digester shell.

Relief of the digester pressure is taken care of in the blow unit, item 22, which is a pressure vessel equipped with a variable orifice blow valve and a rotating wiper paddle to keep the outlets free of knots or foreign materials. The pressure drop is accomplished in the blow line through two valves; and as most of the heat has already been removed from the chips by the diffusion-extraction system, discharge can be made into an atmospheric blow tank.

Having covered the general principles of the system, let us now examine the potential danger points in the system and the steps we have taken to ensure safety of operation.

First, with reference to the pre-steaming vessel—it has been designed for an operating pressure of approximately 15 psi with a maximum pressure of 30 psi. The vessel is equipped with a relief valve discharging to atmosphere in order to prevent overpressure. Since the vessel is filled with chips and steam, it has been necessary to place a screen in the relief line at the point where it is connected to the steaming vessel shell. A small 40-pound steam line is connected to the relief line behind the screen. Periodically the operator will clean the screen by blowing back into the steaming vessel with 40-pound steam.

The lower portion of the steaming vessel is clad with stainless steel for 180 degrees of the surface. This cladding is necessary to combat the erosive action of the chips and the corrosive action of the condensate cooking from the chips. The steaming ves-

sel should be checked at least once a year internally for signs of corrosion.

The high pressure feeder also acts as a sealing valve between the digester which is at 165 psi pressure and the steaming vessel which is at 15 psi pressure. You will note from Fig. 2 that the high pressure feeder is so designed that at no time is the high pressure side of the system connected to the low pressure side. Thus if there is a power failure, there is no danger of a blow-back of high pressure liquors from the digester to the steaming vessel.

The digester shell is designed with extreme care, from the point of view of safety. The smaller shells up to, say, 150 tons per day capacity are shop-fabricated to ASME code specifications and are completely stress-relieved and tested to 280 psi, as compared to the operating pressure of 165 psi. Generally, digesters with a capacity of more than 150 tons per day must have field-erected shells. In this case, rolled cans are shipped to the site and the complete shell is erected and welded in place. After welding, all welds are X-rayed. After approval of the welding, the exterior of the shell is insulated and the entire shell is raised to a temperature of 1100°F for stress relieving. After stress relieving, the shell is hydrostatically tested to a pressure of 280 psi at the top.

Since this particular type of continuous digester operates with the vessel 100 per cent of liquor at all times, and since the digester is held at a uniform temperature for months on end, we do not appear to suffer from the shell corrosion that is so common in batch digesters today. The units in operation on this continent today show negligible loss of metal on the shell walls due to corrosion. However, as a precautionary measure, we still include approximately one-quarter inch of shell wall thickness as corrosion allowance over and above the code requirements. It is advisable to audit the shell wall every year or two during the first five years of operation to determine if your particular combination of liquors and woods is resulting in any corrosion.

We have had some history of erosion in the bottom head of the digester at the point where bottom scraper has been discharging the chips. We today stainless-clad the bottom head to combat this erosion.

We have had some history of corrosion in the top head of the digester due to improper relief of the vessel allowing a small vapor pocket to form. We also stainless-steel the top head of the digester shell as a precautionary measure.

The digester shell can be completely isolated from the feeding and discharge system by closing valves 51, 52 and 81. This is normally done when stopping operation for short periods of time due to interruptions in the rest of the mill and in some cases as a regular practice, where mills operate for only six days out of seven in the week.

Since the material in the center portion of the digester is at a temperature of approximately 340°F and the material in the top portion of the digester is at only 240°F, there will be a gradual rise in temperature of the liquor in the upper portion of the digester. This results in a thermal expansion and it is necessary for us to provide a relief valve to compensate for this. This relief valve must operate under difficult circumstances, since the material in the digester is a mixture of super-heated liquid and chips.

The relief valve utilized in this case is valve P10 on the flow diagram. This is set to automatically open if the digester pressure rises to higher than 185 psi. The amount of liquor that has to be extracted from the shell to compensate for expansion is very small.

There is always the possibility that the relief valve would open to compensate for thermal expansion and then would remain open due to being plugged with a small chip under the seat. This could result in draining liquor from the digester shell. In order to combat this we connect the relief line to the shell behind the cooking circulation screen.

We also provide valve 55 immediately ahead of the relief line. This is a hand-operated shut-off valve and should be wired open. In the event of valve P10 failing to close, the operator can close the hand

valve to prevent complete drainage of liquor.

The piping on this type of digesting system must be designed to take care of rather large expansion problems. All piping connected between fixed equipment and the digester shell is provided with expansion loops, and in some cases the pumps and heaters are equipped with spring-loaded foundations to allow them to move upwards and downwards with the digester shell.

Special safety switches are provided between the digester shut-off valves 51, 52 and 81 and their connecting piping. These valves cannot be opened until the connecting pipelines have been filled with liquor and brought up to pressure. If it were possible to open these valves without the connecting lines being filled with liquor, the high pressure liquor in the digester would be released at such a high velocity that the feeders connected at the other end of the pipelines would probably be torn completely from their foundations and the pipelines would most probably rupture. Great care must be taken to see that the pressure switches on these lines are not by-passed.

All piping connected to nozzles at the digester shell utilize male and female flanges at the point of connection to the digester. This is done in order to reduce the possibility of blowing a gasket at the digester shell.

We have, in the course of this paper, covered very briefly the general principle of the operation of this type of digester and have enlarged on some of the major facets of the safety features which we do build into the system.

A digesting system such as we have described is simple, and safe to operate so long as the safety features which are designed into it are not by-passed. Thus those people connected with safety in the mill should make sure that modifications are not made to the system without investigating to determine how they effect the safety features which have been incorporated into the original design.

WHAT DOES TOP MANAGEMENT EXPECT FROM AN INDUSTRIAL SAFETY PROGRAM?

By G. A. OECHSLE
Plant Mgr., Continental Can Co., Elkhart, Ind.

I sincerely believe in sound industrial safety programs.

The subject assigned to me—"What Does Top Management Expect from an Industrial Safety Program?"—could possibly be answered in one sentence: *Management expects a safety program that will reduce industrial accidents and their resulting costs to an absolute minimum.*

I'm sure that each of you could probably agree with me that this sentence is, and well should be, the objective of any safety program worthy of the name. I am also aware that each of you is undoubtedly better versed in the field of industrial safety than I am—so while some of my observations may seem somewhat basic or elementary to you, at least they will give you an idea of what one manager expects from safety.

Although there are some rumors to the contrary, top management people are human beings just like anyone else. First and foremost, they abhor the physical suffering which results from any industrial accident, and when such an accident results in permanent disability, or even death, any of you who have had such an experience will attest that the matter is given the attention of even the highest executives of a corporation.

Most states have statutes which fix the amounts of compensation to be awarded for various disabilities, but who can really set a price for the lost limb, the lost eye, or the lost life? Even if the worker is able to resume active employment, chances are that his future earnings may be greatly limited due to his disability. I am sure that all of you probably have some examples which come to mind, especially in the paper-making industry where you are considered a rookie until you have lost a finger or two in a calender stack.

Another group which may well suffer as a result of an industrial accident is the employee's family, not only because of temporary or permanent loss of income of the

bread-winner, or of reduced future income, but also the discomfort and shock of seeing good old Dad laid up, to say the least; or permanently maimed or disfigured, to say the worst.

No good manager can ignore the suffering which can be brought about as a result of industrial accidents, so no good manager can expect less of his safety program than to keep accidents and injuries to an absolute minimum.

Money spent in caring for and compensating those who have experienced needless industrial injuries is pure waste. It adds nothing to the business, and if permitted to get out of hand can well mean the difference between making a profit or not. What top manager worthy of the name can fail to realize the economic impact of unreasonable compensation costs?

This, then—the *keeping of cost to an absolute minimum*—is the second great area of what a manager expects, or should expect, from a good safety program.

I am sure that I do not need to emphasize or even discuss the direct costs associated with any injury. There are, however, indirect costs which are associated with any injury that I would like to call to your attention.

1. *Last production.* This occurs when the injured employee is part of a crew, and, without the injured employee the crew cannot function.

2. *Repairs and waste.* This is something that each year adds thousands of dollars to our cost of doing business and something which management wants to see reduced.

For example, the power truck driver who drives into a retaining wall, or loses a load of cartons or board and a truck off the end of a loading dock. I'm sure this is a familiar area to most of you.

3. *Morale effects—Supervisory time lost.* The effect on the morale of the employees is another cost item difficult to measure in dollars and cents, but can be substantial.

JOINT SESSION WITH WOOD PRODUCTS SESSION

SAFETY IN PULPWOOD LOGGING

By CHARLES T. WRIGHT
Safety Eng., American Mutual Liability Insurance Co., Raleigh, N. C.

Last February, I had the pleasure of meeting with the Safety Section of the American Pulpwood Association in New York at their annual convention; an informative meeting.

Many constructive ideas and plans were developed. However, on several different occasions, I heard the supposition mentioned that a rather wide difference in educational levels exists between worker groups in the woods in different geographical areas of the United States. Somehow, this so-called "educational level" was getting the blame for differences in work methods, types of tools, etc., between different geographical areas. The impression was left that this somehow created an insurmountable problem safety-wise. Nothing tangible, mind you, just an impression.

For instance, one man gave an opinion that this "educational difference" is the reason the bow-type chain saw is used down South while the blade-type saw is used farther North. I leave it to you to judge whether or not this is significant in the measure of accidents.

I mention all of this only in making the point that we sometimes use pointless and often unrelated excuses for not having effective accident control in our operations. Is it not a fact that when we have a problem to cope with we must take *whatever* approach and action is necessary to an effective solution? You might say that "Teddy" Roosevelt's policy of "walk lightly but carry a big stick" meant that when he had a tough problem he managed to get just a little bit tougher and solve it for a desirable solution.

About two years ago the North Carolina Forestry Association decided something had to be done in the logging and lumbering industry in North Carolina, as a whole. Putting their decision into action, as a first step they organized an insurance committee and began doing research analysis to de-

termine just what the reasons were behind the high cost of insurance in logging operations.

The committee, after much study, found out what insurance companies and the various state labor and compensation departments had known for some time. They found that while a number of factors were actually involved, just one major item was visibly responsible. What was this? Just this: The logging industry was having a high frequency of accidents which were, for the most part, of a rather severe nature. That is, they were costing a lot of money in hospital bills, doctor bills, and in many other tangible, directly related ways. All of this cost was in addition to the very high cost of inefficient operations which resulted from the same basic causes as the accidents.

What are these basic causes? The most important, at least the most basic and most in need of immediate attention, were:

- (a) Lack of adequate top management safety policy.
- (b) Poor to no enforcement of any existing policies.
- (c) Poor liaison or supervision between management and field.

The basic lack of top management policy had resulted in a disparity in equipment, tools, etc., used in the woods. A nearly complete lack of adherence to any safety standards existed. In a nut-shell, everything was wrong. Something had to be done about it.

On receiving the committee's report, the North Carolina Forestry Association and the North Carolina Department of Labor, who had worked so effectively in development of accident prevention in other industries in the state for so many years, called on some of the insurance companies' safety engineering departments to work jointly toward the attainment of the safety objective dictated by the high accident frequency referred to earlier. American Mutual had

opened to be one of those available and willing to do everything within reason to help.

The over-all record in both the pulpwood and saw log experience indicates that a lot of people have either forgotten some of the things they do know, or else they just aren't taking time to plan ahead and be guided by the things they have learned.

The main points we are trying to make here are:

First, people who are concerned with pulpwood in its various phases of production and use, go to great length to assure full growth and high production of pulpwood timber, but give *considerably less* attention to safety, in either the use of proper tools and equipment or in training workmen in safe work methods and practices.

Secondly, I would like to show that these same people are capable of accomplishing the latter by showing evidence of certain types of effective planning which they are doing, in a contrast comparison to some of the weak points where planned attention is missing.

Workmen's Compensation insurance carriers and other organizations, as well as individuals interested in safety, found many years ago that high accident frequency and severity go hand-in-hand with low operating efficiency, and therefore, result in high operating costs. The same sound engineering principles that can and do control accidents will normally produce highly efficient operations as well.

Safety in pulpwood logging can also mean efficiency in pulpwood logging.

The forest in North Carolina is third-ranking in product value in the state. It produces approximately \$730,000,000 in product value annually. The forest is second only to textiles as a source of industrial employment, furnishing 78,000 jobs. The total annual payroll amounts to approximately \$243,000,000.

These figures give us a basis by which we may estimate the value of safety as an efficiency factor. They also provide a measure of exposure to accidents and suffering in the industry as a whole. A relatively high percentage of this exposure, and certainly the majority of severity is to be found in the log woods.

The forest, in most any area, is a beauti-

ful place, that does not readily reveal the vast number of hazards that lie there waiting to trap the poorly equipped, the poorly trained, or the careless pulpwood worker.

The great progress that has been made in controlling and improving the growth of forest timber is phenomenal, to say the least. Read the story in growth rings. Is there any doubt that the same brainpower that has developed such control could also develop controls that would prevent accidents and suffering to workmen? No, I'm sure there isn't.

There are examples of the results of very poor or no attention to planned forestry. Misshapen and damaged sections of trees which you often see are proof that many men in the pulpwoods are operating or have operated unsafely and without planned control of accidents.

An outstanding example of control of timber growth is found when a tight intersection of growth rings indicate the forest was being choked off by too thick growth for the first 15 or 16 years, but after thinning, the width of the growth rings increased immediately. Such a tree grew as much in the last six years after thinning, as in the 15 years prior to thinning.

When you see planning in action, the forester marks the butt of a tree, using a yellow dye and a manually operated pressure can. The tree is marked also at a higher point. When this tree is harvested, it will be cut because it is marked, and the stump, left in the ground, will show the mark. Trees that are not marked will not be cut. This is planned thinning.

The forester checks height of trees, and measures diameter. Often he takes a boring sample as a means of checking width of growth rings to determine rate or speed of growth. Seedling trees are used in reseeded clear cut land.

Certain tools should be available and used by pulpwooders in the woods. Fire control items are a must for a well rounded control plan. Unfortunately, on many woods operations, we do not find these items.

Woods workers must learn basic safety precautions. Often you may find a man filling a chain saw gasoline tank by using an unsafe type can, perhaps with a spout too short and too large to enter the opening in the tank. Gasoline is often spilled on

saws with this type of unsafe equipment. This creates a rather serious burns hazard to the operator, to say nothing of the potential for setting fire to the entire woods area. Explosion is also a major accident producing potential.

Another unsafe operation is often found in starting the saw. On a very still day, the fumes that have risen from the gasoline filling operation are still hovering in the area. When the saw is started, the fumes may be ignited. If the unsafe gasoline can is too close, this can, and probably will, start a fire. It isn't necessary to explain the many heartaches that could result from this unsafe practice.

When felling a tree, the men should be properly equipped with safety helmets. When a tree is over 10 inches in diameter, it should be notched before cutting, in order to be sure of controlling direction of fall. Many other things must be taken into consideration but this is a primary need in directional control.

The men should be warned about felling a tree without first properly clearing or "swamping" on the back side of the cut, although the opposite area is clear enough to allow a proper escape route.

When you see a man pushing the tree with his hand, to control direction of fall, this puts him in a rather awkward position. Obviously it is necessary that he push the tree, because he has not notched it. It is all right to push the tree, but this should be done by another man with a pole long enough to reach well above the man using the saw.

When the tree falls through brush that was not properly cleared before the cut was started, the brush could whip back and strike the eye of the sawyer. A man experienced in this type of occurrence usually will turn his head well away from the potential whipping brush. However, this does not constitute proper protection. Certainly the man should have spent just a few seconds clearing out the area before cutting, thus minimizing the exposure.

When a felled tree has lodged on the heavy limbs on the underside, the sawyer may limb the tree by cutting underneath the log to remove the supporting limb. This means a high probability of the tree falling

and causing injury to the man. He should have properly blocked the tree to prevent its falling. Better yet, proper study of the tree would probably have dictated falling the tree in another direction where there would have been no blocking limbs.

When a sawyer is cutting tree into pulpwood lengths without proper support underneath, his saw will probably hang, creating additional hazards in trying to loosen the saw. It is conceivable that damage could be done to the saw causing interruption of work. Need for proper shoring here is obvious.

Woodsmen must be always on the lookout for the "widow maker" (broken limb hanging above men who are preparing to cut a tree below). Any disturbance of this broken limb could drop it on a man's head or shoulders.

At times you may find a sawyer breaking just about all the rules of safety in felling a tree. You can see that he does not have on a safety helmet. He is pushing the tree with his right hand while holding the saw with his left, throwing himself into a rather awkward position. Then you'll observe the vulnerability of his head to any loose or dead limbs that may be overhead and become dislodged. The brush is so thick that the saw could hang and cause it to jump into the man's leg. Worse, the brush will probably obstruct his escape route. In addition to creating unnecessary hazards, this is a case in point of complete inefficiency in the woods.

After the cut the tree may hang suspended in the air and the men are going to have to cut other trees before they can drop the intended one. This means they will expose themselves to serious "falling objects" hazards.

Proper pre-planning for direction of fall and good clearing would have allowed a clean fall to ground. This further demonstrates what we mean when we say safety and efficiency are one and the same.

When a small tree is bent over by the tree that hung, the man cutting it with a hand axe may be setting up a dangerous situation by cutting from the top side of the tree rather than underneath. With his first cut, a long sliver splits off and springs outward. This frequently causes injury to either the axeman or other personnel. This is a completely unnecessary operation that

could be eliminated or avoided if proper planning is utilized in the first place.

Fortunately, there are occasions in the woods when you see a little more planning for safety. The men are all wearing safety helmets, and are properly dressed otherwise. The sawyer who will be wading out in the swampy areas is wearing snake bite leggings in addition to the safety helmet and good protective clothing. Men with yellow helmets are supervisors. You may see the producer who stays with and supervises this particular pulpwooding crew.

You will see one of the sawyers approaching the tree, with his foreman looking on. The sawyer will be sizing up the tree, determining best direction of fall, etc. He will take into consideration shape of top, location of other trees, direction of wind, velocity of wind, most advantageous point on ground for limbing, etc.

Prior to cutting the tree, the sawyer will use an axe to swamp out around the tree or clear the area for freedom of movement and safety. This is being done to prevent saw from hanging and jumping into his legs and also to give him a clear path to get out of the way of the tree when it begins to fall.

When the sawyer is making a cut, in the properly cleared area, he will be using both hands on the saw. This demonstrates what we referred to earlier. That is, the sawyer can hold onto his saw with both hands while another man uses a stick with a sharp point that will reach up some 10 feet on the tree for the purpose of pushing so it falls in the proper direction. And the supervisor will be looking on.

The limbing operation with chain saw presents the hazard of the saw hanging in brush and jumping into the legs. Severed limbs should be moved out of way as they are cut, as a means of improving controls over this potential accident producer.

A limbing operation with an axe should be done on the opposite side of the log from which the axeman is standing. Loose limbs also present a very serious hazard here in that they may be deflecting the axe into the person.

In some operations, logs are snaked out of the woods into a clear area for additional cutting and loading. There will be a protective cover over the tractor cab. This

protection is a must for safety of operators. The hard hat will protect against relatively light limbs, etc. and will give a measure of protection against larger trees. However, the sturdy cab protector is necessary for full protection of the operator.

One of the most hazardous situations in logging is found where a man is operating a farm type tractor which shouldn't be in the woods in the first place. In addition to the fact that it does not have any protection overhead this machine is not designed to snake logs. The tow chain is positioned above line of axle.

The center of gravity, that is the line of force, is located well above the axle and if the log hangs, the tractor can turn backwards onto the driver. This frequently happens.

In a specific accident resulting from one of the farm type tractors turning backwards on to the operator occurred recently down near Beaufort, North Carolina. Investigation revealed that the operator was 15 years old (violation of the North Carolina Labor Law) and had been placed on the tractor without any previous experience, although he had told the pulpwood producer that he had driven a tractor some place before.

At any rate, the log being towed by the tractor hung against the stump and the youth's foot slipped off the clutch and the automatic drive caused the tractor to turn backwards and crush the young fellow. The details of the investigation of this accident are too numerous to mention here but they did reveal many areas where planning was lacking and apparently absolutely no attention was given to safety of workmen.

Another major producer of accidents is lifting and handling of heavy materials. This produces serious strains. The safe handling of material requires a thorough knowledge of the correct way to lift; requires putting this knowledge into practice at all times, not just part of the time. It is estimated that manual loading of logs is practiced in approximately 90 per cent of the cases.

If anyone doubts that loading a truck of pulpwood logs is a big job, just multiply the weight of the log (about 80 to 90 pounds) times the distance it is handled, times the number of logs on the truck and you get a pretty good idea of the foot pounds of energy expended during a loading operation.

By monitoring the radio channel, the inspectors can determine the location of the company trucks. It is an easy matter, then, to follow and watch for poor driving habits. This procedure allows the inspectors to pick out those drivers who need to improve. Further, since the drivers do not know when an inspector may be near by, they tend to use safe driving habits all the time. This company has improved its safety program with this procedure. It could not have been accomplished without two-way radio.

In another industry, ready mix concrete, the value of radio is looked at in a different way. One company reported that its safety record was in poor shape—so poor that the insurance companies were inquiring about it. With the aid of a radio system, this company built its safety record to the point that it was specially honored by the National Safety Council. How was this accomplished?

In this company, many of the dangerous situations encountered by the drivers occur not on the road but at job sites. Much of the safety supervisor's time is spent traveling from job site to job site for routine inspections. Radio has been installed in the supervisor's vehicle. Now, when a driver encounters an apparent hazard on a job site, he does not proceed. The driver contacts the safety man, by radio, and he moves to the job site immediately and sees that the hazard is eliminated. This procedure has substantially helped efficient and timely delivery of ready mix concrete and once again the safety record was improved.

Portable two-way radio has been successfully applied in the construction business to provide greater safety. A company engaged in the erection of steel frame work in multi-story buildings has made good use of radio. The crane operator unfortunately does not always have good visual contact when moving a girder into position. This lack of visual contact allows some potentially dangerous situations to exist while the beams are moved.

These dangerous situations were eliminated by providing the foreman with a pocket sized transmitter and placing a radio receiver equipped with a loud-speaker accessory in a central location. The foreman can use the transmitter, no matter where he is located in the structure, to talk directly over the loud-speaker. He can give instructions to the crane operator or the rigging

crew and everyone is simultaneously alerted. All personnel on the site are now aware and alert to girder movements and safety is maximized.

There are more specific examples of which I am aware and thousands of which I am not aware. The point made is that the ability to communicate alone can substantially enhance your safety program. The ability to get the right person to the right place at the right time can prevent accidents. Most of you have operations which require movement of personnel and equipment so that they cannot use standard wire line communication.

Radio is the only answer. In many cases, the increased efficiency obtained through the use of radio in your operations can more than cover the cost of equipment purchase. In these cases, the increased safety is a bonus. In other cases, the increased protection to life and property will fully justify equipment purchase.

Let's move to some specific examples closer to your interests; namely, the logging industry.

One of the most modern methods of signalling in yarding operations is a radio device known as the "Talkie Tooter." With this device, members of the rigging crew can directly control the Yarder whistle. Through the use of a whistling coding system, everyone in the area is kept informed and alert to movements. Keeping the working crew alert to movements makes the operation substantially safer.

Use of the Yarder whistle as a method of signalling was in use prior to the application of radio. It was handled by running a wire line from the Yarder to the point where the rigging crew was working. One man was assigned to the job of controlling the whistle from the wire line. This was the man's only function.

The application of radio, then, did not improve safety, but it provided a means to have equal safety at substantially lower operating cost. The man previously assigned to controlling the whistle is no longer needed because the rigging crew chief can control the whistle directly from the small transmitter which he can carry on his belt. This allows the crew chief to move about freely and perform all of his normal functions.

Credit for applying radio to the specific requirements of the logging industry, in this case, goes to Rottenbuhler Engineering of Sedro-Wolley, Washington. This company has taken this standard radio product and added modifications which perform the signalling function. The system works like this.

The rigging crew chief carries a small transmitter which has an encoding device added. When he wants to actuate the Yard whistle, he depresses a lever switch on the belt unit in accordance with the predetermined code. This signal is transmitted to a mobile receiver with a decoder unit which is mounted in the Yarder. The signal is received, decoded, and actuates the whistle. When a situation arises not covered by the code, a voice message can be transmitted from the belt worn unit to the Yarder.

This is a relatively simple system, but it is effective and reliable. It satisfies the safety requirement and at substantially lower cost. One logger using "Talkie Tooters" on three sides, reports that he saves \$1,200 per month because he needs three less men. He paid for the equipment in less than four months of operation.

An extension of the "Talkie Tooter" principle was outlined in an article in the January-February 1961 issue of the *Western Construction Journal*. It was written by John Gruddall of the Shagit Steel and Iron Works. The article describes a system which combined a radio controlled sky car with a Mobile Logger, equipped both as a grapple loader and a self-propelled mobile tower to support the sky line. In this system, the movement of the sky line carriage and the choker lines is radio-controlled by the rigging crew utilizing the same "Talkie Tooter" which I described. The system provides efficient operation with maximum safety because movements are controlled by the workman who has visual contact.

This example represents a case where remote control of machinery is provided through the use of radio. It is probably in the area of remote control of equipment, or automation if you will, that great advances in equipment application are yet to be made. And it is here, that radio will play an important role as the communications link required to provide the remote control. Unfortunately, standard products

will not generally be available for this purpose because each system will have a uniqueness. But standard equipment will provide the necessary building blocks for our systems engineers to provide workable, reliable control systems to help solve operational and safety problems.

I shall not take your time here today to review the many standard radio products which Motorola has available. Many of you are already quite familiar with our line. I would like to mention two specific products, however, in our portable line of equipment, since portability is so important to many of your operations. One unit is a fully transistorized pocket transmitter with an R.F. power output of 1/2 watt. The smallest, lightest, most reliable communications class transmitter yet made available.

Another unit is a fully transistorized pocket receiver with performance equal to that of any good mobile communications receiver, except for the antenna efficiency. These two units combined can provide easy to carry, two way voice communications never before possible. The ability to communicate with the roving man on foot without burdening him with a large package to carry, has opened up new applications in many industries. Perhaps some of you can already see where equipment of this type can aid in your programs.

In a brief period of time, we can only scratch the surface of the possible application of radio to safety programs and your business in general. I hope that some of the examples and equipment applications discussed may have application in your operations. As a manufacturer, it is our responsibility to learn about your industry and your problems so that we may demonstrate to you new systems which can benefit and serve you. Our representatives in your area stand ready to assist you in working out answers to your communications problems. Call him in on your problems. Motorola has the systems engineering department ready and capable to evaluate your problems and recommend solutions. Motorola is expert in the communications business, but no one knows more about your business and problems than you. With our combined knowledge, I know that systems can be evolved which will aid you in your safety program.

PRINTING & PUBLISHING SESSIONS

THE CRAFTSMEN'S INTEREST IN SAFETY

By MICHAEL IMPERIAL

Mgr., Finishing Dept., Skinner Kennedy Co., St. Louis, Mo.

I have had a very busy schedule the last month traveling practically all over America. I have visited many, many printing plants and I think I can speak from experience, from visitations, and also from my long experience in actually working at the trade with my hands, and I have the hands also to prove that some 32 years ago I thought I was smart but machinery is just a little smarter than we are.

In my opinion, I think that our safety programs are essentially based on good communications. Without communication, all the posters, all the backing up of management, and so forth, is of very little use. Back in 1938 the firm that I work for now had many small accidents in printing plants. Incidentally, the principal supervisory capacity I have at Skinner & Kennedy is with about 80 per cent ladies and about 20 per cent men.

We find that in any bindery there is room for human accidents, made by the human being. They are not accidents that ordinarily would have happened. They happened because we want them to happen—carelessness. I think that we as supervisors—I consider myself in the supervisory field rather than the top echelon—we carry the ball. We are the men that make safety worthwhile. My job is production, getting things done, getting them done on time. And many, many times our workers will sacrifice not only production but their limbs and their lives for the sake of doing things easily. It is up to the supervisor to create an image and an attitude, and I like to use the word "willingness." If people don't do things willingly, then they don't understand them. It is up to the supervisor to create that image and that attitude of doing things willingly, have them understand what safety does and what it means.

Communication. Let people understand what we are trying to say. Reverting back to 1938, in our plants we had many accidents. At that time I was chairman of the policy committee and I knew the advantage of having a safety program that would work. We didn't want management to run the safety program. We wanted their backing but we supervisors wanted to run the program. We have some fifteen supervisors in the plants and we delegate three each month, and one person to be chairman. They go through the building and inspect every known hazard there is. We had a report that we would make out. But this is the thing that is important. Reports are no good unless they have teeth in them.

If there were violations, the report would go directly into the department that was responsible for it. If they weren't corrected in ten days, they would go to management and then management would see that they were abided by. That is where we need the support of top level management. Without their support, a safety committee is of no use.

Then each month you would have three new men that would find some of the hazards that the other people wouldn't find, particularly in the department that they were working in. They overlook some of the hazards in their own department. But when you had a new chairman and new group, they would find the faults in these other departments. The thing we liked about this program, which I believe had the greatest amount of benefit, was that some supervisors weren't in favor of safety, but once they were on the committee, they too became enthusiastic and willing, and once they became willing, you had a safety program that would work.

Printing and Publishing Sessions

It is important that the individual worker understands safety for their own good. We say that safety sometimes holds up production. It certainly does. If we were to be selfish, we would admit that every accident that we have in our printing plant costs money. It holds up production. In a bindery

operation, if you take a girl from the street and try to break her in on a given operation, it takes from three to six months to become anywhere near proficient. If that girl should be hurt and you start a new operator, you are holding up production and it costs money. Safety does not cost. It pays.

SAFETY LOOKS TO MANAGEMENT

By O. R. SPERRY

Senior Vice Pres., R. R. Donnelley & Sons Co., Chicago

There are no unimportant people in the printing industry because wages and salaries comprise well over half of the cost of our operations. Therefore we are dependent upon people for our existence, and when we are dependent upon something, it is not expendable. So, strictly from a cold-blooded and hard-nosed business standpoint, to maintain the safety of our people at the highest level is a profitable endeavor.

I doubt whether this opinion is generally shared by all of our top management people. If it were, I think we would find greater interest, greater concern and, above all, greater participation by these VIP's in safety. The big question is, how interested is the top management of your company in this subject?

The title that was assigned to me is "Safety Looks To Management." I imagine that if this were erroneously printed in the advance notices of this meeting to read—"How We Can Eliminate Safety Programs Because Safety Programs Cost Money"—most every one of your top management people would be here. If there is anything lacking in industrial safety today, it is too much tolerance and not enough demonstrated personal interest on the part of top management. What I have to suggest on the subject may be more properly directed to your top management, and may more appropriately be entitled "Safety Looks To Management For Help"—or, "Safety Depends Upon Management."

First, let's discuss management participation and management support and I emphasize *participation*—not just approval. Now the term "management" is relative and

must include every level of management from the first-line supervisor to the president of the company. Assuming that any first-line supervisor not interested in safety would be replaced, let's talk about higher echelons of supervision.

Of course we don't expect that the chief executive officer of a corporation will participate in every meeting of a safety committee, but we can expect that he will be kept informed, and that he will communicate to this group in such a manner that they know he is informed, and, above all, that he takes serious interest in their accomplishments (and, conversely, that he is seriously disturbed if there is a lack of accomplishment). People like to know that the big boss is aware of what is going on, and who is involved, in areas of activity other than the bread and butter operation, mainly those in the field of quality, service and production.

It is my belief that most of the people in top management have to be pushed, urged, egged and, above all, staffed, on this phase of managerial function and of course that is the responsibility of the person who is in charge of the safety program.

And it is a continuing chore on the part of this person, because if there is anything that can cause this activity of safety to bog down, it is a one-shot program without regularly repeated boosters.

Now, about "management support." I'm not referring to the normal day-in and day-out approval of expenditures for a series of safety posters—meetings on company time—improved first-aid kits and the like. I am referring to the enthusiastic support of safe

practices, rules, regulations, policies, etc.; enthusiastic support of always making safety first in the order of importance of any and all company policies. And, included in the term "enthusiastic support," I refer to backing up the line management organization in support of strict enforcement of safety practices and rules—most of which are developed as a result of experience (and sometimes sweat, bitter and costly experience). I happen to believe that there is no such thing as a workman being "accident prone." It is a worn out cliché. What I do believe is that to the extent that management will tolerate the repeated use of unsafe methods of procedure and, of repeated carelessness, a workman may repeatedly sacrifice safety for production, and consequently be more susceptible to accidents.

Let me give you a case example. A number of years ago we had one particular man out of a group of several operating similar machines—and by comparison it was a relatively hazardous operation. As a result of experience, we had developed a safety procedure for handling the product on this operation that actually reduced the daily output of the operator. This particular man was an exceptionally efficient operator but on the liability side in this case he was allergic to any change that reduced his output. Now this is a most remarkable asset except that it cannot be tolerated at the expense of sacrificing safety. If safety is first in the order of importance, and it well must be, then there is no choice but to make something else second, and since quality was not involved in the case at point, it was production.

This man insisted on reverting back to what we had previously determined were unsafe practices and the foreman finally had to demote him because he was unable to change his habits. As a result of the change, the unit cost of the operation increased considerably, because this man, by comparison, was our highest producer to the extent of some 20 to 30 per cent, under any method. Here was a case where safety looked to management (for support) and got it—and it is a good thing that top management did support it, because I was the foreman. A reflection on the supervisor for not being able to change the man's habits—certainly—but a clear-cut case of safety first, meaning what it implies.

Another basic factor, not specifically related to management but in my opinion, one that may be too often overlooked in safety promotion, is that of "change." Unlike the philosophy of "let us not change simply for the sake of change," when it comes to retaining worker interest in safety, "change for the sake of change" is the life's blood of the program. I'm not in any sense referring to the development and maintenance of safe practices and procedures, but specifically to the gimmicks, the glamor, the novelties, the attractions that will keep people conscious of and interested in the subject of safety. In this field, today's standards are tomorrow's antiquities.

Have you ever noticed that the completely demolished automobile that you occasionally see in the main circle of a small town to remind motorists of the terrible consequences from reckless driving, usually impresses the tourist who is driving through the town, but a week after it is put on display, the townspeople walk by it countless times without ever seeing it. It's old hat and they are not interested until the display is changed after someone else has been killed. The same is true in our plants with respect to safety posters, safety records, and other conventional procedures. Let's change for the sake of change. Let's constantly look for something new, something different, something novel, and then remember that when you find it, change it—frequently. Safety committees are rotated frequently and each committee should be charged with the responsibility of coming up with something new, novel and different to keep up the workers' interest in safety.

Now, in conclusion, I want to touch upon what you may call a cold-blooded approach, a thought for attaching more significance to the factor of frequency of accidents that we are in the habit of attaching to the factor of severity.

If we are ever to reach perfection and eliminate accidents entirely, we would automatically eliminate both of these factors. We of course know that we will never attain that goal. However, I do believe that if we succeed in effectively reducing the frequency of accidents, we will automatically reduce the severity factor. This same philosophy worked at one time in our company when applied to the principle of spoiled work. "Spoilage" we called it, where every

item of cost related to repairing a defective product had to be isolated, classified and accounted for separately in each instance. We laid so much stress on frequency, that taking out a spoilage job number became a reflection of sin. In one particularly large department having almost a thousand employees, the idea took hold so well that anyone who caused a spoilage was actually frowned upon by his co-workers and, as a result, in one year that I recall, the frequency was reduced by 50 per cent and the

severity, in this instance, the cost, was reduced by 90 per cent.

I believe that if we attach enough importance to frequency in our safety programs, so that we will take corrective action to reduce frequency, we may be saving a person's life. We need disciplinary action to reduce frequency and when we get it, we will reduce severity.

Yes, it's just good plain business sense for safety to look to management and for management to support safety.

WITHOUT KNOWING IT YOU MAY BE KILLING YOURSELF

By ALFRED A. JASSER
Chief Chemist, Anchor Chemical Co., Inc., Brooklyn, N. Y.

Safety is everybody's business. Members of the National Safety Council especially should be aware of the hazards present in our industry. We owe it to ourselves, to our employers and to the men under us to spread the word and the habit of practicing safety.

Directors of safety know that workers are safe workers if they have the proper knowledge of potential hazards and the correct attitudes toward their jobs and the tools and equipment with which they work.

Practical psychologists, and I guess every director of safety has to be one, recognize that one of the most powerful forces controlling human conduct is the desire for self preservation.

That in a nutshell, is the reason for the startling title for my talk on the chemical hazards in the graphic arts. Its purpose is to bring to your attention the little known but definite dangers that lurk within some of the materials many of us use in our everyday work.

For purposes of discussion, I classify these hazards into three groups:

1. The danger of fire.
2. The danger of toxic fumes.
3. The danger of skin ailments.

The danger of fire is too frequently caused by ignorance as well as carelessness.

In my visits to hundreds of plants, I've found men who did not know that the solvents they were using were EXPLOSIVE. In some cases the men were confused by the words "Inflammable" and "Non-inflammable." Webster says that "inflammable" means "Easily set on fire, that which will burn readily or quickly." "Non-inflammable" means, "Not easily set on fire, will not burn," etc.

In New York City, the fire department regulations define an inflammable liquid as one which has a flash point below 100 degrees Fahrenheit. The ICC requires a red caution label on materials which have a flash point below 80 degrees F. Some cities have regulations which require red labels only on products which have a flash point below 70 degrees F.

It certainly is a confusing situation.

Most safety engineers use the Underwriters' Laboratories lists as their guide and usually consider any product that has a flash point below 100 degrees F. as requiring special precautions in use.

The vapors of those inflammable solvents which have a flash point below 25 degrees F. are usually explosive. In this class are such solvents as: ether, acetone, methyl ethyl ketone, benzene (benzol), gasoline, carbon disulphide, collodion, most lacquer thinners, and paint and ink removers that

contain these. Whenever possible they should be replaced with safer materials having higher flash points.

You would be surprised to know how much gasoline is still being used to remove ink from type, rollers and blankets. Recently on one of my trips, I had the opportunity to visit one of our governmental agencies. The duplicating department was a neat clean looking shop. But whenever the men need blanket wash, they would send down to the Division's garage for some "gax." "Of course," the foreman hastened to assure me, "we always send down a safety can." He was aware of the potential dangers. But what precautions had he really taken? Hardly any.

For when the safety can was brought upstairs, the men poured a quantity of gas into an open pan which was kept alongside the press. You see, they claimed the safety can was too heavy. The men felt it was a nuisance to lift it each time. It was easier to dip the rag into the pan. No one thought of buying small bench cans or quart dispensers.

They never stopped to think about the three hazards involved.

The car in which we drive to work each day is powered by a motor designed to use the EXPLOSIVE FORCE of each molecule of gasoline. On the coldest day, even way up in Alaska, just a faint spark is all that is necessary to explode that drop of gasoline. The chemists of the petroleum industry have added chemicals and changed the octane rating of all gasoline to the highest it has ever been.

In the plant, the foreman forgot to think about the spark generated by the electric motor on the press. He forgot about the static electricity generated on the press, about the gas flame on the Kelly Press nearby, about the heat generated by the friction of the rag due to the "elbow grease" needed to loosen the dried ink because gasoline at best, is a poor solvent. Any one of these factors, plus a careless smoker could have turned his plant into a flaming inferno in seconds.

A plant in Massachusetts forgot to care for the "gas-soaked" rags and the effect of spontaneous combustion. The semi-headline was, "\$25,000 payroll lost." There was no watchman, so nobody was injured, but the

plant was damaged, and people were out of work for some time.

But even if the plant continued to be lucky, what about the second danger—that of toxic fumes. Most gasolines, including the "regular" and less expensive grades contain tetraethyl lead. This lead salt and other additives make its use as a cleaner prohibitive. Many states now have regulations which prohibit the use of gasoline as a solvent in order to prevent lead poisoning.

Lead poisoning is that same disease which we used to worry about in composing rooms and line-casting shops years ago. Today, there are few cases because we are careful to exhaust all vapors from the melting pot and we wash our hands thoroughly before eating.

Then why should we use as a cleaner any liquid which already contains a dissolved lead salt, easily absorbed by the body? It doesn't make sense. Furthermore, the continued use of this poor solvent very often leads to dermatitis. Over 17 per cent of all compensation claims are found to be in the class listed as dermatitis and skin troubles.

Maybe gasoline is cheap, but I think it only proves that old adage, "The cheapest things are usually the dearest in the end."

Because gasoline and the rest of the petroleum derivatives are such poor solvents for dried inks, many people have turned to the more powerful coal tar solvents—benzene—benzol and toluol.

Benzene is a darned good solvent and it is fairly inexpensive. It is a colorless liquid with a pleasant but penetrating odor. You may have smelled it when you used your rubber cement thinner or watched the shoemaker apply adhesive to a rubber heel.

Not only is benzene highly inflammable with a flash point down near zero degrees Fahrenheit but its vapors are highly explosive. It is one of the most poisonous solvents used in the industry. Safety regulations require that its vapors be confined and down draft exhaust ventilations be present whenever it is used.

Inhalation of its concentrated vapors can lead to death. Pamphlets distributed by the U.S. Department of Labor warns that "chronic poisoning, due to daily exposure of unsafe concentration of benzene may so

reduce the blood forming functions of the bone marrow as to cause anemia. Contact with the skin should be avoided."

What is an unsafe concentration? Imagine a pressroom 30 x 100 with a ten foot ceiling. Allow to evaporate over a period of eight hours, only one pint of benzene and you have reached an unsafe concentration.

What size is your pressroom, or stripping department, or composing room? Half that size? 50 by 50? Then all that can be evaporated is eight ounces.

Is your room 25 x 50? Then all that can be safely evaporated is only four ounces. In the pressroom that is as much as you might use in only one wash-up.

The injurious effects of benzene poisoning are usually slow in being noticed. The body stores up the toxin until suddenly the effect is pronounced. Very often, unfortunately, the symptoms are easily mistaken for other common ailments, such as that tired feeling, frequent headaches, dizziness, loss of appetite and even nosebleeds.

Listen to what the U.S. Public Health Service says in their booklet, "Clara gives benzol the run around"—"Chronic benzol poisoning comes from breathing small amounts of vapor every day. Not all workers so exposed become ill. If it goes on long enough without being noticed, it may at least have the same effect as an acute attack. It also makes people more susceptible to infections like pneumonia, blood poisoning and other germ diseases."

When the patient drops dead, the doctors may call it "heart failure" or people may say "Poor Joe, he worked hard."

But pressmen and compositors are not the only ones susceptible to this poisoning. I know of a bookkeeper who contracted this illness while he worked for a printing company. Only recently a stripper in a litho shop dropped dead at his desk. The coroner found the cause to be benzene which he had been using to clean the film before sending it to the camera.

Cases of benzol poisoning have also been found in the bindery, where girls were tipping in art work with a rubber cement.

Benzol degenerates your skin and makes hands dry, scaly and sore—then they are easy marks for infections.

While benzene has its place in many

industries where proper safety measures and methods of handling it are part of a controlled operation, you must agree that it should not be used in the graphic arts field.

After many printers took notice of these facts they wanted replacements for benzene. We found that many were supplied with cleaners which were formulated with methanol, Methanol, or wood alcohol, as you may know it, is an excellent solvent for aniline dyes but it too is very poisonous and inflammable. Its flash point is 65 degrees F. It is one of the few solvents that the government suggests should carry a skull and cross bones warning label.

When methanol is absorbed into the body, it affects the central nervous system and does particular damage to the optic nerve. It also has a damaging effect on the kidneys, liver, heart and other organs—irrespective of how it enters the body.

The maximum allowable concentration is only 200 parts per million of air. Poisoning from methanol is slow and symptoms may be delayed because it accumulates in the body and is slow in being eliminated.

Handling of wet rags can cause very dry skin, sores and dermatitis. But the most common complaint with methanol is the damage it does to the eyes. Many cases of blindness have been due to the use of this dangerous material. Here too, it doesn't matter how it gets into the blood stream—by mouth, through the skin or nose—it is dangerous.

Unfortunately, the odor of methanol causes it to be confused with "corn liquor." Many serious accidents have occurred when this solvent was dispensed from unlabeled cans or bottles.

Methanol is quite corrosive to lead. This, added to all the other facts outlined above, should make you agree that methanol does not belong in the graphic arts.

Because people are aware of the fire hazards of the inflammable solvents, many have switched to those that will not burn—and thus assumed that they were safe.

If these fluids contain carbon tetrachloride, and most non-inflammable cleaners do, then they are dangerously in error. The vapors as well as the liquid itself, are capable of causing serious poisoning and even death.

Several years ago, a large tag and label printer in the east, decided to save some money by buying naphtha and adding carbon tetrachloride to raise its flash point. The alchemist who decided this, thought that they would surely be protected by mixing the two—50/50.

Everything went smoothly until one day, several of their pressmen became ill. The doctor discovered that they were suffering from carbon tet poisoning. But that's not all. They suddenly had a fire caused by static electricity due to the flow of the naphtha from the full drum through an ungrounded hose. After the plant was out of production for several weeks, the supervisor decided that only safe mixtures, bought outside, would be permitted in the plant.

Let's get back to the carbon tet. The maximum allowable concentration of carbon tet vapor permitted by safety engineers is 25 parts per million of air. Compare this to deadly carbon monoxide gas with which you are all familiar. Carbon monoxide has a rating of 100 parts per million and you now can see how deadly carbon tet can really be.

This is what the state of California says in Bulletin #125—"This concentration (25 parts per million) would result from turning into vapor one-half a teaspoonful of carbon tet in a room 10 feet long by 10 feet wide with a 10 foot ceiling. Don't rely on your nose to detect harmful concentrations of carbon tet. It won't detect concentrations of less than about 80 parts per million, and when you can smell the odor, it may have already harmed you."

Many people have become ill from exposure to this popular solvent without realizing the cause. The symptoms of carbon tet poisoning are similar to heart, liver and kidney diseases. In milder attacks, the symptoms are headaches, nausea and a tightness in the chest.

I know a man who operated a small offset duplicator in an office. Each evening, upon his return home from work, he had to sit on the porch for at least ten or fifteen minutes to "catch his breath" before going in. He told me that he lost his appetite and that he didn't feel right, until he had filled his lungs with "good country air again."

I learned that he was using a blanket wash which I knew contained 60% of carbon tet. Not long after, he followed my suggestion to stop using that mixture, he wrote me that "he felt good again."

There have been cases in shops where only some people in the group using carbon tet, became ill. Investigators have reported that those who are most susceptible are those who drink alcoholic beverages, those who are malnourished and all those who have had a case of poisoning before.

Sometime ago I read a news story about a husband who returned from a drinking "binge" with his clothes dirty. While he was lying on the sofa, "sleeping off his hangover," his good wife attempted to clean his clothes with a carbon tet mixture. The windows were closed. The husband died of poisoning, but his wife was unaffected.

Although carbon tetrachloride is the most deadly of the chlorinated hydrocarbons, many others, often found in cleaning fluids, are also potentially dangerous. These include: trichloroethylene, perchlorethylene, chloroform, trichloroethane and ethylene dichloride. They should all be used with care and only where there is sufficient ventilation.

When any solvent accidentally spills on your clothes it is important that you remove them at once. The portions of the body which have been touched by any solvent should be washed with plenty of soap and water immediately.

Although much of my talk has been about solvents, there are other dangerous materials found in our plants. Time prevents my doing more than listing some:

1. Among the inks are the yellows and reds which contain lead and chromium salts.
2. Rotogravure ink which contains coal tar solvents—benzol, toluol, etc.
3. Aniline dyes found in flexographic inks and toners.
4. Spray fluids and powders that contain silicates, carbonates, talc phenol and formaldehyde.
5. Chromic and bichromic compounds found in platemaking and fountain solutions—even spills on shoes should be removed at once.

I know of several cases of platemakers who had severe cases of dermatitis and it

was traced to the fact that the material spilled on the shoes, and the people didn't take the trouble to clean it up, to change the shoes.

6. In the bindery may be found adhesives that contain phenol and formaldehyde preservatives.

7. Care should be taken with thinners used in finishing operations. Static electricity, built up on cellophane and plastic laminates can cause explosions when loosely handled.

8. Care should be taken with nitric acid and other acids used in platemaking. Nitric acid can cause explosions as well as give toxic fumes.

9. Lye, caustic soda and other such potential disablers should be used with extreme care.

Some printers, who have not kept up with next advances in chemistry, have been giving their synthetic rubber rollers a weekly lye bath to get rid of glaze. This operation of soaking the roller and scrubbing it with steel wool and benzene, has caused many an accident. It is a risky job even with gloves, apron and goggles. It is no longer necessary. You can now clean every roller in your plant without using lye or benzol or any of the toxic materials—and do a faster and better job at that.

Another risky habit which should be discouraged is the use of naphtha, turpentine, typecleaner, etc. to remove ink and dirt from the skin. Some of these solvents may be toxic, some highly inflammable, but all have a drastic de-fatting action which can lead to infection.

I hope that my remarks have succeeded in making you aware of some of the chemical dangers. Unfortunately, time does not permit me to give you more details.

In closing, may I repeat this advice:

1. Accept nothing in your plant which is not properly and freely labeled.
2. Be sure to read these labels.
3. Replace toxic materials with safer substitutes.
4. Store inflammables in a safe place, away from work rooms.
5. Dispense inflammables only from approved safety cans.
6. Be sure to label each flammable container correctly.
7. Dispose of waste inflammables carefully. Spent liquids should not be poured down the sink.
8. Know what you are using and handle it properly.
9. See that everyone else in the plant does too!

SAFETY MOTIVATION

By LARI BURKHART

John L. Gwydir Co., Inc., New York City

This area of motivation is not peculiar to safety alone. In fact, we are coming in at the very hind end of it. You have been exposed to motivation in advertising for many years. The cereals that your children browbeat you to buy for them, the automobiles your wife wants you to buy, all this type of indirect stimulation is by motivation.

What I am going to try to do this afternoon is to speak broadly of the concept of motivation, and then to tie this in with specific safety examples as others and my-

self have been able to apply them to printing plants and newspapers.

Dr. Sonntag states that motivation is nothing more than directed learning. "The basis for all learning is the striving by the individual to lessen anxiety by mastering problems as they arise." Keep this in mind. We will be using it a little later.

Dr. Earl Hannaford has developed a sequential definition for motivation, where he takes motivation and then several parts of it and defines them in turn. "Motivation," according to Dr. Hannaford, "is supplying

the incentives which impel an individual to achieve a pre-selected goal and the incentive is anything the individual feels will satisfy a drive or a motive." And he says, "A drive is a persistent stimulated condition usually arising out of body tissue needs which demand immediate satisfaction. A motive is any condition, and it is usually emotional that arouses, sustains and directs an individual's activities toward a pre-selected goal."

Obviously, from our definitions it would seem that motivating people for safety would center primarily about proper individual incentives, which is a motive, since safety is not a one shot thing but calls for sustained persistent, directed activities on a continuing day after day basis. Moreover, it has a high emotional content.

Before we make any more conclusions and comparisons with respect to drives and motives, let us allude to a few of the basic drives and motives: Hunger, sex, exploratory instinct, masterliness. All are familiar with the drives which are shown in the order of dominance. Actually, masterliness lies between drives and motives. There has been recent research which places masterliness more as a drive than it does as an emotional motive. This is a natural deduction because there is new evidence that our motives have their own roots in the natural drives. The important thing to remember is that drives have an order of dominance; in other words, a precedence which operates so that the strongest one in that order of precedence gets attention before the others. With motives it is different. Motives, being emotional, do not have a natural fixed order of dominance but can vary in strength, depending on the appeal to the emotions. Since many motives can be and usually do compete for our attention at times, the one that appears to be the greatest—*anxiety or fear*—usually wins out over the others.

A motive must withstand repeated competition with the other repeated drives and assaults over a period of time. Drives with their tissue order do not have to face such competition. In fact, it is obvious when thirst or hunger are extreme, these override all others. We see that the particular motives can face several fates. The motive can be successful in competing with other

motives or it can be only partially successful. It can be replaced or give way to a substitute or block inhibition. I am afraid too often in safety we find our motives blocked or inhibited. From this we can see why motives must be strong. In the struggle of the survival of the fittest, we know from experience that safety has strong competition, so it behooves us to know the facts and use them realistically.

Let's list some of the motives that we are talking about: Social appeal; conformity; security; achievement; belonging; attitude; self expression; interest; and prestige.

Probably many of you are wondering why I haven't included praise, reproof and reward. That is just the point here. Before we can arrive at the secret of motivation, we must be sure of what we mean by drives, motives and incentives. There is a good deal of confusion on this point and how they function. All too often incentives and motives are interchangeably talked about and this, of course, is wrong. It leads to conflict and confuses the effort to motivate. The underlying truth is this: Drives and motives are the same for every one. They are broad concepts. Incentives vary with the individual, for they are the intermediate achievements which impel the person to achieve the goal. Remember our definition of motivation: Supplying the incentives which impel an individual to achieve a pre-selected goal. Incentives may be anything which makes an individual feel will satisfy a drive of a motive. Such things as praise, reproof, reward, participation, and so forth, are incentives. It is the incentives we must supply. Far too often we are trying to supply motives. Motives are universal, human conditions are the same for every one, the same as drives are the same for everyone.

Our definition of motives, we said, is any condition, usually emotional, that arouses, sustains and directs an individual's activities to a pre-selected goal. Motive is a condition, we also said, that drives an individual but is a different kind of a drive, a persistent, stimulated condition, usually arising out of body tissue needs of the individual and demands immediate satisfaction. Here is the important concept that distinguishes drives and motives from incentives. Drives and motives are conditions. A condition is

something that precedes and sets up the climate for an action and the result, and does not in itself produce that result. It is the incentives which produce the result that is the achievement of the goal. Any one drive can provide the necessary conditions under which the incentives can function.

Before we sum up the key facts about drives, motives and incentives, I will get down to some actual accident situations, case illustrations.

There is a very important concept, the pivotal concept. I borrow this from Hannaford. He has dug up quite a word which we are using across the nation. This pivotal concept is the point of departure which determines whether we are going to motivate in the true sense, or if we are going to try to prevent, divert, practice thought control, brainwash, propagandize, or what-have-you. The pivotal concept is this: There are two kinds of motives—positive and negative motives. In the partial list of motives we spoke of a couple of minutes ago, we mentioned the positive motive. Too often discussions deal with the positive motives, because precisely only things that give pleasure reduce that tension. That gives us a distorted picture.

We have motives that can be both positive and negative: Attitude, tension, punishment, discipline; then going down to negative discipline, negative tension and negative attitude. They appear on both sides of the pivotal point. These four motives of discipline are what we psychologists call ambivalence. They are opposites of love and hate.

Let's take discipline. Understanding discipline in the interest of the person being motivated is positive. While discipline solely in the interest of the motivator, and particularly when not in the interest of the motivated, is negative. At the same time, this is true of punishment. When both are negative, they have a close kinship with fear and anxiety. Too highly and solely negative motives can disable a person and in the extreme case cause panic. When they are positive, they are among our strongest motives. It is unfortunate these two motives are viewed from the negative standpoint, and the same is true of tension. People see attitudes differently. Most people agree it

can be good or bad. We can see further out from our pivotal point.

Here is an interesting thing about the ambivalent motive. It has an unconscious added impact on an individual. When he senses the intent behind it, the effect can be intensified and amplified. This can be true even when the person is griping about it. Why? His ambivalent feelings are associated with an authority figure. When we have confidence and respect for the authority figure, we get a relief from tension by assuming the responsibility.

Emotional content, impact and positive and negative nature of this motive are dependent on the use made by them by the authority figure. The solely positive motives are effective. So the negative ones are barriers to goal seeking attainments. Even so, negative motives—fear and anxiety—can be strong motives. Here is an example of its use in a field which requires strong motivation. This I borrow from Dr. Barnes, who is the psychologist for the National Collection System. He consults with the collection agencies. The basic approach in the collection of debts is the creation of fear and anxiety in the debtor, which he can only dispel by paying the debt. He can't get away from the use of fear and anxiety as motives and the collector has to create a certain amount of anxiety and fear.

From Herlock works, in three carefully chosen incentives, where the discipline is the startling factor, he used four groups: A control group which was given no incentives; a group which received high praise; a group which was given severe reproof in their own interest; and a group which was ignored, but heard both the praise and reproof.

Using the control group's performance as a percentile figure of 100%, the ignored group had performance of 104; the reproof group had performance of 105.8; and the praised group a performance of 180. Discipline of a positive nature is a motive which is inherent in all of our captive groups. It is a condition and climate which probably cannot be duplicated. The praise group increased its performance by 80 per cent over the controlled group. This is direct testimony to the solely, socially approved motive effectiveness when praise is used as an incentive. We must keep in mind that

praise was given to a captive group, operated under a state of discipline, and whenever the praise was warranted. This incentive can be associated with the discipline and a usually approved motive of this kind is closer to the discipline motive.

Please understand why I am dealing with ambivalence. It is not because I am ranking discipline above the other motives but because of its key position and impact. It is all too frequently misunderstood. All the jobs of safety motivation take place in a setting where discipline exists as the way of life. We don't have free choice, but we do have on-off-the-job work.

When we motivate, we select a goal, decide upon what motives are most closely related to the goal, and then proceed to provide the incentives which will appeal to the individual or group as satisfying that motive or motives. Because of the possible mortality or fall-out of motives, it is best to use several and to choose your incentives accordingly. We don't provide motives but we supply incentives which satisfy a motive that already exists for all of us.

A couple of simple examples of how we can put this to work. Because of the time element, I will take just one example which we all run into in our composing rooms and stereotype departments—eye injuries. This is our goal—no eye injuries; positive motive, security; positive discipline, dealing with security. These are possible incentives: publicize loss of sight cases; publicize cases of eyes saved by safety glasses; provide safety glasses, and also paying the cost for prescriptions ground into safety glasses, the taking of personal responsibility. Possible incentives were the plus motivation of discipline, enforcement of the rule of wearing safety glasses at a time when on the job.

Appropos to this, when we try to get full use of glasses and are paying for prescriptions, we achieve 70 per cent reduction of eye injuries. When we made it mandatory to wear glasses all the time on the job and enforced it, we brought our eye injuries down to virtually nil.

Talking about how to successfully motivate people for safety, we have to be realistic. I am going to use four actual cases: two concern group motivation and two deal with motivation of individuals. Since we

took time to explore just what motivation is and also discuss basic definitions, we can cash in on it. All we have to do is put the pattern of successful motivation in flow diagrams which I am sure you use for routing of material. We will use it in discussing our four cases.

First, in setting up our flow diagrams and what to do, on this hand, and how to do it. We selected our goal. We became acquainted with the objectives. We reiterated frequently what these goals and objectives are: Develop and sustain good safety attitudes. On the other hand, personal contact, individual and group participation. We test for achievement, check for better performance, persistence, interest and attitude and goal. As the goal is approached, we inform the people of our progress—again personal contact and mass media. We command, when it is justified, on what to do and how to do it; again personal contact. I work this personal contact to death. It is the only way I know of selling safety.

The only new term we have introduced in talking about the motivation pattern is goal grading. If motivations work, the nearer we get to the goal, the stronger the motivation. It also applies when we provide a continuing long term goal, with intermediate, successive goals. For instance, if you want to achieve "no amputations" in your pressroom, rather than give the whole setup as to your goals, start with no accidents for, say, seven days, then for longer periods, until one of these goals is achieved and you build on each one until your pressroom will be running without amputations. If we'd analyze these cases in detail, we'd be here for hours but I am describing briefly what was done and some of the factors involved.

The first group was a group of 900 women, divided among five newspapers throughout the non-mechanical departments—phone solicitors, clerks, runners, girls in secretarial positions, editors, and just about anything you can mention outside of the mechanical operation. When we started this, we had a frequency rate of 1.19. This was reduced to 0.16 over a twelve-month period. The people I work for aren't interested in frequency figures. They are interested in dollars and cents. We had a figure of \$2,595 at the beginning, and the

costs for the next twelve-month period were running \$172.

When we started out, we made a careful and detailed field study that showed all of our safety programs and activities were basically oriented to the mechanical department needs, objectives and the way the men were thinking. We got a couple of our lady editors together and tossed the ball in their laps. What are we going to do to interest the dolls in safety so they won't stand on chairs or trip over phone cords? The women's safety committee was oriented and developed objectives, programs, material and activities in terms of women's needs, incentives, interest and thinking. The program activities were given to women by the women. The men stayed completely out of it, much to the ire of several of our managers.

Here are some of the motives and incentives used: The motives—belonging; the incentives—participation in small groups of ten or twelve discussing subjects such as "A Woman's World," "It Is Smart To Be Safe," and actually working on safety activities suited to women and their needs.

Another motive—challenge and achievement—and here we had individual rivalry, group rivalry, women vs. men, and women vs. women. The motive—social approval. Top management had personal interest in what these women were doing and paid frequent visits to their departments and spoke with them. There were many more motives and dozens of incentives and all of these items were designed to follow the pattern of successful motivation. There was evidence that they did.

Case No. 2 was a diversified group of 90 mechanics and pressroom workers, working under stop paper conditions. The frequency rate, under normal working conditions, is 1.9. Under emergency conditions, no accidents whatsoever. This case differs from the preceding one in group motivation. It has situational motivating factors which Case 1 didn't have.

Looking at our pattern of successful motivation, we can see that the goal is clearly defined. When we got to sheet rolling, the previously developed safety attitudes, habits and training were all brought into focus due to this emergency. We had to get the edition out. Without question, the achieve-

ment is constantly before them as to the progress of their work, and warranted praise is quickly given to them, including word of praise by rival departments—stereotype, composing and editorial.

An added incentive arising out of the situational motive operates to strengthen the pattern of motivation in this case. As for these incentives, there is a multitude of them. For some, it means to help in the time of need; for others, the reward of overtime; for others, the group effort and the esprit de corps; for others, rivalry between the different gangs getting the web back up and putting in the new roll and putting on the new blanket. All these things came into play. The critical thing about situational motivation centers on this one point. Unless the situation impact has been preceded by good sound safety attitude development, habit formation has nothing to build on and will increase injuries rather than reduce them or prevent them.

The third case is one I think most of you probably run into if you have just one truck driver or anyone driving for you. This was a situation where we had a man with a very poor driving record, having continual accidents, both personal injuries to himself and damage to equipment, but yet the circulation department wouldn't let him go. He was the one fellow who would get out in the poorest weather and get the paper delivered. In both this case and the last case I am going to talk about, I will limit the discussion to the unique aspect rather than to reiterate the principles we have discussed.

This case concerns a driver with a very poor accident record, but whose physical and mental qualifications were quite satisfactory. The incentives were group and individual rivalry, financial reward, participation in the motive of achievement, conformity, identification. The poor performer was put in with three drivers with good records. These rules were applied: Each driver was to get \$50 bonus at the end of the accident free year. If all four drivers had an accident free year, all four would receive \$150. These three good drivers really went to work on this poor one, and he tried to conform and identify with the good ones. It worked so well that all the drivers in this particular company, which is on the coast, are now work-

nure looks even better. So what we are doing and what we have done works for us fairly well.

When our safety engineers call on a printing company, these are the objectives that we have: We try to help the insured; we try to help the printer help himself safety-wise. We do not attempt to do the safety work for him. We feel that isn't our province, that it is strictly management's job and, frankly, we can't get there often enough. If we are able to call on each policy holder every 30 days, that would be fine. I know some companies do that and do beautifully at it. I mean, some insurance companies.

But our aim is to advise with the insured, to help him plan and set up a plan that is appropriate for the size and nature of his operation. Obviously, we wouldn't use the same plan for a large plant employing five or six hundred people, as you would one that has 35 or 40.

We start, of course, with the owner, the top management, and filter down through the supervisors and foremen, working on them primarily. The thing that we are trying to get over to them is to make sure that they understand clearly the relation between safety, accident prevention, and efficiency. It is rather difficult to sell safety on its merits alone. It has to have a dollars and cents value, as Mr. Burkhardt mentioned. That is what they are interested in. We try to increase their safety activities and stimulate their interest in safety, and finally—I purposely put this last—we make inspections of the plant, not that that is less important, but we think it is something they should do themselves on a regular basis—a daily inspection, a weekly inspection, a monthly inspection, in degrees. We try to show them how to do it most effectively.

We will take a small printer with 50 employees, who is mightily concerned with getting business, getting the work out and getting it delivered and collecting the money. Accidents with him are not a real serious problem as a rule; not that their accident record is better, but they don't have accidents on the scale that the larger plant does, or where the insurance company is looking at hundreds of plants.

The one thing that we have learned is that somebody in the plant understands every

machine in there and every operation, and understands it thoroughly. They understand it far better than we outsiders, even those who make a living in safety work. Now, the question is, do they always make use of the knowledge they have of that machine? Obviously, they don't. That is why there are accidents. Where we put a great deal of our stress, safety-wise, is with the manager of that department or that area, who is responsible for the people that operate the various machines, to make sure that they make a job study as needed for each operation.

The printing industry, I believe more than any industry that I have had any experience with, is geared to production. I mean, that is their bread and butter, their life, that is their life's blood—production—and sometimes it is such a problem that safety comes way down the ladder, just about the last place. So we come to the type of accidents that we have. I am going to hit the highlights of this and talk about accident types, with just one or two illustrations later.

Machinery accidents. In other words, getting caught in moving machinery is the most serious type of accident that we have encountered. In our analysis by types, we found that 18 per cent of accidents involve some type of machinery, I mean, getting caught in it, or by it. The average cost—and this is always important to a printer, the man who pays the policy—the average cost of a compensation claim in this category is \$223. Perhaps I should also explain that in figuring cost, for instance, we don't figure frequency, like the National Safety Council, where lost time injuries are involved. Quite often we don't even have that information. These cost figures are composed of medical expense and hospital, if any, the adjuster's expense that had to handle the claim, and compensation payment, those three things. Out of 100, 93 of the claims did not involve any workmen's compensation payment with medical and adjustment cost; only 7 involved that. So, you see, we have the total cost here, and that is what the insured is interested in, because that is the bill he is going to pay.

The second most expensive kind is material handling, usually lifting and moving materials, resulting in back injuries, muscular troubles, hernias. That involved 13%, with an average cost of \$206.00.

Falls is the third highest category in terms of cost, being 6%, with \$154 average cost per claim for that type.

Then other types of lesser consequence, objects struck someone, or vice versa, someone bumped his head, and so forth, with an average cost of \$28.

Cuts, foreign bodies in the eye, dermatitis, skin rash, burns, things of that sort, make up the others.

The one thing that we recommend after we have had our discussion with management is that they persuade their foremen and supervisors, whoever has the responsibility for a certain group, that they actually go out and make a job study of every operation, and by that we explain what we mean, the procedure, like time studies in a Ford plant, or something like that. But determining the most efficient, the most productive and the safest way to do every job. Usually, we work with them on that if we can. We find that oftentimes very simple rearrangement of material or stock, or changing the floor plan, or the positioning of the operator can mean the difference between a safe and an unsafe operation, and we thoroughly recommend that.

In the smaller plant particularly—we will in all plants—but in the smaller plant, we ask the owner to talk frequently with his employees about safety, about their welfare, pointing out that he is interested in their welfare, he doesn't want to see anybody hurt, and that is very true. The smaller the plant, the closer the relations. Also pointing out that involvement in an injury can seriously affect not only their own well being, but their income as well, which we are all vitally interested in. Once again, the emphasis is on the foreman part of it.

As we go into any plant, the first thing that we are concerned with, and I am sure all of you are, is housekeeping conditions. Believe it or not, it is a simple thing but it is the one thing that causes so many accidents. If you don't believe it, just look over the list of accidents that you have had during the past year in your plant, or that you are familiar with. You will find that you've got probably one very serious accident that cost \$1500 or \$3,000.

Due to the fact that there was a little puddle of oil or grease, someone hurrying by stepped in it, his heels shot out and he

tell and sustained a bad injury. This is so elementary that I feel ashamed even to mention it, but it is the thing that creates really bad accidents.

Crowded conditions. Sometimes there is not much you can do about it. But other times it is the thing that has grown like Topsy—you haven't become aware of it. You have let things be stocked or piled in an area when they really belong out in the warehouse or some place apart from the working area. Whenever you have crowded conditions, you have an unusual accident hazard.

Hand trucks, dollies and things that are left in the aisles, even mops and brooms. That is a frequent violation that we find. Obviously, it can be corrected and it should be corrected, and the only way to do it is to make sure that somebody is continuously alert for those things.

One particular hazard that one of my engineers points out is the use of fork trucks, industrial trucks, in the plant. He said, "My experience is that they travel far too fast for the safety of other people," and he mentioned that they are always difficult to hear because there is a lot of noise when the prestes are running, and they can sneak up on you. It is a thing that usually grows in proportion to the use of the number of trucks. They really form a serious hazard, and accidents will attest to that.

The cleaning of the rolls presents a serious accident problem and we have had mighty serious injuries from that. It will always be a problem. The one thing that you don't want to use is carbon tetrachloride. But I am sure the method you use, and every man that works at that job knows how he should do it, but too often takes the short way out. They do it the hard way. If they use the rag, the rag is caught while moving and the hand is put in and it is a very serious injury.

The thing that we look for as we visit a plant is what the foremen are doing. If we see some workmen doing something that is obviously unsafe, that any school boy would know wasn't safe or the best way to do it, if he does it in front of the foreman and the foreman ignores it, he doesn't notice it or passes it off, then we have a foreman problem, and we talk to

the foreman rather than to the man that made the violation. We feel that it is the foreman's position to correct that, and we think that is the biggest field we could work with—the foremen of management.

Last year the safety manual for the graphic industry was discussed. It is a fine publication. It was put out by the National Safety Council, but the objection to it was that it dealt mostly with books and periodicals and such, and had very little newspaper production in it. I believe there was some thought given to revising or making a new one for the industry. I don't believe that has been done yet. But it is a fine thing for anybody that has time to study it. But that is the catch in it—having time and interest to go through it. We bought a lot of these and began giving them out to our larger printers, feeling that they would be interested in it. They had never seen it. But just like if somebody had given it to me I would probably turn it around in my hand and say "That looks good and I will read that when I get time." But the point is I probably would never have gotten time.

We have found that in order to get through to a busy man, a man that is running a printing business, we've got to boil it down to essentials, and that is what we have done in our one-page basic safety program, "A Basic Safety Program To Prevent Injuries to Employees." We have listed six principal points, with subheadings under each one. If we can get them to take the time, after we have left their office, to read that and consider doing as much of it as they can, we feel that we had made great progress. I don't blame them, and I don't blame you folks for not taking time to go through that. It isn't your field. You haven't the time, but if you can try to do as many of these six basic points, it would help you.

For instance, the proper selection of new employees. That is basic. It eliminates a lot of needless expense. If you hire somebody that has a back injury or a hernia, weak heart, diabetes, epilepsy, you have hired yourself a workman's compensation claim that is going to cost from \$1,000 to \$10,000. Not only do you save on compensation cost, but you get a more efficient, a more dependable work force by selective hiring. Your unemployment taxes, an even greater cost to you than your workmen's

compensation insurance, is vitally affected by your hiring program. It even affects your hospitalization, Blue Cross, or whatever you may have. So it is extremely important that you give thought to that. However, you've already got a houseful of people and there is nothing you can do about that. But when you hire new people, that is very important.

Then teaching and training everybody for a job. I think it is important that you teach every man, I don't care if he has worked twenty years at a particular job and you are going to place him on one just like it, he still should be trained and taught. He should be shown what you want done, not the way they did it somewhere else, because that is not the way. He may have twenty years of bad experience instead of good experience behind him, so it is worthwhile to take the time to train him.

Then supervise the working practices of all employees regularly.

Then institute a safety education program, a thing that each company has to work out for its own needs, to stimulate employee interest, keep it alive, give them safety tips.

Make plant inspections, do that yourself and don't wait for the insurance company, and study and analyze past accidents.

We have found that inasmuch as we can only get around to each printing company once, twice, three, maybe four times a year—I would say that twice a year perhaps is the average for our visits—obviously we are not going to do a great deal to improve the safety record of that company, unless what we do the day we are there carries over. In other words, have we helped them to help themselves?

Now we supplement our engineers' visits, maybe two or three a year, with a monthly safety suggestion letter, a simple little letter that we write with a certain industry in mind, and we mail that to the owner of each company we insure. We try to get over a very simple message about safety.

We thus give twelve more shots, and they are rather painless for the insured. They don't break into his working day. They don't tie him up in his office for an hour or two hours. He reads it, and I think we have accomplished a great deal by that.

If you have an interesting message and say it simply, and leave lots of white space, that is the best part of the message—the white space. You know, somebody has said that anybody could make a good speech, or write a good letter, if they have the three principal ingredients: A good opening, something that catches your attention and attracts your interest, then a good ending, a good summation and summary, then practically nothing in between. So that is what we try to do.

When we first called on them, the safety engineer inquired about their safety program. He said, "What sort of a safety program do you have, if any? Perhaps we can work with you on that." The man was very frank and said, "Well, we don't really have a safety program. We are interested in preventing accidents and we have done a pretty good job, we think, but we just don't have any formal program. We are very careful who we hire. I don't want to hire anybody that isn't going to be an asset to us. We want somebody that we can build on and we are very careful. They fill out an application form and we check back with former employers for at least four or five years. We check on all of the jobs they have had, and we inquire by telephone what they thought of the man, what his work record was, what his accident record was, what about his health, and so forth. Unless it comes up to real good, we are not interested in hiring that man."

Our engineer said, "That is good. What else do you do?" He said, "Well, we hire nobody without a thorough medical examination." The engineer said, "That is even better, that is wonderful." The man continued, "Oh, yes, we have little meetings every once in a while. I have them in our office with the foremen and then the foremen have little meetings on the floor when time permits, with his people, but we don't have any safety program."

Our engineer said, "It seems to me like you have a pretty good safety program, whether you know it or not. What do you do about accidents, when an accident happens?" The man said, "Well, we are concerned when somebody gets hurt and we try to find out exactly what caused the accident, what went wrong, and then we try to prevent it ever happening again. Let

me show you what we do. Here are some that recently happened.

"Every time they have an accident of any consequence, or one in which there is a lesson to be learned, particularly, after they have investigated it thoroughly, they go back to the machine on which that accident happened, or wherever it happened, and they take a photo. Then they reproduce that picture. And let me just read what it says:

"Safety is a full time job. Think safety in every task you undertake. Know your machine and respect it. You will never be asked to perform a task which doesn't provide you with safe working conditions."

"Then it says what happened:

"The printing department was short-handed and all of the pressmen were busy. The operator wanted to help, so she started washing the large impression roller on the 20" printing press. The clean rag got caught and the operator followed a natural tendency to try to pull it out of the press. Instead, her hand was pulled between the two metal rollers. The press was not running, just on jog, but the roll of this press was enough to pull her hand into the press."

"That is what happened. Then it describes the nature of the injury, how her hand was hurt. Then it says 'How could this accident have been prevented?' All operators should have sufficient knowledge of the equipment they are working on before they undertake such a task. Experience in handling this equipment would have taught her caution in this operation. She should have waited until a pressman was available before attempting to clean the machine."

"That is one accident and they went to extreme lengths and yet they felt they didn't have a safety program. I just wish we had about 100 per cent of our printers that had 'no safety program' like that."

So often we get committee reports, perhaps minutes of a safety committee meeting, where they have been reviewing accidents that happened, and they will describe it thus: "John Brown accident; did so and so." Then down at the bottom, they say "We voted guilty." That isn't the point. We are not trying to pin guilt on somebody.

1961 National Safety Congress

Where we have safety committees, and lots of your plants probably do have safety committees, I would advise that every man on that safety committee see the National Safety Council safety film entitled "Cause and Cure."

I just wonder how many here have ever seen that film? Do you remember the title? It is an extremely interesting and very informative film, which shows a safety committee in action. It really makes a member aware of what he is trying to do and how he should go about it.

Those of you who are responsible for safety back home, or are interested in it, or have anything to do with it, don't be afraid to repeat a good idea, or every day instructions if they are needed. Believe me, so many things can be repeated dozens of times and be just as effective the second time. Perhaps you think you are wearing it out. You are wearing the people out by telling them to mop up, clean up, keep the aisles straight and don't put things in the aisles. If you think that, if you think you

are wearing it out, believe me, it isn't true.

I was interested in a little article from the NATIONAL SAFETY NEWS for October, 1961. It is on page 9 under the heading, "The Safety Valve," by Carmen Fish. I am just going to quote the first part, which applies not only when you are writing a directive, a bulletin, but also when you are doing it verbally.

"Old Stuff. One of the shortcomings of most publications is that they are so afraid of repeating. Editors kid themselves by thinking every reader has read everything they published. Inevitably, of course, editors do repeat. But they always feel guilty about it. It is an admission of sterility when they dish up old stuff and even dress up well worn out ideas in new dress."

Whether you are a supervisor, or whether you are the man in charge of the supervisors, or whether you are going direct to your employees, believe me, don't be afraid to repeat the good old fashioned safety rules that make a lot of sense.

OFFICERS OF THE PULP AND PAPER SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—VINCENT P. COULON, Safety Dir., Sealright-Oswego Falls Corp., Fulton, N. Y.

Vice Chairman and Program Chairman—ROBERT J. GELL, Staff Asst., Paper Mills Div., Eastman Kodak Co., Rochester, N. Y.

Vice Chairman and Newsletter Editor—ROBERT M. GILMORE, Gen. Safety Supvr., Rayonier, Inc., Hoquiam, Wash.

Secretary—MERLIN C. RACE, Dir. of Safety, St. Regis Paper Co., New York, N. Y.

Regional Representatives—*FRANCIS H. WAGNER (Chairman), Dir. of Safety, The Mead Corp., Chillicothe, Ohio; *Lake States*—*ARTHUR CARLE, Safety Dir., The Northwest Paper Co., Cloquet, Minn.; *Middle Atlantic*—HARRY J. HAHN, Safety Coord., Hammermill Paper Co., Erie, Pa.; *Southern*—*DALLAS E. HENRY, Safety Supvr., Continental Can Co., Inc., Paperboard & Kraft Div., Hodge, La.; *Pacific Coast*—DAN ADAIR, Safety Coord., Pacific Coast Assn. of Pulp & Paper Mfrs., Portland, Ore.; *Canada*—*V. E. MINOR, Safety Supvr., The Ontario-Minnesota Pulp & Paper Co., Ltd., Kenora, Ont., Canada; *Midwest*—*EARL F. RIFSTRA, Personnel Mgr., Container Corp. of America, Chicago, Ill.; *Central*—H. E. NEWBURY, Safety Supvr., Ecusta Paper Div., Olin Mathieson Chemical Corp., Pisgah Forest, N. C.; *New England*—ORRIS K. WEBBER, Personnel Mgr., St. Regis Paper Co., East Pepperell, Mass.

Committee—A. SCOTT DOWD (Chairman), Pres., Fritz Publications, Inc., Chicago, Ill.; RICHARD H. WAHLFELD, Co. Safety Coord., Engrg. Dept., Bemis Bro. Bag Co., St. Louis, Mo.; RICHARD DYER, Corporate Mgr., of Safety, Scott Paper Co., Philadelphia, Pa.; *J. FRED HERRY, Gen. Ins. Mgr., Alton Box Board Co., Alton, Ill.

Special Projects Committee—GORDON B. LEMKE (Chairman), Research Engr., Employers Mutuals of Wausau, Wausau, Wis.; LAMBERT J. LOUVE, Indust. Relations Mgr., Container Corp. of America, Chicago, Ill.; RUSSELL E. BELL, Safety Dir., The Crosscut Co., Crossett, Ark.; ROSS E. SCOTT, Mgr., The Ontario Pulp & Paper Makers' Safety Assn., Toronto, Ont., Can.; D. L. EISENACH, Safety Dir., Minnesota & Ontario Paper Co., International Falls, Minn.; C. C. MACPIKE, Safety Dir., Kraft Div., St. Regis Paper Co., Pensacola, Fla.

Off-The-Job-Safety Committee—MRS. MARIAN IRVING (Chairman), Asst. to Indust. Relations Dir., Stone Container Corp., Chicago, Ill.; *D. V. HILL, Safety Dir., The Mead Corp., Kingsport Div., Kingsport, Tenn.; *GEORGE R. MERRIMAN, Coordinator of Safety, International Paper Co., Southern Kraft Div., Mobile, Ala.; A. E. HAMMERSTEIN, Safety Dir., Gaylord Container Div., Crown Zellerbach Corp., St. Louis, Mo.

Pulpwood Logging Committee—E. C. CORDON (Chairman), Louisiana Forestry Commission, Alexander State Forest, Woodworth, La.; E. N. DENTON, Mgr., The Quebec Pulp & Paper Safety Assn., Inc., Quebec, P. Q., Canada; A. R. BENTLEY, Safety Supv., Hiwassee Land Co., Calhoun, Tenn.; J. S. HENSEL, American Pulpwood Assn., Wausau, Wis.; J. OMER LANG, Chief, Woods Employment Unit, Brown Co., Berlin, N. H.

Pulp Manufacturing Committee—HARRIS K. WILLIAMS (Chairman), Asst. Coordinator of Safety, Southern Kraft Div., International Paper Co., Mobile, Ala.; ROBERT G. ISON, Mgr. of Safety Services, Kimberly-Clark Corp., Neenah, Wis.; JACK F. ROBERTSON,

Gen. Safety Supv., Crown Zellerbach Corp., Portland, Ore.; H. G. BARRETT, Safety Dir., Ontario Paper Co., Ltd., Thorold, Ontario, Canada; JOHN S. TURNER, Safety Coordinator, Bowaters Southern Paper Corp., Calhoun, Tenn.

Paper Manufacturing Committee—JAMES M. PINKSTON, JR. (Chairman), Personnel & Safety Supv., The Crosssett Co., Crosssett, Ark.; A. E. TOPMILLER, Safety Supv., The Champion Paper & Fibre Co., Hamilton, Ohio; R. H. BLUNDEN, Safety Mgr., Scott Paper Co., Marinette, Wis.; FRANK C. HARMON, Employment Mgr., Hollingsworth and Voss Co., West Groton, Mass.; GEORGE W. OFFERJOST, Supv., Organization Development and Training, Containerboard & Kraft Paper Div., Continental Can Co., Inc., New York, N. Y.; JANE E. JONES, Dir., Ind. Relations Div., American Paper & Pulp Assn., New York, N. Y.; CHESTER W. MATZENGER, Safety Dir., International Paper Co., Mobile, Ala.

Ran Committee—HAROLD HEWITT (Chairman), Asst. Personnel Mgr., Bemis Bro. Bag Co., Peoria, Ill.; ALLEN H. WATTS, Safety Dir., Union Bag-Camp Paper Corp., Savannah, Ga.; JACK A. KOHL, Training Supv., Converting Div., St. Regis Paper Co., Pensacola, Fla.; TOXIE R. TRIM, Safety Dir., Gaylord Container Corp., Bogalusa, La.

Rubber Committee—HARRY R. MESLER, JR. (Chairman), Dir. of Safety, The Ruberoid Co., South Bound Brook, N. J.; M. H. MILLER, Dir. of Safety, Dominion Tar & Chemical Co., Montreal, Quebec, Canada; MATT F. PINK, Supv. of Safety, Certain-Teed Products Corp., Paoli, Pa.; ROBERT C. SMITH, Supv. of Safety, Industrial Health and Plant Protection, Johns-Manville and Co., Waukegan, Ill.

Insulation Committee—BUDDWIN J. LEE (Chairman), Safety Dir., Wood Conversion Co., Chiquet, Minn.; M. F. MATSON, Safety Supv., Minnesota & Ontario Paper Co., International Falls, Minn.; WILLIAM BIGHAM, Personnel Mgr., Abitibi Corp., Alpena, Mich.; C. HOCTEL, JR., Dir. of Safety, The Celotex Corp., Morrero, La.

Specialties Committee—ALFRED B. BARNES (Chairman), Safety Engr., Fibreboard Paper Products Corp., San Francisco, Calif.; EDWYN D. LEWIS, Personnel Mgr., Container Corp. of America, Philadelphia, Pa.; OTTO WAGERS, Safety Adm., The Champion Paper & Fibre Co., Hamilton, Ohio.

Shipping Container Committee—JACK DUNSMAN (Chairman), Asst. Mgr., Industrial Relations, Container Corp. of America, Louisville, Ky.; RALPH H. EFFLER, Mgr., Employee & Training, Packaging Corp. of America, Hutchinson, Kan.; WILLIAM B. GITTENS, Dir., Industrial Relations, Fibre Box Assn., Washington, D. C.

Folding Carton Committee—FORREST E. KIMMEL (Chairman), Safety-Medical Dir., KVP Sutherland Paper Co., Sutherland Div., Kalamazoo, Mich.; HENRY KVINTUS, Personnel Mgr., Weyerhaeuser Co., Boxboard & Folding Carton Div., Chicago, Ill.; WILLIAM W. JOHNSON, Supv. of Organization Development & Training, Boxboard & Folding Carton Div., Continental Can Co., Inc., New York, N. Y.

Staff Representative—ROBERT CURRIE, National Safety Council, Chicago, Ill.

Chemicals Chairman—H. BURT WALLACE, Safety Dir., Montreal Star, Montreal, Que., Canada

Co-Chairman—JOHN BRADLEY, Asst. to Mgr., Magazine Press Div., The Curtis Publishing Co., Philadelphia, Pa.

Guarding and Controls Chairman—F. N. BURT, Mgr., Trip Control, Minneapolis Honeywell, Freeport, Ill.

Co-Chairman—ROBERT M. GORSIAN, Asst. Personnel Dir., J. W. Clement Co., Buffalo, N. Y.

Fire Chairman—LAWRENCE G. BURKHART, Risk Control Inc., New York, N. Y.

Co-Chairman—WILBERT R. MAY, Safety Officer, Treasury Dept., Bureau of Engraving & Printing, Washington, D. C.

Staff Representative—E. E. KOCH, National Safety Council, Chicago, Ill.

REPORT OF THE RAILROAD-HIGHWAY TRAFFIC SAFETY COMMITTEE

By G. M. DEMPSEY
Chairman

Other Volumes of 1961 National Safety Congress Transactions	Back Cover	

First, I would like to point out that the statistics of the Interstate Commerce Commission for the past 26 years, ending with 1960, show an annual average of 3,787 highway-railroad grade crossing accidents with an annual average of 1,596 deaths and 4,140 injuries. The number of accidents ran from a high of 4,489 in 1937 to a low of 3,075 in 1959. The high figure for the fatalities occurred in 1942 with 1,970 and the low of 1,203 in 1959; the high in the number of injured occurred in 1937 with 5,136 and the low in 1958 with 3,161. The number of casualties (killed and injured) per accident ran from a high of 1.61 in 1935 (the beginning of the 26 year period) to a low of 1.40 in 1956. The grand total of all motor vehicle deaths during this same 26 year period was 901,038 and those which occurred at rail-highway grade crossings amounted to a grand total of 41,551 or 4.6 per cent of the total. For the year 1960 this percentage was 3.6, representing the ratio between 1,364 grade crossing deaths to 38,200 total motor vehicle traffic deaths.

Taking the figures for the year 1960 we find that the family automobile accounted for 2,332 of the total of 3,195 rail-highway grade crossing accidents, or 73.0 per cent and motor trucks accounted for 621 of the total of 3,195, or 19.4 per cent.

Instances where motor vehicles were struck by trains amounted to 1,923, or 60.2 per cent, and those where trains were struck by motor vehicles amounted to 1,086, or 34.0 per cent.

So much for the statistical record. Now, let me tell you about a few of our activities during the past year. Bear in mind that the new Committee on Motor Vehicle Traffic Safety at Railroad Grade Crossings of the Traffic Conference has been, to a large extent, in the formative stage. Having started from a small beginning with a few railroad safety officers we now have the following representation from all conferences of the National Safety Council:

Industrial Conference—10 representatives,
5 each from Railroad and Petroleum Sections.
Motor Transport Conference—6 representatives.
Traffic Conference—6 representatives.
Farm Conference—2 representatives.
Womens' Conference—2 representatives.
Labor Conference—2 representatives.
School and College Conference—1 representative.
Religious Activities—1 representative.
Members at Large—6 representatives.
Total—36

In addition we have several alternate members which we think is a good thing guaranteeing full representation at all of our committee meetings.

Attended by 26, the initial meeting of our expanded committee on September 13, 1961 got off to a splendid start by being addressed by General George C. Stewart, executive vice president, National Safety Council, who outlined the desirability of having definite objectives and invited use of the Council staff and solicited recommendations on which the Council could take action.

Pertinent remarks were also made by Henry G. Hoeffer, Asst. Genl. Mgr. and Harry Porter, Jr., Manager, Traffic Dept., both of the National Safety Council.

The scope of activity of the new committee was explained as follows:

- 1—Assemble and analyze the facts about highway-railroad crossing accidents.
- 2—Undertake to study and promote the following activities:
 - (a) Uniformity of State Laws pertaining to vehicle operation at railroad grade crossings.
 - (b) Stronger enforcement of traffic laws and improved engineering at railroad grade crossings.
 - (c) Safer operation of School and Inter-City buses at railroad grade crossings.

(d) Programs to help prevent accidents involving trains and commercial vehicles at railroad grade crossings.

3.—Recommend actions and activities the National Safety Council should conduct to reduce highway-railroad crossing accidents.

4.—Assist the National Safety Council in conducting its nationwide Signs of Life educational program, which reminds motorists of the need to know and obey traffic signs, signals and pavement marking, particularly those guarding highway-railroad crossings.

5.—Develop an annual summary report suitable for publication and distribution among all agencies and interests involved in preventing railroad-grade crossing accidents.

To implement these objectives, the following subcommittees were established and chairmen and members of each were named. The subcommittees and the chairmen selected are:

Committee A—Publicity and Publications—Herschel H. Patterson, Chairman.

Committee B—Uniformity of state laws covering operation of motor vehicles at railroad grade crossings—Ralph F. Gross, Chairman.

Committee C—School bus operations at railroad grade crossings—D. M. Ferguson, Chairman.

Committee D—Operation of commercial vehicles at railroad grade crossings—E. W. Hobbs, Chairman.

Committee E—Traffic law enforcement at railroad grade crossings—Robert E. Raleigh, Chairman.

The duties of each of the subcommittees were outlined but to conserve the time these will not be explained at this time.

On October 17, 1961 during the National Safety Congress and Exposition, another meeting of the committee was held with

26 attending. Duplication of engagements during the congress prevented attendance by several committee members.

At these two committee meetings separate group meetings of the subcommittee were held.

These resulted in several suggested items for further handling, among them (1) a recommendation that the American Association of Motor Vehicle Administrators urge state administrators of motor vehicles to include more questions about railroad grade crossing safety in the state driver license examinations (2) a recommendation to the National Committee on Uniform Traffic Laws and Ordinances to consider a provision prohibiting stopping, standing or parking on railroad tracks at any time or place. (3) a recommendation was also made to the American Association of Motor Vehicle Administrators that consideration be given to making a traffic law violation at a railroad grade crossing a serious one, having a high point value (4) that railroad chief special agents be urged to contact state police associations or similar organizations to which they belong and request more enforcement attention to violations of traffic laws at railroad grade crossings and (5) that a news release covering the activities of the committee be prepared and distributed on a nationwide basis.

These are some of the things on which the committee has taken definite action. It is only a beginning. There is still a great deal to be done. With the outstanding spirit of cooperation which exists between all members of the Committee which represents varied interests as the record shows, even greater accomplishments will be made. A deep conviction of the magnitude of the task ahead and a fervent desire to obtain results prevails throughout the entire group of individuals dedicated to the prevention of rail-highway grade crossing collisions.

WHY OFF-THE-JOB SAFETY?

By R. P. HAMILTON

Supt.-Safety, St. Louis-San Francisco Railway Co., St. Louis

How many of you have asked yourself this question? It would be interesting to know how many others all over America are asking the same question. I will try, in a few minutes, to tell you why it is felt that we should have an active off-the-job safety program, the same as we do on-the-job.

On February 17, 1961, the following headline appeared in practically every newspaper in America: "93,000 Die in Accidents. 9,400,000 Injured during 1960." Accidents killed 93,000 and injured 9,400,000 men, women and children; they cost \$13,600,000,000. Traffic accidents, as usual, topped the list with 38,200 killed, followed by home accidents with 27,500 deaths; accidents at work caused 13,800 deaths; accidents in public, excluding traffic fatalities, resulted in the loss of 16,500 lives; deaths from burns totaled 7,300 and drowning, 6,500.

Let's take another look at the accident picture in America during 1960: needless deaths, injuries and destruction of property. The property that was destroyed can no doubt be replaced, but no one can replace the lives of the 93,000 who were killed, or erase the suffering of those who were injured.

You will note that out of the total of 93,000 killed in accidents during 1960 only 13,800 were killed at work. This leaves a total of 79,200 killed off the job. Of the 9,400,000 injuries, 1,950,000 occurred on the job, which makes a total of 7,450,000 injured off the job. These figures, in my opinion, clearly demonstrate why we should have off-the-job safety programs.

Another good reason is that if the money paid out for accidents during 1960 could have been used constructively, it would have meant much to America and to each of us as citizens and taxpayers. A large insurance company estimated that the \$13,600,000,000 could have provided a 100 per cent salary increase for every public school teacher, principal, supervisor and school superintendent in the United States. It could have built more than 300,000 Class A school

rooms for 9,000,000 youngsters; it could have provided a four-year college education for 12,000,000 students; it could have given every taxpayer a 30 per cent reduction in taxes; or it could have built more than 100,000,000 new single family homes. Yes, it would have meant much to have saved those 93,000 lives, the suffering of the 9,400,000 who were injured, and the \$13,600,000,000 which was spent for loss of life, suffering and destruction of property.

There are those who continually talk about the hazards of working in industry, yet records show us that we are twice as safe on the job as we are at home. We are safer at home than we are on the streets and highways of our nation today. That brings us to this question: What are you as an individual doing about your safety and the safety of your family? Do you read about the accidents which occur in your community, your city and your state and say, "That's too bad," then forget them? Or do you really do something to prevent the same thing happening in your home to your family?

We teach our children literature, art, music, drama, cultivation of the voice, but are we teaching them to meet the ordinary hazards of this mechanized and perilous age? We would not arm our children with machine guns or place in their hands poison, drugs and narcotics with which to amuse themselves, yet we often leave those things where the children can reach them, or we take them by the hand and walk across the street against a red light or "don't walk" sign. If you don't believe the latter statement, stand on any street corner in any city and see how often this happens. This is another reason why we need off-the-job safety.

It has been my privilege to serve as chairman of the off-the-job safety committee of the industrial conference, the Railroad Section of the National Safety Council, and the Safety Section of the Association of American Railroads and I know what the leading companies of this country

1961 National Safety Congress

are doing to promote off-the-job safety. There are 28 sections of the industrial conference and seventeen of those 28 have off-the-job safety committees. I am proud that the Railroad Section was one of the first sections to start this worthwhile safety activity.

If we are to have a good safety program, either on or off the job, foresight and advanced planning are essential in every operation but the planning should be done at the proper time and place. We are frequently caught in a whirlpool of thoughts of things that happened yesterday or become lost in a muddle of thoughts of the future. We should clear our minds of the troubles of the past and the expected troubles of the future while at work, at home, on the highway, or wherever we may be.

You realize, I'm sure, that in the space of a few short years, we have been handed

the automobile, the tractor, the diesel, the radio, the television, radar and the atom bomb; and as you know, scientists are working to perfect rocket and space ships. It is an old axiom that man can finally accomplish anything he can imagine. Would it not be fine if we could imagine everybody taking safety seriously, whether on or off the job, and reduce the needless number of fatalities and injuries occurring in America today. We have been able to do practically everything else but be safe.

A man's first duty is to his home and family and he must fulfill each and every obligation to insure for them a full, safe and happy life. When we do the best we can to promote safety everywhere, we will always have the satisfaction of knowing that the good deeds we do as we go through life are etched deeper in the hearts of our fellowman than all of the material wealth we may acquire.

REPORT OF COMMITTEE ON HOME AND OFF-THE-JOB SAFETY

By R. P. HAMILTON

Supt., Safety, St. Louis-San Francisco Railway Co., St. Louis

The National Safety Council wrote to all railroad members of the Council requesting them to submit a resume of their home and off-the-job accident prevention program for the year 1960, for entry in the competition for the Council's Public Safety Activities Award. Twenty-two railroads furnished the Council with a brochure outlining their off-the-job safety programs, and fifteen of them won the award. A few of the fifteen railroads have won the award for the eighth consecutive year. The winners were:

*Atchison, Topeka & Santa Fe, *Atlantic Coast Line, *Canadian National, *Canadian Pacific, *Chesapeake and Ohio, *Chicago, Burlington & Quincy, Chicago, Milwaukee, St. Paul & Pacific, *Cincinnati, *Delaware and Hudson, *Duluth, Missabe & Iron Range, *Illinois Central, *New York Cen-

tral, Norfolk & Western, *Pennsylvania, *St. Louis-San Francisco. (*Also won the Public Safety Activities Award for the year 1959.)

The Council asked for information concerning the following activities: off-the-job accident prevention program (employee and general public), type of program (traffic, home, school, employee), safety meetings (family, public, school), active in city-state safety work, signs of life program, other public safety projects, promotion through advertising and other media.

In practically every instance those who submitted an entry answered "yes" to each question.

The total number of meetings, signs of life material distributed, etc., by the railroads furnishing the information requested by the Council is listed below:

Kind of Meeting	Number	Attendance
Family Group Safety and Public	4,462	730,118
School Safety Meetings	2,658	1,481,232
Civic Clubs	444	24,312
Boy and Girl Scouts	1,225	65,015
Families & Children conducted through Safety Car County Fair Safety Exhibits (2 Railroads)	325	4,554
Tours of Railroad Property for children	912	36,457
Radio and TV Programs	75	?
Films loaned to Industry & Others Number of times shown and attendance	2,302	481,958
	12,383	3,057,466

Safety material such as signs of life pamphlets, posters, key chains, reflectorized auto bumper stickers, safety calendars, drinking cups and book matches with safety messages on them, distributed and used — totaled 1,537,990

Other Safety Activities	Number	Attendance
Employee safety meetings on-the-job in which off-the-job safety was stressed	88,846	4,842,300

Railroad Industry

Your committee noted with interest the following projects being undertaken by those railroads that submitted brochures to the Council:

Trespassing programs, talks to safety conferences, Boy Scouts, safety councils. Civic meetings, local and state safety conferences.

Public safety meetings, and work with other industry.

Maintenance of film libraries, safety instruction cars, and activities of operating and safety officers in local safety projects.

Good program of reporting grade crossing violations by school buses and gasoline transports.

Many other things were mentioned that help to promote safety both on and off the job.

The railroads that submitted brochures to the Council are to be commended for their safety programs. Your committee is confident that there are a number of other railroads with outstanding safety programs of their own but they did not furnish the Council with the information requested. We hope that each railroad will submit a resume of its safety activities to the Council for the year 1961 so the railroads may receive the credit they deserve for the safety work they are doing both on and off the job.

THE RELATIONSHIP BETWEEN SAFETY AND TRAINING

By T. L. HILDEBRAND
Safety Supervisor, Soo Line Railroad Co.
Minneapolis, Minn.

In its report to the American Association of Railroad Superintendents at the meeting in Chicago, June 6-7-8, 1961, Committee No. 5 gave a report called "Effective Safety Action." In this report, the committee decided that "It must originate with the supervisor, and, of course, the supervisor is management."

To further stress the point of the supervisor's job in safety, the following paragraph is quoted:

"The supervisor should have a clear understanding as to just what is expected of him; in other words, how to prepare reports, proper investigations, proper corrective action, proper minimum on-the-ground safety meetings required, and proper method of property inspection to uncover safety hazards, etc. and how to handle them for correction. We are attempting to stress that unless the supervisor is thoroughly versed on all phases

of a good sound safety program, there can be no effective safety action."

In this report, the record is silent as to who is going to train this supervisor; what type of training he should have; and with what materials he should be supplied. It is this aspect of training that I will discuss today.

It has been said "knowledge is power." Knowledge is power only when properly used.

If a supervisor is to be effective in any phase of his work, he must first be trained himself and then be able to teach others.

Since we start with the premise he must be trained, and must be trained to teach others—who is going to do the training?

In most organizations, the training is going to be assigned to the safety department. The officer in charge of this function will then have to decide how best to approach the job. In the smaller organizations, the job, probably, will be given to someone who is qualified either by experience or by having some of the personnel functions already assigned.

There are several ways open to management to train the trainers:

1. Many progressive companies feel that it pays to spend a little more money and are willing to send their people to a university or college for a period of time. This has the advantage of giving the person on-campus training in a concentrated period. The college has many resourceful people and can do a better job of teaching. The results from this kind of training have been excellent.

2. Many colleges have extension courses through their business service departments. Through these departments, they can supply teachers in a company to do a specified job, if there are enough people involved to make it worth while. The teaching can be done on campus or on the property of the company ordering the service. If the training is done on the property, the teacher can draw on the company for resource people. This method is less costly per man than the campus training, since the men would not have to have expenses paid while away from home. The latter method is one with which I am most familiar, having taken several courses this way.

3. In a place like Chicago, for example, the National Safety Council, through its many services, could set up a training course tailored to the needs of the railroads in the city. The course could be so set up that all railroads could take advantage of the training offered. This method has many things to recommend. The council could draw on the railroads involved for people in all fields to augment the staff of the council itself. This program could well be integrated with the other courses in safety direction that the council now gives. The cost to those railroads in and about Chicago would be reasonable.

For those who have limited budgets and want to do the job, there are many ways to do it. The National Safety Council has two home method courses which can be used effectively. All they need is someone who will spend the time to study the leaders' guides, which are supplied with the other material. If the directions are followed carefully, the course can be well presented.

The two courses I am talking about are:

1. Supervisor's Safety Manual—This consists of a hard-covered book which is divided into 12 chapters. Each chapter can be used in one discussion period for one hour. As stated before, a leader's guide is available for use with the book. The advantage of this item is that the employee has a book which he can use for reference if the occasion should arise.

2. The National Safety Council has recently put out another series of six pamphlets entitled "Men and Motives in Safety Supervision."

Should you choose either of these two courses, you probably will want to use some of your own materials to add to the value of the course. Both are good vehicles for safety training.

Now that we know how to go about getting the job done, the next question is—Whom do we train?

We should train men who have most of the training work to do when out on the job. These are the trainmasters, yardmasters, roadmasters, general foremen, and others at this level. Since these men are in constant contact with the other supervisor levels of the company, they are the logical

men for training others. These men have been chosen for their jobs, partly, because they are leaders. When we train these men, we increase their value to the company. They have an additional asset in that they know the job; its hazards; how it should be done; best method of doing the job; and know and understand the people with whom they work. There is no better place to start than at this level. These men must train the foremen under their jurisdiction, so they can take the program to the employees.

We now know how to teach, and we have suggested whom to teach. The next question is—What do we teach? I have a few suggestions. I know that, as I go along, you will have many more ideas of your own.

1. It is important that they know the company policy on safety before starting any training. How does the company feel about accident prevention? If a recommendation is made, will something be done about correcting the condition? Is the company really interested in suggestions from its people?

2. The trainers should know all about the term "accident." They should know what accidents are disabling, reportable, or just reported when a man is hurt and wants to go on record with the company. They should understand that we must consider all accidents in the prevention program. We cannot make a safe railroad if we count only the reportable accidents. When we cut the frequency, we will, naturally, cut the severity. They must be instructed in such a manner that all accidents are reported.

3. They must know how to investigate an accident. Too often we have been satisfied to find that someone has been careless and let it go at that. We have not taken the time to explore all the possibilities. An accident is not fully investigated until such a time as the following conditions have been checked:

a. The tool, machine, or type of equipment involved.

b. The type of accident or the manner in which the employee was injured. Did he fall; was he struck by a falling or flying object; caught between moving parts of a machine; or boarding or alighting from a car or locomotive? Was he injured setting a hand brake;

throwing a switch; coupling or uncoupling cars or engines? Just what was the thing which hurt him?

c. What was the condition of the tool, machine, or material being handled—the brake, the steps, the switch stand points, or rod? If a guard or some protection was provided, was it used?

d. The unsafe act of the employee. If the employee was guilty of an unsafe act, was it due to lack of knowledge? Did he disregard instructions? Was he thinking about something else when he was injured? What about his physical condition? We must analyze the whole make-up of the man so that we can do something about his education. If his health is not good, we can help him by suggesting that he see his own doctor or have him examined by the company surgeon. Many people do not know that they are not well. How is his eyesight? We must do a complete job.

4. They should learn the importance of good housekeeping. This should include how to make a good inspection, and, if suggestions are made, the importance of follow-up.

5. Since "no man is an island unto himself," they must be taught that it is important to correct conditions or circumstances which cause accidents. They must not only correct the conditions under their own jurisdiction but must transmit ideas to other areas of the company where a similar accident might occur, so that corrections can be made before an accident of the same type does occur. We learn from one another. It has been my experience that, if it had not been for many of the men sitting in this room, mine would have been a dismal record of accomplishment.

A good safety program must have good records. These records are only as good as the man receiving them and the way he interprets them. When the safety department sends out periodical reports, we expect that they will be clear and to the point. When we train our supervisors to be teachers, we should train them to use the reports we send them as tools to prevent accidents. We, as the safety people on the railroad, should do everything in our power to make the re-

parts clear, concise, and readable. We should endeavor to make them interesting. Last, but not least, we should give reports to these men so that they are enthused about them and will do something about running a safe operation.

We should teach them how to use the educational literature we send them. Posters should be hung carefully. They should be replaced regularly with fresh ones with a different theme. Posters and hand-outs are only as effective as they are used, and when and where they are used.

Our men who are being trained should be taught not only the three main facets of the safety program, "Engineering," "Education," and "Enforcement," but must add another big "E" for "Enthusiasm." A mediocre safety man with enthusiasm often will do a better job than one better equipped but who lacks enthusiasm. We can do much if we get excited about this safety idea. Without enthusiasm, we lose much of the drive to get the job done.

In talking about this program of training trainers, I know there are those who think that railroading is entirely different from other industries. I have been told this many times by the people in my own organization. Since I do not come out of a railroad background, I find this difficult to believe. I spent five years of my time with Employers Mutuals of Wausau as claim adjuster and claims manager.

In my experience adjusting workmen's

compensation claims, I had the opportunity of visiting many different types of industries. Each of these had some individual peculiarities, but, across the board, their problems have been the same. I have come to the conclusion that, with the exception of the fact that we put cars together and make trains of them, the accident causes run pretty much the same. We must orient our thinking to our problems instead of our peculiarities. We can lick our problems, and, when we do this, the differences disappear.

Whatever training course you decide on, you will have to tailor it somewhat to your own needs, but, in the main, the program that fits others can be made to fit the railroads.
