The railroads have made great strides in the direction of safety. We cannot look back on past accomplishments—we must train for the future, if we are to make the gains in the future that have been made in the past. Our railroad economics are changing—more and more, we are accepting automation. We must educate our people in the latest methods of accident prevention and look to the future, so that we can meet further changes, which are sure to come.

Train for the future—train leaders who will think about things that are coming and who can take care of the present. Well trained supervisors and foremen pay dividends.

Knowledge is power, but only when properly directed.

RELATIONSHIP OF OPERATING RULES TO SAFETY RULES

By **WOODWARD B. BAUGH**

Gen. Supt. Transportation
Richmond, Fredericksburg & Potomac Railroad Co., Richmond, Va.

The relationship between operating rules and safety rules is very close, so close that, in fact, they "lovetail." To those who have made a study and have a thorough knowledge of the operating and safety rules, this fact can be truly appreciated. However, it is evident that a large number of our employees are not familiar with the relation-

ship, because we continue to have entirely too many accidents and personal injuries on our properties.

Through our operating rules, we learn the physical operation—how to go into a shipper's siding, move the loaded car, deliver it to the classification yard and through the proper lining of switches, proper sig-

nals and proper orders, deliver the car to its destination. Through the operating rules, we learn the hard, cold facts of railroading, which is the backbone of our nation, our economy and the first line of our national defense. Here, we are concerned with the mechanical functions only.

From our safety rules, we learn how to carry out the operating rules safely, or, in other words, to perform our respective duties without personal injury. Our good companies have spent an untold amount of money to provide us with the proper equipment, safe tools, compiling safety rule books, pamphlets, and arranging for safety meetings, demonstrations, etc., this being done with the thought of and desire to protecting us, their employees, from injuries or loss of life. This reflects the warm interest our management has in each of us. Here, we are concerned with the human function and here we find the true relationship between operating rules and safety rules.

Each operating rule has a historic background, based upon an operating failure in the past. When we have an operating failure, we usually have an accident. When we have an accident, it saps the strength of our employer, but, usually, money can replace the loss.

Each safety rule, also has a historic background, based upon many hours of misery. When we have a personal injury, this also saps the strength of our employer, but no replacement can ever be effected.

Many times, the subject of safety has been referred to as "old stuff," but so has eating, sleeping and breathing. For almost a thousand years, church bells have rung each Sabbath, to remind you and me to go to church. Religion has been preached to the people since the beginning of time. Still, we deem it necessary to continue preaching, day after day, so that salvation can be brought to our attention. There is no substitute for these things, or for the "old stuff" concerning safety.

No one objects to having a problem if it can be solved. But, one of the most frustrating experiences one can have is to be constantly faced with a condition that, although previously corrected, is continu-

ally recurring. Such is the problem about which we are talking.

I have observed, in attending many safety meetings and meetings of this nature, that supervisory and so-called "white collar" employees are predominantly in attendance. We attend, we have made a study, we have prepared ourselves.

Some years ago, I had two buddies who were ministerial students. One of them completed his education and was ordained and assigned a church. We were very close. He confided in me quite a bit. I remember, one Sabbath morning, after the services, we were seated at the front of the church. The congregation had gone. He said, "There is one thing that gives me a lot of concern. I'm wondering if it isn't true that too often the melodious tones of this huge organ, the beautiful hymns from the hymnal, the reading of the Scripture of God's Word, and my feeble efforts to deliver the true Gospel stop at that door." He said, "As I look about the congregation, I know that they have heard the truth, most of them have seen the light and accepted salvation, but my concern is how far does my message get beyond that door?"

I'm thinking the same thing. We have a nice meeting, a splendid spirit of fellowship, we know what we are dealing with, but I, too, am wondering if it doesn't too often stop at that door. Does the work stop here, or are we delivering the message where it rightfully belongs?

Mr. Khrushchev made a statement, a few days ago, that intrigued me somewhat, and I might say that this is the first time he has made a comment or statement that I felt was worthy of consideration. Just recently, Mr. Khrushchev said, and I quote, "No Communist has a right to be an onlooker." Couldn't we apply this thinking to our subject this afternoon? Couldn't we say, "No railroad safety worker has a right to be an onlooker?"

I once heard a supervisory employee say that he did not have the necessary qualifications, that he didn't know the proper approach. This reminds me of the popular song of just a few years ago, "It's What You Do With What You've Got." If you would just have the initiative to approach the employee on the job who is violating

a safety rule, correct him, show him the proper way, and thereby, possibly, prevent his being injured or having a fatal accident, you would accomplish far more than the man who knows, who has the ability and qualifications, but stands by and permits these things to happen.

I am wondering just how many of us, more especially yardmasters, have turned our backs when we saw a trainman adjusting a drawbar, knuckle, or lock pin between moving cars, or a trainman standing in the track to board an approaching engine, or a man cutting cars down the ladder too fast for the "rider," or how many of you shop foremen have witnessed men working at a drill press, lathe or welding job, without their safety goggles. These and many others, too numerous to mention, are violations of the safety rules, but we turn our backs, simply because we thought we might be advancing the job slightly.

I also wonder how many of us have given real thought to the seriousness of this thing, of its far-reaching effect, how it may affect that which is most sacred to him, that for which he has striven and worked, his home, his castle; how it could even mean the loss of the home, his life savings, or how it may affect the family, perhaps, necessitating the wife, the mother, having to go into the business world, leaving the children, his loved ones, with relatives or neighbors, and it could mean having to place them as wards of the state, making them orphans. I shall never forget a safety poster which I saw a few years ago, on our property. There was the picture of a small child, a little girl of five or six years of age, with out-stretched arms, and it was worded: "Take care of my Daddy, he is the only one I have."

What are we going to do about it?

I believe it was Ruskin who said, "What we think or what we know or what we believe in is, in the end, of little consequence: the only thing of consequence is what we do."

We know there are only two things that cause personal injuries, namely, defective equipment and safety rule violations. We know that statistics have proved that injuries attributable to defective equipment have been few, so it seems that this gen-

eral situation calls for greater efforts to instruct, train and know the weakness of each man on the job. The knowledge of how to do things safely is gained by experience properly directed. It simply means that we must educate all of these employees. Our men are not different from those in other fields.

You ask if you are your brother's keeper. Our companies have seen fit to appoint a number of us to supervisory positions, not only to see that the job is done properly but, also, to protect our men, and to see that the job is done safely. So, we are, in a sense, indeed, "our brother's keeper." He may, or may not, have read the safety rule book; we require him to have a copy of the safety rule book but how many of us require an examination on the safety rule book? Some weeks ago, I was walking over our freight yards with the terminal trainmaster, and we observed a yard conductor, an employee with 17 years' experience, walking from one side of the yard to the other, and frankly, I don't believe he failed to step on a rail over the entire 31 tracks.

Now, you may think this is a minor violation to use as an illustration, but, it ceases to be a minor violation when 31.1 per cent of the total personal injuries on our property, during the year 1960, were attributed to insecure footing. This violation was promptly brought to the attention of the yardmaster, who went directly to this employee and corrected him on the scene.

The following night, I attended a meeting and when I entered the auditorium, I was met by this employee, who informed me that he was very much embarrassed, the previous day. I concluded that I knew what he was referring to, and I told him that he had no reason to be embarrassed, he had a copy of the safety rule book and the rule was in the book. He replied, "Yes, I have a copy of the safety rule book, and I have read the book from cover to cover, but, frankly, I have forgotten a good portion of what I have read. Now that I have been corrected on the ground, I can assure you that I will never be guilty again."

May I emphasize to you supervisory people that far more can be accomplished on

the ground, at the scene, not only in getting the job done, but also, in getting it done safely, than can ever be accomplished with bulletins, letters, telephone calls, etc.

We must take the message back to the property, on the ground, where it rightfully belongs. We just can't continue to attend meetings, such as this, study, prepare and train ourselves, and then selfishly keep it within ourselves. We must take it on the property. We have fallen down on the job, have neglected our duties. Lend a hand to the employee who isn't here, instruct him, correct him, and if he should be one who doesn't seem to give a "Continental damn," then reprimand him.

The question has been asked about the habitual violator. I know of but one answer. Call him into the office, on the carpet, so to speak, and straighten him out. We've had such cases on our property, and this procedure has proved to be effective.

Next Thursday night, on the occasion of our annual RFP Family Safety Program, as the leader of the Transportation team of

the railroad, I am to be the happy recipient of the National Safety Council Award of Honor. Our Transportation Department worked almost a million man hours, 831,781 to be exact, during the year, 1960, without a reportable injury. We understand this is a singular honor for a railroad transportation department, and we, as a team, are, indeed, proud of this honor. I am satisfied this record would not have been accomplished but for the diligent efforts of our supervisory people on the ground. For example, in addition to our regular monthly safety meetings for all crafts, we have a regular monthly safety meeting for our yard operating people and our trainmaster or one of his staff has a regular monthly safety meeting for our road service people. These meetings are conducted around the clock, in a small building equipped for the purpose with a meeting for each individual crew called. The crews are called 15 minutes earlier than actually needed and the time is allotted to a discussion of previous accidents, picture slides, short talks and safety suggestions.

OFFICERS OF THE

RAILROAD SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—H. C. DAULTON, The Louisville & Nashville Railroad Co., Louisville, Ky.

Vice Chairman—D. P. RUSSELL, Canadian Pacific Railway Co., Montreal, Quebec

Vice Chairman—W. V. HAYES, New York Central System, New York, N. Y.

Secretary and Newsletter Editor—G. R. HUNTOON, Chicago Rock Island & Pacific R. R. Co., Chicago, Ill.

Associate Newsletter Editors

Southeast—G. W. MEREDITH, Norfolk & Western Railway Co., Roanoke, Va.

West—M. A. NOGENT, The Southern Pacific Co., San Francisco, Calif.

Central—A. W. SHEA, Chicago, Milwaukee, St. Paul & Pacific Railroad Co., Chicago, Ill.

Eastern—H. A. HILL, Richmond, Fredericksburg & Potomac Railroad Co., Richmond, Va.

Southeast—G. R. KNIGHT, St. Louis Southwestern Railway Lines, Pine Bluff, Ark.

Canada—J. R. BANNERMAN, Canadian National Railways, Montreal, Quebec

Content and Statistical Committee—W. C. LARAWAY (*Chairman*), The Delaware & Hudson Railroad Co., Albany, N. Y.; E. L. DUGAN (*Vice Chairman*), Atchison, Topeka & Santa Fe Railway System, Chicago, Ill.; G. E. GETTY, Bureau of Railway Economics, Assn. of American Railroads, Washington, D. C.; T. L. HILDEBRAND, Soo Line Railroad Co., Minneapolis, Minn.; G. W. MEREDITH, Norfolk & Western Railway Co., Roanoke, Va.

Plan and Sound Committee—M. A. NOGENT (*Chairman*), Southern Pacific Co., San Francisco, Calif.; A. B. AUERHAAR (*Vice Chairman*), New York, New Haven & Hartford Railroad Co., New Haven, Conn.; E. H. BLEWIS, New York Central System, Cleveland, Ohio; G. R. KNIGHT, St. Louis Southwestern Railway Lines, Pine Bluff, Ark.; L. C. McDOWELL, Chicago & North Western Railway, Chicago, Ill.; A. W. SAFETY — FOR WHAT?

The Gordon Graham Memorial Lecture

By DR. S. M. BROWNELL
Superintendent of Public Schools, Detroit, Mich.

Living is precarious. It always has been. It probably always will be. There are constant forces and circumstances—natural and artificial—which may endanger the life and safety of individuals. One of the great concerns of man through the ages has been to reduce the hazards which would hurt, harm or kill individuals. As civilization has progressed this process of safeguarding the physical well-being of mankind so that his living would be more safe has become organized as safety programs and safety education.

It was Gordon Graham who provided leadership in school safety in Detroit for many years. The influence of his constructive work extended far beyond Detroit. As one who called upon him for advice when I was in a school district neighbor to Detroit and who now sees day by day the fruits of his work since I now am superintendent of the Detroit public schools, I welcome this opportunity to pay tribute to Gordon Graham and commend those who recall and extend his influence through the Gordon Graham lecture.

As I have reviewed some of the materials from your previous sessions and the excellent volume "Safety in the 60's" I realize that I am an amateur amongst a group of pros. For me to try to present to you information on safety and safety education would be presumptuous. But perhaps I can raise some questions in your mind and can help to set our concern for safety education in the broad perspective of education by asking—*Safety for What?*

Why do we want persons to be safe? I presume most of us would answer safety in order that they will be spared pain and discomfort; that they will be economically more productive; that they will contribute more to the well-being of others and make living more worthwhile for all. We could

generally subscribe to each of these as valid reasons.

When I grew up many of us joined the Army to make the world safe for democracy. Our concern was not for physical safety but safety for the values which to us were more precious to life than mere physical safety.

How much progress have we made in safety education for advancing individual freedom and responsibility since that time? I should like to address my remarks to some of the problems of safety of our ideas and our ideals as they are challenged today by Soviet education. I should like to consider some of the problems facing our schools today as we face that same problem of making this world safe for the ideas and ideals that "brought forth upon this continent a new nation conceived in liberty and dedicated to the proposition that all men are created equal." This education is challenged today by Soviet education, and of what profit is education for physical safety which fails to safeguard and strengthen the safety of that which makes the difference between existence under communism and living under the freedoms of constitutional democracy.

You and I probably should assume that the education which brought to us our strong convictions about the importance of making safe in the world human freedoms would bring the same convictions to those who followed us in the same educational pattern.

What is it, then, that makes some people today worry lest the youth of today will be less convinced, less willing to believe in freedom, to understand the consequences of loss of freedom than we were when we were their age? Do we have less faith in them as persons? Do we have less faith in our schools? Do we distrust the education of American democracy? Or, are there

things about Communism and Communist education more appealing to this generation than to us as we grew up?

I think the answer to the first question is "No." We still have faith in youth, in schools, and in American democracy. At the same time we feel that conditions today call for youth to know more about Communism than their parents did and to understand better what American democracy means to them. Our problem is a tough one because we are trying to get them at their age as concerned about the perils of Communism and as aware of the values of American democracy as adults are with added maturity and experience.

One of the fallacies which exists in the thinking of many is that people react to the same information in the same way. They believe that if we expose them to the same materials and ideas the same learnings will result. They believe that what impresses and excites them will do the same for others. We, as adults, wonder why young people aren't concerned about conditions, facts, information which concern us. They, in turn, wonder why we aren't interested in what interests them.

Any article in the paper on schools or education I never read. My son, an electrical engineer, reads the same paper and may miss those items, but sees items on electronics that I didn't notice. My son-in-law, a psychiatrist, picks from the same paper items on the behavior of criminals, politicians, movie celebrities, or others which have a relevance to him that my son and I had not noticed. And when my wife and daughter have finished the same paper they can tell you about new fashion notes or sales that none of us men realized were in that paper. All of them will have a wonderful laugh together about *Peanuts* or *Pogo*, and I failed to even recognize such characters existed.

How, then, can we hope to get all pupils to believe in American democracy and to want it more than Communism? Are there some things about Communist education which make it especially effective? Should we pattern American education after what is taught in Russia?

I know very little about Russian education. I've never been there. But I have read about it. I have discussed it with educators

who have observed it. I have attended international conferences which included Russian educators, and have conferred with Russian educators about education in the United States and Russia.

There are a few conclusions I have gained as a result:

1. *One great strength in Russian education is the importance which the Russian government, parents and pupils attach to education.* Each reinforces the other. This commitment to education is characteristic of other Soviet countries, including the Red Chinese. It is otherwise notable in the emerging nations that are not Communist.

Education is recognized almost universally today as essential for the development and progress of any country. This is a new factor in the world which may turn out to be as important to our future as the spread of nuclear energy and development of space travel to all ends of the earth. We have not as great a relative commitment to education in the U.S.A. as is true in the Soviets and in other emerging nations.

2. *Education is what makes the difference between an uncivilized and a civilized person.* That difference for a person takes place within his lifetime. We are all born uncivilized. There is no difference that researchers have been able to discover in the innate ability of babies born today from those born hundreds of years ago or in one part of the world from another. There is about the same distribution of ability to learn in all races. Some learn fast and some learn slow in every race.

If you were to pick up 1,000 babies in a United States city and exchange them with 1,000 babies in Russia, or China or the Congo, the chances are pretty good that the 1,000 United States babies thus exchanged would grow up as typical Russians, Chinese or Congolese youth. The babies from Russia, China, and the Congo would become typical United States teenagers. How civilized each generation will be is thus dependent upon the education of that generation.

3. *We are faced quite suddenly with a commitment by Russia, by China, by India, and all of the new nations that all of their children shall be educated.* This commitment is shared by the Arabs, our Latin American neighbors, the European nations

which heretofore have been highly selective in those who should receive education beyond elementary levels. I saw this pressure for extension of education in 1954 when I represented the United States at the UNESCO Conference in Montevideo. I was greatly impressed by the spread and advance of this commitment to the principle of education for all which has been made in six years when a year ago this past summer I served as chairman of the United States delegation to the International Conference on Education in Geneva. In this meeting we had the official reports of the ministries of education of more than 70 nations. Here we had the facts and figures on what national governments were doing to support and to extend education. The evidence is clear that Russia, all the Soviet countries and all of the new nations count on having an educated citizenry as rapidly as possible. They are committing whatever funds and manpower resources are necessary to accomplish this purpose. They are making remarkable progress.

4. *The Russians face the same basic problems in education that we do.* They are dealing with human beings, just as we are. The same fundamental laws of growth and development hold there as here. Young children have hurts and pleasures, are squirming, are ambitious, get tired and have remarkable recuperative power, are inquisitive, learn and forget just as do United States children. It takes the same number of months for them to be born and for them to become adolescent. Their educators are concerned about what to teach, when to teach it, how to organize instructional materials, and how to divide up the 24 hours to gain the most effective learning. These decisions, however, are made in the Central Ministry, rather than locally for the most part. This is true in most nations other than the United States.

They are concerned about the fact that not enough of their young people want to use their schooling to produce the goods and materials they need. They want to increase the efficiency of their instruction and have better teachers, just as we do. They raised more questions at Geneva about our co-operative vocational program, our vocational technical education and our use of television in teaching than about other parts of our educational system. They want to

learn from our experience. We would be well advised to see what we can learn from them. To put these conclusions in another way, we should never forget that the education of each child, wherever he is born, must start at scratch. You can inherit the ability to learn. You cannot inherit education. This is what makes it extremely important that the educational program be maintained at a high level continuously. There is much more in common about education in all nations than there is difference—but, as is true in comparing the similarities and differences between men and women—how important these differences are to us!

One of the important differences in United States and Soviet education, and one which troubles me because as yet I do not see that we are making any progress toward lessening the difference, lies in our failure to arrive at common understandings with them on how to guide conduct. Until they and we accept in common a belief in the value of individuals as creatures of God, what firm base have we upon which to rely for moral behavior, for faith and for confidence in each other?

I think that because of our difference in basic principles and our abhorrence for what the Soviet government seems to countenance or inspire, we sometimes credit to communism accomplishments or behavior beyond what it deserves.

Not all persons who dislike the United States or who do not believe in capitalism are communists, and yet some persons give the impression that anyone who questions practices in the United States or who disagrees with their ideas is a Communist. Some of the ruthlessness and intrigue which we associate with Communist Russia appears very similar to practices under the czarist regime. Some of the economic and industrial progress in Russia is paralleled in non-communist nations. So it is that I think we must ever be on guard against attaching the Communist label indiscriminately to troublemakers or to ideas disagreeable to us. Nor should we give Communism credit for all of the progress made where Communism controls.

There are other differences between United States and Communist education. Communist education is totalitarian. From its beginning and continuously throughout the education of youth the principles, doctrines and beliefs of Lenin and Stalin are taught and empha-

sized. Furthermore, as I recently heard Dr. T. H. E. Chen, of U.S.C. explain Red Chinese education, school instruction is coordinated with total political and all other forms of contemporary activity. When the government has a "Hate America" week schools at all levels and the press, radio, theatre, museums and political speeches are all geared to this theme. Demonstrations accompany exposition of ideas. It is a case of seeing that action and ideas are synchronized. This is a great difference between totalitarian education and education in these United States.

I don't know how successful totalitarian Communist education will be in the long run, or how consistent it is actually in its basic practice. But I do know that it is in accord with some of the fundamentals of learning that the effectiveness of learning is increased as it is reinforced by experience. Perhaps when we wonder why we are not more effective we should examine how we reinforce what we teach in our schools.

Now let me turn to the problems of preparing American youth to meet the challenge of Communism. It may be well to ask ourselves what are the reasons that might make American youth believe in Communism or any other "ism." I shall mention four and comment at some length on the fourth possibility.

1. *They might be dissatisfied with what they have.* This is possible under any form of government. We recognize it in our common saying that grass is always greener on the other side of the fence. It is a characteristic of youth—even Communist youth—unless they are made to see, understand and to believe that what they have is the best. The effectiveness with which this can be done is demonstrated by the loyalties developed by colleges and service academies to those institutions. But even in these institutions we have campus leaders who are sure that changes are needed in what is done, or how it is done. This is particularly noticed about this time of year.

2. *They might not see the dangers of what is made attractive to them.* Inexperience and curiosity are just as much an aid to bad learning as to good learning. Many a college youth of ability has found himself outside of the college gates because non-scholastic activities were made to seem more attractive than his studies. He didn't

see until too late the dangers of pursuing these activities. Dialectic materialism can have an attraction in many persons who may look upon it only as an interesting idea, and who fail also to see how it is used. What you and I call maturity is usually the result of experience in which the individual has had the chance to make decisions of importance to him and to others. From the responsibilities he has had grow his recognition of what is involved in making choices that affect him and others. Without experience of this nature the dangers may be overlooked and disregarded.

3. *They might have been frustrated in attaining and in the prospects of attaining what seems important to them.*

There are many things which young persons consider important. They want some money that they can call their own and the chance to decide how they shall spend it. They want the independence from their home which is associated with a job. One of the effective procedures of communists and the organizers of other "isms" is to give those who have not been recognized by their peers a mission to accomplish. It is a way to gain their loyalty and support because it satisfies their desire to feel that they count for something as a person.

4. *They might feel that what they have been taught is not very important or that it is not true because what they observe in life does not square with the teaching.*

This is the reason that I wish to discuss at some length. If we teach them that democracy is important to human progress we need to show not only the progress of individuals in freedom and justice in the Western World, but also to show what has happened under Communism. We have a good record to match in this respect and we need to display it effectively. This is a task appropriate for schools. At the same time, if we are to be effective, we also need to have current practice which squares with what we teach.

Let me examine for a few moments some of the problems we face in this respect. What do young people see and read about today that does not square with what they are taught in school about democracy? They see and hear about:

1. Persons in leadership positions in government, business, industry, entertain-

ment, or labor who violate moral or civil laws, and exploit others in order to gain for themselves privileges, power or prestige. They see this condoned by many adults, publicized in the press, and glamorized by movies and television.

2. Persons of lesser education and competence being selected for jobs because of their race or religion or their connections, rather than upon their competence.

3. Persons barred from living in sections of a city because of their color or their nationality or their religion.

4. Persons not eligible to attend tax supported schools, to eat at public lunch counters, or to ride on public conveyances because of their color.

5. Individuals in the United States deprived of voting because of their color.

6. Labor unions which have no members of certain racial or religious groups.

7. Unemployment so lopsided in reference to the per cent of colored and white in the population of the area as to make it clear that the odds of this being merely a coincidence are far greater than chance.

These are things they see and know from experience. If they have been taught well to make judgments based upon evidence, I ask you how effective do you think the schools can be in instilling a firm belief that the principles of American democracy are what we say they are, that they are important to the individual, and that the freedom of American democracy is as precious as we teachers try to make them believe?

There is another aspect of the problem of making what we teach about the importance of American democracy as effective as we would like to have it in our schools.

We pride ourselves on individual initiative and upon our freedom to solve problems by private enterprise or on a local basis, without having to wait for the state or the Federal government to solve them.

Let us take a look at what our teachers see—the ones we depend upon to teach how much better is American democracy than Communism. They see in my state, and in many others, that a city which wants good schools has almost insuperable odds. Local support has been limited by state law or by

the state constitution to one form of taxation—property tax. Business and industrial leaders who want the best schools for their children have moved from the city and sent their children to more adequately supported suburban schools or to privately supported schools. At the same time the representatives of their business or industry, working with the legislative representatives, help to pass constitutional limitations on the property tax rate and against measures to open up other sources of taxation to local school support for the cities they have left.

I am as sure as can be that many of these fine, public-spirited men who speak often about the need for better quality education do not realize that more effective than their words are the activities of their company representatives in preventing increased local support for schools. This is also true at the state level. These same forces are at work to prevent additional state funds for schools. All of us here are concerned because we do not have more effective teachers and teaching, especially about the values of American life as compared with Communism. But when a professionally trained teacher, who has much preparation for his job, and who has the responsibility for helping young people to gain the knowledge, the skill, the insight, the ambition and the value judgments that will guide wisely or unwisely business, industry, family fortune and government ten years from now, can expect to gain a maximum income of even to eight thousand dollars after 15 to 30 years of devoted service, what can you and I expect?

It can't make very good sense to them to hear the leaders of business and industry saying we must have better schools, and then paying their often relatively untrained legislative agents who work against school support at local and state levels more than they make it possible to pay the best prepared, ablest, most dedicated teachers. This is a situation which I regret to say can be found in nearly every state to some extent.

Eight years ago I took a federal job as Commissioner of Education. In the session of the Congress immediately following my taking office, a bill was passed which I had recommended and which became a part of the administrative legislative program. It authorized a White House Conference on Education to follow upon conferences on

education in each state and in localities. These conferences were designed to give grass roots consideration to education needs of the locality and state so that there could be developed programs to remove roadblocks to local and state educational progress. The White House Conference was to give a chance for the local and state leaders from each state to share their ideas and thus to speed up efforts to improve schooling. This was prior to sputnik and the emphasis on Russian educational progress.

As I survey what has happened since that time I am convinced that the investment of money and effort in that White House Conference program has paid good dividends in arousing interest and action to improve education in this nation. The most disappointing development, however, is that states have not removed the legislative and constitutional roadblocks to local and state school support. The result is that if cities and towns are to do what schools must do, if youth are to compete with Communist-prepared youth in this world, they are forced to look to the only other tax collector there is—the federal government.

We are thus faced with the age-old dilemma of having to decide whether we will eat our cake or save it. Our cake is the perpetuation of a strong faith in individual freedom and American democracy. We can save it if we have adequate and competent education of youth. We can't have adequate and competent education without paying more for it than at present. This has been repeatedly documented by study after study by all kinds of individuals and groups.

It will cost money, much more money than we are now paying to provide enough well-prepared teachers and give them the working conditions they need to do the job you and I believe needs to be done. In other areas of our life we have spent the money and made the progress. Look at the investment in hospitals, drugs, x-rays, specialized equipment and auxiliary staff we provide each doctor and dentist today to treat us on physical problems that are far less complex to diagnose and treat than are the problems of diagnosing and treating Jolynn's difficulties in learning to read, to spell, to write, to do arithmetic problems, and to make sense out of the problem of our contemporary civilization. Look at the office equipment and the air conditioned

offices and the skilled consultant and research service you provide in your business and industry to make it able to survive and keep ahead of Communist business and industry. Look at the investment in scientists, researchers, technicians and material to develop weapons of defense against Communist aggression that would take away our American system of values.

Then take a look at schools on a comparative basis. You probably can go back to the school building you attended and maybe even the same school desk. The teacher will probably be a different one, a person with two to six more years of specialized education than your teacher had. The texts and the curriculum will have changed a good deal. But the teacher and pupils will not have much better working conditions, nor anything like the specialized help that has been provided to make medicine, dentistry, defense, agriculture, business and industry meet the competition of Communism. If we are to compete in education we have to provide more adequately for education besides just information about communism and democracy.

If we are to make young people convinced that we really believe in American democracy, there are other ways in which we need to bring our practices more closely in harmony with our preachings. We cannot expect the millennium, but if what we say is to be accepted by youth they must at least be able to see that we are making steady progress in the direction we point as our goal. This we must do locally, statewide, and nationally if we are to convince young people that American ideals are more than pie in the sky and are worth preserving.

One of the things we preach in school and out is that every citizen should contribute his share to the economic strength of this nation. We expect that every boy or girl who goes to school should become able to be a productive worker and a taxpayer. He will some time be expected to enter the world of work to make a contribution at some level. Increasingly and very rapidly the levels of necessary preparation for entrance to employment and success as a worker have increased. Unskilled and lower skilled jobs are decreasing. Skilled and specialized job needs are increasing proportionately. This is true in service fields as well as production jobs.

It follows that if limited ability persons are to be economically productive, rather than economically dependent, we must use them in the available unskilled jobs. Persons able to enter and hold lower skill or skilled jobs must be prepared for and enter jobs at this level rather than allowed to enter and remain in unskilled jobs. And so it goes for the whole range of employment—it we are really to utilize effectively all levels of jobs. We cannot afford the luxury of unemployed unskilled labor and shortages of highly skilled personnel because we have let able youth be satisfied to take unskilled jobs when they had the ability with more preparation to become highly skilled and technically prepared. In other words, we have to upgrade school preparation at all levels and see that all talent is discovered and developed more effectively than present. We have to do it by wise instruction, counsel and guidance of teachers and parents because we don't believe in the totalitarian scheme of forced placement. Then when these young people are prepared we have to make it possible for them to enter the work force.

Today in our cities we are sending from our schools and colleges thousands of young men and women who find the world is not a world of work but a world of unemployment. They have the energy and ambition of youth. They have been taught that this is the land of opportunity. They want to be doing something constructive, to be considered important, to have the independence that comes with employment and income. If they are left unemployed, how long will it be before they are unemployed because of the habits and attitudes they develop? How likely are they to hold fast to the teaching of the values of democracy as against the promises of Communism or some other "ism"? There are thousands of these young people in our great cities. They are our great hope or our great threat for the future.

One of the great challenges of the Soviet to American education seems to me to be, to see if we can find for American youth a bridge from school preparation to membership in the world of work other than through a Soviet type compulsory labor force or through compulsory military service. Let me suggest that one possibility lies beyond our present vocational courses in schools, guidance

and counseling, job upgrading and other programs, work camps for delinquents and other constructive measures. It is one which some of us have discussed because it seems to be one that could be operated locally on a state basis, or nationally. It could be expanded or contracted as the supply of jobs fluctuated. It would recognize that most of the young people today reside in and are going to live and work in urban areas. The program has been called "An Urban Service Corps." I shall not take the time to spell out what is proposed, but I feel confident that if youth can see that they have a place in the work force of the nation they will be much less vulnerable to Communist propaganda than if they are idle.

So, if we are to maintain and advance the safety of freedoms for individuals we must meet the challenge of Soviet education to American education through greater understanding of Communism by American teachers and youth. In the schools, through systematic study of constitutional democracy and of communism, young people need to be made fully aware how the striving of mankind for a better life has prospered and is more possible under constitutional democracy than under any form of totalitarianism. But if this teaching is to be effective it calls for operation of our society so that it is consistent with the promises of democracy. Significantly increased financial support of schools is essential so that education at all levels can compete effectively with Soviet education. So, also, it is necessary that all American youth be able to count on entering the world of work and contributing their share to the economic strength of the nation.

As I look ahead in this world I see little chance for life that is meaningful and significant to be other than insecure and dangerous. We are developing with great rapidity new and stupendous possibilities for devastating destruction and crippling of the human body and mind. It seems inevitable that man will unlock with greater ease the forces that will take him to all parts of this earth and into space with increased speed or which will send anywhere powerful and sophisticated weapons designed to destroy, maim or paralyze mankind. It seems certain that the greater numbers of mankind, living closer together as they must, will find that survival increasingly depends

upon development of personal reactions, group procedures and careful instruction for protection and safety.

I am glad that you are carrying forward the objectives set forth by Gordon Graham to protect individuals from unnecessary hazards and from needless injury or death.

This concern for the dignity and the preciousness of each human being we need to make clear to American youth today. The physical safety of the individual is of little significance unless we also make safe the freedom and sanctity of the human mind and soul under God.

SCHOOL TRANSPORTATION

Presiding: JOHN M. PARSONS, Supvr. of Transportation, State Dept. of Education, Columbus, Ohio

Discussion leader: IVAN L. ELAND, Dir. of Safety Education, Iowa State Teacher's College, Cedar Falls, Iowa

Recorder: T. F. RHOTON, Supvr. of Pupil Transportation, State Dept. of Education, Nashville, Tenn.

Subjects of interest, suggested by members present:

1. Should pupils leave the bus by passing in front of the vehicle or by passing to the rear?

2. Problems of transporting mentally or physically handicapped pupils.

3. School bus evacuation in case of accident.

4. Accidents which happen because a school bus is stopped, loading or unloading.

5. Standards for employment of bus drivers, and what are the reasons drivers are dismissed?

6. Transportation of parochial school pupils.

7. Training of bus drivers.

8. How far are pupils expected to walk to school or to catch a school bus?

9. Loading or unloading problems on one-way streets.

10. Special license demanded for bus drivers?

11. Use of student control lights for loading or unloading.

12. Problem of school bus stops in cities, resulting in traffic jams.

13. Support given bus drivers by school officials in court.

14. Use of seat belts in school buses.

15. Number of pupils transported and accounting for afternoon load.

16. Pre-bus safety drill required by law?

17. When is a supervisor for pupil transportation needed?

Discussion by topics:

1. The general belief is that pupils should go in front of the bus in loading or unloading because (a) the driver can better supervise pupils entering or leaving the bus, (b) fewer accidents happen when pupils go in front of the bus, and (c) drivers of other vehicles have become familiar with pupils using the front of the bus in most sections of the country.

2. We are obligated to transport mentally or physically handicapped pupils with public funds. Special buses constructed for easy loading of wheel chairs or those on crutches are recommended. Parents should assume more responsibility for getting handicapped pupils to and from the bus. Safety belts and other special safety measures should be used on buses for the handicapped. A supervisor and/or a nurse, in some cases, has proven most helpful with handicapped pupils while riding buses. A special driver, well trained to handle such pupils, is recommended.

3. Some training in evacuation of buses is needed in case of accident. The training can be given with the bus parked on the school ground. Extreme care is to be used if drills take place on the highway. A few systems train a student to stop the bus and activate bus signals in case the driver be-

comes ill or is hurt so seriously that he cannot perform his duties.

4. There seems to be little information on the numbers of accidents caused by buses being stopped to load or unload pupils. Many such accidents could be avoided by selecting safer stopping locations, where buses could be seen for greater distances. Better use of stop signals will help prevent accidents caused by stopped school buses.

5. Some areas have special tests or requirements which have to be met before drivers are employed to operate school buses. Special tests given by the state safety department, physical examinations, special school bus driving schools, local check on moral character together with fingerprinting, running of drivers by local school boards or representatives, and minimum and maximum age limits are some of the devices used to check ability of proposed bus drivers.

Dismissal of drivers may occur under any of the following heads: violation of traffic laws, one chargeable accident, attainment of a certain age limit, except in those areas where there is no such limit.

6. Transportation of parochial school pupils is practiced in some areas at public expense, under any of the following conditions: where they live on the bus route, when their riding will not overload the bus, in cases where regular runs are made to such schools, and where local or state funds are specifically earmarked for such transportation.

7. Interest is increasing in driver training for school bus drivers. Some areas require the training before employment. In other areas, on the job driver training is required from once a year to once in three years.

The training is received from one of several sources: representatives from state

departments of education, special courses conducted in state schools, local supervisors of pupil transportation using driver education instructors in the program, in which the training ranges from classroom instruction to a combination of classroom and behind-the-wheel activities.

8. It appears that school bus service ranges from front door loading to a walking distance of two miles. The trend is to offer more service to pupils in traffic hazard areas, regardless of distance to a school or to a regular bus line. State approval is required in some areas for reducing the regular walking distance. More attention is being given to selection of safe school bus stops and increasing the distance between stops in congested areas.

The lack of time prevented a full discussion of the other topics.

The question was raised, in closing, of how many buses must be in operation before a pupil transportation supervisor can be justified.

It depends on: the number of miles covered, the number of runs made by each bus, and the number of pupils being transported.

It was suggested that a fleet of fifteen vehicles would justify a transportation supervisor.

Another question was raised in regard to loading and unloading from the rear of the bus when the vehicle was stopped on the left side of a one-way street. The general opinion was that the bus should park on the right side of the street and load and unload in the regular manner.

The pupil is accustomed to right front door use with pupils going in front of the bus. Special doors would be required for rear service, thereby increasing the cost of vehicles.

EMPLOYEE SAFETY

Presiding: IVAN J. STEHMAN, Coordinator, Highway Safety Education, State Department of Public Instruction, Harrisburg, Pa.
Discussion Leader: LESTER L. WASSERBURGER, Supervisor, Employees' Safety and Accident Prevention Unit, Safety Section, Los Angeles City Schools
Recorder: H. JAMES ROKUSEK, Teacher, Montgomery County Schools, Rockville, Md.

Mr. Stehman asked Mr. Wasserburger to briefly describe and provide background information on the topic in question. After this had been accomplished Mr. Stehman asked that the group conduct an informal question and answer period on employee safety and that the remaining time be devoted to this action.

The first portion of the question-answer period was devoted to the organizational plan used by various states, and particularly California, in determining the responsibility and authority of the various departments concerned with safety. Both the Los Angeles plan and the Chicago plan were diagrammed on the chalkboard and compared.

The question of policy forming also came up during this time and Mr. Wasserburger responded to this item by stating that recommendations are made by his department to the head of each department concerned with an accident. Once the department receives this recommendation, it is necessary for them to take some action with a copy of their directive sent back to the safety director.

The second portion of this meeting was concerned with employee accident reports. Mr. Wasserburger encouraged all persons in attendance who had this responsibility for employee safety to procure a copy of every employee accident report and to analyze these accidents in several ways.

Through analyzing these accidents it is possible to call them to the attention of school officials, and to make recommendations to various department heads in all phases of the educational program. The question of standardized accident report forms was brought to the attention of the group and most people in attendance indicated that they used the standard accident report form prepared and distributed by the National Safety Council.

In the matter of reporting employee accidents, as well as reporting student accidents, Mr. Wasserburger strongly emphasized that it is necessary for the safety director to convince or attempt to convince school administrators to set up a formal procedure in handling accidents and in recording accidents. His next point was that once this convincing had taken effect responsibility has to be established for employee safety.

Although this session was primarily designed to consider the topic of employee safety, several questions were asked relative to student accidents. The question of treatment of pupil injuries was given some consideration in addition to the question of student accident insurance.

The third and last portion of this meeting was concerned with some of the procedures used by industry in dealing with the safety of employees. Two procedures used by industry for dealing with this problem were brought to the group's attention and seemed to be applicable to school plant operation.

One procedure concerned the matter of recording and analyzing employee accidents. By using the three words "Material", "Action" and "Accident" as heads for three columns, an industrial representative explained how all accidents might be recorded and analyzed. Through this method safety directors can spot major problems and causes of accidents.

The second procedure identified was concerned with a foreman accident prevention program. Through this procedure a conference between the safety director, general foreman, plant manager and perhaps another administrative official would be scheduled by the safety director after each accident occurred. During this session questions such as "What happened?", "Why did it happen?", and "What action can be taken to avert a similar accident?" would be

discussed. It was brought out that most foremen do not particularly enjoy appearing before the plant manager for this type of conference, and that it seems to indicate an area of weakness in his section.

Thus, this procedure if handled properly can help to prevent accidents and to better insure that the foremen will have day-to-day contact with his men on safety problems and issues.

WHAT YOU DON'T KNOW CAN HURT YOU

By A. F. SCHAPLOWSKY
 Education Consultant, Div. of Accident Prevention
 Public Health Service, Washington, D. C.

When your public health department studies those community problems which are affecting its health and well being, accidental injuries and deaths always appear as a major problem. The health officer determines the relative importance of various community health conditions by comparing the number of premature deaths, cases of disability and the amount of lost productivity which they cause.

Accidents continue to be the leading cause of death for individuals in this country between the ages of 1 and 35 years and the fourth leading cause when all ages are considered. The National Health Survey also tells us that each year 10 million people in this country incur a bed-disabling accidental injury and 1.7 million of these are hospitalized. We are told these disabilities result in the annual loss of over 107 million workdays. You can rapidly calculate that this is equivalent to the absence of over 400,000 men from our work force everyday.

Today we are at a time in our country's history when every resource, human or material, is vitally needed and therefore, those measures essential to conserve these resources have a special urgency. We cannot continue to afford human losses among our promising young people nor among men and women of age and experience.

All of you know as well as I that accidents can be prevented by bringing about changes in man's environment and in his behavior. Most of us in this room are more concerned with changes in his behavior. We know that behavior may be changed as a result of an increase in man's knowledge, improvement in his skills or modification of

his attitudes. We also know that lack of knowledge affects attitudes and beliefs.

In accident prevention we are faced with some of the same thinking that public health and medicine faced with the communicable diseases not too many years ago. Before the causes for various diseases were known, people blamed sickness upon evil spirits or bad air or some other superstitious belief. It was only after specific causes for these diseases were discovered and understood by the people that these beliefs were largely dispelled. Today since the causes of accidents are not generally known, people blame them on luck or chance. As more specific information about the causes of various kinds of accidents become known and are understood these beliefs will also change.

In traffic many accidents can be traced to genuine lack of knowledge about the rules of the road, mechanics of the motor vehicle or the physical laws which govern the performance of the automobile and capabilities of the driver. Yet today there are 85 million drivers and 180 million pedestrians in this country who must have a complete understanding and acceptance of the rules of the road if we are to reduce the number of injuries involving motor vehicles. Many people are still uninformed or misinformed about the advantages of using safety belts in the family car. Yet the evidence is very substantial that the number of serious injuries and deaths could be markedly reduced if a large portion of the motoring public habitually used this simple device.

Lack of knowledge about the quality of air to be used in the compressed air containers used in SCUBA diving recently re-

sulted in death for two individuals and serious illness for a number of others. It seems these individuals recharged their containers at a local gasoline service station. Unknown to them the air compressor at the station filled their containers with air containing tiny droplets of oil. After breathing this air they developed a form of pneumonia, called lipid pneumonia, which was difficult to treat. Since pathogenic organisms had not caused the pneumonia it would not respond to the usual drug therapy.

From the large number of accidental poisoning cases among children which involve aspirin, it can be assumed that many adults do not regard aspirin as a medicine or know that it can be poisonous if ingested in large amounts. There is also general lack of knowledge that many common household articles can be poisonous if ingested.

In rural areas the misuse of liquefied petroleum products have resulted in many accidental injuries. Since these products are bottled under pressure, they have been used for such things as inflating flat tires on trucks and farm tractors and to provide air pressures for paint sprayers. The users because of lack of knowledge about the explosive and flammable properties of this material were not aware of the possible hazards involved.

Lack of knowledge about the properties of ultra thin plastic bags during the past several years have resulted in their being used in ways which have caused the suffocation of many children. Many mothers without realizing the danger have used these material to cover pillows or mattresses in baby beds or have left them within reach of small children.

Lack of knowledge about the side-effects of certain drugs such as tranquilizers and anti-histamines has resulted in many accidents. It may be particularly dangerous to drive an automobile after taking some of these medications.

All too many deaths are caused each year because the properties of carbon monoxide are not understood. It is difficult to comprehend the dangers of something which is colorless, colorless, and tasteless.

These examples are just a few of many that could be given to illustrate the point that many accidents can be traced to a lack

of knowledge by an individual. How can we do a better job of imparting knowledge?

Perhaps we need to be more dramatic and utilize more imagination and ingenuity in preparing our safety educational messages.

Perhaps we also need to give more consideration to helping people recognize and understand the human factors which underlie many accidents. These factors are generally thought to be of three types: physical factors (poor vision and hearing, disease), emotional factors (hate, fear) and physiological factors (fatigue, drugs, alcohol).

It has also been suggested that a list of premonitory signs could be developed to help people recognize when they are not functioning up to par and, therefore, more likely to have an accident. One individual I know has developed a few such warning signals for himself. For example, when he is working in his woodworking shop, if he makes several errors in judgment or in such things as measuring a piece of wood, he regards this as a signal to change his pattern of work or to discontinue work in which he is more likely to injure himself. He has developed similar personal warning signals which he uses in driving his automobile. He believes helping people to recognize such individual premonitory signs may be more fruitful in reducing accidents than trying to impress upon people all the possible hazards in their environment.

Perhaps we need to concentrate more on teaching people the "WHY" of safety gadgets or rules rather than insisting that people simply learn the rules, use the gadgets or adopt a safe behavior. When an individual learns why he does a thing a certain way, his precautions become a part of him. In talking to a group about the advantages of using a safety belt in their automobile, one is likely to succeed in having them recognize the value of the device if they can see a film for example, which shows what happens to occupants with and without seat belts in an automobile when it is involved in a collision. He may not be as successful if he shows them pictures of the gory results of accidents or tries to impress them with the statistical results of the research.

When we help people to understand how accidents happen, we are helping them want to be safe and helping them to recognize that accidents like diseases have causes.

As an example of helping people understand the causes of accidents, let me briefly describe a project that the Public Health Service has supported during the last few years. This project was located in Mississippi County, Ark., where the number of fires and burn injuries and deaths were unusually high when compared to other sections of the country.

One man was assigned to the local health department and he developed a program using the traditional public health approach in attacking a new problem. The approach essentially follows these steps. Defining the problem, selecting an appropriate solution and applying the solution.

In defining the problem an extensive reporting system was set up in order that all information about fires and burns could be assembled and studied. A comprehensive investigation of most of the fires occurring in the county was conducted in order to obtain information about all factors possibly related to causation. As a result of the information gathered it was learned that most of the fires were caused by inadequate elec-

trical wiring, misuse of petroleum products, and poor installation of heating and cooking stoves.

In relation to these causes, it was also determined that many residents did not know the purpose of the fuse in the electrical system and in general just how the electrical system worked. There was misunderstanding about the properties of gasoline and kerosene. Individuals did not understand that the vapors given off by gasoline are heavier than air and that gasoline was explosive only when its vapors became mixed with air. There was general lack of information about the flammability of other materials like hair sprays and fingernail polish removers.

The solution to the problem seemed to be the development and conduct of an educational program directed at eliminating these deficiencies. Such a program was developed. It was made as simple and yet as dramatic as possible. Intensive efforts were made to reach a large per cent of the total population of the county.

CIVIL DEFENSE AND DISASTERS DISASTERS YOU HOPE WILL NEVER COME

By FRED H. BRANTLINGER

Deputy Dir., Educational Relations Office, Office of Civil Defense, Dept. of Defense
Battle Creek, Mich.

As presiding chairman for the civil defense and disasters meeting, I was informed by Dr. Ronald Patterson that one of the two speakers scheduled could not be present. Therefore, after introducing Francis Svarc as the recorder, the chairman announced that he and Dr. Patterson were prepared to fill in the time that might be used by the second speaker. The writer indicated he would cover the general area of *safety and fallout protection*, with special emphasis on some of the misunderstandings and misconceptions in the field, and present guidelines as a basis for use by schools that are preparing operational procedures. Dr. Patterson planned to present the practices followed in the Detroit Public Schools, and to indicate places where smaller school systems might want to make

changes. His presentation could be considered a "model" for a school fallout protection shelter program.

I am sure that you who are engaged in safety education are more aware of the potential effects of a major disaster than any other group of professional educators.

The expression disaster preparedness implies advance planning. The plans must consider all emergencies, encompass all sources of aid, and they must be flexible. Further, there must be a continuing evaluation and updating of these plans to assure maximum readiness, efficiency and life-saving potential.

Certain simple but fundamental concepts must be understood by all concerned with disaster relief. For example, it is important

to know that refuge in the appropriate part of a basement will afford protection against tornadoes and hurricanes. It is equally important to know that this is precisely the wrong thing to do in event of a flood.

Any disaster involves both primary and secondary effects. For instance, most people tend to associate only high water with a flood, and high winds with a tornado or hurricane. Obviously it is necessary to take precautions against these primary hazards. Not so obvious, however, are the secondary effects of such situations. High winds and water can disrupt communications, causing confusion and panic. Power and light failure can hamper rescue operations. The water supply may become contaminated, thereby spreading disease. Highways and bridges may be washed out making evacuation extremely difficult or impossible.

One of the major problems in establishing a school disaster preparedness program is the development of a realistic, factual, awareness of the problem. Many people believe, for instance, that since their immediate area has never been struck by a tornado, hurricane, flood, or earthquake, it never will. This despite the fact that they may live in a belt which is potentially subject to one or more disasters of these types.

An even greater number of people believe that the continental limits of this country will never be subjected to nuclear attack. We all of course hope that this is true. However, current world tensions and technological developments by potentially hostile world powers tend to make such a belief unrealistic in the next decade.

Civil defense is primarily concerned with the protection of the civil population in the event of such a disaster. On August 1 of this year the Department of Defense assumed new responsibilities in this field.

In a statement before the Military Operations Subcommittee of the House Committee on Government Operations, Secretary of Defense, Robert S. McNamara, said in part:

"Defending the civilian population of the United States against the dangers of thermonuclear attack is not in itself a new responsibility for the department. Our primary reliance is on U. S. military forces as a deterrent against attack. But if miscalculations, intentionally or accidentally, produce an attack against continental United States,

our defensive forces are prepared to meet and engage the attacker.

"Despite the damage that we might inflict on enemy aircraft, some of these aircraft would probably penetrate our defenses far enough to release their weapons. We do not yet have any effective operative defense against ballistic missiles, and some of these missiles would undoubtedly reach targets in the continental United States. In a nuclear attack, several million Americans—perhaps several tens of millions—might be killed."

Many of these casualties would result from the blast and heat resulting from the thermonuclear explosion. There is no financially practical Civil Defense program that could save all of these people from the direct effects.

However it is a different story when we consider the secondary or delayed effect of a nuclear attack, particularly radioactive fallout. It is perfectly feasible to provide adequate fallout protection for all survivors of the direct effects.

As you may know, fallout results when a nuclear weapon is detonated close to the ground. Tons of earth and debris are forced up into the familiar mushroom cloud. These particles become contaminated with radioactive materials from the explosion. They are scattered by the winds, especially at high altitudes, and later fall to earth in the form of radiation emitting dust. These particles themselves may or may not be visible, but the radiation they emit cannot be seen. It is damaging to human tissue and can only be detected by use of special instruments.

Two basic protective measures against the hazard of nuclear radiation are distance and shielding. Various hypothetical attack situations have demonstrated that few areas of the country would be completely free from the fallout hazard. Further, distribution patterns will depend upon weather conditions at the time of, and immediately following, a detonation. Thus accurate fallout forecasts cannot be developed very far in advance of actual attack. This, coupled with the lessened expected warning time reduces the potential use of distance, by means of evacuation, as a protective measure.

Shielding against radioactive fallout can be accomplished by placing a large mass of material between individuals and the radiation source. This principle is incorporated

in the design and construction of fallout shelters.

The most competent of the nation's scientific and medical experts have agreed that fallout shelter is one of the most important requirements for survival following nuclear attack. The National Academy of Sciences and the American Medical Association have strongly urged the construction of such shelters. In the Academy's words, "adequate sheltering is the only effective means of preventing radiation casualties," and "there is adequate technical knowledge to permit a program of shelter construction."

Outside the zones of blast damage, fallout may begin in 30 minutes to several hours after the attack depending upon the distance from ground zero and the speed of the winds. Therefore, outside of likely target areas, there may be an adequate period following an attack warning for the children to get home from school and the breadwinner to get home from work. In the United States there are over 100,000,000 people who do not live in or near a likely target area. Their primary requirement for survival is a properly stocked fallout shelter; and in most instances there would be sufficient time for the family to congregate in the home shelter or some type of communal shelter before the arrival of fallout.

In potential target areas, in the developing missile era, the situation is different. Between the issuance of attack warning and the actual attack, there may be only time for movement to shelter. Although a nuclear weapon can destroy the heart of a city, a miss or near-miss must be considered a distinct possibility. Such a miss, up-wind, could also wipe out the city's population, unless the citizens know how to take advantage of the time following warning to seek previously identified and previously prepared fallout shelter. For these situations, two or more shelters are the best solution. This requires not only shelters at home, but shelters at school, shelters within industry as well as community-type shelters in the downtown or business sections of the city. In target areas, the reunion of the family might be delayed for a period of days.

One other important fact concerning fallout is vitally important from a civil defense standpoint; namely, its radioactivity decreases or decays quite rapidly. Actually, two

weeks after attack the level of radiation will have decayed to 1/1000th of the level that would exist with the fallout on the ground one hour after explosion. It is considered, therefore, that a two-week shelter occupancy will be sufficient for survival. In nearly all cases the majority of shelter occupants will be able to emerge in two or three days, part time at least. Thus the idea advanced in the novel "On The Beach," that the fallout from a nuclear attack would gradually engulf the world and wipe out everybody, is seen to be unfounded.

Obviously this has many implications for the total school program and particularly safety education. The school civil defense or disaster preparedness program should be two-phased. The first is an action program designed to protect students immediately. The second is a curriculum program designed to build citizens who are and will be competent to live in a world in which disaster survival promises to be an important, continuing, and perhaps permanent part of their way of life. These phases are simultaneous programs in the schools and are not necessarily mutually exclusive.

By virtue of his office, the chief school administrator is the responsible authority who sets up school programs to protect lives and property. School board policy should explicitly assign him this responsibility. Oftentimes much of this responsibility is delegated. I'm sure this is not news to those who are specialists in safety education. The point is that someone should have responsibility and authority to establish a disaster protection organization within the system and to take the necessary steps to assure its operational capability.

Disaster protection plans must be developed in consonance with those of the community. Protection measures cannot be effective unless all public agencies cooperate. In event of nuclear attack the decisions regarding protective actions to be taken locally must be made by local authorities. Thus a carefully coordinated plan for all disaster contingencies is imperative. It should be carefully detailed in writing with personnel assignments and alerting diagrams.

One of the first requirements is to determine the extent and quality of available fallout shelter within each school building. Obviously many of the recently constructed

buildings will have little if any suitable protection. Basement areas of older structures may provide a surprising amount of potential shelter which can be made suitable with a minimum of modification. A building survey might be accomplished by specially trained persons to determine shelter quality in accordance with established standards.

The Department of Defense, at the direction of President Kennedy, is currently embarking on a vast shelter survey program. This is designed to identify, mark and stock available community shelter space in existing buildings throughout the United States. This will provide a large number of shelter spaces at the least cost, and in minimum time.

The shelter space identified and marked under the federal survey program will also be equipped and stocked at federal expense. The stocking will be on an austere basis, including water for two weeks, food for five days, first aid and medical supplies, radiological detection kits, sanitation supplies, and tools for exit in emergencies.

Some schools may be shown by the survey to have acceptable shelter space, particularly buildings with basements. In other cases near-by buildings may have acceptable shelter space which can be used by school populations.

The shelter survey, identification and marking program, will get underway in the very near future, and will be conducted under the supervision of the U. S. Army engineer districts, assisted in certain areas by shore establishments of the navy. Details concerning the survey in your area may be obtained by contacting the local district engineer office.

Should there be no suitable shelter space in the school buildings or in other buildings in the vicinity, the plan to be used should be worked out with the local authorities responsible for the safety and welfare of the people. No one plan will fit all communities.

Since the public shelter as identified and stocked will necessitate austere living therein, school curricula could well include psychological and social pre-conditioning for such an eventuality. The necessity for people to work together and not panic should be stressed.

It should be emphasized that new school construction might well incorporate dual purpose shelter. A school cafeteria below ground

with appropriate shielding qualities makes an excellent day-to-day use of a shelter area. Students generally occupy this facility for only short periods each day, and the normal cafeteria food storage would serve as a good nucleus for the emergency stock. It is worthy of mention that the school system of Artesia, N. M., is currently constructing an elementary school completely underground. Thus the entire building can be used as a fallout shelter to accommodate approximately 2000 people. To the best of my knowledge, this is the first school of this nature in the country.

In addition to shelter provision, an adequate attack warning system for the school should be developed. This must be tied in with the community warning system. The manner in which this warning is received is not as important as that it be quick, accurate and certain. Care must be taken, however, to assure that the civil defense action signals relayed to the students cannot be confused with other signals, such as fire warning, or the dismissal bell.

Within the next year or two it is planned to provide direct warning to homes, schools, offices and factories by means of the "near" system. "Near" stands for "National Emergency Alarm Repeater." Under this system, a special signal is superimposed on the power distribution lines which operate an alarm plugged into a wall outlet. Thus any building or structure wiring for commercial power may, at a cost of \$5 to \$10 each, install the alarm device. Every effort now is being made by the federal government to expedite the installation of the signal equipment at power stations through the nation.

Since attack may come while school is not in session, some school facilities may be destroyed and others in the same system be left relatively undamaged. Therefore, each school system should make provision for preservation of essential records through microfilm stored at an alternate site outside a potential target area, or by other suitable means. Similarly a line of succession should be established among school officials to assure continuity of authority in the event the regularly constituted official or officials are unable to act.

Consideration should also be given to a student identification program. Identification assists in quickly bringing together the in-

jured and their families or at least in transmitting accurate information in their behalf, thereby eliminating much uncertainty and anguish.

Emergency groups should be organized among older students for purposes of fighting small fires, light duty rescue, first aid, and radiological monitoring. Training of such groups for institutional protection purposes can be accomplished under the regular curriculum, but their operational function must be under competent faculty direction.

The foregoing represents a few guidelines that must be considered in developing a school protection program. This very limited treatment serves to point up the complexity of such a program in addition to outlining the basic considerations involved.

The second phase of a school civil defense program is embodied in the curriculum. Civil defense in itself does not encompass a precise body of academic knowledge. It does, however, cut across many curriculum areas.

At the elementary level the principles and concepts introduced must be within the level of understanding of the particular age group. This principle has always been recognized and followed by safety educators and therefore represents no departure from standard practice.

These students should become familiar with the disaster plans of their school and community. They should know the warning signals and what they mean and also the nature of Conelrad (640 or 1240 on the Standard AM radio dial for emergency information). They should understand that shelter affords the best protection against fallout, and where the closest shelter is located. Necessity for stocking certain extra supplies of food, water, etc. in the shelter is a necessary understanding. Elementary first aid is a further practical area of instruction.

In addition to knowing what to do in case of a disaster the educational system must also strive to develop appropriate community attitudes. Many parents exhibit concern that civil defense instruction will develop a fear or panic complex in the minds of youngsters. It is my opinion, however, that many children today are more aware of the realities of nuclear attack than are their parents. I believe therefore, that the subject of nuclear attack can be approached on a calm, objective, basis with the attitude that there is a good

chance to survive. This will assist measurably in avoiding the so-called "scare approach."

Students must also be prepared mentally to depart from their daily routine: to inhabit temporary austere facilities, and to adjust to the many inconveniences, including possible separation from family, that may result from such a major disaster. The concept that students, after saving their own lives, can help look after the needs of others will assist in keeping them busy, thereby focusing their attention away from their own troubled situation.

At the secondary level new and more complex items may be introduced in addition to the safety aspects. I should like therefore to provide a few limited examples for consideration.

Social studies might include the study of ideological differences of governments as a basis for present world tensions; a study of community agencies and how they as a part of government would function in emergency; an exploration of how weather affects fallout distribution patterns; and an examination of population trends and how they affect vulnerability, as well as survival chances.

In science the study of protective measures against chemical, biological, and nuclear warfare is appropriate including effects, detection, monitoring, and decontamination.

Home economics can include a study of a balanced emergency diet, special techniques of emergency mass feeding, emergency sanitation measures, as well as emergency home nursing.

Similar appropriate activities should be carried on in health, language arts, vocational education, and of course throughout the safety education program.

Institutions of higher education can also incorporate even more specialized and technical principles. It is imperative for instance that all future architectural and engineering graduates understand the principles of fallout shelter design and construction. Emergency casualty care poses some difficult problems with which medical and nursing education must contend. Family welfare, control of delinquency, and prevention of criminal acts during periods of emergency are a part of sociology and or public administration. Emotional reactions associated with disaster situations is a suitable subject for psychology.

These few examples serve to point up some of the actions necessary to accomplish the complex task which faces us.

The federal government has provided some assistance in this area. Approximately 15,000 sets of radiological detection instruments with curriculum guides have been distributed to high schools and colleges nationwide. This was designed to provide science teachers with the necessary tools to incorporate radiological defense principles into their curricula. Further it provided a geographic distribution of instruments which enhance a radiological monitoring capability in event of emergency.

A federally subsidized civil defense adult education program is currently operating in 15 states. To participants in this program, a 12-hour course in personal preparedness in the nuclear age is offered through existing adult education facilities without charge.

A number of national professional education organizations have developed, published, and distributed "support" publications for their membership. These publications indicate endorsement of the civil defense education principle by the organizational leadership. They also provide recommendations for participation of local membership to further this effort.

The U. S. Office of Education, Department of Health, Education, and Welfare, is currently preparing civil defense curriculum material for student study in the areas of secondary school science and social studies. These materials should be released shortly.

These are a few representative samples of actions undertaken, but the list is by no means exhaustive.

As you know, President Kennedy has indicated that there is a definite need to strengthen and accelerate the total civil defense effort. His active support and the positive steps he has taken have stimulated national interest immensely. It is expected that considerable additional federal leadership will be evident very soon.

The nuclear age necessitates re-examination of the total educational program in terms of adopted protective measures and additional curriculum concepts. Planning and executing such programs for educational institutions require people with courage, foresight, integrity, and all the other qualities that constitute leadership.

Through this aggressive leadership coupled with proper planning and action, the overall effects of a nuclear attack can be minimized, the majority of the people will be saved and the nation will survive. The schools have a major role in this preparedness for disaster you and I hope will never come.

Following the talk by Mr. Fred Brantlinger the following talk was made by the chairman, Dr. Frank Dennett (in summary):

It is rather interesting to note that when the program was developed a year ago, little did we think of the importance of civil defense and the associated problems. However, we must admit that Dr. Patterson, chairman, and his committee made good use of the "crystal ball" and planned the program, knowing full well that we would have to meet and discuss this very important subject.

For more than thirty years, the philosophy of safety education, as expressed by the late Albert Whitney, related to greater and better adventures for safe living. Today, our philosophy has changed to teaching of safety for survival. This last summer, as a reserve officer, I spent two weeks in Alabama taking a refresher course in chemical, biological, and radiological warfare exercises. With this background, I feel more prepared and confident in trying to explain some of the concepts with respect to fallout that will be mentioned.

We understand from Dr. Clifford Brownell that we must all get accustomed to the fact that life at the present time, and in the future, will always involve risk and insecurity. For a long time people were not concerned because they knew that no one would "leave this world alive." However, with the scientific advances in recent months, Shepard and Grissom have accomplished this feat.

From nuclear bombs we get effects from blasts, heat, radiation and fallout. The effects on buildings, grounds, and population vary according to the height of the target blast area. The Civil Defense Agency has assumed that its greatest contribution can be made to saving of lives and property through preparation and planning in areas outside the direct blast area. This usually includes the area outside of a zone with a radius of 15 to 20 miles. In considering every type of protection, the Civil Defense Agency agreed that it could save the greatest number

of lives, with the smallest expense of money and effort, through the use of fallout shelters. Those in the blast area would be affected immediately by blast, heat, and radiation; and very little could be done for those who are unfortunate enough to be in these target locations. But, outside these areas, where the tremendous blast of the bomb would suck up many thousands of tons of dirt and debris, they would be subjected to radio-active materials which would fall to the ground as tiny particles. The fallout would not occur for at least an hour, depending on distance from the target area, wind direction, speed, weather conditions, etc. With this amount of time, if advance preparations have been made, there is every reason to believe that all could survive.

In planning for the meeting today, I thought I would like to share with you some of the impressions of our people with respect to this important problem. Recently, I clipped statements made by various people when they were surveyed with respect to certain questions pertinent to the problem. Take for example this question: "Has your family discussed a fallout shelter?" The following are the answers given by three or four of those surveyed:

One housewife said: "We've discussed a fallout shelter and come to the agreement that when the warning blast sounds I will take the children to the basement of a school a few blocks away. I wouldn't want to spend two weeks in a shelter by myself."

One man said: "We've talked about fallout shelters, but that's as far as it has gone. I've instructed my family in the event of an attack to keep calm and do what they're told by authorities. Like everyone else, we know we should have a shelter, but by the time we got around to doing something it'd be too late."

One woman said: "To discuss a fallout shelter just never occurred to us. In fact, we don't even like to talk about the possibilities of needing one. We'll never need one, and those who are building shelters are betting we'll have a war, while I'm praying we won't. You know, like an insurance policy."

Another man said: "While I think there's a need for fallout shelters, where can you build one in the city? The people living close and in the city will just have to take their chances; and from what I've read

about fallout and explosive force, even fallout shelters wouldn't do much good."

To a second question—"What would you do if you heard the air-raid sirens wail steadily for 3 to 5 minutes?"—the following answers were given:

One man said: "Well, I tell you what I would do. I'd run. That's what I would do. And no one would see me stop until I hit the nearest corner in the deepest hole of the nearest building. Even with all this publicity civil defense is getting now, people in general still think they can duck a bomb like in the days of World War II. They don't realize that, man, this ain't the same bomb. A little old steel helmet on your head is not going to help you, that's for sure."

Another man replied: "Ha, I've got it all figured out. . . I hope. I live near the Patterson Park swimming pool and the locker rooms there are underground. Pretty good idea? But, then again, I would probably be in the Court House if the sirens started. I've been there for more than 21 years, but I hope I'll never have to use the basement there. Yes, it just seems a shame we even have to think about precautions like this, it really does."

Another person said: "If it happened while I was 10,000 feet up in the air (I'm a stewardess), I suppose I wouldn't even know about it. And maybe it would be better that way. My employer has not given stewardesses any instructions on what to do in case of an attack, as far as I know. But you know, it seems a little strange for civilized people to even talk about how to protect themselves and survive in case of mass extermination of the human race. Who knows? Perhaps we won't have to wait for another Ice Age after all."

Another said: "If I was driving, I would pull over to the side of the road, light a cigarette, and think about the incredible stupidity that brought the whole mess about. Take shelter? Who wants to live in a hysterical world when men start throwing super-bombs around with millions of innocent men, women, and children as targets? Not me. I think some people won't be happy until the bombs start falling anyway. I visited Hiroshima and that grim reminder is a silent gallery of horrifying pictures and exhibits. It makes me sick to my stomach when I think it could happen again."

Another said: "Me? I'd try to get right into a shelter, that's what I'd do. And I wouldn't stop running until I was underground in a basement someplace. I think shelters are a good idea if bombs start flying around, but I guess people will depend upon basements for the most part."

To the question: "In view of the step-up in civil defense education, do you favor civil defense in the city and county schools?" the following answers were received:

One man replied: "Yes, I believe civil defense training is necessary. It might be best given in some additional program in the schools. It should be made impressive, however, so it carries over from the school environment to the time outside school. Civil defense training is a definite necessity especially in times such as these. It is necessary, I think."

Another replied: "Definitely, civil defense should be taught in the schools. Children today need to be taught the things necessary for their protection as soon as they can absorb it. As long as the world situation continues as bad as it is now, children need some sort of instruction in civil defense."

Another replied: "I think it should be part of the child's training, but I don't know that it should be part of the curriculum, as such. It's taught in the classroom it implies that a large number will attend, that it is part of the formal educational program. It might best be implemented as an auxiliary to the regular school program."

One man said: "In these times a program of training for children certainly is needed, if only to enable them to look out for their own safety. It seems to me that the school is the ideal place for civil defense training to be given to children. It could perhaps be made part of outside activities or taught right in the classroom. Some sort of training is definitely needed in any case; if the schools can't or won't do it then it is the duty of parents to do it."

Another replied: "Yes, in this day and age I think civil defense training should be given in the schools. With Khrushchev screaming about a new bomb, every child should at least know what to do in case of attack. It should be taught at least from the high school age up. After all, they are the coming generations of this country."

In the area of civil defense education, at

least, most people seem to agree that our schools should accept this challenge and incorporate civil defense as part of a child's safety education program.

I would also like to share with you a letter that was sent to our superintendent of schools, Dr. George B. Brain, by the president of the Baltimore Teachers' Union. This letter, somehow, was reproduced recently in the Congressional Record by Congressman Ryan of New York because of its interesting point of view. Because of time, I will read only several paragraphs that have interest for us today. The following is quoted:

"Vigilance concerning the welfare of our children is of first importance. How best to protect them is the concern of all citizens. Teachers have perhaps been more zealous than most citizens in cooperating with civil defense in the past. While guiding students in air-raid drill, crawling under cafeteria tables, taking cover on cement corridor floors as in World War II, many teachers have felt the futility of such methods of dealing with the H-bomb."

We teachers, who will share with our pupils the "securitis" of these methods, are convinced that the building of fallout shelters is no improvement.

We call your attention to the statement in his report to Congress of Secretary of Defense McNamara (*The Sun*, August 2, 1961) that fallout shelters are good only for cities which do not suffer direct hits. It is generally agreed that in case of war, Baltimore will be a primary target. The recent articles on civil defense in *The Evening Sun* demonstrated that Baltimore could be completely destroyed by H-bombs with devastation spreading for many miles around. Lethal fallout is equally annihilating. Secretary McNamara in his report stated further that, "A near miss up-wind from a large city would still wipe out the city's whole population, leaving the city undamaged."

"But in the nuclear age, our children's physical safety can no longer be achieved through the physical means of steel and concrete. Knowledge, intellectual ability, and creativity in dealing with the new demands of a new age are the only ways of protecting our children's bodies. It is these capacities of the mind which desperately need

instilling and which cannot be fostered by building bomb shelters."

"Only by achieving quality education for all our children—only by providing adequate classroom space, reduced class size, and fully qualified teachers—can we realistically meet the nuclear challenge. Those who hope to depend on bomb shelters are dreaming in the past."

It is interesting to note that in the area of traffic safety, it is difficult to get people to understand that they might get hit by a car when they cross streets improperly. In fact, you may note that on wet days they do scamper across because they know they can get wet—but the fact that they might get hit by a car—this is considered an impossibility!

You may remember that several years ago, in Connecticut, they had a strong drive, the theme of which was "SLOW DOWN—SAVE YOUR LIFE." The drivers did not slow down, and lives were lost. But, when they changed this to "SLOW DOWN—AND SAVE YOUR LICENSE," this was "for real," and drivers did slow down to save their licenses and also their lives. In the area of nuclear warfare, while most people are certain that they won't be hit by a car, each and every person is convinced that the bomb will blast off directly over his head. We know that there are not enough, at the present time, to strike at all the targets; the enemy would like to "knock out"; yet the hysteria and alarm has reached proportions where each and every person feels that there is a nuclear bomb with his name on it! This leads me to say that "what we don't know can't hurt us!"

We heard earlier that the two important factors in fallout are the concentration of radioactivity and density of barriers. The best means of protection, of course, is "just not to be there." Therefore, every effort is made to have as much material between yourself and the outside world—considering all other hazard factors. We have heard many times that we should be prepared to stay in shelters two weeks. This is a possibility; however, the concentration of radioactivity may be low, or the decay rates may be rapid, so that perhaps ten (10) hours or

48 hours may be all that may be required to stay in shelter areas. Children will not have to stay in the highly protected areas all the time. They can move out to make use of toilet facilities, cafeteria facilities, and others, for short periods of time.

Information will be sent via CONELRAD, giving the amount of radiation and suggesting safety factors so that school authorities may make decisions as to whether children should be dismissed or retained in school; whether they may be permitted to go outside for short periods of time, etc. It may be perfectly reasonable for schools in one part of the state to evacuate, and in another area in the direct path of radiation, children will be kept at school.

This will be our "way of life" for some time ahead. School authorities should prepare and plan a civil defense procedure for their own schools. These plans should be checked with the local civil defense authorities, and then the information should be sent to parents so that they may know the school's procedures, and make the necessary plans for all situations as far as possible.

Those living in large cities or major industrial centers, may take some comfort in knowing that "Mr. Khrushchev and Company" do not have sufficient bombs at this time to "knock out" all good target areas; and therefore it would seem that his first choice would be knocking out our retaliatory capacities. This would include the Strategic Air Command bases, missile bases, and other installations of a similar nature.

Mr. Ronald Patterson, of the Detroit, Mich., public schools, read an outline of the Detroit school disaster plan and then conducted a general audience discussion on school civil defense. Among the topics discussed were: (1) the proper name for a civil defense drill, (2) systems of communication for various alarm signals, (3) what to do when the alert sounds.

Mr. Brantlinger concluded the discussion with this advice: each school should have a disaster plan that is tailored to its special needs; the plan should be designed in close cooperation with local civil defense authorities.

HOW THE SAFETY COUNCIL MANAGER AND SAFETY EDUCATION SUPERVISOR CAN COOPERATE IN THEIR ACTIVITIES

A PANEL DISCUSSION

Remarks of G. Ernest Bourne, manager, Utah Safety Council, Salt Lake City, Utah.

Cooperation, as our dictionaries and thesauruses tell us, means, among other things—partnership. Certainly you and I are partners in our mutual objectives. As such, there is a deep obligation for us to share our ideas, resources, and information.

To do this we need two-way communication with each other. All too often the safety education supervisor and safety council manager don't even know each other exist! I can't tell you, for example, who, if there is one, is the safety education supervisor in the San Juan school district down in the southeast part of my state. By the same token, he probably does not know me. And that's too bad, both ways.

But from a professional standpoint, we are both missing the boat, and I will explain why.

First, he is missing out in maintaining possession of much valuable local safety information and access to safety educational resource materials and training aids that could be put to good use.

Secondly, I am missing out in failing to secure optimum outlets for the safety education program of my organization.

These two failures, involve a great many things too numerous to elaborate upon, but by the two of us getting together, we could discuss them in considerable detail.

One of these things that would be proper to discuss when the two of us got together would be elements of system thinking and methods, and the timing of certain projects or activities. One can save a lot of wheel-spinning by doing so. In this business of safety there are many complexities which involve inter-agency cooperation and use of varied resources. This interlace of interests and knowledge of who is best equipped to do or assist with a project is often familiar to the safety council manager. He is therefore a useful man with whom to work.

By membership in the National Safety Council, the safety education supervisor has access to, or should have, the outlines and teaching guides and other materials we council managers find in our Chapter Libraries. These contain excellent suggestions and ideas to incorporate into classroom teaching. Failure to use them for reference purposes would simply be playing the old ostrich trick again.

Close liaison should also be maintained with the local or regional PTA safety chairman. They in turn are usually in touch with the local or state safety council. With this chain of communication added participation in the National Safety Council Honor Roll program could be stimulated. Frankly, I think this is one of the finest and most appealing contributions in the entire safety program relating to the schools. As a council manager, I will not be satisfied until all the schools in my state are enrolled because of the many things this program embraces and means. The safety education supervisor can and should make a real effort and contribution in this. The safety council manager is ready and eager to be of help to him.

Closely related to this is the need and value of gathering accident data involving school children. This is done by use of the standard student accident report forms and summaries. Far too many schools, in my observations, fail to use these forms. The result is often poorly directed safety programs that miss priority targets. Because of this, it is only natural that some school officials are cool to otherwise needed safety programs in the school. Your safety council manager would be glad to help here, too. Once the routine of setting up the accident gathering program is accomplished, it is not an undue burden. Overcoming inertia to get it started is the problem, it seems. But this is a fundamentally important part, it would appear to me, of a safety educator's job.

The schools, and particularly the safety education supervisors, should make it their business to find out what the priority needs in their area are relating to traffic safety. This can be done by asking city officials what findings and recommendations relating to the schools are contained in the Annual Inventory of Traffic Safety Activities for his city. If the city is not participating in this program, help get it to do so. After ascertaining what the priority needs are, offer assistance and cooperation to the city officials in carrying out the inventory recommendations.

The safety council manager, on the other hand, can spur his organization to take the leadership to sponsor, or assist in the development of, regional and statewide youth safety conferences and seminars. These provide opportunities for the students to develop interests and activities that have broad chain-reaction effects. They also identify problems, projects, and programs that can have community-wide impact.

These conferences and seminars will suggest and assist in development of student safety committees or councils that have many worthy objectives and possibilities. The safety council manager should always have on hand a supply of the National Safety Council student safety kits. These can then be issued to a school, on request. We only issue them in this manner because first we do not wish to force anything upon anyone, and secondly we couldn't afford promiscuous distribution of that kind.

These student safety committees would then, in turn, find it useful and desirable to affiliate with or form a statewide youth safety association, and the national association sponsored by the National Commission for Safety Education.

So much has been written and said about the driver education program that I am going to pass over this area with but one comment. See that your school's training cars are equipped with seat belts and that the students use them. It's a good habit to get them addicted to! High-school students are not the only ones needing driver education. So if there is a move on for adult driver education, cooperate and assist in such an undertaking. There is much to be done in this area of need.

We have had considerable experience in

developing and promoting safety legislation. Frequently we have observed that school people will unilaterally propose and try to get bills of a school safety nature through the legislature. Usually such efforts fall flat on their face. We saw this happen at this year's session, and in other years.

The reason is not necessarily that the proposals themselves are faulty, indeed some of them are good. But legislators are often prone to view with a jaundiced eye proposals coming directly from school people. Our legislature, at least, sometimes is that way, as they have trouble enough with school financing problems.

On the other hand, measures that are proposed and supported by the state safety organization and the Governor's Official Traffic Safety Coordinating Committee have a considerably better record of success.

Thus, if school safety educators and officials would review their safety legislation needs with the safety council and other similar agencies well in advance of the legislative session, more success would be possible. Not only that, sometimes even the original proposals could be improved upon so as to enhance not only their chances but avoid mistakes that, if enacted, would have to be corrected at the next session. We have seen that happen, too!

As a close observer of the total accident problem, I am acutely conscious of the urgent need for reducing and eliminating accidents in the home and its immediate environment. As driver education has a carry-over effect upon the parents, so too can home safety stimuli brought home from school by the child. This, of course, can be done in many ways. One of the most helpful techniques is to provide the student with a simple home safety check-list. The safety council can provide such a check-list. This should be taken home, with instructions on how to get the parents help in completing it, and bringing it back to school for summarizing and brief class discussion.

I am not suggesting that this is primarily a school responsibility because it is not. But I do mean that the school can not close its eyes or mind to things outside the classroom, or areas not directly related to it. We are told that safety is a way of life

and certainly the school is one of the main-springs in developing this.

But equally important, in the same manner that an employer wants his worker on the job every day, so does the teacher want his student in class. Students are all too frequently prevented from such regular attendance because of the stupid but preventable mishaps that occur in the home and its surroundings.

The sight of an eight-year-old boy in bare feet or tennis shoes steering a rotary power mower around the lawn never fails

to chill me. This, and hundreds of other hazards that attention could be attracted to could prevent mishaps that would save thousands of child-hours in the classroom over a school term, I am sure.

In closing, I reiterate that a close working partnership between us can and will produce more success in our mutual objectives. We cannot delegate to other vaguely-identified people our chores and responsibilities. By each contributing his part the end-product will be better schools, a better community, and certainly a happier and more profitable life for all of us.

LOCAL SAFETY COUNCILS

By HAROLD COX

Mr. Howard Cox, of the Detroit, Mich., Traffic Safety Association, briefly outlined the Detroit program. The Detroit Association works closely with the schools and the local police. The schools have an extensive safety education program, with a patrol group in every elementary and junior high school and the largest high school driver education program in the nation. The Traffic Safety Association supplies some safety education instructional material to the schools, and works closely with the street and highway department to plan safe routes to and from schools.

In addition, the Detroit Traffic Safety Association brings the safety message to the general public through the use of communications media. Mr. Cox played a tape of "Showcase," a radio program on safety that is regularly aired by station WGRK.

Mr. Cox concluded his presentation with a short question and answer period where specific problems were discussed.

Mr. W. J. Danforth, manager of the Fort Worth, Texas, Safety Council described their school program as a "coordinated effort to prevent and reduce accidents. Each school has a safety committee that regularly inspects areas such as school crossings and lunchrooms for accident hazards, as part of a "Green Cross for Safety" program. Every six weeks, each school reports to the safety council. After 10 suc-

cessive safe periods a gold cup is awarded to the school.

To aid in school safety education programs, the safety council and local organizations have supplied over 150,000 pieces of material to the schools, including appropriate visual aids.

In conclusion, Mr. Danforth commented on the program's success. He says that it has resulted in a carry over of safety practices into the home and community. Last year, the school system reported only 230 student accidents and 869 days lost due to accidental injuries.

Mr. Forrest Gaines, managing director of the Greater Baton Rouge, La., Safety Council, opened his talk by stating that a program of proper cooperation between the schools and the local safety council is of major importance to a full scale community safety effort. A school-safety council cooperative program that is conducted in the proper manner can have the greatest single impact on the total safety of the community. It is important that the council be informed of school policy and that the council abide by it in all association with the safety supervisor. Through cooperative planning, the supervisor can define major needs and indicate the types of assistance which the safety council can render to the schools.

In discussing the Baton Rouge program, Mr. Danforth emphasized that all plans

are made cooperatively. For instance, when one school principal mentioned that patrols needed more recognition, the safety council promoted a plan whereby on Monday and Thursday of every week, one school patrol group appears on a local television program. Among other activities, the council also supplies the schools with safety lesson outlines for the teachers, and has set up a cooperative plan for promoting the National School Safety Honor Roll.

Opening his remarks, Mr. Albert Phillips, executive director of the Greater New Haven, Conn., Safety Council, stated that the New Haven council has a particularly difficult job because the city school system has no coordinator charged with responsibility for safety education. To compensate

for this lack of supervision, the council has worked with a committee of principals in formulating plans for safety education programs.

At present, no school in the state of Connecticut has a coordinated program. In New Haven, the council has been working to convince schools of the need for safety learning. Although the schools do have patrols, fire prevention programs, and some participation in the National School Safety Honor Roll, they have done no work in accident reporting. The council has participated in formulating a system-wide curriculum change that will include safety education as part of class work, and is working with the schools to set up a complete program of accident reporting.

HOW THE SAFETY EDUCATION SUPERVISOR AND THE LOCAL SAFETY COUNCIL CAN COOPERATE IN THEIR ACTIVITIES

By HAROLD F. LILLIE

Dir.-Secy., Safety Council of Greater Lansing, Mich.

Since its organization in 1939, the policy of the Safety Council of Greater Lansing has been to support the official agencies of government, responsible for the safety of our citizens, through public education programs.

We would like to present two significant examples of the cooperation between our council and our schools, that has resulted in the knowledge that "we have one of the finest school and child safety education programs in this nation."

Back in the early days of the organization of our council, we offered our cooperation to the local boards of education and found that safety education materials and teaching aids would be welcomed in all of our public and parochial schools and would be used in every way possible, if the safety council was willing to buy or produce this material.

At that time we did not have a safety director or supervisor as such in our local system; however, a local high school faculty

member was acting as safety supervisor for the schools, and doubled in brass for the safety council as chairman of our School Safety Division. This gentleman was eventually given full departmental status and made director of safety for the Lansing Public Schools and is still chairman of our School Safety Division. Probably many of you have heard of him or worked with him in the national School and College Section programs. I refer, of course, to Lewis E. Clark.

Because of Lew's work in the public schools in Lansing as safety director and his interest in the total child and school safety programs which involve all of the public and parochial schools in Lansing, East Lansing and Ingham County, in the School Safety Division of the safety council, much has been accomplished in our service area.

So great is the value of the safety education materials available from the National Safety Council—both as a teaching aid in

the schools and as it is carried home from the schools—that, at the present time, our council purchases and distributes, each month, to 126 schools administrators, departmental directors, and to teachers, the following quantities of N.S.C. school and college safety education materials:

- 135 subscriptions monthly to *Safety Education* magazine
- 2,350 Lower Elementary and 1,550 Upper Elementary Safety Lesson Units, monthly
- 140 Secondary Safety Lesson Units, monthly
- 685 Elementary and 90 Secondary Posters, monthly
- 10 subscriptions monthly of the *Safe Driver* magazine for driver education instructors

It has been our policy also, outside of the materials mentioned above, to supply on request additional materials that are asked for by departmental directors for use in special programs. Some of these are: school safety fire packets, fall proof pamphlets, safety education reprints shop safety, school shop safety poster packets, food service safety check lists and safety education data sheets such as *Safety in the School Lunch Room*.

We know the value of the wide-spread use of this material, and can report to you that business, industry and government who support the Safety Council of Greater Lansing, are only too happy when we report on the expenditures we make from our budget, for the school safety education materials that have proven of such worth in our area.

Another valuable example of the cooperation between the official education agencies of government and our council, comes about through the programs designed by the School Safety Division, chaired by our school safety director.

This division, made up of public and parochial school administration, departmental heads, elementary and secondary faculty members, and enforcement officials from Lansing, East Lansing and Ingham County, plans and designs and writes pamphlets, booklets, flyers and brochures. These publications are not only used in our schools

as teaching aids, but are distributed through the schools, P.T.A.'s and other club groups through our Women's Division, and are carried into some 50,000 homes in our service area.

This type of material is printed and produced in the safety council office and is specifically designed to meet the needs of our citizens wherever a potential accident hazard is apparent, or wherever a need for greater safety education in a specific field is felt.

As an example, in our City of Lansing, we have some 8,000 licensed bicycles—We believe there must be a like number of unlicensed bikes—There was much concern on the part of parents, teachers and enforcement officials over the bicycle problem in our area. The result was the writing and production of 100,000 pamphlets "What Every Bike Rider Should Know," which has been used during the past three or four years in the schools and homes of our community.

Some of the others that have resulted from this program, and made similar use of, are: *Wise Walking Pamphlets*, *Hunting Safety Blotters and Bookmarks*, *A Message of Importance To Parents on Rainy Day Safety*, *Safety Hints for Christmas* (Reprints from N.S.C. pamphlet), *Winter Fun Pamphlets*, *The Child In Lansing Traffic Book* (annual edition), *Lansing Traffic Rules* (for driver education classes), *City of East Lansing Traffic Law Digest* (for driver education), *The Talking Bike Scripts*, *What Every Operator of a Power Lawn Mower Should Know*, *A Guide for Elementary Teachers* (safety education book), *Squirm the Safety Bookworm*, *Traffic Safety Placemats*, *Green Pennant Posters*, *Stop-Look-Wait-Walk* (screen door stickers).

Both Lansing and East Lansing have been three time winners of the America's Safest City Award. We are unable to evaluate how much the cooperation of the safety education supervisor with our local safety council has helped us in gaining this recognition, but by all standards, we know, we are doing everything possible to assure the greatest degree of safety for our youngsters in the schools and in public places, and to give them a strong background of safety education to meet their needs for the future.

STATE LAWS FOR SAFETY EDUCATION

By JAMES F. NIHAN

Dir. of Safety Education, State University of New York, Albany, N. Y.

The purpose of this study was to evaluate existing safety education laws and regulations and to make recommendations for their improvement. The laws were compiled from official statutes. The regulations were abstracted from state education department publications.

Forty-eight states have legislation and 19 have regulations affecting at least one major phase of safety education. None have legislation or regulations pertaining to all phases. Several state education departments use the laws in lieu of regulations. Evacuation drills are covered by law in 34 states, by regulations in nine. Twenty-four states have laws regarding driver education; 15 have regulations. General safety education is included in the laws of 23 states, in the regulations of 14. Fire prevention education is legislated in 18 states but covered by regulations in only one state. School safety patrols are provided for by law in 12 states, by regulations in four. Statutes providing for traffic safety education were found in 11 states, regulations in only three. Civil defense education is affected by legislation in three states, by regulations in five. Six states have laws dealing with education in firearms safety.

Many laws fail to provide flexibility for local initiative and adaptability. There are conflicting standards among the states and within states. Many codes are ambiguous as to authority and responsibility. Several states' regulations are hortatory rather than regulatory.

The laws and regulations identified were abridged and the major provisions refined into separate evaluation instruments. A panel of seven state education administrators

evaluated the provisions in the instruments and applied to each item a qualitative rating of Excellent, Good, Fair or Poor. The judges favored existing regulations over laws. They accepted more prescriptive details in the regulation, but consistently criticized excessively prescriptive or inordinately permissive items.

A quantitative value was applied to each of the four evaluation terms. To be recommended, an item required two-thirds of the maximum value attainable. The following recommendations reflect the fundamental principles contained in the 26 legislative and 49 regulatory items which qualified. Safety education laws should: 1) require all schools to offer instruction in the several phases of safety; 2) authorize state education departments to regulate the details of such instructions; 3) authorize the expenditure of school funds for safety instruction; 4) avoid prescribing the details of safety instruction; 5) not mandate that non-educational agencies participate in, regulate or control education functions; 6) refrain from providing special financial support for certain phases of safety instruction and, 7) not involve the schools, directly or indirectly, in the granting of licenses or permits.

Safety education regulations should: 1) establish the basic framework within which school districts may adapt safety instruction and, 2) provide uniform minimum standards relative to granting credit for safety courses, time devoted to safety instruction, distribution of safety education funds, grade levels for such courses, and the extent of participation by non-educational agencies.

THE SAFETY EDUCATION PROGRAM OF THE PHILADELPHIA PUBLIC SCHOOLS

By DALIBOR W. KRALOVEC

Dir., Div. of Safety Education, School District of Philadelphia, Philadelphia, Pa.

The Problem and Its Scope

The main purpose of this study was to describe and analyze the safety education program of the Philadelphia public schools. This involved four problems: 1. to trace the early development of safety education in the Philadelphia public schools, 2. to determine the present status of the program, 3. to develop an evaluation questionnaire for Philadelphia based on national, state, and local recommendations and standards, and 4. to evaluate according to the evaluation questionnaire the present status of the safety education program of the Philadelphia public schools.

This study dealt primarily with the instructional program of safety education in the Philadelphia public schools. Emphasis is placed on the organization and administrative phases of the program. Evaluation of the program is based on the evaluation questionnaire for Philadelphia developed in connection with this study from national, state, and local recommendations and standards.

The need for safety education in the modern world is everywhere apparent if one reads the newspaper accounts and pictures of mishaps in traffic congestion and other hazardous conditions; and in the statistics of accidental deaths and injuries in the home, at school, in play and recreation; with fire, in work, and in numerous other situations. The critical need for safety education in a large metropolitan city such as Philadelphia is especially acute because of the extent of exposure to hazards.

Stack and Elkow point out that "In a world of constant change, objectives cannot be set for all time." There was need, therefore, to study the safety education program of the Philadelphia public schools to see that it was attuned to the facts and the times. No recent comprehensive study or analysis of the program has been made.

The need for a study of the type projected here was evident from a review of previous research studies in safety education. These studies are primarily of a broad survey

nature. The present study is designed to give a detailed analysis of the comprehensive safety education program of the Philadelphia public schools. It may be, in addition, a means of stimulation and inspiration to other communities in the organization and administration of vital and adequate safety education programs.

The safety education program of the Philadelphia public schools has evolved over a considerable period of time. There appears to be a need to ascertain direction and present status of the program. This study, in addition, should be of considerable value to the improvement of the safety education program of the Philadelphia public schools.

Method of Investigation

General references in the area of research methods and techniques and specific safety research references and studies indicated in the bibliography were consulted. Special attention was devoted to doctoral studies in the field of safety education. Background for this study was developed over many years through a study of the literature of safety education and long-time service in safety work.

Historical Aspects of the Study

Chapter IV of this dissertation, "A History of Safety Education in the Philadelphia Public Schools from 1818 to 1960," was written almost exclusively from primary source materials. A study to discover references to safety and safety education was made, and statistical reports from the superintendent's office were culled for references to safety and safety education. Locally published educational magazines were consulted. Additional sources of information were early manuals, courses of study, reports, bulletins and letters contained in the files of the safety office of the school district of Philadelphia. Personal interviews with leaders in the safety movement in Philadelphia helped to fill in gaps in the printed material. Careful notes were made from sources of materials indicated. The data

were arranged in a chronological sequence to give the story of the development of safety education in the Philadelphia public schools.

The evaluation questionnaire for Philadelphia was specifically developed for use in this study to serve as an evaluative instrument for the safety education program of the schools and as an administrative device to stimulate thought and activity in the school.

In 1949 the safety committee of the Philadelphia public schools prepared a short survey check list intended for distribution to principals throughout the Philadelphia public schools. It was called "School Safety Diagnosis for the Principal and His Staff." This questionnaire was never distributed to the schools. It was used in this study as a starting point and basis for the development of the evaluation questionnaire.

The first plan for the evaluation questionnaire for Philadelphia consisted actually in the development of four questionnaires along the lines of the original "School Safety Diagnosis for the Principal and His Staff." The four questionnaires were designed to ascertain the reaction of administrators, teachers, parents and pupils to safety and to the safety education program of the Philadelphia public schools. An attempt was made to have all four questionnaires similar in construction and in general items in order that reactions of the four groups could be compared and summarized in a significant manner.

Several months were spent in the development of these questionnaires, but they were eliminated from the study because they attempted too much and they were too general in nature. It was decided to concentrate on one questionnaire directed to the principal and the administrator of the school. A single comprehensive questionnaire seemed to have possibilities for coverage of a variety of safety areas in a much more detailed, specific and objective manner.

The evaluation questionnaire for Philadelphia, then, followed the general plan of the original "School Safety Diagnosis for the Principal and His Staff." The questionnaire developed for this study, however, was considerably enlarged and was made more specific and objective than the original questionnaire. The questionnaire was aug-

mented and changed to include elements from national, state and local standards for safety education together with numerous items which seemed particularly appropriate to the Philadelphia situation. The questionnaire considered five areas, namely:

1. General organization and administration.
2. School plant and grounds.
3. Instructional program in safety.
4. Community relationships.
5. Evaluation.

The questionnaire was revised a number of times in the light of suggestions made by the sponsoring committee and a jury of experts in safety education and by an informal pre-test of the questionnaire by a limited number of selected principals.

In early April, 1959, the questionnaire was mailed in duplicate to all Philadelphia public school principals with a covering letter from the superintendent. Responses were checked against the distribution list for completeness of the returns which were requested to be returned by May 15, 1949. In view of the official nature of the questionnaire and its covering letter, little difficulty was encountered in securing a one hundred per cent return.

The principal and his staff were requested to answer the questions in terms of "No," "Partly," or "Yes," or "Slightly," "Moderately" or "Extensively," and they were encouraged to make explanatory remarks on any part of the questionnaire. In view of these directions several methods of tabulation were considered. It was decided that a hand rather than a machine tabulation would meet the needs of this study, since only a part of the questionnaire response was numerical in character.

As a first step, the questionnaires were sorted for ease of handling them into the eight administrative districts from which they came. Returns from elementary schools, junior high schools, and senior high schools, including vocational-technical schools, were separated within the district returns.

Blank questionnaires with a "No Response" column added served as forms to tabulate the numerical returns from the questionnaires. Explanatory remarks were taken verbatim from the questionnaires returned from each of the administrative districts

and these were organized in terms of the five major areas covered in the questionnaire. The handbook of the school district of Philadelphia for 1960 listed the following school units as of September 1959:

TABLE I NUMBER OF DAY SCHOOL UNITS	
Senior High Schools	16
Senior-Junior High Schools	2
Vocational-Technical Schools	3
Junior High Schools	28
Elementary Schools	158
Residential Schools	1
	248

In addition, twenty-two elementary school annexes were maintained and attached organizationally to other schools. Six of these annexes were considered by the principal to be sufficiently different from the parent school to have questionnaires submitted separately for them. A total of two hundred fifty-four questionnaires were returned and used in this study.

The conclusions consisted of interpretations of the most important findings presented in the summary. Recommendations were offered for improvement of the safety education program of the Philadelphia public schools based on the findings of this study, in terms of the possibility and desirability of constructive practical application to actual situations of at least some of the conclusions, and in terms of the need for further research or study.

Summary of Historical Development of Safety Education in the Philadelphia Public Schools.

1. Twenty-five important communications were found in the early journals of the Board of Education concerning general "physical hazards" between the years 1875 and 1908.
2. Twenty-five important communications were found in the early journals of the Board of Education concerning specific "fire escape" needs between the years 1875 and 1907.
3. Safety patrols were established in Philadelphia in 1914 by the Philadelphia Rapid Transit Co. Safety patrols were officially approved as an integral part of the plan of instruction in February, 1925.
4. Safety patrol operation, except duties on school grounds, was suspended from 1929 to 1931. In May, 1931, the superintendent of schools was authorized and directed to organize school safety patrols in accordance with section 510 of the school laws of Pennsylvania. Safety patrols have operated continuously since that time, from 1931 to the present time.

5. Safety education became an established part of the curriculum of the Philadelphia Public Schools in 1932 with the issuance of a "Syllabus in Safety Education."

6. The Philadelphia public school defense committee which was organized in 1941 immediately after Pearl Harbor became the forerunner of committee organization for safety in the Philadelphia public schools.

7. The driver education program was instituted in the Philadelphia Public Schools in September, 1950 by the Board of Public Education.

8. The safety office in the division of physical and health education of the Philadelphia public schools was established by official action of the Board of Public Education on July 10, 1951.

9. Safety education was centered in the safety office, division of physical and health education, from 1951 to 1960.

10. The division of safety education was established by action of the Board of Public Education at its meeting on July 12, 1960.

11. The division of safety education began its official operation on September 1, 1960.

Summary of Present Status of the Safety Education Program

1. In 1960, there were more than 6,000 safety patrol boys serving in the public schools.
2. In 1960, a new safety patrol manual was issued for pilot study in a number of schools throughout the school system.
3. In 1960, there were 34 full-time teachers in the driver education program teaching approximately 4,000 students to drive in a fully approved state-standardized program.
4. A new course called "Resource Unit Outlines for Safety Education in the Elementary Schools" was issued for pilot study in 1959.
5. No independent time allotment was provided for safety education at the elementary or secondary school level in the Philadelphia public schools, except in driver education.

6. Approximately 30 written safety communications were issued to the schools each year.

7. At least one original safety flyer was developed by the Philadelphia public schools each year to carry a significant safety message in attractive way to students and parents.

8. All Philadelphia public schools received each month of *Safety Education* magazine of the National Safety Council.

9. The traffic safety program of the Philadelphia public schools was supplemented by the full-time services of six traffic officers from the Philadelphia police department.

10. Philadelphia had a force of 720 firemen school crossing guards.

11. Bicycle safety was a regular part of the safety education program.

12. Railroad safety programs were offered by the major railroads serving Philadelphia.

13. Fire safety regulations were spelled out in Administrative Bulletin No. 1 entitled "Fire Safety in Schools."

14. The fire safety program of the Philadelphia public schools was supplemented by the full-time service of three firemen from the Philadelphia fire department.

15. Safety in the home received emphasis in the school program.

16. The playground safety program utilized many of the safety personnel and services offered during the regular school year safety program; the safety patrol supervisor; six police officers assigned to the pedestrian safety education program; three firemen assigned to the schools; and the services of numerous community agencies, including the automobile clubs.

17. The schools were active in the civil defense program.

18. Supplementary-type programs included safe handling of dogs, kite flying, soliciting rides, and port tours.

19. Safety conferences such as teen-age conferences, bus driver's safety institutes, and coordinator's conferences were held as a regular feature of the safety education program.

Summary of the Evaluation Questionnaire

1. Teachers and/or safety patrol sponsors were designated as safety coordinators in

most Philadelphia public schools. Vice principals were given this responsibility in a number of secondary schools.

2. A committee comprised of the safety coordinator and other staff members assisted with the school safety education program in 76 per cent of the schools.

3. Schools achieved balance in the safety education program in more than 94 per cent of the schools by including safety in all areas of the curriculum, using a variety of generally-recognized valid methods and appropriate aids and involving all personnel.

4. Approximately 97 per cent of the schools declared that they eliminate safety hazards by encouraging cooperative group action, reporting hazards to proper authorities, executing an appropriate inspection plan, and following up on complaints and suggestions.

5. Eighty-nine per cent of the schools checked with the staff each school term on the rules and regulations contained in Administrative Bulletin No. 1, "Fire Safety in Schools," safety information and suggestions contained in the safety file and directions to the custodians.

6. Ninety-three per cent of the schools made known fire and defense procedures to faculty, children and parents through such means as oral communications, written communications, and drill exercises.

7. Ninety-one per cent of the schools disseminated information contained in safety communications from the Central Office through such means as assemblies, faculty meetings, special communications to parents, suggestions to the coordinator, bulletin boards, special safety projects, and through evaluation of the program.

8. Seventy-eight per cent of all the schools had the "Course of Study in Safety Education—Grades One to Six" available for teachers' use. Ninety-two per cent of the schools reported that they have safety pamphlets, booklets, or books available for use. Ninety-six per cent indicated that audio-visual aids are available for teachers' use.

9. Eighty-nine per cent of the schools declared that they had organized a school-wide system for the use of Form FHV 51, Record and Report of Accident, and 82 per cent said they have organized a school-wide system for the use of Form M 98, Record

of illness and/or injury. Eighty-eight per cent asserted that they followed up accident reports.

10. Student safety groups were organized in the schools as follows: 33 per cent had school safety councils; 80 per cent had school safety patrols; 87 per cent had indoor safety guides; 26 per cent had junior fire patrols or departments; 38 per cent had civil defense messenger service groups; and 74 per cent had sanitation or good housekeeping squads.

11. Schools claimed that they checked regularly on the proper functioning of student safety groups as follows: on the street, 90 per cent; in the playground, 89 per cent; on the school bus, 44 per cent; and within the school building, 94 per cent.

12. Seventy-six per cent of the schools stated that they used the literature and services of recognized safety agencies in organizing and planning the safety program of the school. Approximately 90 per cent used the booklets, pamphlets, posters, flyers, and magazines of such agencies.

13. Eighty-eight per cent of the schools made use of Safety Education magazine by circulating the magazine among faculty members; over 60 per cent reviewed articles and used the lesson outlines; 12 per cent claimed to write for the magazine.

14. Schools generally reported moderate provision of in-service safety education for staff members. Approximately 80 per cent of the schools reported the use of resource persons and participation in safety meetings and discussions.

15. Eighty-nine per cent of the schools reported moderate to extensive provisions for acquainting new teachers in the school organization with the safety education program of the school.

16. Ninety-seven per cent of the Philadelphia public schools reported that they instructed the staff and students to live in a safe environment.

17. Ninety-five per cent of the schools indicated inspections of the school plant and grounds in order to eliminate hazards such as slippery surfaces, loose plaster, unsafe furniture and equipment, broken glass, defective pavements, steps, and blocked passageways.

18. Ninety-seven per cent of the schools

declared that they took precautions to see that all exit doors are unlocked and unobstructed during school hours.

19. Approximately 96 per cent of the schools revealed proper use of "built in" safety features of the school building such as panic bolts, fire doors, handrails, and alarm systems.

20. Sixty-seven per cent of the schools noted that they have studied the traffic layout on stairways and in corridors.

21. Schools reported on the question of taking special precautions to insure safety in special areas as follows: 41 per cent, in shops; 39 per cent, in home economic rooms; 33 per cent, in science laboratories; 42 per cent, in cafeterias; 75 per cent, in auditoriums and stages; and 92 per cent, in gymnasiums and playgrounds.

22. Ninety per cent of the schools showed that they checked with the custodian to see that an adequate inspection for fire and other hazards was made of the building and grounds at the close of each day.

23. Eighty-six per cent of the schools reported that they have made plans and safeguards to meet common neighborhood hazards.

24. Over 94 per cent of the schools reported that teachers and parents observe children for unsafe behavior so that they may improve planning, instruction, supervision, and environment factors in safety.

25. Approximately 85 per cent of the schools indicated that they have diagnosed moderately or extensively, the school accident report to determine what can be done to reduce accidents by improving the safety factors in school activities, curriculum, supervision, and environment.

26. Eighty-two per cent of the schools felt that they developed the judgment and maturity in their pupils which would enable the students to arrive at the wisest way to deal with the safety factors in any situation.

27. Over 80 per cent of the schools stated that they instructed pupils in the safe routes home. Fifteen per cent of the schools reported that they do not instruct pupils on the safest way home.

28. Approximately 84 per cent of the schools reported moderate or extensive opportunities for pupils in the safety program to assist in the purposing, planning, organ-

izing, administering, practicing, and surveying of the program.

29. Eighty-five per cent of the schools gave evidence of teacher use of a wide variety of safety activities in terms of pupil levels appropriate to the developmental level of the child.

30. Schools declared that teachers encouraged children to participate creatively as follows: 81 per cent by initiating projects of their own; 82 per cent by writing original safety plays, stories, and poems; 94 per cent by drawing or painting posters; and 62 per cent by conducting needed surveys.

31. Over 80 per cent of the schools declared that their safety programs afforded opportunities for integrating safety activities in the subject matter areas.

32. Approximately 90 per cent of the schools asserted that their safety programs included traffic, school, home, playground, fire, seasonal, and civil defense safety.

33. Over 90 per cent of the schools affirmed that they took advantage of the opportunities offered by special events such as holidays, emergencies, vacations, and special drives.

34. A high percentage of schools used a variety of media in the safety program. Ninety-nine per cent used posters, 84 per cent used dramatics, 72 per cent used original writings, 97 per cent used assembly programs, 90 per cent used safety patrol activities, 88 per cent used bulletin boards, and 84 per cent used slogans. Twenty per cent of the schools revealed that they have not used original safety writings.

35. Schools reported that they plan for safety with the staff and community in a cooperative effort. Sixty-eight per cent hold safety meetings and discussions, 76 per cent hold home and school meetings, and 82 per cent use community resources and agencies. Fifty-six per cent cooperated in and/or sponsored conferences and campaigns.

36. Approximately 90 per cent of the schools indicated that they did not sponsor such community activities as courses, forums, and debates. Approximately 50 per cent revealed that they did not sponsor discussions and plays on safety.

37. Over 90 per cent of the schools promoted an instructional program of pedestrian safety which included observation of traffic

controls, obedience to traffic control personnel, use of pavements, and alertness for turning cars. Eighty per cent of the schools had pedestrian safety instruction on safest routes home.

38. Approximately 60 per cent of the schools made systematic attempts to inform parents of pre-school as well as school age children of safety habits through special meetings, written communications, distribution of safety materials, and information on available safety services.

39. Approximately 75 per cent of the schools declared that they promoted a program on home or out of school safety by means of written communications, meetings and discussions, and distribution of safety literature and provision of speakers.

40. Approximately 50 per cent of the schools affirmed that they informed parents of regulations governing automobile loading and unloading and request parental cooperation.

41. Eighty-four per cent of the schools recorded that they cooperated with community efforts to prevent accidents during holidays and vacations by making playground space available.

42. Approximately 90 per cent of the schools asserted that they fostered the building of informed public opinion and the development of public support for programs designed to make the community safe for children and adults.

43. Ninety-one per cent of the schools reported that there are fewer accidents.

44. Eighty-eight per cent indicated that accidents are less serious as the result of the safety program.

45. Eighty-four per cent felt that there were fewer near accidents.

46. Ninety-one per cent evidenced safe behavior on the part of the children.

47. Ninety-one per cent of the schools asserted that they cooperated with other groups in safety programs.

48. Eighty-five per cent of the schools stated that fewer complaints are received.

49. Seventy-nine per cent of the schools believed that more commendations are received for safe practices.

50. Sixty-five per cent of the schools reported that they are listed in the National Safety Council School Honor Roll.

Conclusions

1. While much attention was given to the physical structure and condition of school buildings, according to the early journals of the Board of Education, the matter of inadequate fire escape facilities appeared to dominate the evidence.
2. Safety patrols have played a significant part in the safety education program of the Philadelphia public schools since 1914.
3. The instructional program in safety in the Philadelphia public schools made its first steps as an organized program with the issuance in 1932 of a "Syllabus in Safety Education."
4. World War II gave considerable impetus to the safety education program of the Philadelphia public schools.
5. The driver education program which was started in 1950 has expanded considerably.
6. Guides and/or courses of study in the Philadelphia public schools made use of special techniques such as integration in the various subject areas to provide time for safety education in the school curriculum.
7. Many safety communications, safety materials, safety services and resources were furnished to the schools.
8. The safety education program of the Philadelphia public schools featured a wide variety of safety activities.
9. A number of school-year safety education programs were carried over into the summer playground program.
10. Safety conferences formed a significant phase of the in-service education of teachers and other school personnel.
11. Safety Patrol sponsors, safety coordinators in each building, and driver education teachers were key persons in the safety education program of the Philadelphia public schools.
12. As a result of the safety education program, significant effort was made to eliminate safety hazards.
13. Considerable emphasis was placed on fire and defense procedures.
14. A high percentage of use was made of safety communications, instructional material and services and resources furnished to the schools.
15. Accident reporting constituted a sound basis of the safety education program.
16. Student safety activities played an important part in the program.
17. The Philadelphia public schools gave a high degree of attention to the safe use of school plants and grounds.
18. The instructional program in safety appeared to be comprehensive and used a wide variety of approaches.
19. The evaluation questionnaire for Philadelphia seemed to indicate only moderate individual school efforts in community relations in safety.
20. School personnel generally felt that the safety education program was achieving its purpose.

Recommendations

As a result of the findings and conclusions drawn from the body of this study, the following recommendations are made:

1. Complete files of historical materials in safety education should be kept so that these materials may be readily available for subsequent reference and research.
2. The safety patrol manual, issued in 1960 for pilot study in a number of schools, should be revised in the light of suggestions received and should be prepared for printing.
3. Driver education should be continued and expanded in order to reach all students of legal driving age.
4. The new course called "Resource Unit Outlines for Safety Education in the Elementary Schools" issued for pilot study in 1959 should be revised in the light of suggestions offered by the schools and should be prepared for printing.
5. Time allotment for safety education in the curriculum should be considered for elementary and secondary schools.
6. Additional financial resources should be sought to support the distribution of original safety flyers which meet the needs of the Philadelphia situation.
7. The safety education program of the Philadelphia public schools should be continued and expanded to meet growing safety needs. A study should be made of staff needs in order to implement an expansion of the program.
8. Safety conferences such as the teen-age traffic safety conferences, school bus driver's

safety institutes, and school safety coordinator's conferences meet a real need and should be continued.

9. Items from the evaluation questionnaire for Philadelphia developed for use in this study should be examined one by one by those responsible for the safety education program in the Philadelphia public schools to ascertain possible areas for improvement in the program.

10. School personnel should be encouraged to contribute to safety education magazines and other media of public information.

11. Research of the informal and formal types in safety education should continue to be encouraged. A few research projects for future consideration might include:

Development of improved curriculum guides in the many areas of safety educa-

tion including driver education, vocational safety education and science;

Creation of new approaches and materials in safety education with special emphasis at the junior high school level;

Study of the influence of safety education on the lives of students in terms of the development of safety attitudes and the meeting of civic responsibility;

Development of an employee accident prevention program to a greater degree than is presently in operation;

Determination of the direction of the future development of the safety education program of the Philadelphia public schools as a whole or in its various facets to include new developments such as air safety, boat safety and other safety needs as they arise.

CASE STUDIES OF ONE-CAR ACCIDENTS INVOLVING YOUNG DRIVERS

By RICHARD W. BISHOP

Asst. Prof., Highway Traffic Center, Michigan State University, E. Lansing, Mich.

The purpose of this study was to determine *who* was being involved in one car accidents, *how* and *why* they were being involved, and *what* implications the findings had for driver education and improvement. To accomplish this general purpose the investigator worked through the following specific problems: 1) to prepare case studies of selected one-car accidents involving young drivers, 2) to determine common characteristics or combinations of behavior, conditions, and biographical factors in these case studies, and 3) to develop educational content and technique based on an analysis of the individual case studies and the cases viewed collectively.

The population studied consisted of drivers under 30 years of age involved in one-car accidents in three central Michigan counties during a three month period in 1959. Information about the accidents and the drivers was obtained from police accident reports, interviews with the drivers, visits to the accident scenes, state driver license records,

and school records. Aid from one college and two high schools was obtained to help determine effective procedures for using traffic accident case study analysis to achieve driver education objectives.

One hundred twenty-four drivers were interviewed out of a possible 135 drivers involved in the type of accident being investigated. Interviews with eleven drivers could not be obtained because the driver lived too far away or refused to be interviewed. Five interview cases were eliminated when the information supplied by the driver proved to be unreliable. So 119 cases were ultimately used in the study. With few exceptions these 119 interviewees were cooperative and seemingly uninhibited in discussing the accident.

Common Characteristics and Combinations of Factors Related to the Accident

Each individual case included from 2 to 12 factors which appeared to relate to the accident. Most individual cases included

driver, vehicle, and environmental factors. In only one case did the driver seem to be a victim of circumstances.

The accidents tended to occur within six miles of the driver's residence (67 per cent); at night (69 per cent); in open country (65 per cent); on a straight road (60 per cent); on highways of asphalt or concrete construction (77 per cent). Subsequent information will show other environmental factors related to the accidents.

The ratio of men to women involved in the accidents is 4 to 1 which is identical to the male-female ratio for all accidents in Michigan during 1959. This ratio is not consistent with the male-female ratio of Michigan drivers under 30 years of age which is 1.8 to 1. However, these figures do not consider the driving exposure rates for the sexes. Women reported fewer miles driven than men in this study, but the information appeared to be too unreliable for any accurate comparison.

Forty-four per cent of the subjects completed a high school driver education course. Two-thirds of this group were under 20 years of age while only two of them were in the 25-30 age group. This condition made it pointless to compare the driver education group with the others.

Analysis of driving records revealed: 1) that the subjects reported to the interviewer an average of 200 accidents while the official records showed a 1.76 average; 2) twenty-six per cent of the subjects, all men, had accumulated from 5 to 20 violations, or at least 3 within the last year; 3) forty-one per cent of the drivers had no previous accidents, but none of these were men in the 25-29 age group.

A study by Siebrecht and others² concluded that 1 out of 14 women drivers and 6 out of 10 men drivers under 30 years of age have an accident record. In this investigation more than 1 out of 3 women and 2 out of 3 men had an accident record before being involved in the one-car accident investigated.

Numerous factors combined to create each of the traffic accidents in this study, and frequently one of these factors stood out as an obvious cause. For example, the driver "fell asleep," "reached for a cigarette," or "exceeded the critical speed on a curve." However, when one looks for

underlying factors which prompted the "trigger" event, speculation replaces certainty. Alcohol, worry, fatigue, or poor attitude may be present as a circumstance, but the condition may or may not be a cause. The biases of the investigator toward accident causation further complicate the process of trying to identify objectively and accurately the factors which contributed to the accident. This study was not exempt from the problems and limitations expressed here.

As planned, each accident was studied as a "whole." Case studies were prepared from a view of the interacting driver, vehicle, and environmental factors. An accounting system was developed to determine how frequently each of the accident factors occurred. A subsequent step revealed the most common combinations of factors. Each accident was classified according to the following prominent human errors which directly precipitated the accident:

1. Asleep or blackout—18 cases.
2. Distraction—36 cases.
3. Perception—judgment error—60 cases.
4. Passenger fell from vehicle—4 cases.
5. Lack of skill in backing—1 case.

The distraction cases were further classified under pre-occupation, passenger distraction, and distraction within or outside the vehicle (non-passenger). Specific errors under the perception-judgment category include misjudging approach or critical speed to curve, misjudging surface and skill error, misjudging critical speed on straight slippery surface, overdriving perception distance, and misjudging position of vehicle. Three of the passengers who fell from the vehicle were children, and the fourth was a teenager attempting to ride on the hood of the vehicle.

Underlying human factors, vehicle defects, and highway and traffic engineering deficiencies were related to the direct cause described in the preceding paragraph.

Human factors which appeared in at least 20 per cent of the cases reviewed were: 1) alcohol; 2) unsafe attitude toward speed; 3) emotionally upset or excited; 4) fatigue; 5) in-a-hurry; and 6) poor corrective action.

The only vehicle defect appearing in more than 5 cases was "smooth tires." How much this deficiency contributed to the accident is highly speculative.

Accident Analysis Try-Out in Driver Education Classes

Representative cases were selected to use in two high school driver education programs. Top priority was given to those cases best demonstrating that the accident could have been avoided if the driver had possessed accurate information, different attitudes, better control of his emotions, or improved skill. Furthermore, the cases selected involved drivers near the age level of those who were to analyze them.

The two high school teachers involved did not use the same technique in presenting the cases to the students. Teacher A divided his class into small groups and gave each group a different case. The students analyzed the case within their group for causes and preventative measures, and then each group reported its composite and individual conclusions to the class. Eight cases were analyzed in one period. Teacher B requested the students individually to analyze each of eight cases and write their conclusions. This required more than two class periods. The same evaluation form was administered in each school.

Both students and teachers responded favorably to the accident case study analysis as a learning experience in their driver education classes. The specific learnings mentioned most frequently, and those the students felt would help them become better drivers were: 1) the importance of attend-

Highway and traffic engineering defects appeared in 44 per cent of the cases, with "defective surface" accounting for almost one-half of these defects. Other engineering defects were: 1) inadequate or defective shoulder, 2) curve poorly designed or marked, and 3) exceptionally narrow road or bridge.

Table I shows the number of times each of the underlying factors appeared with more direct causes of the accidents. Fatigue and alcohol appear prominently in the "asleep" accidents, and emotional factors show up in 22 of the 36 "distraction" cases. The most certain conclusion seems to be that alcohol, attitudes, emotions, fatigue, etc., can contribute to almost any direct cause.

The interview data were reviewed for background attitudes and emotional problems which seemed to relate to the individual's driving behavior. Attitudes which appeared most frequently were:

1. Fatalistic attitude toward chances of accident involvement—33 per cent of the cases.
2. Unrealistic attitude toward own driving ability—22 per cent of the cases.
3. Hostility toward traffic law enforcement—13 per cent of the cases.

Twenty-six drivers had a history of nervous disorders or emotional instability, and 19 of these subjects were emotionally upset just prior to the accident.

TABLE I
Direct Causes of the Accidents and Frequency of Related Underlying Factors
(Based on interview data and visits to the accident scenes)

Direct Causes	No. of Cases	Alcohol	Attitude (fatalistic)	Attitude (unrealistic)	Emotions	Fatigue	In-a-hurry	Poor judgment	Poor corrective action	Vehicle defect	Hostile or U. S. Aggr. Driver
Asleep	18	8	5	4	4	14	2	5	7	2	1
Black out	3	0	0	0	1	1	2	0	0	1	0
Distraction (non-passenger)	14	4	3	2	7	5	1	0	6	4	4
Distraction—passenger	13	0	0	0	8	1	1	1	7	0	5
Preoccupied	9	1	1	3	7	8	5	1	7	5	7
Misjudged speed—curve	17	6	4	7	4	6	2	0	11	6	8
Misjudged surface—skill error	16	2	0	3	8	4	3	0	16	6	7
Misjudged speed—straight	12	2	2	7	3	2	4	0	7	4	8
Overdrove perception distance	10	1	2	5	2	1	3	1	5	2	7
Misjudged position	5	2	1	3	1	1	0	1	3	2	4
Passenger fell from vehicle	4	0	0	0	0	0	1	0	2	2	1
Improper backing	1	0	0	0	1	0	0	0	0	0	0
Total cases	119	27	18	37	46	40	25	9	64	36	52
(% of total cases)	(100%)	(23%)	(15%)	(31%)	(39%)	(34%)	(21%)	(8%)	(55%)	(30%)	(44%)

ing and adjusting to road and weather conditions, 2) the importance of avoiding distractions which take a driver's eyes off the road, 3) an understanding of driver errors in emergency situations, such as skidding, driving on the shoulder, etc., 4) the need for intelligent interpretation and judgment in operating a vehicle, and 5) the danger of driving when emotionally upset. These factors happened to be highlighted in the selected cases. If the teacher desired to stress the effects of fatigue and alcohol or other factors, he would choose cases in which these factors were involved.

The students permitted to analyze the cases in small groups and then report their findings to the entire class rated the accident analysis technique higher than the students who wrote their individual analyses of each case.

General Benefits suggested by the Try-Out of Accident Analysis in Driver Education Classes

1. Studying actual accident cases focuses student attention on the "crucial learnings" needed by drivers to operate safely and efficiently on the highway.
2. An accident case may involve important concepts from all the traditional units of driver education instruction. Integrating and relating the concepts around a focal point, the accident, tends to establish a meaningful learning experience.
3. Students learn that most accidents involve more than a single cause, and that none of the factors are trivial if they were needed to create the accident.
4. Teachers discovered that accident cases "triggered" group discussion which helped students to clarify their beliefs, attitudes and understandings of concepts involved in the accident.
5. Students felt that the accident analysis experience helped them develop the ability and desire to recognize accident-producing situations and adjust accordingly.
6. Accident analysis shows promise as a way to modify and evaluate the interests, attitudes, knowledge, and thinking habits of students.
7. Based on student reactions, one of the greatest values in using accident case studies for analysis appears to be in preparing drivers to react correctly in emergency driving situations.

8. In summary, this technique seems to integrate content in a meaningful, vital and interesting way; placing emphasis on crucial learnings needed to survive on the modern highway.

Selected Accident Report Data on One-Car Accidents in Two Different Three-Month Periods

A comparison was made between the three month period of this study (October-December, 1959) and the preceding three months (July-September, 1959) to discover similarities and differences. Since no interview data were available from the July-September period, only police accident report data were used for this comparison. This is a collateral phase to the study designed to identify different results one might expect if another three month period were used.

Little, if any, difference was found between the two three-month periods in the following:

1. Ratio of drivers under 30 years of age to those over 30 involved in one car accidents—3 to 2 ratio in each period.
2. The mean age of the drivers under 30—mean of 21.62 in July-September, and mean of 20.71 in October-December.
3. The male-female ratio—4 to 1 ratio in each period.
4. Locality of the accident—approximately 61 per cent in open country, 27 per cent in a residential area, and 12 per cent in a shopping or business district, in each three month period.
5. Road characteristics—exactly 49.6 per cent happened on a straight and level road in each time period.

Considerable difference was found when comparing:

1. Frequency by light conditions—accidents during darkness 16.4 per cent higher in the October-December period.
2. Surfaces and weather conditions—twice as many dry road accidents happened in July-September compared to October-December, and it was snowing in 12 per cent of the October-December accidents compared to no snow in July-September.
3. Road construction—a higher percentage happened on gravel roads in the July-September period.

A comparison between the actual frequency of accidents for the combined period (July-December, 1959) in three age groups—under 20, 20-24, and 25-29—and the expected frequency, if the accidents were in direct proportion to the percentage of drivers in each age group, revealed that the under 20 drivers had 1.76 times the expected number, and the 25-29 group had .45 of the expected number.

Implications of the Findings for Research

When convinced they will be anonymous, young drivers involved in a one-car accident will consent to an interview and freely discuss the causes as they see them. They will also reveal their driving records more completely than the official record. Since this is true and since a review of 246 one-car accidents over a six month period involving drivers under 30 indicated a highly disproportionate number under 20 years of age, a study of this group alone seems appropriate. The project should aim to determine the intellectual, physical, physiological, social and emotional differences between teen-age drivers with an accident and violation-free record and those with repeated violations and accidents.

If studied now, all the drivers in this group would have completed a state ap-

proved driver education course due to the Michigan driver education law which became effective in February, 1967. This fact would permit the investigator to evaluate and suggest improvements for driver education, in addition to discovering information on teen-age traffic violations and accidents.

Furthermore, findings of this study suggest the need for research into the following areas:

1. To determine the differences between men and women in the human factors related to accident causation, so that appropriate educational efforts can be designed to meet these differences.
2. To compare the case study method suggested in this study to other teaching methods with respect to their potential for imparting knowledge, modifying attitudes and affecting driving behavior.

A SURVEY OF GENERAL SAFETY EDUCATION COURSES

By JOHN E. CORBALLY

Prof. of Secondary Education, University of Washington, Seattle, Wash.

Preface

At the 1960 annual meeting in Chicago, of the College Safety Education Division of the National Safety Council's Higher Education Section, a work project was approved that would have as its purposes (1) collecting of various course and curriculum outlines in safety education, (2) analyzing such course outlines, and (3) recommending a "model" course outline that might be used as a guide for colleges and universities which are offering safety education for the first time. Out of such a study it was hoped that there would be found many common

elements in basic college courses in general safety education.

A committee was appointed in January, 1961, to evaluate such college courses. Members were Lillian C. Schwenk, Iowa State University, Ames, Iowa; Dr. William A. Stebbins, State University College of Education, Brockport, New York; Dr. Robert T. Bowers, Jr., The University of Georgia, Athens, Ga.; and Dr. John E. Corbally, University of Washington, Seattle, Washington, as chairman.

This study would not have been possible without the help of Dr. James F. Nihon,

director of safety education of the State University of New York, and Dr. Bernard I. Loft, Associate Professor of Health and Safety at Indiana University, and members of his classes. Dr. Nihon prepared and distributed the inquiry form used in the study, and Dr. Loft and his students summarized the raw data. Members of the committee made specific suggestions which have been incorporated in the final report.

Introduction—Those who have taught a general basic course in safety education recognize that there are many topics that might and should be included, that there is great variation in time that might be devoted to each topic, that various methods can be used effectively, that many resource persons are available, that the field is rich in audio-visual aids, and that all age groups need instruction in safety. How to prepare prospective teachers so that they will be equipped to teach and practice safety in the school environment is a continuing problem in teacher education. Not all teacher training institutions provide a course or courses in this field, nor do all teachers recognize their legal responsibility for the safety of their pupils. A basic course should be developed in such a way to be of value to all teachers—elementary or secondary. It also should have in mind school administrators and prospective college teachers in this area. Such a course, too, might have an occasional appeal to college students in areas other than teacher training as an elective.

Not only is there a need for more higher institutions to offer work in safety, but it is important that there be some uniformity in a basic course as a means of up-grading teacher preparation in safety education. Teachers who receive their training in one state may teach in another, and to facilitate transfer or acceptability of credit there needs to be comparability and equivalency of course offering to make such transfer possible.

Many other reasons could be advanced for such a study, but to those working in this area it is obvious that a start such as this one should stimulate further curricular research and provide an incentive for re-evaluating one's own offering using the suggested course outline developed from the data obtained.

Procedure—Early in March, 1960 a letter

was sent to various colleges and universities throughout the United States asking them to forward outlines of their basic courses in general safety education. Respondents were asked to indicate (1) total credit hours for the course; (2) total clock hours; (3) number of minutes devoted to each major topic or subject area; (4) textbook preferred for the course; (5) recommended references; and (6) teaching techniques and audio-visual aids used. These schools were selected not only by geographical location, but also by the reputation of each institution for having a valid general or basic course in safety education.

Forty-six colleges and universities sent course outlines and supplied the supplementary information requested. Since two failed to give sufficient information, the data used came from 44 higher education institutions. These were well distributed geographically, and included public and private teachers' colleges, and other colleges and universities. It seems fair to assume that this represents a valid sampling for the purposes of this study.

Analysis of the Data

Total credit hours for the course. Of the 44 schools reporting, 26, or 60 per cent allowed three semester hours of college credit toward graduation. Eleven schools granted two semester hours; two allowed one and one-half semester hours, and one allowed one semester hour credit. The most common practice was to make this a three semester or five quarter hour credit course.

Total clock hours. There was a wide variation in practice as to the total clock hours devoted to the course and credit allowed. This is shown in Table I.

TABLE I

Total Clock Hours Devoted to the Course in Safety Education		
Number of Schools	Clock Hours	Semester Credits
1	60	3
13	50-59	3
11	40-49	3
3	30-39	3
7	20-29	2
2	20-29	2
2	20-29	1½
1	10-19	2
1	10-19	1
1	15	2

The range in hours for three semester credits was from 30 to 60. For two credits the range was from 15 to 39. Three schools gave three credits for 30-39 clock hours, while seven gave only two credits.

Number of clock hours devoted to each major topic or subject area. Twenty-three of the 44 reporting schools supplied information for this part of the study. This time was broken down into the following general areas: introduction, farm and home safety, fire safety, industrial safety, bicycle safety, pedestrian safety, traffic safety, sports safety, school safety, civil defense, legal responsibility, and evaluation. The range in time is shown in Table II.

TABLE II
Number of Clock Hours Devoted to Each Major Topic or Subject Area

Topic or Area	Range in time	Average
1. Introduction	1-31	7½
2. Farm and Home Safety	1-18	4
3. Fire Safety	1-6	3
4. Industrial Safety	1-9	2
5. Bicycle Safety	1-9	2
6. Pedestrian Safety	1-9	2
7. Traffic Safety	1-18	4
8. Sports Safety	1-9	2
9. School Safety	1-12	4½
10. Civil Defense	1-9	2
11. Legal Responsibility	1-9	2
12. Evaluation	1-9	2

More time was spent in introducing the course than on any other topic. The average

Audio-visual aids and recommended references. Audio-visual aids used to assist in teaching were many and varied. Those most widely used by the respondents were: flannel board, posters and charts, display boards, puppets and models, magnetic boards, tape

time was almost twice as much as in the areas of school safety, farm and home safety, and traffic safety.

Textbooks preferred for the course. Only four different texts were used by the 36 institutions replying to this question. Twenty-two preferred Stack and Ekow, *Education for Safe Living*; nine used Florio and Starnford, *Safety Education*; three selected Brady and Stack, *Highway Safety and Driver Education*; while one institution used the American Automobile Association text, *Sportsmanlike Driving*.

Teaching Techniques. The lecture method was found to be predominant throughout those institutions which reported on teaching procedures. Other methods used, usually to supplement the lecture method, and the number of institutions using these are shown in Table III.

TABLE III
Teaching Methods and Frequency of Use in Classes in Safety Education

Method	Number of Institutions
1. Group Method	10
2. Oral Reports	9
3. Guest Speaker	8
4. Class Discussion	8
5. Outside Written Reports	8
6. Field Trips	5
7. Panel Discussion	3
8. Demonstration	2

recorders, projectors, slides, psycho-physical testing devices, testing for alcohol consumption, auto stimulators, brake reaction detector test devices, and film.

16. *Who is Liable for Pupil Injuries*, by National Education Association.

Conclusion—From the information obtained from the 44 colleges and universities, and from an analysis and evaluation of the courses of study submitted, a typical or representative basic course in Safety Education is submitted for consideration.

A Suggested Basic Course of Study in Safety Education

1. Total credit hours for the course—3 semester hours.
2. Total clock hours—three class meetings per week, 18 weeks, or 54 class meetings of 50 minutes each or equivalent.
3. Textbooks mentioned most frequently for the course:
 - a. Stack, H. J. and J. D. Elkow, *Education for Safe Living*, Prentice-Hall, Inc., New Jersey, 1959.
 - b. Florio, A. E., and G. T. Stafford.

Safety Education, McGraw-Hill Book Company, New York, 1956.

4 Content:

- I. Introduction (Lecture) 7 clock hours

- A. Need for safety education

- B. Nature and scope of the accident picture
 1. Motor vehicle
 2. Occupational
 3. Public, home, farm, recreation

- C. The accident problem—philosophy and principles of prevention

- II Home and Farm Safety (Lecture, oral reports) 4 clock hours

- A. Home accidents
 1. Annual deaths and injuries
 2. Falls cause most fatal home accidents
 3. Burns, poisons, firearms rank next in order
 4. Causes and related factors

- B. Farm accidents
 1. Machinery and equipment
 2. Animals and plants
 3. Insecticides and pesticides
 4. Flammables and explosives

- C. Preventing home and farm accidents

- D. First aid (See footnote at end of outline)

- III Fire Safety (Lecture, guest speaker) 5 clock hours

- A. Nature of fire problem
 1. Loss of life; injuries
 2. High economic cost
 3. Decreasing earning power; increased taxes
 4. Causes

- B. Fire prevention
 - a. Classes of fire; fire extinguishers
 - b. Learning and understanding
 - i. Chemistry of combustion
 - ii. Correct use of matches; smoking habits
 - iii. Care of defective and overheated chimneys and flues
 - iv. Spontaneous combustion; housekeeping
 - v. Use and maintenance of electrical appliances
 - vi. Holiday precautions

- C. First aid

School and College Sessions

- IV. Occupational Safety (Guest speaker, written reports, field trips) 4 clock hours

- A. Overview of occupational hazards

- B. Elements in a complete plant program
 1. Machine guards
 2. Personal protection
 3. Instruction in safe practices

- C. Home shops

- D. First aid

- V. Traffic Safety (Guest speaker, class and panel discussion) 8 clock hours

- A. Nature of traffic problem
 1. Rural and urban motor vehicle accidents
 2. Pedestrian problem
 3. Relationship of alcohol
 4. Accident factors: age, vision, speed, vehicle defects, weather, and the like
 5. Bicycles, motor scooters, go-karts

- B. Driver education

- C. First aid

- VI. Pedestrian Safety (Guest speaker, demonstration) 4 clock hours

- A. School child
 1. Community-parent responsibility
 2. School responsibility for safety education
 3. Some guiding principles

- B. Student aids
 1. School patrol
 2. Safety council
 3. School parking problem

- C. First aid

- VII. Safety in Swimming and Recreation (Lecture, class discussion) 4 clock hours

- A. Physical education; interscholastic competition

- B. Water activities
 1. Swimming
 2. Skiing
 3. Boating
 4. Fishing

- C. Individual sports
 - D. Hunting
 - E. Camping
 - F. Vacation Safety
 - G. First aid

- VIII School Safety (Guest speaker, lecture, group method) 6 clock hours
- A. Plant
 1. Buildings and facilities
 2. Grounds
 3. Inspection and follow-up
 - B. To and from school
 1. Pedestrian
 2. Vehicular
 - a. Motor scooter
 - b. Bicycle
 - c. Auto
 - d. Buses
 - C. Student activities
 1. Field trips
 2. Surveys
 - D. School shops and laboratories
 - E. Relation to community program
 - F. First aid
- IX Legal Responsibility (Lecture, guest speaker, written reports) 4 clock hours
- A. Liability
 1. Teacher
 2. School
 - B. Negligence
 - C. Legal defenses
 - D. First aid protection
1. Insurance
 2. School board
 - E. Student insurance
 - F. Workmen's compensation
- X. Disaster Preparedness and Civil Defense (Lecture, panel discussion) 4 clock hours
- A. National emergency
 - B. Riots; demonstrations
 - C. Fire
 - D. Natural disasters
 - E. First aid
- XI. Evaluation 4 clock hours
- A. Class participation
 - B. Projects, panel, survey
 - C. Special assignments
 - D. Mid-term examination
 - E. Final examination
5. Bibliography. To be built around local, state and regional problems.
6. Audio-visual aids, as available.

Note: First aid considerations in the course (e.g., II-D and in other places in the outline) do not constitute complete first aid instruction but rather highlights of injuries commonly incurred in the area under discussion or unique to the area of discussion.

Where students in the course have been drawn from a particular area of specialization, opportunity should be provided for discussion of safety problems and their prevention in that area.

STUDENT PROJECTS IN COLLEGE SAFETY EDUCATION COURSES

By C. FRAZIER DAMRON

Dir., Research, and Teacher Preparation in Safety Education
University of Wisconsin, Madison

Student projects, carefully conceived and selected, provide an excellent opportunity for supplementing the instruction and learning involved in regular class procedures. They also provide a motivational environment for the specific needs and interests of the student. Both factors are vital when it is recognized that one college course in safety allows a very limited amount of time for teaching content alone, much less the time to provide experiences that will motivate students to be actively involved in developing good safety programs wherever they are.

It is fortunate, and necessary, that we lean heavily upon the students' previous educational backgrounds and experiences for the general qualities involved in a good teacher. However, when it comes to teaching them specifically how to teach safety, the thinking, planning, and design of our courses must take into account two major problems. We must insure that students know and continue to plan and demonstrate good instructional techniques. We must be certain that we teach, thoroughly, course content and all that this implies.

A project, to provide optimum learning

opportunities, should be selected and assigned on the basis of three general criteria:

(1) It is a specific task involving a scholarly investigation.

(2) It is an educational experience that requires initiative on the part of the student.

(3) It supplements or extends beyond the basic course content discussed in class.

Other questions to be considered when projects are being selected and assigned are:

1. Does it provide opportunities of learning something that for the student is worth knowing, something to stimulate him to be a better teacher and leader in safety? A few suggestions of projects of this type are: plan and develop a filing system for safety education, plan a safety program for a particular school, community, or organization, identify organizations (local, state, or national) that are involved in safety activities and describe their contributions, develop a plan for integrating safety into selected subjects in the total school curriculum.

2. Is the project activity of general interest to the student and is it related closely to the common activities in which they are or will be engaged? For example, an industrial arts major may prefer to do a project relating to shop safety, while a history major might be interested in developing the history of the safety program in his school or state.

3. Does the activity pertain to the kind of experiences teachers will have both on and off the job. Projects of this type could include: the planning and demonstration of a TV program on the values of a good safety program, an outline of the functions and values of safety committees in the school or community, or a series of five-minute speeches planned for groups such as the I.T.A., civic clubs, school faculty, or teenage clubs.

4. Does the project provide an opportunity for students to select, develop, and demonstrate real or simulated learning situations such as: how to conduct skill tests

in driver education or bicycle safety, develop a role playing situation in which a safety program is planned by the school faculty, or design and construct an off-street driving area for driver education.

5. Does the project activity have an application on integration potential with other areas of knowledge? Examples: identify and describe the safety implications in teaching a particular subject, i.e., science, math, physics, civics, physical education, etc.; debate the issue of "subject matter integration versus special courses" in safety at the elementary and secondary levels.

6. Does the project activity lend itself to creative thinking and original ideas? This is one of the most valuable points to consider. Projects which promote new thinking about how to teach for safe behavior are a fruitful frontier endeavor. Examples: construct and design a teaching machine with tests for use in safety instruction; plan and develop a new series of bulletin board materials for classroom use; plan and develop a series of attractive safety exhibits for promoting safety in a school.

7. Does the project activity lend itself to the building of the safety profession? Examples: develop plans for building the state safety and driver education associations, list and evaluate selected free and inexpensive materials in safety education, outline a series of ten newsletters for members of the Safety and Driver Education Association, or design a brochure that describes how to get safety legislation passed in your state.

Any project assignment should provide specific opportunities for students to explore and think through as many important safe behavior concepts as possible. They should be encouraged to apply these concepts in behavior patterns that apply to their own everyday activities and teaching responsibilities.

In essence, this means that those of us who are responsible for preparing teachers in safety education should be very concerned that our students have such basic knowledge of safe behavior that it is a definite example to those they are to teach.

COLLEGE AND UNIVERSITY ADVANCED COURSES IN SAFETY EDUCATION

By J. DUKE ELKOW

Associate Prof., Dept. of Health & Physical Education (Men)
Brooklyn College, Brooklyn, N. Y.

"The opinions expressed by the writer are his own and reflect only from experience his professional identification as a Visiting Associate Professor of Education, Center for Safety Education, New York University, nor do they indicate acceptance or endorsement of these remarks by that fine institution."

Our small town newspaper, *The New York Times*, editorialized last week on a shocking fact: "... half the operations performed in American hospitals are done by physicians 'unqualified' to perform in accordance with the standards of the American College of Surgeons." Equally shocking is the fact that safety education functions are carried on by persons who, at the time of their initial appointment or in some instances individuals currently functioning or about to function, are unqualified to meet the vital functions of preparing youth for safe living in our complex environment.

Comparatively few areas within our nation have established standards for the initial appointment of safety educators that meet even the recommendations of the Third National Conference on Driver Education, or the consistent exhortations of national leaders in the field of safety education. This profession of safety education does desperately need a national conference on the professional preparation of safety educators. Such a conference would establish current standards and give direction to future professional growth.

The safety educator has need for many competencies. He gains them from many sources: his early exposure to safety experiences; his academic and pre-professional curriculum preparation; his laboratory and field work along with practice teaching; his in-service training; his convention and conference participations; his certification for competency within his state, and like experiences.

It is the concern of this brief report to identify the course work that may be made available in the development of the

safety educator—more specifically the advanced course work. To further delimit the scope only credit course preparation is to be considered.

In the fine publication, *Safety Education*, September, 1960, a listing of "College Safety Education Credit Courses" was published. At 156 colleges and universities in 43 states 338 courses are offered. No doubt some had escaped inclusion. The listing identifies basic and advanced courses of varying credits and accreditation at undergraduate and/or graduate levels. More careful count reveals the following distribution:

Safety Education Courses	
Advanced	78
Basic	175
Advanced and Basic	10
Undergraduate	201
Graduate	37
Undergraduate and graduate	85

The identification of basic or advanced was left to the mental agility of the individual reporting his courses to the National Safety Council. Significantly courses called basic at one institution were labelled advanced at another and vice versa.

To set the stage—for the purpose of more leisurely and lively review later—there follows a listing of basic, intermediate and advanced courses labelled by this writer:

Title

Basic	
Safety Education (or General Safety Education)	
Safety and First Aid	
Driver Education (or Driver Education & Traffic Safety)	
Intermediate	
Advanced Driver Education	
Civil Defense and Disaster Control for Safety Education	
Community Organization for Safety	

Communication Media and Public Relations in Safety Education
Industrial Applications of Safety Education

Organization, Administration and Supervision of Safety

Psychology of Safety Education and Accident Prevention Education

Traffic Engineering for Safety and Driver Education

Traffic Enforcement for Safety and Driver Education

Driver Improvement Programs and Techniques

Workshop in Safety Education

Advanced

Current Literature and Research in Safety Education and Accident Prevention

Field Experiences for the Specialist in Safety Education and Accident Prevention

Professional Seminars in Safety and Accident Prevention

Thesis Seminar in Safety Education

You may well see that through capricious judgment (25 years of professional experience) the task of identifying advanced work is here simplified. The above does require much review and revision. Of that there is no doubt. It would best be achieved by group discussions. Admittedly intermediate is more advanced than basic but time is too short to comment more fully on any but the advanced.

To discuss and describe a few of the advanced courses is the next task: there are singled out for elaboration three courses that are offered, in this instance, at New York University.

Field Experiences for the Specialist in Safety Education and Accident Prevention. 120 hours, 6 credits. Two semesters. (Required of all full-time students—exclusive of summer sessions). The course description follows: Directed group investigations of educational, governmental, private, community and industrial agencies and organizations concerned with safety; critical evaluation of safety education programs.

Within this program guided visitations are made to 30 agencies each semester. Studied are facts of size, personnel, func-

tions, purpose, accident experience, safety programming, budgeting, program emphasis, special safety problems, measurement of program effectiveness, publications, and, cooperation with other agencies.

It might be added that the proximity of large industry in the New York City area to the university materially enhances opportunities for rich experiences. This would be true as to other large urban centers. Written reports, compilation of collected materials, ten independent visitations with critical reviews are required of all students at part of the course work. Students who have taken this program have been simply thrilled and the instructors rewarded not only with the wealth of integrative safety experiences but in knowing more fully the scope of the safety movement.

The second advanced course:

Current Literature and Research in Safety Education and Accident Prevention. 3 hours, 3 credits. One semester. (Graduate) The course description: Directed readings and class discussion of current literature, critical analysis of research in safety education and accident prevention; steps involved in problem solving. (Outline appended but subject to current revision).

The last mentioned course has been conducted by Drs. Cutter and Elkow. Distinguished resource personnel lecture to students and discuss their research and publications after students have studied the materials under investigation. Students also study various advanced texts, research in the field, and prepare critical reviews of publications assigned them after individual counseling. They report the course to be intellectually stimulating to an advanced degree and highly motivating to them for initiating their own research and writing.

Thesis Seminar in Safety Education is the third advanced-level course. Obviously it is close to the final level of achievement of doctoral candidates and needs no further comment here.

For a report of this type a summary would be too time consuming. But a few recommendations might well be in order:

... that there be established, perhaps under the aegis of the Higher Education Section, a committee of leading safety educators to develop acceptable, concise terminology for advanced course titles, con-

tent and accreditation, as well as acceptance into the many colleges and universities.

... that perhaps under the College Safety Education Section a similar effort in relation to undergraduate foundation courses in safety education be initiated.

... that there be conducted a professional preparation conference to achieve fuller identification of the needs for courses, levels of attainment in the safety education field.

... that scholarships and fellowships be made more readily available by private and governmental sources to aid in the preparation of persons with advanced competencies in this field.

... that recognition of advanced preparation lead to improved professional standards—even licensing within a professional area of safety education.

... that recognition of advanced preparation and improved compensations of a financial nature be more fully publicized.

... that each of us recruit keen mind-for a service in safety education that requires devotion, dedication, long and arduous work, inadequate compensation (tentative)—until the millennium when—through working together to advance our profession greater safety and adventure will be the heritage of all our youth, all of the inhabitants of this universe.

THE COLLEGE-UNIVERSITY HIGHWAY TRAFFIC AND SAFETY PROJECT

By S. A. ABERCROMBIE

Assistant Secy., NEA National Commission on Safety Education, Washington, D. C.

There are two good times to talk about a research project. One is before the project is initiated, when one can speak in glowing terms about the new knowledge which will be forthcoming from it, and of how the findings will redound to the benefit of all mankind.

The other good time is after the project is completed. Then one has at hand the specifics that related to the doing of the project—including the unforeseen problems encountered along the way—as well as the outcomes that have finally been set forth in black and white.

On this occasion I fear that the report is being given at a different and somewhat awkward time—after the project has been initiated, but before it has been concluded. Fortunately, my assignment is to talk about the purposes and procedures of the college-university highway traffic and safety project. This gives me the opportunity to review with you the nature of the project, who is involved, how it was initiated, how it is being pursued, and what may be expected to result from it.

First, some background information lead-

ing up to the project. In the late 1940's a group of five organizations interested in traffic safety joined forces to sponsor the first national institute for traffic safety training. Seven other organizations with similar interests cooperated. This first institute, held at the University of Michigan during two weeks of August, 1948, was attended by 142 persons who enrolled in six different one-week courses and participated in ten general meetings devoted to such traffic safety topics as the car, the road, the driver, accident records, public information, etc.

Over the next dozen years, national institutes for traffic training were held annually on college and university campuses throughout the United States. One purpose of these institutes was to provide in-service training for personnel employed in position-carrying responsibility for one aspect or another of traffic safety. Another purpose was to broaden and strengthen the traffic safety activities of the several institutions which had or were considering offerings in traffic safety. A third purpose and hope of these institutes was that of fostering the development of additional specialized

college and university centers, bureaus, or institutes that would provide education, research, and service in highway traffic safety.

In 1948 the NEA Commission on Safety Education published a report on a questionnaire of "College and University Activities in Safety." The survey sought information about the existence of bureaus or institutes, courses, extension service activities, campus safety, and the coordination of safety activities inside the institution and liaison with outside agencies. Of 259 colleges and universities surveyed, 199 reported one or more activities in or related to safety. The activities reported ranged from the mere provision of a safe college environment in 35 institutions to impressive lists of activities in all five areas of inquiry reported by 20 institutions.

In 1949 the NEA Commission on Safety Education published "College and University Traffic Training," a 12-page statement developed in a workshop on college and university traffic training held in 1948 at Northwestern University. The report dealt with specialized in-service training, specialized pre-service training, integration of safety content in undergraduate courses, and public safety institute type programs.

In 1950 the commission administered the national conference on safety by colleges and universities which was attended by 233 persons. The published conference report treated safety in relation to agricultural education, engineering education, liberal arts education, teacher education, university extension services, and campus safety.

In 1951 Michigan State College (now University) undertook a study under the auspices of the Association of Land-grant Colleges and Universities to determine whether a land-grant college or university could be of substantial assistance to the people responsible for highway traffic administration within its state, to judge the appropriateness of an educational institution devoting some of its resources to that type of service, and to ascertain specifically what it could do to help. A 97-page report entitled "What Can Colleges Do About the Traffic Problem" resulted from this study late in 1953. In his letter of transmittal addressed to members of the Association of Land-grant Colleges and Universities, Michigan State president John A. Hannah

said: I suggest that you regard this report . . . as a fairly applicable analysis of the traffic problem and what your college or university can do to help solve it."

In 1958 the commission and the U. S. Office of Education published the findings of a joint survey of 1,933 colleges and universities, conducted to determine the extent of college and university offerings in highway traffic and highway safety. The survey report showed that 973 offerings were then available in 328 institutions. Some 82 per cent of the offerings were regular courses, the remainder being short courses and conferences. The breakdown of these 973 offerings by areas of major interest was as follows: education, 42 per cent; engineering, 33 per cent; enforcement, 10 per cent; motor vehicle fleet operation, 6 per cent; and specialized offerings (such as accident records seminars and school bus driver institutes), 7 per cent.

This brings us to the report on the purposes and procedures of the college-university highway traffic and safety project, which is now under way. The idea for this project germinated with the American Association of Land-grant Colleges and State Universities. The land-grant group accordingly set up a project committee headed by president Albert N. Jorgensen of the University of Connecticut. Funds became available for the project through a grant from the Automotive Safety Foundation. The NEA National Commission on Safety Education, because of its unique experience in the field to be investigated, was asked to administer the project.

Stated broadly, the purpose of this project is to bring together from selected colleges and universities basic information and experiences related to their work in highway traffic and highway safety that will be of mutual benefit to all land-grant colleges and state universities, and to other institutions as well. It was determined early that the basic information and experiences would be gathered through personal interviews with the presidents and other key persons on the campuses of selected institutions.

Following three-way discussions among the land-grant group's committee, The Automotive Safety Foundation, and Commission on Safety Education staff, a project content and procedures committee was or-

ing what the job opportunities are. It is for these reasons that I have asked to appear with you today.

What is the Army civilian career program for safety management personnel?

Safety management is "the art of planning, organizing, directing and controlling available resources to eliminate accidental losses through safety administration, safety engineering, safety inspection, and other related activities."

Civilian career planning is directed toward the technical, scientific, and managerial development of employees within career fields.

The safety management career program, along with all other career programs in the federal service, had its birth in a recommendation of the Hoover Commission. The commission pointed up the necessity for federal employees to have a planned developmental program not unlike those available to their counterparts in many elements of private enterprise. Accordingly, the Department of the Army, in July of 1957, published Army Regulations 690-5 which prescribed the general plan governing the establishment and operation of civilian career programs within the department. And, in June of this year, the Department of the Army added another "first" to its many pioneering personnel management efforts when it published Civilian Personnel Regulations establishing the Army civilian career program for safety management, the first plan of its type for safety personnel in the federal service.

What are the objectives of the Army civilian career plan?

a. To meet the Army's continuing and future civilian manpower requirements with the highest quality staffing.

b. To provide a system of foreseeable career opportunities and planned programs which will attract, retain, and develop qualified personnel to meet key civilian staffing requirements.

c. To provide an effective means for selection and assignment of qualified employees on the broadest feasible organizational base.

What occupational field does the program embrace?

In the safety management career program of the Army, there are three basic occupa-

tional series; namely: the 018 or the safety management series which includes safety assistants at the GS-3 and the GS-7 levels and safety officers at the GS-9 level and above; the 803 which is the safety engineering series for safety engineers; and the 1820 which is the safety inspection series for safety inspectors.

In addition, the career program includes individuals from several other occupational series who are assigned full-time to support the Army accident prevention effort. These include, but are not limited to, the following occupational series: aviation safety specialists, nuclear weapons safety engineers, microbiologists, bacteriologists, physicians, physicists, and chemists.

The latter group may register in both the safety management career program and in the program for their specific series when such an additional career program has been established and published. In this way, these individuals have an additional opportunity to progress up a career ladder should they desire to do so.

How does one get into the 018, the 803, or the 1820 series?

GS-018's are taken from among federal service entrance examination (FSEE) eligibles. This is an examination which is used to recruit the bulk of college people to government. The FSEE is designed primarily as an avenue through which young people with promise may enter the federal service.

To those who have a college education or equivalent experience, this examination offers many advantages. Persons who qualify are considered for trainee positions at the entrance level in a wide variety of career fields in various federal agencies and geographical locations. Sixty career fields are offered through this one examination. It is, in effect, one application for many employers at the same time.

It is a thorough examination and one which serves as an effective screening instrument. For example, during the 1960-1961 school year, 182,081 persons applied for the examination and 114,200 took it. Of these, 42,702 passed. Upon passing the written examination, the individual's name is placed on the list of eligibles from which many different types of positions are filled, including those of safety assistants.

GS-803's are taken from among those individuals who have established eligibility in appropriate engineering examinations.

GS-1820's are taken from appropriate civil service commission registers.

What kind of a person is the Army looking for to fill its safety management needs?

We are not looking for a man who can fit into the program like the last piece of a jigsaw puzzle, for we know such a man does not exist. We are, however, looking for people who have the intellectual base upon which we can build—hence, the requirement that GS-018's come from among federal service entrance examination eligibles.

Once we have a man with this intellectual base, we are prepared to develop him by scheduling him for a series of training and work assignments. Moreover, if the individual performs satisfactorily and can grasp the training provided for him, he may advance rapidly at the lower grade levels. For example, a young man who has passed the FSEE may start as a GS-018-5 (safety assistant) and, after six months of satisfactory on-the-job performance, may be promoted to a GS-018-7.

And, after an additional twelve months of satisfactory performance, he becomes eligible for a rating at grade GS-9 as a safety officer. This is the extent of command training and promotion agreements with the U. S. Civil Service Commission. Upon reaching the grade GS-9 level, an individual's rise is dependent solely upon his performance, his willingness to accept a variety of assignments in any area of the free world, and his demonstration of a willingness to develop himself through correspondence study, evening courses and other self-developmental exercises and activities.

What of employment opportunities?

Within the next five years, we will lose through retirement, disability, death and other causes, some thirty per cent of the some 700 safety management personnel whom we now have in our inventory. Within the next ten years, we will lose more than half of our people to these same causes. At the present time, in fact, there are openings for some thirty persons in the Army program.

What are the elements of the safety man-

agement career program? I shall comment briefly upon each of the following five elements:

- Inventory and referral service.
- Recruitment and selection.
- Entrance-level training.
- Appraisal and counseling.
- Progressive developmental opportunities.

Which of these elements are of special interest to colleges and universities? Actually, all of them. However, I should like to highlight two, recruitment and selection, and progressive developmental opportunities.

In doing so, I should like to state my views on some current thinking regarding the type of training the "safety man" should have. The best bet for a successful accident prevention specialist is that individual who already has had professional training in a specific discipline or one who has a very good liberal arts background upon which to build. Accordingly, our recruiting is directed toward quality college graduates who have passed the FSEE. Once we have men of this caliber, it is not difficult to develop them in accordance with the plan outlined in the career program.

It would help the cause considerably if colleges and universities could offer a *fundamentals*, a *survey* or an *introductory* course in accident prevention doctrine for majors in various fields of study. In this way, some of these individuals might be inspired to apply their talents to the control of accidental loss and make it their career. To illustrate this point, I should like to relate a recent happening in the Army.

A young mechanical engineer joined the safety staff of one of the Army's technical services. From his record, it was apparent that he could have made out equally well with any one of several employers and in any number of vocations. Curious as to why he had chosen to come with the Army for development as a safety specialist, I discussed this with his supervisor. I was told that the individual reported that he hadn't thought of a career in accident prevention until one day during his senior year when a guest lecturer pointed up the many contributions he could make to society by applying his talents to the field of loss control.

THE LITTLE RED CAR AND WHERE IT WENT

By DIXIE A. THARP

Mill Creek School, Jefferson County Public Schools, Louisville, Ky.

The story of the little red car began in the fall of 1956 soon after the school term started at Mill Creek School, Louisville, Ky. One of the students in my third grade classroom suffered a broken arm in an automobile accident as she was riding with her mother. With this close-at-hand example, I felt that the thirty-one third-graders would accept safety instruction if I made it interesting for them.

The year before in art class, we had constructed a school bus from a large refrigerator box for the purpose of emphasizing safety on the school bus. This had appealed to the children very much since it was large enough for a driver and three or four riders. Remembering the enthusiasm of the children and after discussing it with my husband, who would be called upon for the basic construction, we decided to build a mock car to use as the motivating device.

Since parents of several children were employed by an automobile plant, the third-graders accepted the idea of assembly line construction for our car. The chassis, which was made from the running gear of a coaster wagon that had been acquired with trading stamps, was built in my husband's workshop at our home. It was large enough for the driver and a rider. The car's body was made of cardboard and the steering wheel was donated from a garage. It was then moved to school and the art period was used for painting the little car a bright red and for adding other equipment.

The car was used for teaching common-sense rules of automobile riding, safe walking, bus riding and bicycle riding. Safety instruction became the main theme of other activities in the classroom for the enthusiastic group of children. The teacher gained many new ideas but the school term ended before these could be carried out. However, note was taken and plans made for later and more extensive use.

During the following summer, my husband decided to rebuild the car and to use wood for the body to make it more durable

for our activities in the classroom. Since dual headlights appeared on current car models, we needed the change.

This time, the little car rolled about on ten-inch wheels with rubber tires and white side walls. The steering mechanism was attached to the front wheels so that the wheels turned in the same manner as a conventional car. The steering wheel from the previous model was used. The body which was six feet in length and almost three feet in width was again painted bright red. The interior received upholstery of red plastic.

The trunk at the rear was a convenient storage space for other teaching aids. Bumpers were made from slats of Venetian window blinds and painted with aluminum paint. When taken to school, the new group of thirty-four children were very excited as they had seen and heard much of the little red car. They added refinements that they considered necessary such as the license plate.

They also installed a speedometer, a clock and an AAA emblem. Many said that from a distance, the car might easily be mistaken for a foreign import. Although the children propelled themselves by "walking" as they rode, they were very happy to receive a turn as driver or rider during instructional periods.

Expression of gratitude is due Mrs. Leona Guterthum, the principal of Mill Creek School, for her enthusiasm and encouragement in our "Aim for Safety Around the Clock."

Miss Virginia Wheeler, supervisor of safety and the school lunch program of Jefferson County schools, offered many helpful suggestions and lists of available materials for the teacher. Her visits were enjoyed by the children since she always complied with the request, "Come ride with me."

Since an alert and courteous attitude is important to safe living, the class adopted, "Always Alert, Nobody Hurt," as their motto. After discussion of good citizenship,

the class worked on key words for a bulletin board in the hall just outside our classroom. The words selected were "For my school, I promise to listen, learn, cooperate, respect, exert best efforts to keep M.C. proud of me."

We arranged the words so that the name of the school, "Mill Creek," was obvious. Patriotic colors of red, white, and blue were used. A figure representing our school drum and bugle corps, plus the drum major and a gold key of safety placed above our motto completed the picture.

Other keys to good citizenship such as self-control, responsibility, courtesy, duty, thoughtfulness, and sportsmanship proved effective in building correct attitudes for safe living at all times. The words were posted in the room, also combined into a class dictionary for the children.

In traveling to and from our school, the great majority of the children must ride the school buses. U. S. Highway 31W, which is four lanes and very dangerous, leads to the school. The little red car then must of necessity go to the bus stop and help teach the children to ride safely. After ideas were suggested, they were illustrated with posters by the children for the bulletin board.

When these were removed to make room for other posters, they were made into a booklet with an attractive cover. Each area of safety studied was combined into a large scrapbook that was presented by a parent. Members of the school Safety Patrol became our honor guests. They came to the room regularly to talk to the children and inspect Mill Creek's safety car.

New words were added daily to speaking vocabularies and these primary children were surprised to find themselves known as "pedestrians." Comic drawings of pedestrians proved amusing but convinced the children that they should be "smart pedestrians." A miniature traffic light used with the car emphasized proper walking habits. Twin brothers in the room became known as the stop and go twins. They dressed in red and green shirts to play the role. Parents helped map the safest route to school.

Living at school safely was another problem. Teaching what to do in the classroom, the halls, the lunchroom, and on the playground was important. Ideas for safe play

were carried home to younger brothers and sisters. The car was a valuable aid in teaching the children their responsibility while playing near traffic and parked cars. One eight year old organized a neighborhood safety club of playmates "to teach them to do what was right."

It was convenient during the arithmetic lesson of circles, rectangles, and triangles to call attention to the road markers. The pupils learned to identify all types of road signs. These lessons were enthusiastically carried to the homes. One parent stated that while driving on the expressway he was cautioned by his nine year old son: "Daddy, slow down. There's a yellow diamond shaped sign."

Since every child in the room wanted to drive a car some day, hand signals were popular. This practice would lead to the next part in the program for the little red car.

The hand signals were important in the teaching of bicycle safety. The children made a survey of the number of bicycles owned by Mill Creek pupils. Eight hundred ninety six children were contacted. We found that seven hundred sixty six had bicycles that they rode regularly. Riders numbered about the same in each grade from one through six. Booklets on tips for the safe rider were distributed. An inspection by police was conducted on Saturday at the Shively Park. Each member of our class wore a badge proclaiming this as "Bicycle Safety Week." One of the group won a third place award in the AAA annual poster contest. A child in another third grade won honorable mention.

Holidays presented different problems. Suggestions for trick-or-treaters were written and taken home at Halloween. At Christmas time, the third grades were invited to present a play for the P.T.A. This involved our class and three others. An original play, "Santa's Safetyland Parade," was written. The little red car figured prominently in the presentation. Every child was given a part and their costumes received the safety touch. There were the pedestrians, the drivers, the road signs, the traffic lights, the bicycles, the toys, and of course Mr. and Mrs. Santa arrived at Mill Creek from Safetyland in the red car. Our theme song, "Safety First," was written to the tune of "Jingle Bells."

Our Junior Red Cross project included a tree made from an umbrella frame, covered with poultry wire and painted gold. Red and green ribbons fastened candy canes and lollipops of many colors. The mock trip to the Children's Hospital was made in the little car and Christmas tree safety was learned on the way.

Home safety and fire prevention were combined. The children found many hazards when the check list was completed. A large doll house was used to focus attention on home. Ribbon banners ran from the bulletin board signs to different areas. Each child made an interesting booklet to carry home.

Four years prior to this project, the principal had asked the sixth grade classes to think of something that would appeal to the younger children and encourage better safety habits. Thoughtful Tim was created. When children obeyed safety rules, Tim displayed his smiling face. When they disobeyed, Tim was sad and embarrassed and the reverse side was shown. Each classroom had a small version of the figure which was placed by the door to report accidents with his red face. Now, we found that Thoughtful Tim was an excellent helper with the little red car. We worked hard to keep him smiling.

How did these activities fit into the basic program? The children were given many opportunities for reading. They now searched for stories concerning safety. The book, "In Storm and Sunshine" of The Road to Safety series by Buckley, White, Adams and Silvernale, which is published by American Book Company, was most helpful. Several copies were purchased by our P.T.A. The children collected new words from highway markers and other sources. These were printed on tagboard and inserted in the card holder to be learned. They later were transferred to a large envelope and used by the pupils for a check-up on word recognition.

The Social Studies program also was correlated with safety teaching. Studies of other lands included winter safety with Norway, bicycle with England, water safety with Brittany, strange animals with Spain, and sun exposure with Africa. Film strips were shown and the children were asked such questions as, "Are there stop signs? Any cars? Any bicycles?" "How are po-

licemen like the ones in our own country?" "Can you read some of the signs?"

The map study included activities of charting vacation trips with string. Canceled postmarks located capital cities. Children helped parents plan trips to travel safely. Scrapbooks of interesting places to visit were made. At one time, we had in our classroom a book for each of the fifty states.

Letter writing, important in English lessons, was made interesting with a small post office constructed in the room. Letters written to parents concerning safety gave writing and spelling a real purpose. Many parents sent replies to school along with their suggestions. Newspaper items were exchanged here, also.

Safety talks and dramatization were much more effective with the use of a play microphone.

The art period was a good time for preparing posters and signs. A very attractive mobile of safety items and messages was hung in the hall window. Each day a group of children were looking to discover what the third graders had added.

The pupils loved to sing safety songs and to create original ones to fit familiar tunes.

There was no "special" time set aside just to teach safety. It was interwoven with every activity and every subject.

As a follow-up for the class, a fourth grade teacher found that when the group studied transportation, they wanted to include train safety.

A fifth grade used clippings for a hall board.

In grade six, our special art teacher stated that this group produced many ideas for safety bulletin boards and posters.

Of the original group of thirty-four children, twenty-six finished with the sixth grade of our school last June. Twenty-two of those served on the Safety Patrol. Enrollment at Mill Creek School totals over one thousand pupils. One hundred sixty-five were in grade six. The patrol had thirty-five members. We found one minor home accident reported that resulted in loss of one day from school.

Parents reported that safety habits of the children were greatly improved. Relating classroom lessons to safe living at

home proved an effective technique in securing cooperation from parents. They were eager to help the children apply ways of safe living to their everyday activities.

The project also had effect upon parents. Neither mother or father dared make a mistake while driving with a "safety-conscious" child sitting by his side.

Helping these youngsters get a start on becoming good traffic citizens is a real challenge for any instructor. Words are inadequate to describe the project. It has when one walks on a street and sees a group of happy children who

quels of red roses, their surprise way of saving to the teacher, "Thank you for the little red car."

ACKNOWLEDGMENTS

I am indebted to a number of people for ideas, suggestions, and encouragement. I find it impossible four years later to furnish an accurate bibliography since materials were from so many sources and used to accompany our special need.

I am very grateful to Mill Creek School, the Jefferson County Board of Education, Louisville Safety Council, and the Louisville Automobile Club for materials.

I wish to thank the National Safety Council Program Committee of the Elementary school for giving me the opportunity to report on this project.

VALIDITY, EFFECTIVENESS OF VARIOUS SAFETY EDUCATION TEACHING TECHNIQUES (A GROUP STUDY)

Led by: JAMES W. MANN, Professor of Elementary Education, Roosevelt University, Chicago, Illinois.

With the assistance of: LUCILLE CAVANAUGH, Representing Association for Childhood Education, Homewood, Illinois; CLARISSA HUG, Representing Council for Exceptional Children, Chicago, Illinois; WALTER H. SCOTT, Principal, George G. Meade School, Philadelphia, Pennsylvania; RICHARD TOLSMAN, Representing National Union of Christian Schools, Cicero, Illinois.

Recorded by: HELEN MAE SMITH, Illinois Conference of Seventh-Day Adventists, Brookfield, Illinois.

Criteria for determining the validity and effectiveness of safety education techniques by the group were:

1. In launching a program of safety education, the interest of the children must be captured. Children must be a part of the planning if experiences are to be educational.

2. To make safety education more effective, we must involve the parents, enlisting their cooperation and their active participation, even to the point of insisting on better law enforcement if necessary.

3. Good safety education has carry-over value. The following activities are suggested to determine how much value:

a. Send letter with questionnaire to parents to discover trends for purposes of comparison.

b. Check in the ninth grade to ascertain, if possible, the good habits and

practices that have carried over from previous learning (and teaching) of good safety practices.

4. A school safety program to be effective must have the cooperation of all adults in the community. We must help adults to develop better attitudes toward safety by:

a. Parent teacher meetings and letters to parents. We should call on parents to assist in safety education activities including informing the community.

b. Encourage participation by community organizations—safety council, TV, radio, newspapers and so forth—and city departments—police, fire, traffic engineering, recreation and so forth.

In addition it was suggested that inservice education for teachers in safety not be left for summer sessions and that credit be given for such education.

TRAINING DRIVERS TO MEET EMERGENCIES

By ALFRED L. MOSELEY

Chief Investigator, Research on Fatal Highway Collisions
Dept. of Legal Medicine, Harvard Medical School, Cambridge, Mass.

A lady from Gloucester left downtown Boston on a very hot August afternoon and headed northeast on Rt. 1 and then on Rt. 128. While driving in the high-speed lane, the right front tire blew. The car went out of control to its right across three lanes of traffic and over the curbing. The driver managed to regain some measure of steering control and, for a small distance, the vehicle went parallel to the curbing and then crossed it again. In the process of regaining the roadway, the vehicle turned violently to its own left, crossed three lanes of traffic again, and then crossed the median. As it emerged in the opposing lane of traffic, it was hit at right-angles by a second vehicle which was in turn hit in the rear by the third.

None of the persons who survived this circumstance, and there were seven who did, were able to give any account at all of what happened. There were some false memories; there were some estimations; there were some guesses; there were some impressions. "It all happened so fast."

When the driver of the first vehicle became aware that something was wrong, the vehicle was moving out of control. There was no evidence of braking at this time. The engineering term "feedback" might well be applied. In this instance the steering control motions of the driver were overcorrected. But the driver did not know quickly enough what the control meant in terms of actual change in the direction of the vehicle. Thus the driver steers too far to the left and is out of control.

The driver in the southbound lane was on his own side of the road minding his own business. He was where he had every right to be, and, in all probability, was within the speed limit. He was on a collision course beyond a point of no return before he had any realization that anything was wrong. Suddenly a missile came out of control across the median and entered the lane of traffic ahead of him. He had time enough to make a very small steering correction and to make the earliest pressure change in the braking system, but these were of no avail because

he had neither time nor distance in which to act, or for his acts to become effective.

The driver of the third vehicle was completely without choice. When the vehicle came to a sudden stop in front of him, his following distance was such that there was no possibility of avoidance. One of the interesting things that came out in this case was the observation that in the third vehicle there was evidence of two head impacts in the windshield. One of these was from the inside out, indicating that a passenger had hit it. The other one was from the outside in, indicating that some human body had been acting as a projectile and had impacted this windshield while in flight. The question was, what is the appropriate identification of this person?

Careful laboratory work established later that the driver of the vehicle which went out of control originally was the one who had impacted the windshield of the third vehicle. It is of interest that in the investigation of this particular case, no note had been made of this unusual circumstance by any of the investigating officers and none of the survivors had any awareness at all that a human body had been hurtling through the air as a missile.

With the orientation which has been raised in your minds on previous occasions, you will naturally be concerned with the degree to which protective devices were in use in this particular circumstance. The answer is very simple. With the exception of those devices which were built into the car by the manufacturers, there were none in use.

This case serves to illustrate: (1) that the time factor involved is very short, (2) that the difficulty of managing a vehicle under conditions of explosive decompression in a tire is great, and (3) that the effects of the driver's control movements and his knowledge of their effects is of fundamental importance. The case may serve well to underline the concept that it is a real tragedy for this driver to have had her first blowout on the last day of her life.

The point to be made in the present discussion is a very simple one. *Emergency training is a feasible concept.* It has been utilized in other areas with considerable effect and with a reduction in the severity of injury and a reduction in the incidence of death under extreme circumstances. In addition, it has provided skills, concepts, attitudes and "presence of mind," so that in situations which were completely unpredictable the basic characteristics of the training come to the aid of the individual in solving the unexpected problem.

In making a plea for consideration of emergency training for driver education, it is necessary to engage in a small amount of criticism of our standard procedures. The criticism is not what you might expect. We know very well that training as a principle is extremely sound in any area and that, where it is properly carried out, it provides a person with information, with habits, with skills, with attitudes, with ideas, with concepts, with emotional orientations which act favorably concerning his capacity to meet the practical requirements of life. Driver education is no different from any other field in these areas and it is successful in accomplishing many of these objectives.

In the various studies which have been conducted to describe the difference between the driver-education-trained-driver and the person who receives his training from a friend or a member of the family, the advantages which one would hope to find on a statistical basis do not appear as consistently as might be wished. A part of this is due to faulty statistical manipulation of the data accumulated. Another part of it is due to the fact that, while driver education accomplished what it set out to do, it did not set out to do enough. The training did not go far enough to prepare the driver for the extreme circumstance.

It is not subject to proof at this time, and I must freely admit it, but I hold the opinion that the reason why our driver-education-trained-students do not show the advantages that we might wish is due to the fact that their training does not go far enough to equip them with skills to meet the practical emergencies of highway travel. Therefore, what I am saying is that policy decisions favoring the addition of emergency training must be made. The goal of this training is

School and College Sessions

to provide the student with emergency skills for the occasion of need.

There are several facets to the concept of emergency training which are worth reviewing on this occasion. They are fundamental to any procedure in which emergency skills are to be developed.

Multiple factors.—In every area of man and machine relationships, events occur, sometimes instituted by the man, sometimes initiated by the machine, sometimes originating in the environment around them, which produce the opportunity for errors, or near accidents, or collisions, or accidents. Many of these occur under circumstances in which more than one factor combines to produce a deleterious effect. It is the teaming up of these factors under the conditions of ordinary life that lead one to believe that allowing chance to control the destiny of a person in an emergency is foolhardy.

It is usual to find in the cases we are studying, under a U. S. Public Health Service Grant, that in automobile deaths many important causal factors act simultaneously. For instance, it is perfectly usual to see a person with a strong and important emotional maladjustment history, driving a vehicle with a compromised condition because of lack of maintenance to one or more components.

The person has fallen heir to long periods of work and shows a chronic fatigue; he has now been out for many hours and may be described as being in a fairly acute state of fatigue; he has had alcohol to excess and is operating under conditions of low illumination, when some component in the vehicle, such as a tire, goes flat and the vehicle is out of control.

The principle underlying this description is not an oddity. It is the rule: that multiple negative factors occur simultaneously, compromising the capacity of the human operator to appropriately protect himself by an intelligent course of action. It is entirely possible that the circumstances with which we are concerned as highway emergencies are not predictable as to time and place. It is possible that they are predictable in how they will run their course.

In reasoning from what is known in the treatment of disease, for instance, we might say that a physician might not predict which of his patients will get malaria, but he can,

with fair precision, describe what the course of the disease will be, when the temperature will go up and when it will drop and what the degree of rise and fall will be. He can predict what the probable physiological reactions will be if the person is given no medication and what will happen if he gives him a medication which is specifically for this particular disease. Can we become familiar enough with the course of any given emergency situation so that we can then take its basic nature and utilize it to our educational benefit?

Short time interval—The time interval in which an emergency arises is very short. This means that time is at a premium. I have already mentioned that one may be on a collision course beyond the point of no return before he knows that anything is wrong. In the Grand Canyon accident of two airliners sometime ago, a fraction of a second of warning was about all that anyone had and the possibility of control, when that information was available, was not within the realm of the aerodynamics of the aircraft in flight. The meaning of the inferences concerning the factor of time is clear. If the preparation for that last crucial moment is not completed ahead of time, there is almost nothing to be done about it, short of an act of the Deity.

When you spend a good deal of time interviewing persons who have been involved in injury and death-producing accidents and treat them as witnesses, you find several types of phenomena. Two of these are extremely important. Many of them suffer an amnesia. In some circumstances it is concerned only with the moments of the event. In other circumstances, the memory loss reaches back for a period of several minutes, quite often, and sometimes even a few hours prior to the event. Some of these losses are related to brain injury. Others may be related to emotional trauma. In any event, it means that whatever useful information might have been provided by these persons is completely lost.

The second type of response is from a person who apparently does not exhibit this type of shock reaction, but simply responds with an almost constant, "It happened so fast." Now this means that in spite of all of the careful questioning that can be brought to bear on these people, not only in

the situation immediately following the case, but in days succeeding, no details are described which can be used as anchor points around which to understand the nature of the collision course and what the human operators did. Many of these people fabricate. By this I mean that with their imagination they simply fill in the blanks of their memory and then describe something which they come to believe is true but which objective investigation can show very clearly is not.

First signs of danger—One of the very important factors, now appearing, is that the signs of developing emergencies may be obscure. This means that we find interview evidence, in cases where there has been a blowout, that no explosive sound gave an audible warning to the driver. The term "blowout" itself almost directly implies a sudden sharp sound to go along with the failure of the tire. I find myself using the term "explosive decompression" by way of indicating the rapidity with which the air leaves the tire, hoping by this means to avoid the implication that there is a sound that comes with it.

There may be other clues that a tire is failing. One of these is that the hub cap will go sailing down the highway ahead of the vehicle, or off to the side and attract attention. The second one is that a tread wave is set up as the tire begins going flat and this is felt in the steering wheel as a strange type of road shock. But by the time these things happen, the process of decompression has gone quite far and the problem of control is quite severe. The point is a very fundamental one. If the signs of developing emergencies are obscure, it is all the more certain that intelligent reasoning would lead to experimental investigation of the nature of these circumstances and the development of means by which these can be determined at their earliest time.

Correct response, too slow—In addition to these factors, there are observations made in the course of training for emergencies in other situations which give rise to a very thoughtful concern in the highway field. In the use of the Dehmel trainer in aviation safety, the control operator can set up any warning circumstance so as to teach the pilots how to diagnose difficulties and how to carry out control procedures. Over and over again, the training record shows that,

after basic indoctrination and familiarization, the crews are able to perceive the dangers and decide on the appropriate means by which to manage them.

When this has been accomplished, what do you find in your appraisal of their results? The multiple negative factors are set up in the panel so that the altimeter shows a drop, a wing is low, another prop is feathered, and a fire begins in another engine, then what is the pilot to do? He shows in his training the capacity to do the correct thing. The unfortunate thing is that he does it too late for it to be effective.

Obviously, this clue means that the training has to go far enough to accomplish speed in the recognition of the problem, speed in the accurate decision concerning what to do, and speed in carrying out the decisions with dispatch and with skill. This is what the emergency training procedures are intended to do.

Panic—In an interview with an instructor at Camp Pendleton, California, concerning emergency underwater evacuation from a submerged helicopter, an interesting thing was learned. About one in 100 of the Marine recruits will go through the underwater escape training program panic, though fully aware that the situation is one admitting of considerable control. If this can happen in circumstances where the training is under good control, what might you expect of this panic-stricken person when he is confronted by a horrendous experience? It suggests that the training should go far enough to sort out the limit of the emotional capacities of the trainee. If an individual is to be in control of a situation involving the lives of other people, it is entirely reasonable to wonder if he should not be selected out by some such appropriate process.

The following factors and reasoning apply to the psychology of emergency training:

- Emergencies happen fast.
- Skills cannot be developed when you have only one instant requiring perception of the developing trouble, diagnosis of existing trouble, the need for immediate, accurate decision, the need for accurate remission action.
- To meet this problem, the person exposed to the dangers should be placed in training situations where the educational procedure and the engineering devices have been

carefully structured by appropriate research and which conform closely to the operational characteristics of the real emergency, so that he receives first-hand experience in the diagnosis and management of the emergency situation.

d. The training program should be carried to the point where the student shows his tendency to panic and is eliminated; or shows his incapacity to properly manage the emergency and is eliminated; or develops a skill and capacity to respond to the emergency by doing the correct thing in time for it to be effective.

e. These steps will bring the student to a point where he brings a skill to the occasion of need.

f. The more significant the contribution of the man to the successful performance of the man-machine relationship, the more important it is that the training of the human operator be carried to a degree where he can successfully manage all types of problems which arise. We are dealing here with the attempt to reduce a situation fraught with danger to a point of control and to provide a skill which will act under conditions of imminent danger.

g. Since many primary variables may affect the operational control of a vehicle in emergency training to a considerable degree, consideration of these variables must be taken into account in the training. This will mean that if there is a qualitative change in how a given kind of factor is managed as a function of velocity, then the student will be given an ample amount of indoctrination concerning this change under operational conditions.

h. Emergency training is by no means a guarantee that the details and the training and the procedure, though followed through with accuracy and speed, will produce no injury and no death. There are significant data in aviation presented by Jones, in a paper concerning 850 emergency bailouts in the U. S. Navy indicating that in most of these bailouts, the pilot had little choice but to abandon the aircraft. Eighty-five per cent of the bailouts were successful in that the lives were saved and in 50 per cent there was no injury at all. This is certainly a marked advance and accomplishment over what might have been the case and what certainly would have been the case other-

wise. These data represent a marked improvement in survival but not a complete solution.

i. Sound emergency training must include more than procedures and their successful accomplishment during the training program. It is necessary also to indoctrinate students on the nature of the various components in the physical system and their maintenance. Practice should be extended, not only to the area of maintenance of the emergency skills, but also to the maintenance of the system concerned with their successful completion. Attitudinal orientations are also very important.

j. In real life situations, individual factors of an emergency nature do not happen one at a time. One, two, three, five, seven, nine team up and they operate simultaneously. This means that perception time and comprehension time may be extended, because of the nature of the complexity of the various factors and the effect of the combination of factors in obscuring the clear symptom of the beginning of the emergency problem, to whatever extent this can be taken into account in training.

k. Once emergency training has been accomplished and people with this training are carried into practical situations, there must be an automatic means by which to feed back their observations of these conditions to the training program so that the emotional factors, details and training procedures and modifications of technique, both in training and in engineering, can be accomplished for increasing the success of the program in the future.

l. The nature of habit systems must be taken carefully into account in emergency training. Under stress a person tends to fall back on the oldest and most highly developed habit system that he has. It is necessary that these matters be taken firmly into account in setting up the system, not only in evaluating previous experience in driving a vehicle, but in evaluating habit systems coming from other circumstances which may come in to play here. For instance, if a person is in the habit of scratching his nose, when a horrendous experience begins developing on the highway he will first scratch his nose before he does anything else. The nature of these habit trends must be taken carefully into account in setting up the basic system.

In military and civil aviation, many problems developed because of the shift from one type of aircraft to another. There was no standardization of the nature of mechanical operation of a component nor its designation. A crank that turns clockwise on the right-hand side of the cockpit might, in one craft, lower the flaps and, in another craft, lower the wheels. Very accomplished pilots then demonstrated the capacity to make a landing with the wheels up instead of down. This type of error simply means that whatever emergency training is carried out should be done on the basis of a habit system not dependent on the vehicle in which it is applied. Standardization of the controls and their location and operation can go far in solving this problem.

The following examples of emergency training applications are given by way of giving support to the principle that emergency training is a well-established procedure. Appropriate administrative decisions concerning this type of training have been made on many occasions. Feasibility has been established. Training programs have achieved successes which have modified the expectancy of injuries and deaths which otherwise would have been proven true. Emergency training has proved its worth.

Bailouts in naval aircraft—Jones¹ has described an analysis of 850 bailouts from fighter attack, trainer and other types of naval aircraft which occurred during a five-year period beginning July 1, 1944, through June 30, 1949. All of these were emergency bailouts. Several of the descriptions which Jones has given are pertinent to the problems under consideration here.

He describes as follows: "One pilot was involved in a rather severe mid-air collision in which the tail surfaces of his plane were badly damaged. However, he was able to climb to 10,000 feet to test the stall characteristics of the aircraft. He determined that it was not possible to make a carrier or watered landing with the plane damaged as it was. He jettisoned the canopy and trimmed the plane as much as possible. However, as soon as the controls were released, the aircraft went into a nose-down spiral at about 200 knots. The pilot experienced some difficulty getting out and had to climb back over the fuselage to get completely clear. By this time he had lost

about 2,000 feet. In spite of all these difficulties, his only injuries were minor abrasions. . . . This is an interesting example of how basic emergency training prepares a person for a situation involving some unpredicted difficulties.

Air transport drill—Jones describes how one Navy squadron illustrated a necessity for emergency training practice in large transport planes. The captain had 27 passengers aboard, all of whom, because of their duties either as flight engineers or orderlies, had some understanding and familiarity with safety equipment and safety procedures. Without any prior warning, the pilot shouted, "This is a drill. The right wing is on fire. Put on your parachute and get out as quickly as possible. Get out." It took the first man in this plane two minutes and 20 seconds to evacuate. The 26th man was out of the plane in four minutes and 20 seconds. The 27th man never got out.

The officer in charge of the flight lined the men up outside the plane and inspected them to see how well they had carried out the emergency evacuation procedure. He found that five of these persons had their chutes on upside down. Five of them had the harness wrong side out. Several others had attached the buckles of the harness to the wrong component and several others had attached the harness so loosely as to fall out of it in the air when the rip cord was pulled. Following this, some detailed instruction was given about how to attach the parachute and fasten and adjust it under these conditions and how to evacuate the plane. The drill was then repeated with the following results: The first man was out of the plane in 8 seconds. The 27th man was out of the plane in 20 seconds and, in every case, the gear was properly attached.

The disaster—In any circumstance in which there is a new type of procedure, theoretical calculations can be made on the basis of previous operational, clinical and experimental evidence and very sound estimates of how to meet the predicted circumstances can be made. These are occasionally substantiated to a large degree by succeeding events, some of an experimental nature and some essentially accidental.

In the case of high altitude bailouts in

the Air Force, it was expected that because of the decreased density of the atmosphere at high altitude, there would be no severe opening shock. This line of reasoning did not take into account the possibility that the rarity of the atmosphere would serve to increase the rate of initial acceleration because of a diminished drag, and that therefore there would be opening shock. It was expected that the jump would require prolonged use of oxygen because it would take a fair period to get down to where the oxygen pressure would be sufficient to maintain normal respiration.

Colonel W. R. Lovelace, II, MC, U.S. Air Force, made an experimental jump to study these conditions from 40,000 feet on June 24, 1943.² "He suffered an extremely hard opening shock which rendered him unconscious and caused him to lose both gloves from the left hand. When he recovered, he had a frozen left hand and was suffering from shock. The nylon glove retained on the right hand served to protect it from frostbite."

On July 3, 1943, Major P. J. Ritchie made an emergency jump without oxygen from 32,000 feet. "He delayed pulling the rip cord until he was about to lose consciousness. He remembered a terrific opening shock as his chute opened, and he lost consciousness shortly afterward. Examination showed he had a dislocation of a lumbar vertebrae." Another Air Force officer in August 1944 was given permission to conduct an experimental free fall jump from 42,000 feet to take into account the tests and predictions that had been made in the above cited information.

He chose to use no automatic parachute opening device and proceeded to carry out the experiment. He fell 42,000 feet and landed in the desert sand, fracturing every bone in his body. In all probability, he was dead before he hit. The death would be attributed to lack of oxygen. The objective evidence indicated that he had made no attempt to pull the rip cord. The literature does not make a clear description of the degree to which dissent played a part in this particular instance, but the objective material reported strongly favors the circumstance with dissent, to the point that even secondary protective apparatus was not included.

If this has any meaning for emergency training in the highway field, it is simply that the dissenter, who chooses to "fly by the seat of his own pants," will disregard the accumulated knowledge, results of experiment, and descriptions of the variables, to his own destruction. Steps must be taken to identify him and to understand him, so that compliance with the requirements of the problem can be accomplished.

Escape by parachute—In one of Da Vinci's drawings, there is a picture of a parachute. When the Wright brothers flight-tested their aircraft at Kitty Hawk, they made no provision for getting down independently if something went wrong. As experience with aircraft developed, it became clear that something was necessary to make it possible for the pilot to escape from the plane under certain conditions. Parachute training developed in remarkable steps after basic designs were completed. We have a high degree of sophistication in this field in the military areas.

In Jones' study of bailouts, he makes the point that bailouts, under relatively controlled conditions, are generally safe. They become hazardous, at best, when the plane is on fire, or plummeting out of control, or after a mid-air collision. No matter what the circumstance otherwise, the pilot may make matters worse, no matter how badly off he was to start with, if he (1) waits too long, (2) loses altitude so that the craft is too low, (3) stands up in the seat so that he is swept away into the tail section, (4) opens the chute too soon and becomes entangled with the plane so that he is dragged down to his doom with the aircraft.

The reasons for bailouts in primary categories involve mid-air collisions, power failure, fire, loss of visibility, traveling in inclement weather and being lost, a normal spin, an inverted spin, loss of fuel, structural failure and also the category in which the circumstances are unknown.

In order to underwrite the whole process of emergency escape from a plane in flight, one of the steps taken by the U.S. Navy was the development of a bailout trainer for practice on the ground. This is accomplished by tying the plane down with the tail elevated in a flight position; with the engines running, the slip stream of the

plane's propellers enable the student to simulate the jump at air speed and the student lands in a net along side. Under these conditions he is able to learn correct techniques, and especially the kinds of things not to do. One of the important advantages of this training is that it reduces the time required to clear the cockpit in an emergency escape.

As the speed of aircraft became higher, and the maneuverability of the planes changed, and as dual rudders were developed, the problem of bailing out became a very different one. In order to properly manage escape from an aircraft under these conditions, it became necessary to consider how to propel the pilot from the plane by some automatic means. Automatic ejection seemed to be an answer.

Ejection—It might seem that the problem of ejection could be handled very simply by some means of getting the pilot out of the seat so that he would clear the craft, but many other factors get involved in it. Commander Webster² describes the main hazards in escape from high speed and high altitude aircraft as follows: 1) separation from the structure of the plane, 2) aerobolism, 3) opening shock of the parachute, 4) anoxia, and 5) frostbite.

Mr. Richard Frost³ looking at the problem of ejecting a pilot from high performance aircraft describes them as follows: 1) decision to abandon the aircraft, 2) operation of emergency controls, 3) removal of obstructions to egress, 4) egress from the crew station, 5) avoidance of airplane structure after egress, 6) prevention of injury caused by impact, pressure, temperature, deceleration, and/or tumbling, 7) prevention of injury caused by ambient pressure and/or temperature, 8) retention and protection of life-saving and survival equipment until use, 9) operation of life-saving equipment, 10) prevention of injury during landing considering both vertical and horizontal velocities and type of surface encountered, 11) counter-acting effects of surface environment, including hunger and thirst, 12) facilitating search and recovery operations by friends and avoiding these operations by enemy, and 13) training in the operation and maintenance of the system.

It is clear in viewing the Frost list of engineering problems here that once the

ejection from the plane is accomplished, a host of brand new problems enter the picture, which must be dealt with in advance and carefully planned for. Some of these problems require that the means by which they are managed be carried along with the pilot on his way down. It is interesting to see that the solution to a problem often brings on other problems which are very difficult to manage.

Colonel H. G. Moseley⁴, of the USAF, has described 757 known ejections from high performance aircraft. Five-hundred eighty-four or 77 per cent of these were nonfatal. One-hundred seventy-three or 20 per cent were fatal. In the nonfatal cases, 215 were without any injury; 158 had only minor injury; and 110 or 15 per cent had major injury. In analyzing these circumstances, Moseley found that mechanical ejection was clearly the answer to the removal of the crew from high performance aircraft.

He found in analyzing the cases that there were difficulties in initiating the escape procedures and that special training and engineering design had to go into this phase of the operation. He found that there were difficulties, related to 87 deaths, in separating from the seat once the seat had been ejected from the aircraft. He also found that there were difficulties in deploying the parachute.

It is very interesting to see that the choice of the altitude and the entering velocity in ejection have much to do with the success of the ejection from high-speed and high-altitude. If the chute is deployed too quickly, the opening shock may be so great as to rip the harness in two so that the parachute and the aviator fall separately. If the person does not fall for some distance and is not carrying oxygen with him from high altitudes, he may suffer an anoxic death before he reaches the area where the oxygen-partial pressure is sufficient to maintain normal respiration.

One of the benefits derived from the study of the unsuccessful ejections is that if the body is allowed to go through a free-fall for a distance, it actually slows down so that the rate of fall is not as great in velocity as the initial velocity was in leaving the aircraft. This means that the person accomplishes a moderately

high-speed descent into areas where the oxygen-partial pressure is considerably more favorable, that he leaves the area where extremely low temperatures are unfavorable, and that he slows down sufficiently so that the opening shock of the parachute will not be so great as to tear it apart.

In experimental and operational studies of high altitude bailouts, Mazza⁵ describes his test in which a free-fall drop from high altitude was carried out. "In the first free-fall drop from 37,066 feet, the subject free-fell 80 seconds prior to automatic opening of the parachute. In the second drop from 41,586 feet, the subject free-fell 90 seconds. Ground personnel tracking the drops by radar, estimated the openings to occur at approximately 15,000 feet above sea level."

These data give some indication of what the time factor is in the problems of low oxygen pressure at high altitudes. If you had the experience recently of having the pilot of a jet airliner give the temperature, you have probably been surprised to hear him say that you were travelling at 25,000 feet and the temperature outside was 40 and then, with a pause, add "below zero."

In the drop experiments oxygen equipment consisted of a mask connected to a bailout bottle; a second bailout bottle with a simple pipe system was utilized in case the primary system should fail. Both of these were checked by actual use prior to the jump to be sure that they were properly functioning. In addition, each of the subjects in the experiments wore a stop watch and an altimeter sewed to the sleeve of his outer garment and a knife sewed to the trouser leg so that he would have information concerning the length of time involved in the fall and the altitude, and means by which to take care of problems which came up in flight.

Aircraft accident analysis—Zeller⁶ has analyzed the information developed in the investigation of 536 Century series fighter aircraft accidents in the period January 1, 1953 to June 30, 1957, inclusive. His data are carefully managed from many standpoints and some of his comments are apropos. "The role which the knowledge of emergency procedures played was considerable. Study of the accident reports indicated that in 148 accidents, some type of emer-

gency procedure was necessary. In 133 instances, some emergency procedure was used. Of these, the incorrect procedure was applied in over half of the cases.

It is noted that Century series experience apparently has little effect on whether or not the correct procedure is accomplished. This finding is not unreasonable because emergency procedures are ordinarily of use only when an emergency occurs. Whether the pilot experiences the emergency during the first five hours or the several hundredth hour of flight time has little bearing on the knowledge of these procedures if he has not specifically practiced them in the meantime.

"The high number of incorrect emergency responses suggests that controlled use of simulators and trainers which permit practice of emergency operations should result in a decrease in accidents caused by the pilot having an inadequate knowledge of these procedures." This point is very similar to the one made earlier in which it was mentioned that some procedure was necessary for the maintenance of emergency skills in the highway field once they had been developed.

Helicopter accidents—At Camp Pendleton, California, a helicopter dunking device was employed in order to teach military personnel how to escape from a submerged helicopter after falling into the sea due to the loss of a rotor blade. The machine is so designed that an instructor and nine men can sit in the passenger compartment of the helicopter as it is dunked. In a controlled procedure, into 15 feet of water. The procedure, as described by Sgt. Edward A. Roberts and Lt. Colonel W. T. Shafer, is as follows: In the first experiment, the recruits are given a basic description of what is to occur, where they are to sit and how they are to manage the problem of getting out of the aircraft. They go through a minimum of two immersions.

In the first instance, the machine is dropped into the water and stopped at chin height. Here they are given a description of how to take a last breath as the water forces air into compression in the upper part of the fuselage. Men are equipped in this circumstance with full field equipment. This means normal arms, rifle, a light pack, helmet, an ammunition belt and full combat clothing, including boots.

In the second experiment, the machine is dropped to the bottom. They follow the procedure of waiting until the wheels touch and until the motor gives signs of stopping to take their last breath. If they wait until the water is up around shoulder height and take their last breath, they finish it just as the water comes up over their chin. They remove helmet and place it underneath the seat because the chin straps may get caught in the corrugated floor. The other personal gear which they are carrying is removed and put under the seat.

The recruits hold onto the seat with one hand during this operation so that they will maintain a stable position and not interfere with the motion of other people around them. While still holding onto the seat, they trip the buckles of their seat belts and leave in designated order. As they go through the door, it is necessary to grab the door and force themselves down in order to avoid some of the hoist mechanism gear which is attached to the fuselage at a point above the door. It seems necessary to exhale a small amount of the air which has been taken in in the last breath because it is, in fact, compressed. The rest of the procedure is to swim to the surface of the water.

This has been a successful program. It has turned up the interesting finding on panic, already mentioned. "It is important," says Sgt. Roberts, "if you are going to panic, you do it here where you can get away with it."

Flying civilian aircraft as a private pilot—It is an interesting experience to take the position of a student pilot and begin to learn from actual experience in flight what the various structures in aircraft mean and how they perform their functions in flight. The meaning of trim, aileron, stabilizer, pitch, roll, yaw, the reading of instruments, and the reliance upon them is enhanced by the procedure of becoming a student. The concepts undergo important changes as the student sees the structures in use in flight.

In interviews with student pilots and with instructors, one gets the impression that in learning to fly, much of the understanding of the nature of aircraft and flight is accomplished by deliberately doing the wrong thing. This means that you accumulate experience under relatively controlled conditions. You come to understand what

meaning your action has on the capacity of the plane to perform. You learn what the symptoms of these types of problems are as they begin, so that this information can be utilized when it is critical for your safety.

The pilots who operated as bush pilots many years ago and, who will do, report that they find themselves almost constantly busy while in flight looking for a place where they could land it, at this moment, they were to lose their power or if they were to run out of fuel. The process of estimating a glide path and estimating the means by which one would get to a place where an emergency landing could be made is a tremendously interesting phenomenon to observe from experience.

Putting a plane into an altitude where it stalls at 6,000 feet, knowing a spin would be the inevitable result if it were not controlled, gives you a very sound idea of what has to be done to protect the plane from going into a vertical or an inverted spin. When you anticipate that the rate of fall here would be roughly 32 feet per second from the altitude, plus the initial entering velocity, it is very important that the characteristics of the stall and the spin and the management of this problem be clearly understood and the control reactions be very quick.

The reliance upon instruments as the means by which to get information is critical. The psychological responses to the attitudes of the plane under conditions of instrument flight lead you to believe that your capacity to judge what is going on by the means of your sense organs is not only incorrect, but is misleading to the point of being dangerous.

Shafer describes some of the false sensations that result from the stimulation of the otolith organs in the internal ear as a result of acceleration. "For example, in the absence of visual cues, G forces which are present in various maneuvers do not give adequate stimulus to differentiate the type of maneuver; consequently, the pilot may interpret the G forces of one maneuver as originating from an entirely different maneuver."

"1. Sensation of climbing while banking: the resultant G forces of a coordinated turn may produce the sensation of climbing.

2. Sensation of diving while recovering from a turn: The reduction of G forces noticed on recovery from a turn produce the same sensation as reduction of G forces noted in a dive and may be interpreted as such.

3. Sensation of diving following recovery from a dive: in the pull-out from a dive certain G forces are imposed on the body which are reduced following the pull-out. This reduction tends to give the same sensations as are experienced in a dive and consequently may be interpreted as originating from a dive.

4. Sensation of opposite tilt during a skid: Bergin states that in a perfect turn, where the ground or horizon cannot be seen, the angle of bank cannot be sensed because the resultant of gravity and centrifugal force must fall at right angles to the transverse axis. In blind flying, the deviation of the resultant, and, with it, of the angle of turn indicator, may be sensed as an inclination of the aircraft to the side of the deviation. If, in blind flying, the aircraft skids during a turn on account of it not having been given adequate bank, then the resultant no longer falls at right angles to the transverse axis. Thus, the sensation is that of tilt of the aircraft as opposed to the true one."

Flight simulation—At the United Air Lines Flight Training Center in Denver can be seen one of the most interesting simulation centers in civil aviation. Proficiency training, check flights, and practice in emergency procedures are the business of the day. Here are simulators for the CV 340, DC 6, DC 7, B 720, DC 8 and Caravelle. Training programs are designed to meet federal requirements, indoctrinate and provide practice in new aircraft, and make training use of the vast experience accumulated in scheduled passenger operations.

What procedures are included? Maneuvers such as authorized maximum gross take-off weight with failure of a critical engine; maximum weight landing in four engine aircraft with most critical engines at zero thrust; pull out from maximum landing weight with critical engine inoperative. The lesson plans for emergencies include problems such as fire and smoke, emergency descent, power plant malfunction,

hydraulic failure, electrical system failure, and wheel and gear trouble.

It was an interesting experience to watch the progress of a simulated flight. In the procedure to land, the co-pilot radioed for instructions. He was advised to maintain altitude to the outer marker and then descend to 7,000 feet. The flight engineer began the approach descent procedure and reported the first six items on the check list were complete. The tower called United 820 and said, "Cleared to land, runway 126." The check list continued: landing gross weight — 175 M; threshold speed — 121; ejectors — extended; seat belt light — on; anti-skid — armed. The captain called for a weather report and found the ceiling to be 350 feet.

The flight engineer abruptly reported a flame-out in No. one engine. The crew attempted a normal, in-flight re-start while continuing the approach. The engine failed to start. The crew positioned the fuel shut-off lever to "off" and continued the approach to land. The tower was advised of the engine flame-out with a request for standby equipment.

On passing the inner marker at 500 feet altitude, scud clouds rolled over the field blacking out the runway, and the captain elected to go around. The tower was advised and United 820 was re-sequenced to the outer marker for a second ILS approach. On turning inbound at the outer marker, the fire warning light came on, with the alarm indicating an engine fire in the No. two (left inbound) engine.

The captain pushed the master fire warning light to "reset." The crew checked the No. two engine instruments, noting a high exhaust gas temperature. The captain pulled the fire shut-off lever full forward and positioned the fuel shut-off lever to "off." He asked the co-pilot to pull the fire agent discharge handle and check for low pressure indicating light "on." The co-pilot reported fire agent discharge. The captain requested the crew to complete the engine fire control procedure.

The flight engineer moved the generator drive disconnect lever to "disengage" position and positioned the No. two hydraulic pump to "by-pass," and checked the No. three pump to "on." By this time the fire light was out on No. two and the co-pilot

advised the captain, "Fire light is out." The captain requested the co-pilot to advise the tower of the condition and ask for emergency equipment to stand by. He also requested a precision radar assist.

The flight continued down the glide slope, crossing the inner marker, with continuous advice from ground radar. The plane settled in a normal landing without incident.

The above description shows how the flight simulator and the flight check serve to maintain the emergency skills developed in thousands of hours of flying. These procedures are an intimate part of how the aviation industry carries out its efficiency and skill maintenance programs. The air line may carry passengers with full confidence that skills to meet the occasion of need are "built in" each one of the flight personnel.

Suggested emergency training — Some steps in emergency training can be taken now. These are steps that most driver training instructors know or could work out for themselves.

1. **The soft fire.** It is easy enough to set up a simple situation in which one of the tires either on the front or the rear of the vehicle has 10 pounds of air in it and allow the driver to travel at low speeds to get the feel of the situation. Obviously, much driving of this sort is going to damage the tire, so a special one should be used for the purpose and watched carefully for evidence of failure.

2. **Brake pedal loss.** Under some conditions the brake pedal shows a sign of a slow brake loss. You have experienced a mushy and spongy pedal where you have low fluid in the system or a leak in a wheel cylinder. This happens also when the adjustment of brakes is not up to standard. One of the important things here is to teach the person how to recognize that the feel of the pedal itself is not right. This is not to suggest that the person should be asked to operate a vehicle with defective brakes. The point is to teach him how to recognize, by applying pressure to the brake-pedal, that something is wrong with the braking system.

It is recommended that the person be taught how to stop the vehicle with the use of the hand brake. Under conditions of

massive brake failure which occurs while the vehicle is in motion, the possibility of stopping is dependent upon the hand brake and upon having a clear area ahead. The hand brake is certainly going to operate at something less than half braking efficiency in many conditions. If the hand braking system is not in good condition, then the driver is in terrible trouble. To think of the hand brake as a way out requires much practice. To teach the driver from the beginning how to use the hand brake as a means of stopping the vehicle is to provide him with a skill which is extremely important.

3. **Ignition loss.** On some occasions the operator of a vehicle will lose the ignition while in transit. This can be simulated very easily. While the student is driving in a normal fashion, the instructor can shut off the ignition switch. The task for the driver would be to determine that this had happened and to leave the travelled part of the roadway as quickly as possible in order to avoid obstructing traffic, and exposing himself to collision.

4. **Protecting the scene.** Protecting the scene of an accident means giving warning to vehicle operators coming in both directions that there is trouble in the road ahead and that it should be approached with extreme care. Staking out the vehicle with flares, fuses, flashers or flags is required. Distance from the vehicle must take speed into account. The standards of the Interstate Commerce Commission for vehicles transporting cargo and passengers across state lines would appear to be basic standards for the teaching program. Protecting the scene has to do both with an accident and with the condition of vehicle failure.

5. **Sign reading.** Sign reading is a far more important matter for many circumstances than is generally realized. A great deal has been done on legibility, and on minimizing the language and the number of ideas presented to the driver at one time. The traffic engineering profession has contributed a lot to these matters. The accomplishments are occasionally completely lost when a piece of roadway is either in construction or in reconstruction. Temporary signs, signals and markers are put out. Learning how to interpret these changes and how to make sensible judgments

based upon them is a very important matter to the driver.

6. **Inspecting the vehicle.** One of the most important basic areas in which sound and practical training can be given is on procedures for inspecting the vehicle.

In the highway field we assume that human failure is the nearly complete problem and we do not look at the rest of the situation. Our published reports in this field are accurate insofar as data are reported, but they are completely inadequate because systematic investigation of the vehicle is not carried out by any public agency in any state automobile accidents. Therefore, it is extremely important in principle to teach students how to look at each component in the steering system and test it for adequacy. Students should learn where the weak parts are, where connecting mechanisms that can become loosened or disconnected are located, which parts are fragile in design and subject to failure. Tires are extremely important. Each component in the exhaust system, from the manifold all the way to the end of the tailpipe, needs to be inspected regularly.

7. **Deceleration protection.** We have estimated in our cases at the Harvard Medical School that a large number of persons who are killed are on the receiving end of missiles which go out of control and cross into the driver's path.

In one of our recent cases three persons were travelling northbound on a four-lane divided highway. They were all sitting in the front seat. Without warning the vehicle went out of control, crossed the median, and then entered the southbound lanes. The driver of a heavy vehicle going in the opposite direction observed the vehicle while it was in the median and realized that it was coming into the lane. The driver hit his brake and left skid marks for a very short distance, while making a very slight turning movement of avoidance. His reactions appeared to be excellent under these conditions. He was on a collision course beyond a point of no return before he knew that anything was going wrong. In spite of all that he did, there was no possibility of avoidance.

None of the persons killed in this accident were using seat belts. When other drivers go out of control, or other vehicles fail

while in motion, whoever is in the immediate vicinity is in extreme danger. In such cases, the only help possible is that given by deceleration protection. The term deceleration protection here is intended to mean door locks that resist opening, padded foam on the visors, padded foam on the dashboard, a recessed-post type steering wheel and seat belts for each separate occupant in the vehicle. This is a minimum.

Research—Some of the types of emergency training that could be suggested cannot be readily carried from the stage of concept to the stage of teaching activity. Some of these items require detailed operations research. Some of them require engineering design work to devise and manufacture devices to help. The following list is presented, without attempting detailed description at this time, to indicate some of the teaching procedures which should be available in the future. They are:

1. **The panic stop.** This has been mentioned before. You might easily argue that this term should have been in the first list. While this is a defensible position, it is also true that under some panic-stop conditions, secondary emergency problems arise. Until these have been worked out, the panic stop should not be added to the teaching routine.

2. **Sudden brake loss or sudden brake failure.** At Harvard we see the circumstance of having lacerated brake hoses or disconnected lines. We see the results of the vibration of the metallic line against another metallic structure so that the fluid leaks out. Without any prior warning the car is without brakes. Controls are limited. We do not yet know how serious this problem is, statistically.

3. **Sudden power steering loss.** This refers to the type of thing that happens when you are going along in a perfectly orderly fashion, and the power steering fails and you don't know it. You start to steer and during that first moment your hands simply slip across the steering wheel. You have to recover, move back again, grip the steering and then start a recovery movement with added strength. It is during this critical period of finding the failure and developing the strength to override the power steering mechanism that jeopardy occurs.

4. **Returning to shoulder.** In many parts

of the country we have shoulders along the highway made of sand or soil or stone. The shoulder surface may be two inches or three inches below that of the pavement. When the new driver runs over the edge of this, he may have a great deal of difficulty in getting back. Teaching him how to do this without running the risk of putting the vehicle out of control is important. One possible means is to decelerate without braking, and gain the roadway at low speed.

5. **Explosive decompression.** Explosive decompression in a tire is a term used in preference to the term blowouts, in an attempt to indicate the extreme rapidity with which the air loss is accomplished. We have demonstrated in our clinical work that to put your foot on the brake for a massive deceleration under the conditions of a blow-out is asking for death, because whatever steering problem you have as a result of the tire failure will be magnified many times by the hard application of the brakes. Procedures for managing the deceleration and the steering control need to be worked out experimentally.

6. **Vehicle control.** What should the passenger do when the driver of his vehicle obviously loses control? We have one case in which the passenger was obviously trying to give aid. The vehicle continued out of control and hit a tree and the passenger was killed. What his action should be under conditions of fainting, seizure or sleep is a complete unknown.

7. **Skidding.** The vehicle which goes into a skid is in a serious situation. Sometimes a person can go into a controlled skid and avoid some other type of problem by its use. This takes a degree of skill which is beyond the range of most of us. What about the ordinary situation when you lose traction on a wet road? Or when you think you can stop on ice or snow and you find you can't, what do you do? These procedures are being tackled by the Committee on Winter Driving Hazards of the National Safety Council and very soon they will have some recommendations to make. One of the important things here, of course, is careful evaluation of the type of equipment in use on the vehicle respecting winter driving hazards.

8. **Misfires.** What about the situation in which the other driver shows signs of being on the collision course, but you don't know

what to do about it? Assume that he is intoxicated or asleep. Procedures need to be worked out to adequately handle this matter.

The idea of clicking your lights up and down could hardly be more foolish. If a driver has gone to sleep at the wheel with his own car all around him and his own engine and headlights going, it is almost certain that your headlights are not going to wake him up. It is suggested that the horn be used in an attempt to wake him up. In the meantime, pulling over to your own side of the road protects your liability interests. Other work on this problem needs to be done.

9. **Pedestrians.** A short time ago a newspaper writer phoned and asked my opinion about the appropriate action of a driver when a dog runs into the street in front of him. His question included the comment that he had checked with the local safety council. The advice given was that they did not recommend that the driver make any attempt to avoid the dog.

Reaction to this was very simple. This is a useful training ground. We have an important pedestrian death problem in this country. Nearly 8,000 pedestrians are killed by automobiles in the course of the year. When a dog runs into the street, you have an opportunity to use the situation as a training ground for avoiding the pedestrian. The actions of the dog and the pedestrian are probably equally unpredictable, and this gives you a chance to develop emergency skills. If you can avoid the dog, you can also very probably avoid the child.

This statement of principle is not a solution to the problem of how a driver should behave with respect to pedestrian deceleration, but until experimental work is accomplished to set up the means by which the pedestrian avoidance procedure can be established, this philosophy is certainly a useful one. At the present time we don't even use a horn to warn a pedestrian of a collision course. The principles of protection applied for occupants ought to be extended to design work for pedestrian protection also.

Problems of emergency training.—There are several problem areas which need to be looked at rather carefully in looking forward to adding emergency training to the driver education procedure. It is not necessary to go into great detail on these, but some of them are of basic concern.

The first of these is to justify the research which is necessary to develop the training procedures and to devise the engineering devices. There will be some who will find no possible justification for a training procedure which may have an element of danger in it.

We get in the habit of "jay walking" in the point that the very success of this activity leads us to believe there is no danger in it. We drive automobiles under all kinds of conditions, including the most severe weather, with hardly a thought that anything will go wrong which will lead us to injury. The traffic casualty statistics are accumulating at such a rate that the probability of involvements of any of us gets greater and greater as time goes along, as traffic density increases and the number of miles traveled increases.

It behooves us, then, to look into the areas where we know unsolved problems exist and to take firm and intelligent and thoughtful steps in order to manage these circumstances. We cannot prove how many persons die due to blowout conditions. We can document that existing emergency procedures in other areas find their extreme problems amenable to both engineering and educational methods. It behooves us to take the steps necessary to add these methods to the highway safety field.

Research in this field is a fundamental necessity. Research which is basic in an attempt to describe the variables, to properly develop training procedures, and to create sound engineering devices to support safe training. Research must be carried to such a point that we will achieve an almost fool-proof system of training in each of the several areas where emergency training procedures are justified. No amount of effort and money should be spared to successfully accomplish this degree of perfection.

When these several matters have been settled by appropriate research, there are other problems which need to be taken into account.

What should be the level of skill development reached by the student at the time he begins to learn an emergency skill? This requires special study. It is a special instance of learning readiness.

What are the physiological responses to stress which are well known to occur under

other circumstances that will become involved in this type of training? What happens to the adrenals and to the autonomic nervous system? What is the shift in the general adaptation syndrome in the human body? What is the effect of these observed physiological changes in a student who possesses a given disease or pathology? These are matters which need to be explored under experimental conditions with sound medical scientists carrying out the studies.

What can be done to devise an automobile to be used for this type of training? The dual-control cars which are presently in use all over the country have served well for the circumstances for which they were designed. For the type of training which is being described here, complete duplicate controls will be necessary in order to guarantee that the safety of the occupants during the training period will be assured. The engineering genius of the automobile industry can certainly accomplish this objective in line with their long-standing policy of giving sound support to the driver education field.

In many educational jurisdictions, there are existing policy decisions on record indicating that the student cannot under any conditions be placed in a situation of danger while in driver education. We may be quibbling with a language problem to raise this one, but it may be a very real problem. Whatever steps are taken to accomplish emergency training, it is important that all interested parties participate in the developments from the very beginning so that the accumulated experience of public officials in every field can be utilized to accomplish a sound training program. School board personnel should be participants in the development of the program.

What legal requirements should there be for instructors who take on the tasks that we are suggesting? Should they have first aid training? Should they have special indoctrination concerning the mechanics of vehicles? Should they have teacher training preparation with an appropriate stamp of approval by the State Department of Education? Should they have some additional qualification as certified by the department concerned with driver licenses? These several matters must be taken into account so that problems which might arise in the application of the materials can be handled in advance.

What emotional problems develop in the circumstance of training that can be detrimental to the health of the student or detrimental to his safety in the condition of the emergency training? Preoccupation, lapses which come by virtue of illusions, fascination and marked degrees of imagination concerning the lessons must be considered. What of the emotional responses which lead to nausea and vomiting? What is the effect of the training on his sleep? Does unsuccessful activity deleteriously affect what happens in classroom studies in other areas?

These many matters need to be looked at one at a time and very carefully. The road set is one which requires exhaustive preparation and very fundamental research activity.

1. It is the argument of this paper that a policy decision should be made in each of the several jurisdictions concerning it that emergency training in automobile safety is a step which we should take.

2. All interested parties should sit in conference and explore the many steps to be taken for a sound program for developing emergency training areas, training techniques, training materials and engineering devices, and teaching personnel.

3. Steps should be taken to obtain enabling legislation or administrative decisions, where it can be done by decree, to give support to the development of emergency training for highways.

4. The emergency training programs which are developed should be subjected to exhaustive testing prior to use. Experimental comparisons should also be carried out to assess the value of the training under controlled conditions.

This author recommended several years ago that successful completion of an authorized driver education course be required before the license examination for an original license to drive. This does not mean the first license in California, then the first license in Nevada. This means the first license to drive an automobile. Three states have adopted some such provision in the meantime and some others are considering it presently. It is necessary to repeat this recommendation and urge its adoption. We know that the procedure is a sound one and that it contributes significantly to the long-

run successful operation of the vehicle by the student.

Consider along with this some other recommendations which you will agree are very radical. These are not offered individually but should be appraised as a group—which, in fact, cannot be accomplished at the moment. The original license to drive for any driver should carry a restriction permitting the person to drive a vehicle for a period of one year, but at no time with any passengers aboard. During this period he could carry with him an instructor, and the instructor would aid him in the preparation for a re-examination which would follow.

It is not possible to give a complete statistical support for the no-passenger restriction at this time. However, the National Safety Council has provided data, from 13 states in 1957 and 10 states in 1958, which indicate that for each of these years the accident problem for the persons with less than one year of experience is approximately as follows: accidents 16,945; deaths 163. Projecting this to the entire country, it suggests 270,000 accidents, of which 10 per cent would involve personal injury, and 300-1,000 would result in death.

The other justification is that it is a very personal matter to sacrifice one's life when a fire has no traction and the vehicle skids. No state is free of this problem, nor is any vehicle. Is it really morally right that a person should be given a license which exposes him to death by skidding, without ever having had the first word of teaching and demonstration of how to stay alive by regaining control? It is expected and assumed and should be provided that an instructor who is qualified could be aboard for purposes of teaching at any time.

If tabulations were made of the number of rollover deaths, pedestrian deaths, one-car accidents and fixed-object collisions, both fatal and nonfatal, occurring to people during the first year of being licensed, considerable data could be amassed to indicate that with inexperience comes hazard. We have seen in our studies several instances of deaths occurring in and by an automobile before the driver's license is a year old. We have seen one particular tragic instance of a death when a driver's license was one hour old. It is particularly important that this type of problem be avoided.

The next recommendation is that a re-examination be given at some time appropriate in terms of experience and accomplishment in training. The driver would be required to demonstrate his skill at managing a car under certain emergency conditions before the no-passenger restriction was removed from his driver's license. Anyone allowed to continue with a license for a second year would at least have to demonstrate the skill in avoidance of pedestrians.

Summary

In the foregoing materials, an attempt has been made to describe the concept of emergency training as applied to any circumstance in which emergencies are a normal by-product of man-machine relationships. The psychology of emergency training has also been described. A number of examples have been given in which emergency training has been carried out in other fields with strong evidence of success.

Examples of emergency training deemed necessary in the driver education field have been given. Some problems concerning their development and application have been indicated and some recommendations made for application of these materials when the appropriate educational and engineering researches have been completed. It is sincerely hoped that policy decisions favorable to the development of emergency training for automobiles will be carried out with all haste, and with all soundness.

THE DRIVER EDUCATION TEACHER AND TEACHING MACHINES

By CHARLES H. HARTMAN

Assistant Prof., Safety Education, Illinois State Normal University, Normal, Ill.

Within the past several years there has been considerable attention given to discussions centering about what are commonly known as teaching machines. In fact, the previous school year has been described in some quarters as the year when these various teaching machines moved out of the psychological laboratories and into classrooms en masse.

Although a great deal has been said and written on this topic it would appear that there exists both among professional and lay groups a somewhat vague notion of (1) what constitutes a teaching machine, and (2) what such devices can and can not contribute to the development of a quality instructional program.

In this brief presentation an attempt will be made to clarify certain aspects pertaining to teaching machines. Recommendations for the consideration and possible use of these devices in the teaching of driver education will form a second part of the presentation.

First it seems essential to clarify what is meant by a teaching machine. Although it is only within recent years that we have heard so much about "teaching machines," viewed in the broadest sense teachers have had available and have used all sorts of machines in their teaching for many years. A film projector or tape recorder would represent but two examples of this type of machine.

In some quarters, the charts, projects, models and other instructional aids which many of us find opportunity to use in our classes on a nearly everyday basis—both the commercially manufactured models and the models and projects prepared by students and teachers—these instructional aids are also known as teaching machines.

If I may inject a personal reference that is pertinent, it can be reported that earlier this year it was my good fortune to have a brief article published in *Safety Education* which described the preparation and

utilization of a variety of teaching aids, models, and projects prepared by students enrolled in the teacher preparation program in driver and safety education at Illinois State Normal University. Grateful as I am for the publication of the article and convinced as I am of the value of engaging high school and college students in project and survey work such as that described in the article, I cannot refrain from taking exception to the title which was somehow given this article as it went to press. The title appearing with this article was "They Make Their Own Teaching Machines." Unless the broadest possible latitude is allowed, the aids described in the article cannot be considered to be "teaching machines" and the title, therefore, is a misnomer.

Lawrence M. Stolorow defines a teaching machine in his monograph, *Teaching by Machine*, as "a mechanism that presents information to a student and controls his behavior in a predetermined interacting relationship." Interested persons are referred to Stolorow's publication which has been useful in the preparation of this presentation.

Under this definition neither the projects and aids described above, nor "machines" such as the film projector and tape recorder can be properly classified as teaching machines. Driver education teachers may be prone to regard the several simulated devices available in this field (e.g., the Aema Drivotrainer) as teaching machines, particularly since these devices are so machine-like in appearance. Depending upon how such devices are actually used and depending upon how strictly or loosely one interprets the definition of teaching machines, these simulator devices may or may not be properly regarded to be within this category. Under a strict interpretation of the definition it is likely that they would not be considered to be teaching machines.

Perhaps this tendency to lump into the teaching machine category such a wide

variety of instructional aids, might be minimized if the synonymous term auto-instructional device were more commonly employed.

Central to the discussion to use any auto-instructional device is the problem of whether such a device is to be used at the sole source of instruction or as one factor in a total instructional effort. There are research findings available that indicate the effectiveness of each of these procedures in particular circumstances. It would seem that the nature of the skill, knowledge, and attitudinal factors involved in the teaching of driver education suggests that if the use of auto-instructional devices in this field is to be attempted, utilization might well take the form of one factor in a total instructional effort rather than the sole source of instruction. This is, of course, a supposition that the one procedure would be more effective than the other, and can be borne out only through adequate research.

Excluding the possibility that some of the several simulated devices commonly associated with driving instruction are actually auto-instructional devices, it can be said without much fear of contradiction that there has been no great rush to design and use auto-instructional devices in the teaching of driver education. If any such programs have been designed and used there has been a paucity of information made available concerning this innovation.

Are not we as driver educators as seriously in need of the development, testing, and utilization of effective auto-instructional devices as are our colleagues in other fields? Many of us feel the pressures of an all-too-short thirty clock-hours of instruction in the classroom phase and six clock hours of instruction behind-the-wheel forcing us to provide less than a truly complete and comprehensive course. Some of us are facing classroom sessions that grow larger and larger with each passing year. Many of us are constantly forced to justify the relatively high instructional costs of driver education programs. All of us as driver educators, convinced of the value of high school driver education, are seeking support for plans that will make driver education available to all eligible students. Do not these factors, as well as others, combine to form a convincing need to seek

an ever-increasing efficiency and effectiveness for the total driver education program?

If the answers to these questions are in the affirmative it behooves us to initiate actions which will lead us toward a greater understanding of the possible use we might make of auto-instructional devices in driver education. This is not to suggest that we in driver education "jump on the bandwagon" with regard to auto-instructional devices. There is probably little room left on the bandwagon anyhow as it appears that so many have already made their jump.

For this we need have no regrets for despite the attention given auto-instructional devices during the past few years the research reported thus far seems more provocative than definitive, more argumentative than conclusive. Until some important questions can be answered it would seem advisable to use auto-instructional devices in an experimental framework rather than in routine instructional situations. We should not, however, sit back and let the other fellow do it. Consideration and study of the potential uses of these devices in driver education is worthy of our attention at this time.

It is not necessary to promote the idea that we should give time and attention to a study of these devices as they might relate to driver education. Consciously or subconsciously many teachers fear these "machines;" they view these mechanized models as supplanters of the teacher. Those holding to this view will need to be persuaded that their view runs contrary to the facts. Auto-instructional devices are not devices which will eliminate the teacher; rather they are a means of emancipation for the teacher for they can free him from the more routine aspects of his work and thereby give him more time for thoughtful planning of instructional programs, and for gaining more knowledge about his subject and his students.

In summary it should be reiterated that auto-instructional devices or "teaching machines" do not embrace as many instructional aids and classroom "machines" as is perhaps supposed. Further, driver education teachers need to initiate actions which will lead to a competent consideration and study of the possible uses of auto-instructional devices in driver education. This needs to

be done both for enrollment and cost considerations, and for the more important reason that such consideration and study could lead to an increased effectiveness in

the teaching of driver education. Finally, the time to initiate such actions is this year, not next; the persons to initiate it are "we," not "they."

INCENTIVE AND YARDSTICK — NATIONAL COLLEGE AND UNIVERSITY SAFETY AWARDS

By LOWELL L. CARVER

Professor, Industrial Education, Iowa State University, Ames, Iowa

Although the campus safety group of the National Safety Council has been in existence only since 1949, it has always recognized the need for an evaluation and award program which would both give recognition to those colleges and universities which are taking measures to reduce campus accidents, and at the same time would serve as a stimulant to higher education institutions to initiate or strengthen such programs.

When the campus safety committee became a formal part of the school and college conference structure in 1957, as part of the higher education section, it appointed a committee on recognition of campus safety programs to study and recommend for adoption a standard recognition program similar in intent and scope to the honor roll program.

After considerable research, experimenting, consulting and try-out the committee, with the assistance of Daniel Webster, men in the field and National Safety Council personnel, a proposed plan for citation of colleges and universities has been developed. In accordance with the general policy of the National Safety Council, the school and college conference has established a recognition program for outstanding achievements of colleges and universities in safety.

The four levels of awards provided are: Award of Honor, Award of Merit, Certificate of Commendation, and President's Letter.

The awards will be determined by using an evaluation check-list developed by the committee, containing 58 items, each item has an assigned maximum numerical value, varying in weight from two to three, and totaling 150 points.

The awards are noncompetitive and are conferred on colleges and universities achieving a level of accomplishment as established by the awards committee of the higher education section and approved by the school and college conference. Any college in the United States or Canada is eligible if it is a member of the National Safety Council and if it is an accredited higher education institution.

Two committees will be appointed to function in the program.

The awards committee will consist of five members appointed by the school and college conference (submitted by the section) from the field of education and local safety councils. This committee will determine policies and procedures in the program.

The judges committee will consist of five members, likewise appointed by the school and college conference, from industry, a national organization, a state department of education, the NSC board of directors, and the school and college conference. The latter two members may be the vice president for schools and colleges, and the chairman of the school and college conference. The function of this committee will be to review the entries in the program, checking tabulations of scores, and participate to such extent as they can in award presentations.

Other program details are too numerous to mention at this time and will be subject to some variance from one higher education institution to another; however, reasonable uniformity of achievement is assured through meeting the standards set for each award level by the awards committee. At the same time the selection of those col-

leges and universities which receive recognition, as compared with those which do not, provides a limited element of competition. This, in combination with the institution's desire to maintain or to improve its award level, constitutes a challenge or incentive to make programs worthy of recognition.

Program Objectives

1. To improve the environment and related factors of the college campus in reducing accidental injuries to students, faculty and staff members, and the public using the facilities.

2. To promote the sponsorship and conduct of safety research by higher education institutions for application in all phases of human endeavor.

3. To improve and expand the teaching of safety in regular courses of instruction and through special courses for the preparation of safety educators and specialists.

4. To assist in determining those desirable standards for a college in achieving a well-balanced safety program.

5. To give recognition to colleges and universities in educational effectiveness for greater safety.

Evaluation of Achievement

The following criteria are offered to guide colleges and universities in planning and evaluating their safety efforts. They also serve as the main headings for the evaluation check list.

1. Administrative leadership, including responsibility and authority for the conduct of a coordinated program and its implementation.

2. Safety organization, including the designation of a qualified person to coordinate and direct the program; safety committees, boards, and councils.

3. Standardized procedures for reporting all injuries incurred in college-jurisdiction accidents; periodic analyses and summarization of accident causation and related factors.

4. Placement and training of new faculty, staff members, and students, including orientation, physical examination, and in-service training programs.

5. Provision of a safe environment for living, working, and for recreation through

a system of inspections, adherence to legal and recommended standards, and the elimination of physical hazards.

6. An emergency and disaster-preparedness program to control and reduce the possibility of death and injury in the event of accidents, or other incidents with disaster potentials.

7. Promotion of interest in safety through recognized promotional media and educational publications.

8. A continuing program of research and safety education for staff members and students, and the provision of special safety education courses for students preparing to become safety educators or safety specialists.

Many times we have heard the statement, "that unless top management is sold on safety it will be difficult to carry out an effective program." This is just as important in an educational institution as it is in industry. It is essential that a written policy be prepared by the top administration of a given college or university indicating interest in and support of a safety program. It is further important that the administration place responsibility and delegate authority for the prevention of accidents and that the policy of accident prevention and safety be known to staff members and students alike. Staff members and students should be invited to participate and contribute to the program.

It is highly desirable that the head of the college or university appoint a qualified person who will function in a staff capacity, and serve in a full-time or collateral role as safety coordinator, supervisor or other suitable title. This individual should have high interest in safety and time to spend on safety education and accident prevention.

His functions should include the preparation of a master plan of safety programming including unit safety organization, inspections, student and public accidents, fire prevention and control, safety promotion, preparation of rules and regulations, and encouragement of safety education and training. This individual should also endeavor to work with staff members and organizations within the college or university in attaining safety objectives. He should periodically keep the college or university administration advised concerning progress.

the student body. Yet these personnel, and college facilities, in total comprise one of America's greatest challenges to those who would destroy our democratic heritage and way of life.

Although the number of colleges which have activated balanced safety programs over recent years has shown a significant increase, the status of our accident-prevention efforts points up the need for redoubling our efforts if campus safety is to be a fundamental and respected function of administration. We must convey the idea that campus safety activities contribute to the abilities of colleges and universities to perform their stated missions, whether they be in the training of technical or professional workers, or in the preparation of teachers of our future generations. Campus safety is a means of conserving our human and material resources.

Possibly the lack of a "packaged" program, and inadequate communications, are responsible for the failure of many college administrators to recognize the important values of campus safety as an organized and continuing activity. Campus safety is not unique in its slow acceptance, for we have seen the same shortcoming in numerous aspects of college safety.

Records show, for example, that the first verified motor vehicle traffic fatality in the United States occurred in New York City in 1899. Yet it was not until 1923, just short of a quarter-century later, that driver education with behind-the-wheel instruction was first offered as a high school subject.¹ It was not until another 13 years had passed that any college accepted the fact that the automobile, and its attendant fatalities and casualties was here to stay, and that higher education institutions could contribute through the adequate preparation of teachers in this field.² It already was late—in the meantime over one-half million Americans had lost their lives from accidents involving the automobile, the greatest of all killers.³

No influence is intended that colleges have not been making any efforts to create cam-

pus which are safe for work and study, living, and recreation. Early information is fragmentary, but it is known that as early as 1915 the University of Illinois had a student group known as the "Life and Limb Club," devoted to the prevention of accidents in college shops.

It is also known that most of the initial college endeavors in practical safety, on an organized basis, were patterned after industrial safety programs, and as such were oriented to the safety of employees, and the engineering approach to accident prevention through environmental controls. Many of these broadened into programs which also considered the student body, and the activities carried on within the institution. The earliest of these, with full-time leadership, was probably that initiated by Lorin J. Elder at Pennsylvania State University (then Pennsylvania State College), in 1936.

If we were to compare staff and students in colleges with their counterparts in industry, we might imagine that at least half of our institutions of higher education now have organized safety programs. The logic of this belief might rest on the facts that industries of comparable sizes generally have well-defined safety programs, and since colleges have all the accident exposures normally encountered in industry—and many more in view of recreational and athletic, housing and food services, and research activities—they should be out in front in the promotion of safe practices. Unfortunately the Campus Safety Association has conjectured that this is not true, on the basis of its membership. It seems that although colleges virtually are communities in themselves and have all the attendant exposures to accidents found in most small cities, it has not been until some catastrophe has occurred, or there has been an awakening to the extent of the accident problem through liability suits or insurance claims, that administrators have become aware of the problem.

Aside from difficulty in understanding this lack of college effort in accident prevention, when viewed in terms of billions of dollars invested in installations and facilities, irreplaceable faculty members, potential of research efforts, and the worth of students to the future of the nation, the question has been raised, "Is campus safety a form of education in itself?" Do students ac-

quire safety knowledge, attitudes and skills from their observations of the campus and the examples of safe practices set by staff and faculty members? Industry feels that they do, and as in the case of the chemical industries, sometimes wonder why colleges don't do a better job in preparing students for productive roles as technicians or professional workers. Fortunately, the educational values of effective campus safety programs are being given increasing emphasis.

The organizational status of campus safety programs, and the duties of assigned personnel, has been largely a matter of conjecture. Questions have been raised as to the most appropriate place in the administrative structure for safety coordination and stimulation. In some instances, concern for individual prestige or security has been expressed. We have found ourselves stumbling over questions such as, "Is health a part of safety, or is safety a part of health?"

Some insight into the extent and nature of campus safety programs may be derived from a survey conducted in the spring, 1961 for the National Safety Council's Campus Safety Association.

At that time a simple questionnaire was mailed to each of approximately 1,970 colleges and universities in the continental United States. Admittedly, the instrument was not designed to give a comprehensive picture of campus safety programs; rather, through check and completion items, to elicit as complete a response as possible.

The purposes of the survey were to determine:

—if patterns of safety organization exist for institutions of various size.

—where responsibility for safety programming most frequently is placed.

—accident-prevention and other activities of assigned safety personnel.

Information was sought in regard to eight items:

1. Identification of the college or university.

2. 1960-1961 enrollment.

3. Person responsible for coordination and direction of college-wide safety program.

4. Percentage of time he devotes to practical problems of campus safety.

5. His major accident-prevention activities in sequence of time spent.

6. His major activities other than accident prevention.

7. Existence of safety committee or counterpart for recommending of policy and program.

8. Consideration for employment of full-time safety personnel, if such are not presently employed.

A total of 190 questionnaires were returned, representing 90 per cent of all colleges and universities. The number of students which these colleges enrolled, 885,066, however, represented 24.5 per cent of the total enrollment of all colleges for the 1960-1961 academic year.⁴

In treating the data, it was recognized that the varying sizes of institutions could be expected to influence the extent and nature of campus safety programs, and the time spent in different activities. For example, it was assumed that many of the smaller institutions might assign safety coordination duties on a collateral basis with other duties. For this reason, the 190 questionnaires returned were tabulated by four enrollment groups, as well as for all colleges as a whole.

1. Enrollment for the 1960-1961 academic year for 1,970 colleges of degree-credit students was estimated at 3,879,611 by the Office of Education, United States Department of Health, Education and Welfare.

TABLE I
Respondents According to Numbers and Sizes of Institutions

	Under 1,000	1,000 to 5,000	5,000 to 10,000	Over 10,000	Total
Total Colleges	1,842	587	109	71	1,970
Respondents	43	77	38	23	190
Per cent Responded	2.3	13.0	35.0	32.0	3.6
Enrollment	32,481	171,245	195,800	465,800	885,066
Average Enrollment ...	594	2,922	1,900	21,100	

1. Gilbert, Minnesota.
2. Pennsylvania State College, 1936.
3. Estimated at \$14,870 from National Safety Council figures.

Safety Titles

"Safety" or an equivalent term was used in the title of the person designated to head the accident-prevention program at 40, or 22 per cent, of the responding colleges. Assignment of the responsibility to a designated individual was indicated by 149, or 78 per cent, of the reporting institutions.

Place in Organization

Of the 190 reporting institutions, 149, or 78 per cent, indicated that responsibility for the safety program had been delegated to one individual. Departments in which these coordinators or directors most frequently were assigned were buildings and grounds and central administration.

Administrative Supervision

At more than a third (38 per cent) of the colleges which indicated a delegated responsibility for the program, the designated person reported to the president. Others frequently reported to a dean or director in central administration or to the business manager.

TABLE II		Place in Organization and Administrative Supervision	
Place in Organization		Administrative Supervision	
Buildings and Grounds	37	President	52
Central Administration	34	Dean, Dir. Central Admin.	22

Academic Dept.	14	Vice Pres. Administration	7
Health Service	1	Head, Academic Dept.	6
Residence Halls	1	Dir. Health Service	5
Total	149	Total	136

Time Spent in Accident Prevention

At those colleges where the safety responsibility had been assigned for coordination by one individual, time spent in safety work was usually less than 10 per cent. Of the 141 responses, 88, or 60 per cent, of the individuals indicated less than 10 per cent spent on safety; 18 spent 11 to 20 per cent of their time, and eighteen spent up to 60 per cent of time on accident prevention. Seventeen of the respondents indicated full-time, or equivalent, was devoted to the campus safety program.

Safety Activities

The activities in safety in which assigned personnel were involved, and the time spent in various safety duties, showed a close correlation. Most frequently men-

TABLE III	
Time Spent on Safety Activities	
Per cent of Times	Number
1-10	88
11-20	18

tioned were inspections, fire prevention and protection, accident reporting, maintenance of buildings and grounds, and organization and administration.

Other Duties

The most complete answers to this question were provided by the larger institutions, where it appeared that safety duties were augmented by activities in security and protection, maintenance of facilities, instruction including safety and driver education.

TABLE IV		Safety Activities by Frequency and Time Spent	
Frequency		Time Spent

Safety Committees

Over half, 98, of the reporting colleges indicated the existence of safety committees, colleges without committees numbered 7, and 15 of the 190 institutions failed to answer the question. There was apparently a relationship between size of institution and the organization of a safety committee.

TABLE VI		Safety Committees by Size of College

Without Committees	37	47	8	5	77
Not Indicated	6	5	2	2	15

Of the 18 colleges employing full-time safety personnel, 16 had safety committees.

Employment Plans

Of the 169 responses to this question, 129 colleges indicated no immediate plans for the appointment of full-time safety personnel. Seventeen colleges stated that one or more full-time persons already were employed, and in 23 institutions there are plans for such appointments.

TABLE VII		Employment of Full-Time Safety Personnel			
		Under 1,000	1,000-5,000	5,000-10,000	Over 10,000

No Immediate Plans	86	64	14	5	128
Not Indicated	4	2	4	4	21

Twenty-three colleges with enrollments ranging from 11,500 to 87,000 completed the survey form. Total enrollments for this

1. The enrollment figure of 87,000 was for the State University of New York, which has a centralized safety program for all its colleges.

group were 485,500 or an average of 21,100 per institution. These colleges represented 32 per cent of the total of 71 colleges in this enrollment range.

Safety Titles

Of the 23 reporting colleges, 15 had assigned coordinating or directing responsibilities to staff members whose official designation carried the term "safety" or equivalent in their titles. All of the colleges indicated that responsibility had been assigned to some individual.

Place in Organization

The department in which the coordinating or directing responsibility was most frequently placed was fire prevention, safety, and environmental health (10), central administration (4), buildings and grounds or physical plant (3). At two colleges each,

the program was conducted from the department of health, physical education and recreation; or an academic department. At two other institutions, the responsibility was placed in the housing office and the business office.

Administrative Supervision

Most frequently (7) the person to whom the supervisor or coordinator of the campus

safety program reported was a high officer of central administration, such as a vice president for business administration, central administration, comptroller. In three higher education institutions each, the director of health service, business manager, director of physical plant or buildings and grounds, was

the responsible administrator. Responsibility at 13 of the 23 institutions was to a member of central administration, to the head of a service or operations department at seven colleges, and to an academic department head at four institutions.

Safety Activities

Seventeen primary activities were listed on the questionnaire. The 23 respondents indicated a wide range of time spent in these activities in their routine operations.

Time Devoted to Safety and Accident Prevention

In this enrollment group of colleges, there was a significant difference in the amount of time spent in accident-prevention activities. At nine institutions, the person assigned responsibility for coordinating the safety program spent full-time in this capacity. At the other extreme, seven colleges indicated that the amount of time spent was between one and ten per cent. Nevertheless, average time spent was about fifty per cent. Considering safety-related duties of security, radiation protection, and environmental health, fifteen institutions have staff spending virtually full time in health and safety activities.

Irrespective of time spent, accident reporting and inspections were the most frequently checked responsibilities (21 each), followed by fire prevention and protection and employee safety (each 19). Although traffic control, fleet safety and parking, and radiological safety were less frequently indicated as a primary duty, notations on a number of reports pointed up that in these special areas other college personnel frequently were assigned these specific responsibilities.

In the table which follows, it will be noted that overall involvement of safety personnel in specific activities contrasts considerably with the amount of time spent in the activities.

Other Duties

Safety-related activities were most frequently reported as additional duties, such as teaching of safety and driver education; environmental health and sanitation, and security and protection, each reported four times. No added duties were reported three times, while other academic responsibilities and supervision of buildings and grounds activities each were reported twice. Insurance and retirement, and supervision of all non-academic personnel were each reported once.

Safety Committees

Even in those colleges with full-time safety personnel, the assistance of a safety committee as a means of implementing the program was found to be a common practice. Of the 23 colleges, 16 indicated they had safety committees; five stated that such committees were not in existence, and two failed to answer the question.

Employment Plans

Five of the 14 colleges presently without full-time safety personnel indicated plans to add such personnel for direction and coordination of the safety program. More

than half of the colleges with full-time safety personnel stated that more than one full-time person is assigned safety responsibilities, and that future plans provide for staff additions.

Of the 100 colleges with enrollment of 5,000 to 10,000 as listed by the U. S. Office of Education, responses were received from 28 colleges, or 28 per cent of the colleges of this size. The responding colleges represented a total enrollment of 195,800, and ranged between 3,000 and 9,000 students, with an average of 7,000 per institution.

Safety Titles

At 10 of the colleges, coordinating and directing responsibilities were assigned to a staff member with safety or its equivalent in his title.

Place in Organization

At all but five of the 23 colleges, the responsibility for campus safety had been assigned to a designated individual. The departments in which the responsibility was assigned, and the staff or faculty member providing administrative supervision, is shown in the following table.

Time Spent in Accident Prevention

In colleges of this size, the person designated the responsibility for safety coordination or direction tended either to spend very little time in these duties, or virtually all of his time. Time spent in accident prevention was indicated as one to ten per cent at 11 institutions, whereas 91 to 100 per cent of the responsible person's time was spent at five institutions. At the other seven colleges, one did not indicate time spent, and five estimated percentage of time in safety duties of 11 to 60 per cent. The average time spent on safety for the designated individuals was 40 per cent.

Safety Activities

Activities in which assigned safety personnel were involved, irrespective of time spent, were in order of frequency: program organization and administration, inspections, fire prevention and protection, and maintenance of buildings and grounds. The six activities most frequently mentioned on the basis of time spent were: organization and administration, fire prevention and protection, employee safety, maintenance of buildings and grounds, first aid and accident reporting.

Place in Organization

The question as to placement of responsibility for coordinating the safety program was left blank by two reporting colleges, and 19 institutions added comments that no person had been designated to carry out this responsibility. Where responsibility was indicated, most frequently it was placed in the business office or treasurer (13), office of dean of students (10), or physical plant (8).

Administrative Supervision

In 26 of the 38 replies to this question, the person who coordinated the safety effort was responsible to the president. Others included: dean of instruction (4), business manager and director of plant (each 3), and hospital director and director of health, physical education and recreation (each one). Replies were not given by the other colleges in this group.

Time Spent in Accident Prevention

Nineteen institutions did not answer this question. Of the 41 responses, 34 indicated that time spent on safety activities was less than 10 per cent; six stated that 11 to 20 per cent of the designated person's time was spent on accident prevention. At one institution the responsible person spent 21 to 30 per cent of his time in safety activities.

Safety Activities

Activities most frequently listed included student housing, fire prevention and protection, inspections, buildings and grounds and maintenance, accident reporting, student activities, traffic and parking, and activities related to physical education. By time devoted to various duties, these also were most frequently mentioned.

TABLE XV
Safety Activities by Frequency, and Time Spent

supplemented with time in safety related student enrollments presently employ full-time staff members for safety. Two colleges indicated plans for the future, while the majority (56) which replied to the question stated that no plans are being made.

Conclusions

1. Although it cannot be assumed that all of the 1780 colleges which did not return the questionnaire were without organized campus safety programs, it is likely that the lack of programs was related to failure to return the survey form in a great many cases.

2. The 149 institutions which indicated that they had organized programs demonstrated a significant increase over the seven colleges with programs which were represented in a meeting in Chicago in 1949 for the interchange of information in campus safety. The actual number of colleges with organized programs, or with full-time safety personnel is probably considerably greater than that indicated in the survey, on the basis of membership in the Campus Safety Association.¹

3. The greatest need for the activation of organized programs is in the smaller higher education institutions, which probably have as wide a variety of exposures to accidents as do large universities, but do not have budgets permitting them to employ safety specialists.

4. There is no single pattern of safety organization. However, the most common practice is to place safety as a staff responsibility in central administration. In particular, this practice was prevalent in smaller institutions, where buildings and grounds or physical plant departments were indicated as the second most frequent department. Many larger institutions placed the responsibility in a department of safety or equivalent.

5. Administrative supervision was vested directly under the college president, vice president, dean or other high administrative officer, at about two-thirds of the institutions.

6. Although time spent in safety activities by the person delegated or assigned

the responsibility for coordination was often activities such as security and environmental health, in the majority of reporting institutions this individual spent less than 20 per cent of his time in safety operations, usually less than ten per cent. At the large universities which reported, the full-time of one or more specialists was devoted to safety in most instances.

7. The most frequent safety activities in which assigned personnel for coordination were involved was fairly consistent for each group of colleges by size, and for all reporting colleges as a whole. All groups indicated primary activity in inspections and fire prevention and protection; three of the four groups indicated activity in accident reporting and buildings and grounds maintenance, and two in organization and administration. In contrast, institutions of over 10,000 enrollment showed employee safety as a primary function, and activities in housing safety were most frequently indicated in colleges of less than 100 enrollment. Provision of protective equipment, industrial hygiene, and radiological safety were the activities least mentioned for all colleges as a whole, and all groups except colleges with enrollments over 10,000, which showed least activity in traffic safety, radiological, and in athletics and physical education.

8. Although security and protection, buildings and grounds maintenance or supervision, and teaching of academic subjects were most frequently reported as supplementary duties for all colleges, no consistency was found among colleges of various sizes.

9. The use of safety committees is an accepted means of implementing the safety program, and in some colleges is the only coordinating and stimulating force. A number of colleges commented that committees could be useful but as presently organized were ineffective. A majority of larger colleges and universities with full-time safety personnel also make use of a safety committee structure.

10. The majority of colleges presently without full-time safety personnel stated that there were no immediate plans for such employment, or that the matter had not been considered. The number of colleges planning such personnel additions was greater than the number presently employing safety specialists full-time.

¹ Association members in October, 1961, numbered 875, and included representatives from about 200 colleges and universities.

Recommendations

1. Regardless of the size of a college, it is desirable that an organized program of accident prevention and safety education be developed as a means of conserving the resources of the institution, and making for maximum effectiveness and accomplishment in meeting its stated objective.

2. At each institution, a qualified and interested staff or faculty member should be designated to coordinate the safety program. Such appointment may be on a collateral basis in smaller colleges, however it seems desirable that colleges with enrollments over 5,000 appoint professional personnel on a full-time basis, or at smaller colleges with high accident potentials.

3. It is preferable that the safety coordination function be placed within central administration, reporting directly to the president or other high level administrator, as a means of stressing the importance given to the accident prevention effort, and for acceptance of the program by all operational and academic departments and staff members, as well as the student body.

4. It is not reasonable to expect that basic functions of inspections, fire prevention and protection, accident analysis, maintenance of facilities and the many other duties common to the safety coordinator can be performed in any degree of completeness if only 10 per cent of his time is allocated to the function. It is urged that colleges assess their total accident-prevention needs, and on this basis determine the activities in which the safety coordinator should be involved, and the amount of time essential to the adequate performance of these duties.

5. Safety committees are a desirable means of implementing individual efforts in accident prevention and making maximum use of the college resources. Safety committees, to be effective however, must be carefully selected, and should represent the major activities and facilities of the college at a high staff level. They must meet regularly and report findings and recommendations to the administrative head in an advisory capacity.

A MODEL BICYCLE CONTROL PROGRAM

By JOHN A. MEARS

Asst. Prof., Dept. of Police Administration, Indiana University, Bloomington, Ind.

As college enrollments increase on our college and university campuses, we are sometimes faced with a bicycle or motor scooter problem. Where the problem already exists, it will become intensified in the ensuing years. In some instances, it has apparently reached major proportions.

What are some of the typical problems? First, the increasing potential conflicts between pedestrians and vehicles and between the vehicles themselves. Second, controlling the routing of these vehicles. And third, the ever-present parking problem.

Recently, the bicycle and motor scooter problem on the University of Washington campus became of sufficient concern to Professor Ed O. Kanz, manager of the Safety Division, that he checked with other colleges and universities to compare notes only to discover that there was a dearth of fact-

ual data available on the subject. This venture led to a survey conducted by Kanz in co-operation with the Campus Safety Association to develop statistical data on the operation of bicycles and scooters on college campuses.

Based on the survey of Professor Kanz and Lee Sweum, traffic technician at the University of Washington, a model bicycle control program was set up. In their survey, questionnaires were sent to 75 colleges and universities in the Spring of 1961 to determine the extent to which bicycles and motor scooters were used on their campuses during the two academic years from 1958-1960. Forty-four replies were received, but only 34 were used in compiling the statistical data. Ten of the replies were not tabulated for various reasons.

Of the schools surveyed nine had enroll-

ments of less than 2000; 11, from two to ten thousand; and fourteen, more than ten thousand. It is worth noting that the total enrollment increased more than four per cent in one year. At the same time the number of bicycles per thousand students increased 11 per cent, and the number of motor scooters increased almost 50 per cent during the same period. However, no statistical trend in the ratio of the number of two-wheeled vehicles to the increase in college enrollment could be noted after all the data had been summarized. Kanz has suggested that more surveys of this nature be conducted to see whether a trend does evolve.

Even though the tabulated results of the survey indicated less than one per cent of the two-wheeled vehicles are involved in accidents, Kanz pointed out that the data did not give a complete picture of the problem. Some of the comments made on the questionnaires disclosed that records were not kept for bicycle and motor scooter accidents. Kanz also pointed out that minor accidents involving bicycles many times go unreported.

During the two years surveyed, 13 accidents were reported the first year with 15 for the second. Of these 28 accidents, 22 were classified as minor and six as disabling. Of these six, one was classified as permanently disabling. Other problems brought out by the survey were:

1. Inadequate parking facilities.
2. Lack of printed rules and regulations governing the use of bicycles and scooters. According to the survey only ten of the 34 schools contacted issued such rules, and of these ten, six issued them only for scooters.
3. Lack of bicycle registration. Only three schools required students to register their bicycles, but more than half of the schools required permits for motor scooters.
4. Inadequate enforcement procedures. More than two-thirds of the schools contacted had inadequate enforcement procedures to deal with bicycle operators.

What are the steps that must be taken to implement an effective bicycle control program on our college and university campuses? Let us assume first that a traffic

problem does exist. How can we work towards a solution to the problem? I should like to emphasize that there is no one way to organize a university community for the purpose of developing an effective bicycle control program. However, there are certain essential steps to be taken in all effective programs. These are:

1. Support of the administration
2. Appointment of a coordinator
3. Setting up an adequate accident records and reporting system
4. Establishment of legislation
5. Setting up a licensing program

I shall discuss these in this order. If any safety program is to be effective, it must first have the support of top management—in this case, the board of trustees and the president. Of course, you can have a safety program without their support, but I believe that general acceptance of the program will be somewhat passive without their support. It is their responsibility to provide a safe environment for the faculty, staff, students, other personnel, and those who use the facilities of the university community. This in itself is good public relations because the university will be helping to create a favorable attitude among its many publics by letting them know that it is interested in their general welfare. If the administration shows interest, then this interest will usually permeate the campus.

In our next step, the administration should delegate some individual to assume the responsibility of serving as coordinator for the program. His job would be to organize a safety committee made up of representatives from the faculty, staff, dean of faculties, dean of students, head of the safety division, medical officer, student government, fraternities, and superintendent of buildings and grounds. The coordinator, of course, would have access to the president's office and serve in a capacity.

In selecting the coordinator, the particular circumstances will help determine who would be the best man for the position. In some cases it might be a safety education teacher, whereas in other cases it might be the dean of students or head of the safety division. Since the main job of the coordinator will be to develop public support for the safety program, I cannot overemphasize the im-

importance of selecting the best man available for the task. Needless to say the coordinator should be able to work with people and have more than a passive interest in safety. If he should happen to have a good knowledge of sound safety practices, so much the better.

The president should attend the first meeting of the newly organized safety committee to lend support to the program. At this meeting the coordinator should outline the responsibilities of each member of the group and with their help develop plans for making a survey to determine the extent of the bicycle problem, that is, the extent of accidents and congestion. It goes without saying that we must have the facts to determine what needs to be done. When the survey is completed, the committee should discuss their findings, concentrating on the weakest spots first. For example, circumstances or conditions contributing to congestion, such as inadequate parking facilities, should receive major consideration.

Once the committee has determined the extent of the bicycle problem and has agreed upon priorities, its next step is to make its findings known and to explain its aims and planned procedures to the university community. This is one of the better methods to gain acceptance of the program, for if people do not know or understand what the program is, they certainly will not support it.

With the completion of its survey and publication of its findings, the next step the committee must take is setting up an adequate accident records and reporting system. In the replies that Kams received some of the respondents indicated that no records were kept of the two-wheeled vehicle operation. It is impossible without accident facts to plan an effective safety program, for the program will be based on guesswork or opinion. Past experience has indicated that there is a direct relationship between an effective accident prevention program and a good accident records system. The only way to obtain the information needed to formulate an effective program is to require the reporting of all personal injury and property damage accidents. Since this is not easy to accomplish, I should suggest therefore that reports be required in all property damage accidents in excess

of \$10.00.

After the facts have been compiled, they must be analyzed to determine the types and causes of the most frequently reported accidents and the time and location of such accidents. Data of this type will help the safety committee plan more effective programs. Establishing a centralized location for reporting accidents has also proved efficient. Accident reports should be filed by location to be readily available for analysis of accident causes at specific locations. For example, in planning your program you might want to know what the accident experience is at a given location. It would be a simple matter to remove all the reports from the file pertaining to a certain location to obtain a complete accident picture. The establishment of a driver record file would make possible a quick summary of the violation and accident experience of the individual driver. These summaries should be prepared periodically.

This leads us to our next step—the establishment of legislation. In establishing rules and regulations governing bicycle operation, it is essential that they do not conflict with the state law. Before the safety committee drafts any legislation, it should study the state statute governing bicycle operation and check with the local police department to determine whether the Model Traffic Ordinance has been adopted by the community. It is well recognized that non-uniform laws contribute to accidents, cause congestion, and inconvenience motorists and pedestrians. If the Model Traffic Ordinance is in effect, then appropriate sections of it should be adopted in drafting legislation governing the operation of bicycles on campus. (Section XII of the Ordinance is devoted to bicycle regulations.) Even though a community has an ordinance, the safety committee can still set up its own rules and regulations governing the operation of bicycles on campus. However, these regulations should not conflict with the local ordinance, if possible.

One of the most important phases of the safety program is licensing. If bicycle tests have already been developed by the local police department, then the college or university should take advantage of this service. This will avoid duplication of effort. Everyone should be required to complete successfully the bicycle tests before being

granted the privilege of operating a bicycle on campus. We must realize that some of the faculty, staff, and students have never been exposed to any form of safety instruction and that some of them have just started to take up the bicycle habit. Arrangements might be made with the administration to include during orientation week some safety instruction, such as a film teaching the safe operation of a bicycle. During this period it would be well to explain the procedures for registering bicycles. Pamphlets should be distributed explaining the rules and regulations and safe practices. The student government is in an excellent position to assume this entire responsibility.

If the local police department has not developed bicycle tests, then it is up to the college or university to provide such tests. Several organizations, such as the National Safety Council, the Bicycle Institute of America, Inc., National Commission on Safety Education, and the American Automobile Association have available upon request information on how to conduct such

tests and inspection. To those who may question the necessity for administering bicycle tests, let me point out that studies have revealed that two of three bicyclists are violating one or more traffic laws when they become involved in a collision with an automobile. Moreover, approximately 20 per cent of the bicycles involved in motor vehicle accidents had some mechanical defect.

What are some of the benefits that can be expected from an effective bicycle program? I believe that such a program will make the campus a safer place, will help create the proper attitude toward traffic safety, will reduce accidents, decrease congestion, and discourage bicycle thefts. Finally, many of our future leaders are now enrolled in our colleges and universities. The attitudes they develop toward traffic safety will influence them to react positively toward similar safety programs in years to come when they assume parental responsibilities and positions of leadership in their communities.

IMPLICATIONS FOR TV IN DRIVER EDUCATION—EFFECTIVENESS OF TOTAL PROGRAM

By EDWARD WILLIAMSON

Consultant, Driver Education & Safety, State Dept. of Education, Tallahassee, Fla.

Although the data has been collected for a study that will assess the effectiveness of television in the teaching of driver education, tabulation and statistical treatment yet remains to be done. Until these are completed no valid conclusion can be reached as to general effectiveness of teaching driver education by television.

On the other hand, it is possible to form some judgment on the basis of experience, and through use of proven facts, that helps us reach some conclusion regarding future use of this new medium.

Let us consider these points categorically.

1. Since research has shown that one of the most effective ways for developing favorable attitudes is through group discussion, and since driver educators are seri-

ously concerned with this phase of learning, we do not believe that all of the time devoted to teaching of the classroom phase should be used with television instruction. The reason for this is obvious, as no method of conducting group discussion with audiences of 10,000 to 12,000 has yet been discovered.

On the other hand, television used properly, with cooperation between the studio teacher and the classroom teachers, may present material that will set the stage for group discussion under the guidance of the regular classroom teacher. In fact, this has been one of the richest rewards of the program.

2. We know that through television, experiences can be provided to large groups

that might never be possible otherwise. As an example the television camera might be taken into a traffic court or to a congested intersection, or to other places where enriching experiences occur and provide first-hand knowledge to hundreds. Think of the administrative problems that would have to be overcome if this mass of people were actually to visit these places in person. Also think of the use that can come of such experiences for discussion purposes.

3. A studio teacher has one major responsibility, that of preparing his telecast which may be of only fifteen minutes duration several days per week. He has at his disposal every known teaching aid, models, maps, charts, diagrams, film and the services of a wide variety of consultants and resource people. He spends the majority of his day in preparing for his next program. You recognize the impossibility of classroom teachers ever being in such a favorable position for doing a masterful job of teaching.

4. When open circuit television is used for the telecast there is the additional possibility that many non-school citizens are viewing. If this happens what a wonderful public information device this is. There is also an outside chance that these viewers may learn something about safe driving, or some of their faulty attitudes may even be changed.

5. Within the school system itself, under the plan used in our state, Florida, a large number of the faculty are involved because each homeroom teacher, whether a driver education teacher or not, is a viewer because of monitoring responsibilities for students assigned them. From observation, the belief is strengthened that there is greater appreciation of driver education among these

teachers than among those without this opportunity.

Some will contend that everything that can be done with television can also be done through use of films. Even though this reasoning has merit, absence of research in this area leaves the question of relative cost unanswered. Video tape may turn out to be the compromise.

Those planning to institute television programs might profit by the experience of those who have experimented with this medium. There is often a tendency to stress skill development on telecast programs when the time might be used more advantageously in presentations that would strengthen attitudes. This is especially appropriate when open circuit is used, because of the additional benefit to be derived by adult viewers.

I have mentioned some of the observable benefits that the teaching of driver education by television might provide. Doubtless, there are others that have been omitted.

The preceding speaker has described the reduction in cost brought about by limited use of television. So far nothing has been presented that would justify a stampede to abandon traditional programs in favor of television. The criteria for selection of any method or combination of methods of instruction must relate to achievement of the desired educational outcomes. Reduced cost of instruction is not a valid criteria if the quality of the program is appreciably reduced. When the study, which I now have underway, is completed some indication of the effectiveness of teaching by television will be available. Until we have more evidence, let us proceed cautiously, with an open mind that will allow the use of educational television to assume its proper role in the driver education program.

IMPLICATIONS FOR TV IN DRIVER EDUCATION

By W. K. STREIT

Dir. of Health and Safety Services, Public Schools, Cincinnati, Ohio

An airplane flying 23,000 feet above Montpelier, Ind., recently broadcast instruction in 17 subjects to about 500,000 students in schools and colleges in a six-state area

of the Midwest. This \$½ million dollar airborne program financed chiefly by the Ford Foundation uses specially equipped DC-6 planes with the antenna pointing

down instead of up, telecasts elementary school programs of 20 minutes and secondary and college programs of 30 minutes duration, all on video tape in series of 60 to 128 lessons. Five more subjects will be added in January.

There are now 54 ETV stations on the air and 19 more under construction. Two hundred programs are broadcast by educational TV—cultural and informative. Today, almost every course in the school and college curriculum from first grade arithmetic to college zoology is being taught somewhere over TV. It is estimated that 2,000 elementary and secondary pupils in 250 schools are receiving some part of their education by television. More than 20,000 college students are receiving some courses via TV in 250 colleges and universities. Of the millions who have watched the National Classroom, over 8,000 students have been enrolled in 300 schools and colleges for credit.

The exciting growth of educational television throughout the country to date is the result of active interest and support of many philanthropic, educational, civic, and business organizations, as well as by thousands of enthusiastic individuals. Given continued support of this kind, education television should become one of the nation's most valuable educational assets.

In 1952, the Federal Communications Commission set aside television channels for noncommercial educational stations. When it was realized that educational television was more than a dream, the Cincinnati Public Schools became interested in its potential for teaching boys and girls. In October, 1954, the first educational television programs were telecast to Cincinnati schools over channel 48, WCET, the local UHF station. WCET obtained the first license for an educational television station in the United States and was the sixth station to begin operation. The 1950-51 school year showed a total of 918 telecasts, more than 50 per cent of which are live direct teaching programs where the viewing is required.

During the first year and a half, the telecasts were primarily enrichment programs, with a few in the area of direct teaching. Because the latter was a controversial matter, more evidence was needed.

In 1956, a seven-week experimental program in chemistry was telecast. In 1957, a one-semester driver education program for five schools was put on the air.

Both were evaluated carefully to determine the effectiveness of instruction. The findings indicated that, as measured by performance and achievement tests, pupils learned at least as well by television as in conventional classroom situations.

The next year, control classes of students who were not exposed to the television program were set up to match experimental television classes of 175-200 students in a single room. A test was designed to measure the results of both types of instruction. Here are the findings in two sentences:

Achievement of students in driver education, as measured by objective tests, was superior in those classes which received instruction by television. The differences favoring television instruction were statistically significant with pupils of above average ability but lacked significance for pupils of below average ability.

In March, 1958, the National Commission on Safety Education, NEA appointed a national advisory committee on the Driver Education Kinescope Project to prepare outlines, supply materials, offer suggestions and criticisms, review each kinescope and approve the final product. This top level committee was composed of Clara Stratemeyer, chairman; John Eales, J. Duke Elkow, Lonnie Gilliland, Robert Marshall, Amos Neyhart, Leslie Silvernale, Benjamin Tinnel and Norman Key, secretary. The project was completed one year later and the kinescopes are now available through NET Film Service, Audio-Visual Center, Indiana University, Bloomington. The 29 kinescopes of 30 minutes each are suitable for use in secondary schools or for adults. A kinescope may be shown from a motion picture projector or telecast from the studio.

The big advantage of education television is that a gifted teacher can reach thousands of students simultaneously. The big drawback is the loss of personal give and take between teacher and student. This is partially overcome in a 55 minute class period by utilizing 20-25 minutes for discussion following the telecast.

There are many problems to be solved such as, adjusting the programs to the school schedule, coordination between the studio and classroom teacher, gaining the interest of teachers, tendency toward standardization, adjusting to individual differences, and the big problem of quality.

What can you do by television? You can bring top resource people and a great variety of materials to the students which would not be available to the average teacher. You can present a great variety of visuals to reinforce instruction. Each child has a front row seat. The good TV teacher talks to every student all of the time. TV gives careful thought to scope and sequence so that nothing important in the course is omitted. There is no chance of the course going off at a tangent because of a particular bent of the teacher or on the insistence of some class members.

The classroom teacher is one of the team. We don't refer to the "master teacher" on TV but rather think of one complementing and supplementing the other. The classroom teacher gets the students ready, she motivates them and furnishes the enthusiasm for the course. She moves about the room during the telecast and picks up points that need clarification and emphasis. There is immediate follow-up to clear misunderstandings, if any. She does not rehash or reteach the telecast but rather conducts a good discussion on essential points.

Following are some suggestions given to teachers of large TV classes:

1. *The Need for Good Orientation*
Discuss with the students such things as:

1. The need for concentration.
2. The need for carefully prepared homework including the reading assignments in the textbook.
3. Check to see if texts have been read in advance.
4. The need for some discussion on notetaking:
How to take notes
What not to write
5. TV will probably require more independent work on their part. Prepare students for this. Teacher leaves open-ended questions.

II. Physical Arrangements

1. Be sure students can see and hear. If possible, assign every other seat so that students are not huddled together.

2. Check vision—Be sure students with faulty vision or hearing are seated in the front of the room.

3. Give close supervision during telecast to see that students are not sleeping, annoying others, or studying other subjects.

NOTE: It is desirable to place books on the floor under the seat.

4. Time following telecast should be used for following up the kinoscopes before introducing new materials or proceeding with pupil reports or other driver education assignments. *Never* use this time as a study period.

III. Equipment

1. Be sure sets are always in good adjustment.

2. If possible, train students to assist with the mechanics of moving or adjusting sets.

3. Report set difficulties to the assistant principal or person designated in school.

4. Traffic board and blackboard should be ready for use at each session.

After five years of experimenting with the use of television in direct instruction in chemistry, biology, driver education, elementary science, and mathematics in the Cincinnati Public Schools, the following generalizations may be drawn:

1. Neither television nor conventional instruction tends to be consistently more or less effective for all pupils and for all courses.
2. When subject matter achievement tests are used as criteria, there is a trend for televised instruction to be more effective than conventional instruction for older pupils at higher grade levels. Conversely, conventional instruction tends to be more effective with younger pupils at lower grade levels.

3. Television instruction tends to be more effective than conventional instruction with above average ability students unless deliberate efforts are made to direct instruction to less able pupils. Conventional instruction tends to be more effective with less able students as long as deliberate efforts are made to direct instruction to pupils at a below average ability level.

4. There is a negative relationship between preference for television and pupil ability level; that is, the more able pupils tend to prefer conventional instruction while their less able peers tend to prefer television instruction.

5. There is a negative relationship between preference toward television and educational grade level; that is, pupils in higher grade levels tend to prefer conventional instruction while pupils in lower grade levels tend to prefer television instruction.

6. Teachers generally tend to look upon television instruction as an asset to education and feel that being a classroom teacher in a

television situation is a valuable experience. They are evenly divided on issues such as personal satisfaction, amount learned by pupils and whether they would like to engage another class in television instruction.

7. There is some evidence to show that reducing the length of the telecast may result in the telecast being more effective for the less able pupil.

Conditions surrounding the use of television in any given school system may be unique and thereby invalidate the generalization in any single school system. The quality of instruction will differ as will the general support given to educational television and the socio-economic characteristics of the community. Such factors suggest that it is imperative for each community to conduct its own studies relative to the use of television instruction.

Just over the edge of time is world-wide television by the development of satellite relay transmitters. Then a billion people can watch a program simultaneously. Will educators be ready for this day when it comes? Only the future knows the answer, but education had better start getting ready.

NEW DEVELOPMENTS IN TELEVISION AND THEIR IMPLICATIONS FOR DRIVER EDUCATION

By C. FRAZIER DAMRON

Dir., Research, and Teacher Preparation in Safety Education
University of Wisconsin, Madison

It is interesting to note that only a few times in the history of the world have new methods of communication been developed. The late Charles E. Wilson has stated in one of his last speeches that, "Not since the invention of the printing press has a new means of communication been created that offers the opportunities for advancing education that educational television holds forth."

In a new publication of the department of audio-visual instruction of the NEA

titled, "And TV Too," we are told there is no longer any doubt that educational television can provide unique learning opportunities. It states there is no doubt that educational television can provide unique learning opportunities, and also that there is no doubt that classroom teachers must play two key roles if educational TV is to achieve its maximum potential as a teaching tool: the teacher must be a member of the professional team which plans the content of TV presentations, and must under-

stand its uses and be prepared to capitalize on its contributions to learning.

This has direct implications for the driver education teacher and his profession which desperately needs to find a means by which it can speed and at the same time broaden the basic driver education of our youth and adults.

There have been many reports on research and experimentation with educational television over the last decade. Many of them have been favorable; some have indicated shortcomings of various types; a few have cast doubt as to what television can do; and some have indicated great expectations for its future.

Few would argue that a great deal more is to be learned about this modern communications medium, and that it is essential that we explore its many relationships to the teacher-learning process.

In reviewing the implications of television for driver education, we must realize that it is not the facilities that determine the educational value of television, but what is transmitted, i.e., the programs themselves. We must also remember that educational television is a radically new concept, so new that we are prone to compare it with commercial telecasting whenever educational programming and costs are discussed.

They should no more be compared than should a paper-back cowboy story be compared to a textbook, just because both make use of the same medium.

Educational television provides an opportunity for a fresh approach, for a new consideration of the appeal to the eye as well as the ear, and perhaps even for a revision of teaching methods.

As you may know, the educational experience may be communicated over commercial stations, educational stations, or over closed-circuit installations. The two broad types of programs are instructional and enrichment television.

This report is concerned only with instructional television which consists of broadcasts deliberately designed to aid instruction and to develop further the attainment of educational objectives. These broadcasts are presented in an orderly and sequential arrangement, one building upon another, as the learner achieves increased competence. There are four types being used

in American schools and colleges. The type that is used should depend on what makes sense in a particular situation in view of curriculum needs, teacher competencies, pupil enrollment, and television facilities.

One type is total television teaching in which the only instructional help given is that included in the television series. Other necessary learning experiences must be provided by the learner himself, who consequently must be highly motivated to want to learn and be sufficiently mature to carry out the rest of the regimen that the course requires. Most credit or non-credit telecourses offered to adults are of this type. Implications are here for the teaching of adult drivers and perhaps the advanced course in driver education for teachers, supplemented perhaps by correspondence tutelage through university supervision.

The second type of instructional television is major resource teaching. The Midwest Program on Airborne Television Instruction is mostly of this type. The broadcasts carry the main burden of formal course presentation, but learning is facilitated by other experiences under the guidance of the classroom teacher. A great deal of present instructional television on both school and college levels is of this type. Such a plan, it would seem, could be applied to almost any phase of instruction in driver education, with the exception of practice driving experiences in a dual-control car.

The third type is supplementary television teaching, in which the television programs supplement the instruction which takes place in the classroom. Television in this case follows a course of study in a broad way, but adds to it the kinds of fruitful experiences which individual teachers find difficult if not impossible to provide. This type of television program is wide spread throughout the nation and merits serious consideration for use in driver education.

The fourth type of instructional television is observational and a small closed-circuit system is used solely because it provides a better class view of important phenomena. This could be done very well in a laboratory school to facilitate learning in teacher preparation classes by allowing students to observe driver behavior of teenage drivers and demonstration teaching in either class or road instruction.

In summary, I would like to point out that although systematic research is somewhat limited due largely to the newness of television, considerable trial and error experimentation by many schools has pointed up several contributions which television makes to the educational program. There are some things we now know that television can do to improve the quality of teaching and learning when designed, planned, and used for a purpose. All of the following demonstrated contributions of television to education have important implications for driver education:

1. Television stimulates learning. It serves as a springboard for many worthwhile learning opportunities.

2. Television provides resources often unavailable to classrooms. This contribution is one most frequently mentioned by those using television most extensively. It includes the sharing of resource persons, materials, facilities, and outstanding teaching personnel.

3. Television serves as a source of new ideas for the teacher. In this respect, new dimensions have been opened up in both service and in-service teacher education. Teachers can better keep abreast of new developments, new resources, new teaching aids, and methods.

4. Television presents factual content to many students at one time. It communicates content quickly with great emotional impact to a large number of students.

5. Television reiterates minimum essentials for all students. Schools using television in their instructional programs are indicating that the use of television is serving an unexpected function in insuring a higher quality of instruction without limit-

ing the ceiling for students. It is doing this by underlining basic ideas and reinforcing learnings.

6. Television shares student activities. In many localities, schools have used television as a means of sharing the good things which go on in one school with other schools. For example, in driver education, student projects could be brought to the attention of pupils in other schools. Television thus places a premium on individual initiative and creativity.

Despite the numerous positive findings attesting to television's capacity to improving the quality of instruction, it is a matter of concern to note that the majority of schools throughout the nation are still not using television in any facet of their educational programs, nor are they even considering seriously its use. There can be little doubt that the profession as a whole is unaware of the contributions which the television medium can make to the educational program.

The future, therefore, lies in the ability of the educator, or why not driver educator, to initiate and put this advanced system of communication to use. How else will we be able to instruct all eligible teenagers in driver education classes? How else will we be able to provide adult refresher courses to all who need such instruction? How else can we better inform the public about the need and value of driver education? How else can we more effectively upgrade teacher qualifications than through in-service training that could be provided by educational television? How else are we going to meet teacher shortages? And how else are we going to drastically reduce the costs of driver education?

IMPLICATIONS GROWING OUT OF CHANGE TO SAFETY

(Summary of talk by Walter Freeman, Director of Research Division of Community Development and Services, Michigan State University, East Lansing, Mich.)

Mr. Freeman, in discussing the question of mobility in connection with safety, said this is not as much of a problem as it

seems to be. The problem of mobility involves families that move into a new neighborhood during a school year or just be-

ture, making it difficult for the children to adjust to the new school and life in the community.

He said the first thing to do for children moving into a new community is to make them welcome. He pointed out that some transients seem to carry stability with them when moving into a new community and adjustment is no problem. But, particularly when large groups of people move into a community, such as those who go from place to place in their line of work, overcrowding is sometimes a problem.

He said pre-school children often lack proper education if the mother works. But he explained that the quality of relationship between mother and child determines the kind of education rather than simply whether or not the mother works. This factor often is considered a particular safety problem as well as that of the broken home.

However, Mr. Freeman said he does not believe this is really as serious as it might seem to be. He said he doesn't think that the family is breaking up because of more activities and more freedom from work, either. In fact, he thinks the family is just as close as it ever was.

In the discussion period, a question was asked if there are certain techniques that

can be used to make youngsters self-reliant at an earlier age. The answer was that parents should accept the ideas of growing youngsters and recognize that their responsibilities do exist; this way, they will mature faster and accept them.

Another question was on how to build safety attitudes in children. The answer was to teach safety attitudes that leave room for child trust. For example, don't tell the child not to drive more than 50 m.p.h. and then let him see you drive at 60. Also teach the child the proper safety attitudes, to respect laws and those who enforce them.

Those participating in the questions and answers session were: Irma Fricke, R.N., representing American School Health Association, Evanston, Ill.; Harry Lodge, representing General Conference of Seventh-Day Adventists, Brookfield, Ill.; John Tibbett, National College of Education; Arnetta Wallace, National Conference of Colored Parents and Teachers; John V. Fridlund, graduate student, Northwestern University, Itasca, Ill.; Lillian Gilliland, teacher, Andrew Johnson Elementary School, Oklahoma City; and Grace Ellen Sules, assistant professor, Department of Education and Psychology, University of Rhode Island, Kingston, R. I.

IMPLICATIONS FOR ELEMENTARY SAFETY EDUCATION

By EVA M. DRATZ

Professor of Elementary Education, Keuka College, Keuka Park, N. Y.

The formal goal of the educators is to educate children. Our first step is to develop a clear understanding of the groups, concepts, purposes, values and problem-solving practices. In an atmosphere of mutual acceptance, respect and desire to understand and to help each other, communication and change can occur. Teachers must evaluate their techniques in helping pupils to develop attitudes and practices of good citizenship so effectively and to demonstrate their results in behavior so clearly that there will be a united effort in safety.

Learning is improved when the instructional program is based on an understanding of each child's capabilities, interests, and background; when experiences have satisfying emotional overtones for children and they apply the learnings which grow out of vital and stimulating experiences, when children actively engage in solving problems that are significant and purposeful; and, when consideration is given to the child's developing self concept.

Variations in individual growth patterns, ideals, past experiences and home life cause

children to learn in their own ways. Individual needs should be met through this use of such procedures as varying activities, giving individual help, using community resources, and group planning for units in safety. At all times, we must realize that elementary children remember and apply the learnings which grow out of vital and stimulating experiences in which pupils clarify problems, plan ways of attacking them and achieve success in solving them.

When I was teaching in elementary school, I had the privilege of working with a group which wished to organize a health and safety council. The class elected officers and decided on a basic program for the year. Two representatives from each class in the building were invited to attend the Friday afternoon meetings. During the winter, the problem of snowballing was discussed. Folds were suggested, targets were constructed, and penalties were proposed. During the following three weeks, the complaints mounted in number. I questioned the reasons and procedures. The president turned to the group and said, "What will we do?" A first grade representative said, "Just stop!" These pupils realized the values of cooperation, of working relationships, of self reliance, and of desirable attitudes for there were no more criticisms in this area.

Other factors must be considered if learnings are to have upbuilding emotional overtones for children. The applications of skills and information to plans of action of concern to pupils is effective. Opportunities

which help children to realize values of a safety program must be developed. Motivation is brought to a high level when pupils participate in planning. When purposes are clear and the problem is defined, the successes are real and significant to the learner. Evidences of safety understandings are observed in the gymnasium, in craft classes, in the classroom, in the hall, and to and from school.

As the pupil views himself as a competent person in group activities, he will become interested. If he feels that he can be a leader of his peers when he is a successful patrol officer, or president of the safety council, he will approach new problems with a positive manner. The pupil's self-concept changes as he has new experiences in helping to meet the needs of his classmates. As children mature, they develop more realistic attitudes of self acceptance. The teacher must realize that attitudes are deep-seated learnings based on meaningful experiences and are a part of the pupil's self concept. Children learn many attitudes from association with people they respect.

Experiences in which the pupils can earn prestige, feel secure and cooperate with others will provide a foundation for safe living. Continuous emphasis upon and commendation of positive expression of attitudes toward others is imperative. Participation is fundamental for it makes the pupil personally responsible for his own safety and relates his own safety performance to that of others.

AN EVALUATION OF SOME ASPECTS OF THE DRIVER TRAINING PROGRAM IN THE LOS ANGELES CITY SCHOOLS

By CECIL G. ZAUN

Supvr. in Charge, Safety & Driver Instruction
Los Angeles City Board of Education, Los Angeles, Calif.

In May, 1960, the Los Angeles City Board of Education voted to continue driver training for the 1960-61 school year, but to evaluate the program in light of its placement in the curriculum.

The evaluation and research section of the Los Angeles schools was authorized by the board to conduct a survey pertinent in driver training, and from the study results the board would determine the future of the

behind-the-wheel phase of the total traffic education program.

The study dealt with the following questions:

1. Does the present system of selecting pupils to take driver training result in any differences in ability and/or achievement levels between pupils who take driver training and those who do not?

2. What happens to the school marks (grades) of pupils who take driver training, and in what ways do their marks differ from the marks of those who do not take it?

3. What do the various interested groups—school administrators, A-12 pupils, their parents, and the voters of the community—believe and desire with respect to the function of the high school in preparing pupils for driving?

4. To what extent are these groups willing to express themselves with respect to the financial implications of driver training?

By means of a systematic referral to test data on file in the evaluation and research section and to pupil personnel records maintained by schools, a random sample of 3168 A-12 pupils from 37 high schools was obtained, of whom 519 had taken driver training and 849 had not. The two groups were compared to see if there was any evidence of selectivity in the scheduling of pupils to take driver training.

The second project was to investigate school marks earned by driver training pupils and progressive changes in their marks, if any. To do this, a sample of the pupils previously described was matched carefully with a similar sample of non-driver training pupils, using I. Q. as the criterion. The grade point averages of driver training pupils before, during, and after their driver training semester were compared with grade point averages of the non-driver training matched controls for the corresponding periods in each one's high school career.

The third requirement of the study was to sample, by questionnaire, the experiences, attitudes, and beliefs relating to driver training of five groups of individuals, as follows:

A random sample of 1217 A-12's of 38 high schools, both driver training and non-driver training.

A random sample of 683 parents of A-12's of 37 high schools, both driver training and non-driver training.

A random sample of 456 voters representing the proper proportions of all areas of the Los Angeles City High School District, including, of course, parents and non-parents.

Thirty-eight principals of senior high schools.

Thirty-eight head counselors of senior high schools.

The evidence from this study of driver training in high schools of the Los Angeles City High School District indicates that:

1. Pupils selected for driver training instruction within Los Angeles City high schools were not random samples of the school population, but tended to be higher than average in both I. Q. and achievement.

2. School marks of pupils taking driver training did not differ from marks of pupils not taking the course, did not drop during the course, and did not drop after completion of the course.

3. A majority of respondents believed that it would be highly desirable to make completion of an approved driver training course a prerequisite to the granting of a driver's license to young people.

4. A majority of respondents believed that, although the high school might have other more important responsibilities, it is the logical, and perhaps under the circumstances the only, suitable agency to administer a driver training program. In this sense it is the "business" of the schools to teach it.

5. A high preponderance of all respondents have shown their readiness to support the driver training program, even though it is more costly than other elements of the school program.

6. Of A-12 pupils, their parents, and school administrators, few felt that a driver training course had any appreciable effect upon a pupil's school work.

7. Most respondents believed that the most unsatisfactory element of the present driver training program is the fact that many who wish to take it are unable to be accommodated. Minimum facilities should assure enrollment to all qualified applicants.

8. Pupils wished to enroll in driver

training for a variety of reasons, but the most compelling to both pupils and parents appears to have been the prospect of getting lower insurance premium rates.

9. Not only pupils, parents, and school personnel, but also voters in general, are genuinely interested in Los Angeles schools,

and welcomed the opportunity to express themselves on a matter of deep importance—driver training. Their comments and suggestions were carefully prepared, and seemed to reflect a sincere appreciation of the problems and accomplishments of the schools.

SUMMARY AND EVALUATION OF NEW METHODS OF DRIVER EDUCATION AS APPLIED IN LARGE AND SMALL SCHOOLS

By DWIGHT M. DAVIS
Supt. of Schools, Moline, Ill.

By WILLIAM C. HARRIS
Supt. of Schools, Allen Park, Mich.

I. We evaluate our program by asking:
A. What was attempted?
B. How did it work?

II. We should include opinions from our staff, parents, students and other adults.

III. Always include a follow-up study.

IV. The community is entitled to a good program.

V. Ways to insure a good program:

A. Plan well for your individual needs—a program which is good for one area of the country is not necessarily good for another.

B. Work driver education in with the total school program—carefully work out scheduling problems.

C. We must have outstanding teachers.

D. Public relations must be well represented—understanding by others will make sure they like us.

Allen Park, Michigan is a community of 38,000 population with a total public school enrollment of 6,894. It is located in the southern suburb of Detroit and is a part of the Metropolitan Detroit Community.

This community has offered driver educa-

tion to its high school students since 1950. The driver education program has grown from one car and one instructor, to a year around program with 16 teachers, who teach driver education along with art, chemistry, auto shop, speech, business studies and elementary education. They use 5 automobiles of which one is loaned, 3 leased and one purchased. Four of their cars are equipped with automatic transmissions, and one has the standard transmission. All of the behind the wheel instruction is conducted on the street.

In 1950 when driver education was first introduced in Allen Park, this school was confronted with the same problems that most schools must solve. The only classroom available for teaching this subject was a small storage room, adjacent to the gym. The students who enrolled were in the twelfth grade, and were for the most part girls.

Through administrative and community support, the program was located in its logical position in the tenth grade, and boys, as well as girls, enrolled in the course. Because driver education is recognized in this school system as contributing to the general objectives of education, this subject area was considered a part of the school curriculum when the new high school was planned in 1952.

The architects designed driver education into the building just as science, physical education, industrial arts, and other subject areas are planned into a sound education unit.

The driver education facilities were placed in an area adjacent to the school's parking lot and next to the auto shop. It included a classroom to house 30 students, a storage room for testing devices, visual aids, and motion picture projectors. The classroom has access to the auto shop and a parking area which is reserved for the 5 driver education cars. The auto shop facilities are used to maintain and service the driver education cars.

Questions Asked After the Presentation

1. What are the certification requirements for teachers in driver education in your states?

Harris: 15 hours in safety education, but we are trying to raise this to a full minor.

Davis: We don't have a minor re-

quired yet, but are working toward it.

2. Is there any opposition in your area to giving instruction to non-public school students?

Harris: No, all are encouraged to come and are welcome, although there are scheduling difficulties.

Davis: No, they are entitled to come under the state aid law. Many come during the summer.

3. Should we go on record as favoring car-marked taxes for driver education?

Davis: It is difficult to get a driver education program off the ground without state aid. However, we should not expect our program to go on forever that way. It should be continued on its own merits if possible.

Harris: It is a good foundation for a start, but the program should be on its own in the community eventually.

TECHNIQUE FOR RESEARCH

By DR. F. R. NOFFSINGER

Dir., Course Development, Traffic Institute, Northwestern University, Evanston, Ill.

Once upon a time, in the dim history of the past, there lived in a remote region of China, a peasant whose name was Ho-ti. He lived in a straw hut at the edge of a village with his son, Bo-bo, and his prized possession, a sow with a new litter of pigs. One day, as was his usual custom, Ho-ti went into the woods in search of food for his sow, leaving Bo-bo to watch the homestead.

Bo-bo was not too bright, but he had the usual curiosity of boys. During his father's absence he began to play with fire in the area outside the hut. By chance some sparks fell on the dried straw of the hut and set the hut on fire. Bo-bo stood by helplessly, fascinated by the fire.

After the fire died down and in spite of his excitement, there came to Bo-bo some slight glimmering of the plight of the sow

and her litter. So he began to sift through the ashes hoping to uncover and rescue the pigs. As he brushed the ashes away, his fingers touched the roasted body of one of the pigs. By instinct he put his finger to his mouth to relieve the pain of the burn. And he was greatly pleased with the taste that came from the roast pig.

Eagerly he put his fingers into the ashes and on the roast pig to gain more of this new taste. Soon he was tearing the pig apart and gorging himself with the delicious repast.

In the midst of this orgy, Ho-ti, the father, came out of the woods and with dismay saw what had happened to his hut. Immediately he began strapping his son. But Bo-bo paid no attention. He continued to dig into the ashes in search of roast pig. Finally Ho-ti saw the ineffectiveness of his

efforts and became curious about Bo-bo's action. Soon he too was searching for other roast pigs of the litter.

When every last bit of the delicious food had been devoured, he cautioned Bo-bo not to say a word about what had happened to any of their neighbors.

Ho-ti rebuilt his hut, and soon another sow had a litter. Ho-ti could not help recalling the haunting taste of roast pig. And so late one night his hut burned to the ground again and Ho-ti and Bo-bo had another feast.

Neighbors began to wonder when periodically Ho-ti's hut burned in the middle of the night. Spring, they caught Ho-ti setting fire to his hut and brought him into court. His case was all but lost when Ho-ti suggested that they place a sow with a litter in a hut, burn it, and let the judge taste the roast pig, and then decide the case.

This was done and Ho-ti was acquitted. Soon throughout the country hut fires blazed the landscape.

Now this kind of discovery of truth or of the solution to a problem is purely accidental. Eating meat raw posed no problem to Ho-ti and Bo-bo. They had never tasted meat that had been cooked. Bo-bo didn't purposefully burn down the hut just in order to roast the pig. Even then it was only by accident that he discovered the taste of roast pig.

About many things we are no different than Ho-ti and Bo-bo. There was a time when we looked upon traffic accidents as a visit from God—the natural result of driving an automobile—the unavoidable penalty inherent in the act of driving.

At an earlier date yellow fever was accepted as a visitation of Divine Providence and therefore looked upon as a matter of course.

Can it be that in some of our high school driver education classrooms today we can find methods and techniques in use that were discovered in the same way that Bo-bo discovered how to roast pig? Can it be that some of these methods and techniques are as crude as burning down a hut to roast a pig? Can it be that these methods and techniques, once accidentally discovered, are accepted as a matter of course and used over and over again? Can it be that in our

teacher training institutions they are also accepted as a matter of course and handed down unchanged and unchallenged to generations of new teachers?

Don't we find that some concepts are difficult to transmit to our driver education students? Is it possible that the difficulty arises from the fact that in such cases our methods and techniques may be crude—may have been accidentally discovered—may have not been tailored properly to achieve our objective? An old Chinese proverb reads:

If you are finding a thing hard to do, you are doing it the wrong way.

Historic does not tell us how long Ho-ti and his neighbors, and their descendants, burned down their huts to roast pig. It may have been as much as a hundred years. But it is quite evident to us today that at some memorable point in history someone got tired of having to rebuild his hut every time the family wanted a feast of roast pig. He became dissatisfied with conditions as they were and he began to think of how nice it would be if he could have roast pig without burning down the hut. He became conscious of the difference between *what is* and *what might be*.

Now, and only now, did a problem emerge. How could this problem be solved? He knew fire was one of the essentials for roasting pig. But did it need to be his hut? Could it just as well be a pile of brush? He would experiment. It worked! The problem of having to rebuild his hut was solved.

A farmer had in one of his fields a large rock area. It had been there for years, for as long as he had owned the farm. Each year he plowed around the rock, making curved and irregular furrows. One day he sold the farm. The new owner noted the rock area in the field and was unhappy about it for he had trouble in plowing long straight furrows. He thought what a nice field this would be if only the rock were not there. He became dissatisfied with *what is* and dreamed about *what might be*. He had a problem. He investigated. He found that the rock was very brittle—that it could be broken by a stout blow from a sledge hammer. In less than a day he had broken up the rock, loaded it on his wagon, and hauled it away. His desire for a straight furrow could now be achieved.

Some 35 years ago, in a little town in Michigan, Dorothy, a young housewife was busily engaged in her kitchen mashing cooked fruits and vegetables and running them through a strainer. She was preparing food for the couple's first baby. It was a tedious, time-consuming daily task. And now there was a second baby and more of this hard work in prospect. Wouldn't it be nice if by some means or other she and many other members in the community could be relieved of this arduous job. She was thoroughly dissatisfied with conditions as they were. How many other things she could accomplish if only she didn't have to spend so much time each day preparing food for the baby. She became aware of what might be. Out of her recognition of an unsatisfactory condition came the problem of what to do about it.

That night she talked about the problem with her husband Dan who was assistant manager of a small cannery in the town. He was somewhat skeptical about how much time this mashing and straining job took. The next day he went into his office, closed the door and with a big spoon began mashing a pint of cooked peas through a kitchen strainer. After this experience he was convinced that it took considerable time, and since it did, he was convinced mothers would buy prepared baby foods. To check his conviction he made a small survey of mothers in the community and found that they would welcome prepared baby foods if they were priced reasonably and could be bought in a grocery store. This small sideline of the little cannery in the first year sold 500,000 cans, in the second year 4 million cans. Today, well over 3 million cans, jars and packages of Dan Gerber's prepared baby food are sold each day.

Analyzing these illustrations we can readily see that for progress to be achieved in any given situation there are three prerequisites which must be met:

1. A condition must be unsatisfactory. There must be some kind of discontent, some kind of unhappiness with things as they are, some need that is not being adequately satisfied.

Someone disliked rebuilding the hut every time he had roast pig, the farmer disliked crooked furrows, the housewife didn't like

to spend so much time preparing baby food, someone thought it was terrible so many people died from yellow fever, someone was appalled at the number of fatalities from traffic accidents. In each case, there was dissatisfaction, unhappiness, discontent.

2. You must be conscious of the difference between what is and what might be. There must be recognition or visualization of an improved condition—an improvement that removes from the condition that which makes for discontent, unhappiness, dissatisfaction, difficulty.

Someone had to visualize how much easier life would be if for every feast of roast pig there was no hut to rebuild, the farmer had to visualize the possibility of a straight furrow across his field, the housewife had to see herself satisfying other desires in the time it had been taking her to prepare baby food, someone had to visualize how much more pleasant life would be without yellow fever, someone had to visualize driving his car without the constant fear of damage to his car or of injury or death for himself. In each case, there came a consciousness of the difference between what is and what might be.

3. There must be study, investigation, experimentation, the results of which are used as a tool to get yourself out of a difficult or unsatisfactory or unhappy or disconcerting situation.

Ho-ti's descendant was faced with the problem of how to get roast pig without burning down the hut—he had to reason that fire was an essential—maybe the hut wasn't—how would he find out—he'd try an experiment with a brush fire—if it worked he had proven that the hut was not an essential—and he would have his problem solved. The farmer was faced with a problem—how to get rid of the rock—he had to investigate—how big was the rock—could it be broken—he'd have to test that—if it worked he would have his problem solved—he could reduce the rock to small pieces and haul them away.

The housewife had a problem—how to get baby food without taking a lot of her time to do it. Her husband tackled the problem—could he make baby food easily in his cannery—would housewives buy it—he investigated—he found they would welcome the innovation on condition that—

could be met their condition—he could sell it at a reasonable price. But would the geriatrics carry his line—he tried this out—they would—he had solved the problem.

Those interested in the elimination of yellow fever had a problem—they set up a theory—they said maybe invisible particles (which they named "fomites") were given off by the sick—they tested this theory—it didn't always work—they discarded it and formed another—Maybe mosquitos carried the germ—they tested the theory—it worked—they found no cases in which a mosquito was not involved. But there was another difficulty—not all situations where mosquitos were involved developed yellow fever. Was it a particular species of mosquito? They experimented long and carefully. That was it—only one kind of mosquito was involved. The problem was solved—they now knew what carried yellow fever. But a new problem arose—how to eliminate that kind of mosquito—eventually that problem too was solved.

The traffic accident problem—well, that's not solved yet—we're all working on it. It's not a simple problem—it's a very complex one, one that must be broken down into many, many minor problems, each of which requires the application of the same careful systematic scientific method for a solution.

Let's go back now to those three prerequisites. How many of you driver education instructors go home at the end of each day happy and contented with the progress each of your students has made that day toward being a good driver? How many of you college instructors leave your office each evening completely satisfied that you have done the best that could be done that day in the training of each teacher to teach driver education effectively? If any of you here have such feeling of contentment and satisfaction—then you are probably using methods and techniques accepted as a matter of course and discovered in the same accidental way that Bo-bo discovered how to roast pig.

Can any teacher, high school or college, and without wracking your brain to think about it, quickly mention one method—one technique—one device—you are now using

that doesn't seem to be getting the kind of result with some particular student that you would like to get? Are you dissatisfied with the results produced? Are you unhappy about it? Do you carry it home with you at night? Does it worry you—like for example the rock worried the farmer, or the rebuilding of the hut worried the descendant of Ho-ti? If it doesn't worry you, then you have no problem. There is no dissatisfaction and therefore no visualization of the difference between what is and what might be. And there will be no progress in the improvement of methods or techniques or devices used in your teaching.

But even if you are dissatisfied and discontented—even if you do worry—there still can be no progress toward improvement unless you follow through on the third prerequisite. You have a problem but you have not yet taken the steps necessary to its solution. You must study the problem, you must investigate, you must set up a theory and another and another until you find one that works. And then you use the result of your study, your investigation, your experimentation as a tool to remove the worry, the dissatisfaction, the discontent, the difficulty that the situation presented.

You want "research" results that you can use to help improve the driving record of your students—that is "research". This is real down-to-earth, do-it-yourself research that you can use in the classroom, in the laboratory, in the car on the street. This is research that will get results.

Give it a try. Start now by compiling a list of every situation in your teaching day that you believe can be improved, every activity that seems more difficult or time-consuming than it should, every method that does not seem to produce as effective a result as you would like to see. And then get irritated about each of these, one at a time, to the point where you will follow through on that third prerequisite—study, investigate, experiment until you have found the solution to each of your problems. And next year when I see you at the Congress you will be able to say, "I've found a dozen or more new things to do to improve the traffic behavior of the students in my driver education classes."

IMAGES OF DRIVER EDUCATION IN THE '60's

By ROBERT D. BOND

Supvr., Driver Education, Traffic Safety Dept., Ford Motor Co., Dearborn, Mich.

The subject of my remarks—images of driver education in the 1960's—gives me an opportunity to cover a wide variety of matters, some of which have great promise in the years ahead:

Everything's so advanced. Take medicine, for instance. Did you know that by 1970 Americans will be spending more than 18 billion dollars on medical care? And it's really doing the job too for by then it's expected that every doctor will have gotten well.

In looking into the coming decade, I hope I have discretion as well as the discernment to take a sufficiently broad look into the crystal ball. There was, I admit, a temptation as a member of the automobile industry to talk about all the exciting changes in cars that are coming. Instead, I have attempted to keep the automobile in proper perspective along with the driver, the highway and the changing face of America.

It is also necessary to admit that this business of getting properly oriented with future trends is a tricky undertaking, and one that is full of pitfalls; so I don't for a moment imply that my brief and limited comments here this morning do more than touch upon some of the more important developments and innovations which may take place during the next ten years or so.

In examining the first image of what could be, let me attempt a wide-angle view of the situation. It would be a poor crystal ball indeed which did not show the viewer a panorama of a bubbling and boiling America that from shore to shore was busy turning out more cars, building more highways, and producing more drivers to use them than ever before. By 1980 it is estimated that three quarters of our people will live in urban centers with more than 100 million of them in the 200 major metropolitan areas and half of the anticipated 245 million population will live in suburbs.

In terms of cars I see an increase of nearly 25 million by 1970, from some 74 million to nearly 100 million.

In terms of drivers, an increase of about 16 million, from 87 million to over 100 million is anticipated.

The total of miles driven is rising at a rate that will bring it to one trillion miles per year by 1970.

And tragically, the total number of fatalities is destined to increase to more than 40,000 a year.

All this at a cost of some 8.5 billion dollars per year, up from the 6.5 we now must pay annually for our automobile accidents and related costs.

Now, let us rub the ball again and take a somewhat more detailed glance at the situation as it applies to driver education specifically. One of the most prominent things to be noted is that in 1970 there will be 4 million young people reaching the driving age each year as opposed to 2½ million now achieving this status. This is 11,000 a day; a significant figure for all of us who are concerned with the problems of improving driver education.

As I see it, some noteworthy changes will have occurred in the public school systems in the direction of increased ability to give more students better training. For example, the number of high schools offering complete courses—classroom and practice driving will increase 12 to 15 per cent, and the number of students receiving complete instruction will rise sharply from the present figure of 39 per cent to around 60 per cent by 1970.

Another important increase will be a doubling in the number of states providing financial aid to schools (from 18 to about 35); and a significant figure will be the rise from 5 to 15 in the number of states requiring driver education before licensing young drivers.

Looking ahead ten years convinces me that the number of driver education teachers will continue to grow. More important, there will be a marked improvement in the background, training and experience of a great many of them so that the quality of

instruction they give will be of a considerably higher order than it is today.

On the other hand, I see a number of teachers who are teaching driving today who will fall by the way. There will be a multitude of reasons for this fallout. Among these are: the decision by more and more smart administrators to strengthen their driving program by eliminating the unenthusiastic, incompetent teacher (as far as DE is concerned, that is) who was just looking for an extra job weekends or summers; the realization by more school officials that driver education would be supported by the community over the long haul only if the results in terms of well-trained students justified it; the effect the various associations and conventions—such as this one—will have in raising the standards of acceptable competency; and by the increasingly close scrutiny which will be given to the driving course by special community civic groups whose leadership has recognized the need for improving the quality of the driving courses.

What I have just said can be applied to the professional driving school teacher or operator just as well as the high school teacher. In fact, it is my contention that over the coming years these two groups will exert a beneficial influence over each other as a result of their competitive efforts. Leadership on both sides of the picture are coming to realize the dangers of the sniping situation that in the past has too often existed. Both groups must work more harmoniously together while they are also striving to improve their individual level of operations.

Without question more of us in this business are going to awaken to the fact that driver education extends far beyond the high school. We are going to learn to adopt the approach that driver education must be made available and desirable to the 85 million drivers already on our highways. And who in the community is the natural and logical leader in such a movement? Right! The driver education teacher. The one, that is, who has sufficient vision to project his concept of his job beyond the narrow confines of the high school where he now teaches.

Like the average duffer on the golf course or the 20-year bowler who still has

a 150 average, all but about 3 per cent of the licensed drivers on the road have a great deal to learn about the field of advanced driving techniques. It is just not the kind of thing most people learn by experience. For example, how to space properly, or correct use of the rear view mirror is still a mystery to most people. We must find effective means of communicating the necessary additional skills and attitudes to the millions of motorists. The smart driving teachers are going to find new opportunities that are personally productive for them as far as their pocket book is concerned, and beneficial for the community through improved traffic safety.

And now, what about the situation in our colleges and universities? Teacher training institutions offering sound basic and advanced courses for driver education teachers are expected during the next ten years to increase in number, to be better situated geographically, to possess considerably more equipment than is standard today, to have staffs whose quality is markedly higher, with curriculum standards which will be broader, stronger, and better integrated, and with more students attending them each year than is now the case.

I believe these things because of the figures and indications which point to the need for them are irrefragable, as I have tried to point out in my introduction—11,000 students a day of driving age by 1970, etc. I believe these things because I have read a little about the history of the American people, and I know that they have usually, somehow, seemed to recognize certain basic situations and have managed to preserve the worthwhile things in spite of seemingly insurmountable obstacles. And, too, I have talked personally with many people in many states, and they have convinced me of their acceptance of sound driver education as a vital and continuing part of our secondary school system. I believe that colleges and universities will have these advances in their courses because of continually growing pressure to do so. It is my opinion that they will rise to this challenge.

Another factor which can be added to the foregoing ones to account for the significant expansion in driver education during the 1960's is the growing public pressure for some kind of mass preparation of

average teacher to take an active part in such new research. Perhaps not in the major studies, which will be handled under the direction of skilled professionals in surveying techniques, but rather in building smaller studies through their local, state and regional associations and societies.

There is nothing that prevents any teacher from being a better salesman in his particular community for the results of both types of surveys mentioned. In fact, one of the points which in my opinion will be revealed is the need for safety education teachers to take a more active part in community safety affairs than has been the case in the past decade. This is not as difficult or complicated as it sounds. Breaking the ice and becoming involved is the most difficult part, and once the start is made it will be discovered that there is great opportunity for the individual to take part in such a way that both he and the community will benefit. For example, an instructor who started a student group under the aegis of the NEA national student traffic safety program would soon find more profitable activities than he could handle, and many of them could be of the kind that provided information suitable for background reports to the local community.

In the years immediately ahead there is unquestionably going to be a new concentration on programmed learning and the teaching machine. We at Ford have just completed our first draft of a programmed course in driver education. I have no doubt that this short course on passing will look pretty crude in three years, to say nothing of 10, but for the moment it's the latest thing, and the first of its kind made for use in a teaching machine that I know about. Since this technique holds promise of helping the teacher on the spot do a better job with less time and money spent, I suggest that many of you will want to at least look up the basic literature on the subject of programmed learning to determine its possible use in your school.

Incidentally, we are going to have to initiate some new teaching techniques in order to prepare our students for driving conditions they will face during the coming 10 years. Sustained speeds of 90 miles per hour on cross-country highways will not be out of the question during the late '60's. Pre-

paring the student for this range of speed will require a whole new concept of emergency procedure instruction for most teachers, as will the requirements for safely handling a car at these speeds. Do you give high-speed demonstrations, tire failure simulations, panic stops from top highway speed? A recent survey by a magazine indicated that the average man in the street anticipates cars that can be driven at speeds of 100 miles per hour by 1970. All I can say is that we would be well advised to all take the latest police pursuit courses in high speed driving that are just now beginning to be available in a couple of states.

The network of freeways being built as a result of the 1956 Federal-Aid Highway Act will by 1972 span the nation and ultimately serve one-fifth of all motor vehicle travel. We are going to be in an era of high-speed, long-distance travel which was unknown in past years. Our drivers as well as our cars must be up to the job if we are to realize the improved safe driving engineered into these roads.

The conclusion is inescapable that regulatory measures will be modified and improved to an extent that will affect course content and methods now used in teaching driving students. I anticipate significant advances in state licensing laws, which in many cases will mean that there will be reasonably tough tests of knowledge and skills as well as physical abilities before the first license will be given. Good sound licensing procedures are a boon to driver education and the passing of the best possible regulations for the particular state should be one of the important goals of each state teacher association.

One area which every teacher of driving should consistently urge and support is that of uniform traffic laws and ordinances. The Uniform Vehicle Code should be on the desk of every one of us and be used as a guide for classroom discussions, as well as the source of recommendations to the community whenever matters of this nature come up for consideration.

I see, too, the use of driving simulators really coming into its own during the next decade. These devices will vary considerably in capacity ranging from a complicated multi-million dollar one sponsored by the

federal government to simple devices that can reproduce with reasonable accuracy a single function. The demands of the new fast cruise cross country driving will require such equipment be put to its maximum use. Safe testing of new drivers and re-checking of experienced drivers will make far greater use of simulators to duplicate conditions which are too dangerous to try under actual conditions. The new Aetna Drivotron for duplicating realistically certain driving situations is a case in point.

One factor which appears likely to strengthen the hand of the driver education advocate is the continued emphasis by insurance companies through reductions in rates for insurance to young drivers who have successfully passed an approved driving course. We must all continue to encourage these discounts for young drivers as they probably are the single most effective means of gaining recognition and acceptance for driver education. I would go further and suggest that we should undertake to each to put the pressure on the insurance companies to increase the amount of the discount to make them more in line with the figures they quote on the reduction in accident figures of the youngsters who have had instruction.

An area that has been vastly influential in the success of the driving program is that dealing with the cooperation of civic and business groups and organizations. A great many of them have declared themselves on the side of driver education. As an example, the recent decision by the auto industry to double the rebate allowance to teachers who loaned cars to schools for use

in driving classes, is most encouraging. It indicates to me that a very important and substantial element has unequivocally declared itself as an ally in the fight to achieve acceptance of driver education.

The adult driver who is in difficulty for one reason or another in regard to his driving practices could in the past only atone by paying a fine or going to jail. The advent of the driver improvement school will offer an intelligent method of handling the problem driver. Here is a great challenge to both the professional and the public school teacher; here is a most satisfying and lucrative opportunity for them, here is a way to substitute a constructive program based upon building increased knowledge and skill for a negative program based upon punishment. I have every confidence that this challenge will be met and the driver improvement school will become an important fixture in every major community.

And now the crystal ball becomes opaque and I can no longer make out what it shows. I am not naive enough to suggest that all, or for that matter, any significant portion of the advancements I have mentioned will take place without a great struggle on the part of each one of us. I do believe that collectively many of us have been on a plateau, building experience for the climb ahead; and now that we have reached the hill we will make the climb to the next level, even though it strains all our gears in the process. The next time we are given a look into the crystal ball we shall find that many of these predicted goals have, through our own efforts, come true.

TEACHER COMPETENCIES IN SAFETY

By HOMER ALLEN

Chairman, Committee on Teacher Competencies in Safety
Elementary School and Higher Education Section, NSC;
Professor, Physical Education for Men, Purdue University, Lafayette, Ind.

Two years ago a joint committee of the Higher Education Section and the Elementary School Section of the School and College Division of the National Safety Council agreed to investigate the training in safety

education received by grade school teachers. During the following year some attempt was made by various members of the committee to compose a list of competencies which any grade school teacher should pos-

ness in order to best promote safety education in her grade. It became evident that such a list was not suitable for the purposes needed.

Last year the writer volunteered to conduct a survey in the two grade schools in West Lafayette, Ind., in an effort to determine the competencies and training of the various teachers. The attached report is the summary of this survey.

Grace Allen Stiles and Harold A. Seekamp each indicated some desire to conduct similar surveys in their respective communities, and the writer supplied them with the preliminary material which he had prepared. Copies of their reports are available from the staff representative of the elementary school section, Dr. Vivian Weedon.

It is evident from these reports that much work needs to be done along the lines of training prospective grade school teachers in the safety education competencies which will enable them:

- A. To recognize hazards.
- B. To eliminate as many hazards as possible.
- C. To train pupils to live safely with those hazards which cannot be eliminated.

A Survey of the Hazards, Accidents and Injuries in Two Grade Schools in West Lafayette, Ind.

This study was initiated in 1960 primarily to try to determine the safety education background and interests of the elementary school teachers in Morton and Burtisfield Schools. Mr. Carmen Fabian, principal of Morton School, assured the investigator that he was interested in the study and would cooperate to the best of his ability in having his teachers and the teachers in Burtisfield School assist in the investigation.

Mr. Fabian estimated that about 50 teachers and others would engage in the survey. The investigator purchased covered notebooks, hereafter referred to as "LOG" books, and he also prepared a personal information sheet to go with each log book as it was distributed to each teacher. The following instructions were attached to the log book:

Things to Include in the Log Book

1. Any hazards in the school building which might affect the pupils in my room.

2. Any hazard on the school grounds which might affect the pupils in my class.

3. Any new hazards which appear either inside or outside in activities of my pupils.

4. Any conditions which I recognize for the first time as a potential hazard.

5. Any accidents and/or injuries which occur to any of my pupils.

6. Any accident or injury that I could have prevented by anticipating trouble.

The following personal information sheet was distributed to each teacher:

1. Did you have a safety education course in college?

2. What was the nature of the course?

3. If you did not have a safety course in college, are you aware of any lack of safety consciousness?

4. Are you aware of the natural hazards in and around your school?

5. Are you able to guide your children away from hazards?

6. Can you train your children to cope with hazards which cannot be eliminated?

7. Have you been involved in any kind of accident in the past year? Describe it briefly.

8. Would a training course in safety education have helped you not to have an accident?

9. Would an in-service training course in safety education aid you in protecting your children?

10. What are your main safety problems in the school?

The material was distributed to the teachers early in the fall of 1960 and was collected in May of 1961. A rather disappointing total of only 14 persons returned the log books, which in itself may lead to at least one conclusion. Of those who returned the logs 11 were female teachers, 1 a school nurse, and 2 were male teachers.

The personal information sheets were fairly well filled out, with the exception of a few which had no answers to questions 8 and 9. There was a distinct lack of entries in most of the log books, and again, this may lead to at least one conclusion.

Summary of Data

I. Personal Information Sheets

- A. Number of teachers responding: 11 female, 2 males, 1 nurse.

- B. Experience: The range of experience among female teachers was from 2 to 35 years, with an average of 12.9 years. The range of experience among the male teachers was from 5 to 9 years, with an average of 7 years. The nurse did not indicate her experience.

- C. Answers to questions on information sheet:

1. YES (Females 3, Males 1). NO (Females 9, Males 1).

2. Health and Safety and/or First Aid.

3. YES (Females 1). NO (Females 5, Males 2). AT TIMES (Females 1).

4. YES (Females 12, Males 2).

5. YES (Females 12, Males 2).

6. YES (Females 11, Males 2).

7. YES (Females 1). NO (Females 11, Males 2). Fell down stairs due to own carelessness.

8. YES (Males 2). NO (Females 3). NOT SURE (Females 4).

9. YES (Females 2, Males 2). NOT SURE (Females 6).

10. Swinging doors

- Ball going into street

- Steps

- Unpredictable element in children

- Running in halls

- Falls

- Traffic

- Feet in aisles

- Pushing

- Playground activities

II. Areas where accidents occurred:

- Playground

- Halls

- Gymnasium

- Streets

- Stairs

- Walks

III. Types of Injuries:

- Wind knocked out

School and College Sessions

Sprained wrist
Skinned hands and knees
Face and head bumps and cuts
Wounds from falls or collisions
Stabbed self with sharp pencils
Mouth and tooth bruises and cuts
Broken arms

IV. Causes of injuries:

Fell from swing
Fell from bicycle
Fell while playing game
Tripped over obstacle
Playground equipment broke
Sharp edged culvert
Broken glass
Ice
Swinging lavatory door
Thrown ball bat
Improper twirling in swing
Slip on tile
Collisions at hall corners
Carrying exposed sharp pencils in pocket
Collisions in gym while playing games
Improper riding of bicycle in traffic
Falls on playground

V. Precautions taken by teachers:

Boy recovering from broken leg not permitted to play game with other children until completely healed
Children not permitted to climb on decorative design on school building
Had janitor remove broken glass from play area
Stopped ball players from grabbing and swinging on swing supports.

VI. Hazards listed by teachers:

School delivery truck driving on playground while children were present
Running across swing areas
Tiles on playground
Rocks on playground
Children playing in teachers' parking lot
Snowballing in school area
Swinging on stomach or standing
Unsupervised play on playground
Bicycles parked in play area
Parking lot is really part of playground—moving cars
Game equipment not removed when activity is finished

Holes on playground
 Scattered loose coal on playground
 Children running across street after alighting from family car
 Glass on school walks and playground
 Chain across drive
 Hot radiators
 Blacktop playground
 Ice and snow on walks
 Wet stairs during bad weather
 Drivers opening car doors in path of bike riders
 Careless opening of classroom doors into halls
 Waxed floors
 Rolling piano platform in gym
 Dogs on playground
 Green framework at back entrance—small children like to climb it
 Use of folding chairs to stand on
 Child riding bike wearing face mask
 Children running carrying sharp pieces of ice
 Tree trimmers at work near building entrances and play areas
 Girl drinking milk from shattered thermos bottle

VII. Dates of Notations:

September—None	February—2
October—10	March—1
November—5	April—5
December—4	May—None
January—5	

VIII. Questions asked by teachers:

Case of Purdue student forcing indecent exposure on small girl. Do we need to counsel our children concerning such hazards?

IX. Quote of the year:

"No accidents. Just the usual bruised knees from playground activities."

Conclusions

1. A majority of the elementary school teachers in West Lafayette were not interested in compiling "log" books concerning: (1) their own safety background, and (2) the accidents, injuries, and hazards in and around their schools.

2. Most of the teachers who returned the log books showed a woeful lack of

ability to do the job which was asked for. Dates were lacking, as were entries of good safety acts.

3. Most of the elementary school teachers had no safety education courses in their college training program. Hence, one wonders if they knew *how* to keep a log book concerning safety practices.

4. Most of the teachers had complete confidence in their ability to recognize hazards, guide their children away from same, or train their children to cope with them. In view of the accident record, it would appear that this confidence is ill-founded.

5. There is enough uncertainty among the teachers concerning the possible benefits of safety education training courses (collegiate and/or in-service) to permit the assumption that both might be good.

6. We learn nothing new concerning the areas where accidents occurred. These are the same areas in which accidents have always occurred. Likewise the types of injuries and causes are the same as have been listed in past studies. Is it not a good assumption that if these teachers had been trained in safety education, they would have been able to forestall many of the accidents?

7. In connection with the hazards listed by the teachers, there is little indication that anything was done about said hazards. Is this an administrative problem only?

Recommendations

1. This type of survey should be conducted in many representative schools throughout the country.

2. The investigator should personally meet with the teachers, and should make clear to them what is wanted. This is not a particular criticism of the principal. He may think he understands; the investigator may think he understands; but somewhere a link is lost.

3. The personal information sheet should be revised by an expert so as to permit the collection of really pertinent data.

4. The original committee should now review any surveys that have been made to date, and prepare a new master list of competencies which then should be submitted to a large number of elementary school teachers and principals for analysis.

FROM NOW UNTIL THEN

By OLIVE S. BERG

Incoming Chairman, Elementary School Section, NSC;
 Elementary Supervisor, State Dept. of Public Instruction, Pierre, S. D.

I have looked at the safety problem as it affects elementary school children. After all, we are interested in children and their safety.

I believe the following figures on accidents to children are correct:

1. Each year there are approximately 15,000 accidental deaths among children under 15 years of age.
2. Accidents are the leading cause of death among children after the first year of life.
3. Accidents cause almost 17 per cent of all deaths of children, ages 1-14.
4. The most common fatal accidents among children are: motor vehicle, drowning, fire, explosion and poisons. Together they cause more than half of the accident toll.

The National Health Survey estimates that 16½ million children are injured each year. These children are 36.5 per cent of all persons injured. 16 per cent of these injuries occur in and about the home. Among the school age groups, one child in ten is hospitalized as an in-patient as the result of injuries received in an accident.

62 per cent occur in the school plant.
 5 per cent occur going to and from school.
 16 per cent occur at home.
 17 per cent occur in public places.

Death rate—1950-1959: deaths, 934,000; approximate cost, \$100,000,000,000.

According to the U. S. Office of Education, there are 861,035 elementary teachers in the United States. What an army to move toward safety! The safety needs, as they affect elementary schools, fall into several categories. These are: (1) a full knowledge of school safety problems, (2) an opportunity to put into practice the knowledge learned, (3) skill in safety practices, and, (4) change of attitudes of teachers.

These are four basic steps in "safety-proofing" teachers. These four basic steps could be applied to either children or adults.

It is from these basic steps in "safety-proofing" that the safety program should proceed.

The principle preventive methods in the past decade concentrated on eliminating the environmental hazards where children worked, lived, traveled and played. Results have been gained in reducing accidents, but, since it is now known that 80 per cent of accidental deaths are largely under control of individuals, greater emphasis must be placed upon the human factors as they influence accidents. Three steps seem to be appropriate:

1. Selection — This deals with better screening of individuals for job and activity placement.

2. Included is medical and psychological testing as a screening device for better guidance of children in safety.

3. There is need for a modification of behavior through supervision and education. This is the point at which the teacher is the key person in the safety program. It is through change of safety attitudes that progress is made. The change in attitudes depends upon motivation, liability involved, economic considerations, administration and organizational policies, constraint and enforcement of rules and laws.

There must be opportunity for putting into practice the safety rules and laws. Teachers must have more knowledge of safety, both practically or psychologically. Skills in safety must be used by the teacher in her work with children in creating better attitudes. Let it be assumed that by safety attitudes is meant "a predisposition to react in a certain way to a given situation."

Attitudes may be expressed through a degree of alertness. Teachers need to educate children to be alert. This would include observation of the environments in which children find themselves. The observation element draws in precaution on the part of the individual. Precaution may foster apprehension of what may follow in safety procedures.

standing of the elementary rudiments of driving a motor vehicle.

Even today we have those school officials, I am sorry to say, who do not accept the fact that selecting a school bus driver should demand relatively as much time and attention as the selection of any other member of the school staff including the classroom teacher. It would be incomprehensible to most school officials to think of hiring the first person who walked into their office and asked to be hired as a teacher without first checking his credentials, previous experience, and qualifications.

In hiring a school bus driver, however, we are too often guilty of hiring the first available applicant in spite of the fact that we realize no school bus is safe in the hands of a driver who is physically and emotionally unfit, or who fails to follow sound driving practices; and, as a result, school bus drivers are in many cases ill-suited for their responsibility.

There appear to be two major aspects to the problem, apart from the continuing and competent supervision, of providing the best possible school bus drivers, (1) the recruitment and selection of qualified people; and (2) providing adequate training programs specifically designed to prepare these people for the job to be done. Although recruitment, selection, supervision, and training are in a sense inseparable, I will attempt in as far as possible to confine myself to speak to us on recruitment and school bus driver training programs.

Securing responsible and qualified drivers is not necessarily a new problem in the field of school transportation. Even before the advent of motorized transportation in this country when horse-drawn carriages and wagons were the conveyances commonly used to transport pupils to school, both the personal qualities of the driver and his control of the pupils being transported as well as his skill in handling his team were matters of concern and as such received attention in certain localities.

You will recognize, I am sure, this concern also agree that the following comments taken from a report by O. J. Kern, superintendent of Winnebago County, Illinois, schools at the turn of the century

has a certain familiar ring. In this report Mr. Kern describes his visit to several newly centralized schools in North Eastern, Ohio.

"So we drove on to North Madison, in Madison Township, where three wagons are used. On our way there we saw the first wagon. We stopped at the farmhouse and talked with the driver. He carried all the children from one district, about twenty in number. His route was five miles long. That is to say, starting at the first home to pick up a child until he arrived at the central school was five miles. Then he drove back home after delivering the children, thus covering ten miles in the morning. Of course he traveled the same ground after school, thus making 20 miles in all. He got \$1.50 a day for his work. We asked him if he made any money at it. He said he did, as he was working a small farm that did not require all the time and labor of himself and team. We asked him if he had any trouble with the children and replied none. He said he was employed by the township board of education, who put him under bond to be careful with the children; to have a safe team; to provide a suitable wagon, covered and provided with curtains, and containing soapstones and tap robes for the worst weather. We asked what objections the parents along the route had to the new plan. His reply was that the only objection was on the part of two or three at the beginning of the route, as they had to get their children ready somewhat earlier than they used to when they went to this district school. Of course the children had to be ready when the wagon came. He aimed to start at 7:30 and arrive at the building not later than 8:45. Thus there were no children tardy; none came with wet feet or clothing; the attendance was greatly increased and much more regular. The driver believed the movement had come to stay; that the people would not consent to go back to the old way."

Kern goes on to describe school transportation during that period at another school district he visited on this trip:

"The wagons are provided with curtains, tap robes, soapstones, etc., for severe weather. The board of education exercised as much care in the selection of drivers as they do in teachers. The contract for each route is let out to the lowest responsible bidder, who is under bond to fulfill his obligations. The drivers are required to have children on the school grounds at 8:45 a.m., which does away with tardiness, and to leave for home at 3:45 p.m. The wagons call at every farmhouse where there are school children, the children thus stepping into the wagons at the roadside and are set down upon the school grounds. There is no tramping through the snow and mud and the attendance is much increased and far more regular. With the driver, there is no opportunity for vicious conversation or the terrorizing of the little ones by some bully as they trudge homeward through the snow and mud from the district school."

This account of pupil transportation in Ohio at the turn of the century would indicate that many of our current problems in school transportation such as securing

well-qualified drivers are by no means new ones, but rather in one form or another have been with us for over 70 years.

The seriousness of the problem of securing well-qualified school bus drivers has been compounded in recent years, however, as a result of two developments. (1) The rapid growth of school transportation in this country (for example, in 1923 approximately 800,000 pupils were transported in the United States as against about 7 million in 1950 and more than 13 million this year with an estimated 15 million by 1965), and (2) the increased complexity of our transportation technology today, along with the side effects of this technological development in terms of the complexity of the vehicle itself, increased speeds, and our innumerable and varied traffic and highway problems.

There is no doubt about it—the job of driving a school bus today calls for physical, mental, and emotional capabilities of the very highest order. In order to secure qualified school bus drivers possessing these capabilities, it is necessary as an initial step to (1) establish adequate standards that all drivers are required to meet prior to employment, and (2) rigidly adhere to these standards.

The major responsibility for selecting drivers rests, of course, as it should upon the local school authorities. It is conceded, however, that the states have a major responsibility in exercising a reasonable degree of leadership, authority, and control in this area, and that adequate general standards and regulations must be promulgated by the states, preferably through the state education agency, to guide local school boards in this important function. It is recognized, of course, that local initiative should be constantly encouraged to exceed state requirements whenever possible.

The fact that school bus drivers in all of the states are now required to meet at least some standards indicates that the states do recognize this responsibility. Although there are wide variations between the states, both as to the specific items covered and the extent these items are covered in state standards, there does appear to be a definite trend to require that drivers meet more rigid standards.

The following excerpt taken from a recent

School Transportation Sessions

report by the Georgia State Department of Education points out the immediate result this has had in one state.

"In 1959, the State Board of Education tightened up its policies regarding physical examinations. The Board ruled that drivers over 65 could not be employed; nor could a driver with a physical handicap. These newer and more stringent regulations were adopted in order to insure greater safety for the 436,078 Georgia children who get on 4,327 school buses each day to ride to school and home again. When the new regulations were put into effect and more rigid tests required, 222 previously employed drivers failed because of such physical defects as missing limbs, eye or ear handicaps, heart ailments or other disabilities. As a result of the rigid new requirements, school bus accidents in Georgia involving the drivers' judgment were reduced from 18 per cent to 18 per cent."

Generally speaking the standards for school bus drivers in a majority of the states include the following elements: age, physical condition, experience, and character, among others.

Age Requirements

Minimum Age. In 1960, 16 states¹ required their school bus drivers to be at least 21. One state, Rhode Island, required drivers to be at least 25, while in South Dakota, a 15 year old could legally drive a school bus.

In 10 states,² 16 year olds could legally drive a school bus, 5 states³ allowed 17 year olds to drive school buses, and 15 states⁴ allowed 18 year olds to be employed as drivers. One state⁵ required school bus drivers to be at least 19, while Hawaii required all school bus drivers to be at least 20.

Maximum Age. In regard to maximum age requirements, the 1960 survey indicated that 39 states have no specific maximum age limit for school bus drivers. One state⁶

1. Arizona, Delaware, Illinois, Indiana, Maryland, Massachusetts, Michigan, Missouri, New Jersey, New York, Ohio, Pennsylvania, Tennessee, Utah, West Virginia, and Wisconsin.
2. Alabama, Iowa, Kansas, Maine, Nebraska, Nevada, North Carolina, Oklahoma, South Carolina, and Virginia.
3. Arkansas, Colorado, Florida, Mississippi, and Texas.
4. Alaska, California, Connecticut, Georgia, Idaho, Kentucky, Louisiana, Minnesota, New Hampshire, New Mexico, North Dakota, Oregon, Vermont, Washington, and Wyoming.
5. Montana.
6. Delaware.

and accidents due to negligence. If we firmly believe driving a school bus requires special skills and information, then the answer is, of course, on-the-job experience and training for new drivers prior to assignment.

I would like to touch very briefly on only two of a number of other important considerations in school bus driver selection.

(1) Few school employees are in as unique a position as the school bus driver to influence the community's confidence and respect in its school system. A school bus driver's personal conduct and daily performance as observed by the pupils, parents, and the taxpayers of the community can have a serious impact one way or another on the school's public relations in the community.

(2) A school bus driver can have either a positive or negative influence on the young minds which are under his charge for a considerable portion of the school day: his attitude toward promptness, the manner in which he drives his bus, his respect for laws and regulations during the daily run, the manner in which he handles discipline, his personal habits of speech and dress, his self-control and emotional stability, all can have considerable, immediate, and perhaps even a lasting influence on the attitudes and behavior patterns in this particular age group.

As Walter M. Gorden, head of one of the nation's largest school bus operations with 42,000 riders, Baltimore County, Maryland, aptly and humorously put it:

"What we are looking for in a school bus driver is a paragon, a diplomat, a public relations man, a nursemaid, a Prussian general for discipline. He must be able to keep both eyes on the road, watch for traffic situations with considerably more care than the average motorist, and at the same time control 50 or more squirming, yelling, energetic, hell-bent kids who are behind his back."

And I might add, we want his services for only a few hours per day at a salary often in no way commensurate with his responsibility.

A report by G. I. Fletcher, an agent for the Massachusetts State Board of Education in 1898, on the quality of the drivers in that state in 1898 might well be used, with certain modification, to sum up the situation as it exists today in regard to the quality of our school bus drivers across the Nation.

"Nearly all of the drivers are reported to be trustworthy. Some are said to be as good as we can get. Some are of doubtful qualifications. All committees and superintendents regard trustworthiness and fitness in the driver as of the highest importance. One committee says: 'Only such persons should be employed as we would trust with the care of our own children.' A few committees say that they have to watch drivers of convalescents and hold them to strict account. Some complain that children are not under proper control in the carriages; but upon the whole, there seems to be a good degree of satisfaction with such vehicles and drivers as have been employed."

A HYPOTHESIS ON LICENSING THE SCHOOL BUS DRIVER

By THEODORE KOLE
Senior Research Associate, Executive Asst.
Drivers Safety Service, Inc., New York City

From its beginnings in 1840 in one school district in Massachusetts, transportation for students to and from school has grown into the massive enterprise of today. A 1960 publication reports that although only one in every four students relies upon school sponsored transportation, there are nearly 11 million young people riding school buses each day.

Elaboration on the need for safety in school bus programs is certainly unnecessary. There is no question but that the prevention of accidents should be a high priority goal. However, it would appear that adequate measures are not being taken toward this end. As clear evidence of this, national statistics with only 42 states reporting in 1960, concerning school bus accidents,

show more than 2000 injured and 177 killed in a total of 8900 accidents. In Illinois for example, the average accident rate per vehicle in 1958 was greater for school buses than for all other commercial vehicles!

Recognizing the extensiveness of school bus programs throughout the country, and with the evidence of a great number of accidents and injuries occurring, it is clear there is a need for a concerted effort toward maximizing safety within these programs. However, it would appear that in most instances, greater attention is paid to the mechanical condition of the vehicle than to the driving skills of the operator. Federal and state laws exist pertaining to the physical characteristics of the vehicle. Only limited regulations exist concerning the adequacy of the driver.

The annual cost in 1959 of operating the many school bus systems in the nation was over 400 million dollars. The separate school bus systems, functioning within the unit of the school district, are, in most cases, maintained and financed by the local board of education in cooperation with various state agencies. In fulfilling their responsibility of adequately maintaining these programs, several states have established screening, training, and refresher programs for their drivers. There is a noticeable lack of any such preventive measures in the majority of states, however.

Corrective or punitive measures taken against drivers after the occurrence of accidents do serve as a form of preventive action against future accidents. However, it is the thesis of this paper that the more positive approach of taking preventive measures prior to any traffic offenses or accidents represents a far superior method. Thus, the general hypothesis is that a strict and comprehensive licensing examination will reduce school bus accidents.

Hiring and Screening

As was true in the case of national statistics on the number and severity of accidents in which school buses were involved, information concerning the screening and training procedures for school bus drivers, as they exist in the various states, is quite difficult to obtain. Those states which now have, or which are presently establishing extensive programs in this area do report on their efforts and findings. However, the majority

of states in which programs of wide scope do not exist, report limited data concerning the procedures they employ.

The hours for school bus drivers are typically not those of the usual nine to five working day. They are shorter and are divided over the day according to the arrival and dismissal time of the schools. The salaries paid to these drivers must be expected to be concomitant with these limited hours. It is safe to assume that few adults could support themselves and their families on school bus driver salaries. To supplement the salary, the driver may either be employed in some additional capacity by the school district, or he may hold another part-time job. In any case, due to the nature of the job and its obvious disadvantages, a large proportion of school bus driver applicants tend to be retired persons, students, housewives, or persons seeking only short-term employment. These applicants are not likely to be the best safety risks.

One problem which is highlighted by these conditions is that a good many of the older persons who have been retired from full-time employment and who now serve as school bus drivers are no longer in their physical prime. Unfortunately, attention becomes focused upon this issue only on the occasions when tragedy occurs as a result of the sudden physical incapacitation of the driver. While the question of physical fitness is especially pertinent with reference to the older driver, it is also of serious importance for all drivers. Illinois, for instance, requires not only a doctor's certification of the applicant's physical fitness but also yearly examination during the term of employment.

Part of the screening procedures in both New York and Oregon include careful physical examinations. Of course these examinations are usually designed only to detect gross physical deficiencies such as a serious heart condition which would make the individual a risk on the road. Such check-ups in all probability, seldom determine those psychophysical capacities of a driver (reaction time, depth perception, and field of vision) which are equally important to the safety of the vehicle and its passengers.

As one way of meeting this salient problem of the lack of qualified and physically fit drivers, North Carolina has inaugurated a program of hiring and training students

as drivers. At present, over 90 per cent of the school bus drivers in the state are high school students. The training program for the prospective drivers include 12 hours of classroom work as well as a minimum of six hours of actual road training. This instruction is beyond the ten hours of training required for all driver education students in the state. Such a program as this has obvious benefits in providing the opportunity for close supervision of drivers, quick availability of substitute drivers, and greater selectivity in the hiring of personnel.

Initiated by a safety specialist for a local General Electric plant transportation system, another program involving student participation rather than student drivers, was instituted in the school districts in at least one county in Indiana. Two or more students on each bus are trained to provide assistance to the driver in emergencies. This precaution is, of course, taken to avert the disasters which can occur when the driver is unable to handle or maintain discipline with all of his passengers, or to maintain control of this vehicle in a critical situation or when he becomes physically incapacitated.

West Virginia focuses upon the technical ability of the driver and submits each of its applicants to a six hour training program. This is followed by a written examination and an on-the-road test of the applicant's skill in handling the bus. All training and examinations are supervised by the state police force.

In-Service Training and Testing

In Michigan, the in-service training program consists of a 12-hour intensive instruction program held for all school bus drivers in the state. Small subsistence monies are paid to those drivers in attendance for the two day program. The instructors for the training sessions, each of whom have been trained in highway safety measures, are brought in from several of the colleges and universities in the state.

A somewhat similar program has been established in New Mexico. It is reported that each year 700 to 800 drivers attend the Annual School Bus Drivers' Institute for training in safety techniques. Refresher courses of the same nature are also carried on during the year in areas where accidents or violations are reported.

A program in Oregon was instituted by the State Department of Education in co-operation with the Division of Motor Vehicles. The essentials of this program are similar to the elements noted above. Oregon requires special school bus driver licenses. A team of trained inspectors review safe methods of school bus operation and traffic laws and regulations with the drivers. Satisfactory fulfillment of the training sessions as well as certification of physical fitness are required before the license is granted by the state.

As evidence of the efficiency of a screening program, after all school bus drivers in Georgia were tested, the rate of accidents due to errors on the part of the driver were reported to be "cut in half." Furthermore a total of 252 drivers were disqualified from operating school buses as a result of the tests.

There have been numerous reports in the past several years which contain recommendations for national and/or local school bus driver screening, training, and supervision programs. Most of these include mandatory yearly physical examinations as well as some form of training for the driver in safety precautions to be taken on the road. A recent report recommends, beyond the physical qualifications, requirements for high standards of moral character, emotional stability, knowledge of traffic laws and regulations, skill requirements in the handling of the school bus, and experience in driving. Although such a program would indeed be of great value, careful research must precede its establishment. New Jersey, continually active in the general field of accident prevention, is now in the process of doing such research and establishing such a program.

New Jersey Program

In building a comprehensive program in highway safety, the state of New Jersey recognized the need for rehabilitative (corrective and preventive) supplements to its punitive (law enforcement) measures. In 1952, the first Accident Prevention Clinic was established with Drivers Safety Service acting as technical consultants. Since then, the program has grown to comprise eight clinics located throughout the state. The multiple purposes of these clinics include determining those psychophysical and psy-

chological characteristics of the driver which tend to be related to accident involvement, informing the driver of whatever psychophysical deficiencies exist, advising him of how to compensate for or correct limitations, and imparting to him through counseling, more positive attitudes toward law enforcement, traffic regulations, and safety precautions.

In general, drivers who had more than two reportable accidents or who have accumulated a given number of violation points, or who have been convicted of driving while intoxicated, are required by the state to participate in the program. Each subject is given a thorough psychophysical examination, including tests of visual acuity, field of vision, reaction time, depth perception, night vision, color vision, and glare recovery.

Two psychological examinations are also administered to each subject, although at present, the results of these tests are used for research purposes only. Based upon a comparison between the subjects' scores on each of the psychophysical tests and minimum standards which have been established as the basic requirements for safe driving, recommendations are made to each driver as to what he should do to compensate for whatever deficiencies may exist. This processing, including an initial interview and a final counseling session, usually takes about two hours. In cases of extreme psychophysical inadequacies, the driver is referred back to one of the state licensing centers for re-examination and possible action on suspension of his license unless corrective steps can be taken.

Of the 28,834 drivers processed by the Accident Prevention Clinics from September 1952 through June 30, 1959, only 2,469 have continued to reoffend; that is, he involved in either accidents or violations. This represents reoffenses for only 8.5 per cent of the total group of subjects. As a further check on the efficiency of the Accident Prevention Clinics, research is currently underway to determine the reoffense rate of a control group of drivers, who, though "eligible" for action, were not exposed to Accident Prevention Clinic processing.

New Jersey has had a limited examination program for school bus drivers for some years. Until November, 1960, the following procedure was used in school bus

driver licensing in New Jersey: Together with the initial application form, the subject submitted a medical report stating that his physical condition was satisfactory. He also had to satisfactorily complete a test measuring his knowledge of traffic laws. Visual acuity and other psychophysical tests were then administered to the applicant (Porto-Clinic). The final step was a road test on which the driver had to demonstrate his skill in operating a school bus.

In November 1960, however, Drivers Safety Service was asked to cooperate in setting up a new testing program for school bus drivers. At present therefore, applicants are required to go through the complete Accident Prevention Clinic processing. Any subject who falls below the established minimum standards on any three psychophysical examinations is unlikely to be granted a license.

One of the basic problems in establishing a research program within such a practical setting is meeting the needs of the various agencies connected with the program. The Division of Motor Vehicles and the Department of Education, both agreed on the need for psychophysical test minimums as part of the criteria for school bus drivers. However, although comprehensive recommendations have been prepared by Drivers Safety Service, no standard has, as yet, been set on the psychological or emotional qualifications of these applicants. There is now, in progress, a psychological test program as part of the school bus driver screening.

The tests currently used in the program were originally developed by Drivers Safety Service for use in a rehabilitation program which is supported, in part, by a Public Health Grant (RG-6296 (R1)). The program concerns itself with the rehabilitation of that 8.5 per cent who continued to reoffend following their Accident Prevention Clinic processing. The results of these test administrations to school bus drivers will be used initially for research purposes. As indicated, no applicant is currently denied a license on the basis of these psychological tests.

Table I indicates the extent of yearly accidents, injuries, and death in school buses since 1953. The information has been assembled in such a manner that individual bits of information can become meaningful. For example, Column Three (number of ac-

TABLE I
Accidents, Injuries, and Deaths in School Buses

Year	No. of States Reporting	No. of Accidents	Per Cent of Increase	No. of Injuries	Per Cent of Increase	No. Killed	Per Cent of Increase
1953	30	2,941		701		4	
1954	34	4,346	47.77	983	40.22	8	100
1955	36	5,144	18.36	1,306	34.87	18	125
1956	38	5,809	12.92	1,398	6.61	6	-72.22
1957	37	5,953	2.47	1,171	9.07	7	40.0
1958	40	7,136	20.71	1,580	34.92	29	314.28
1959	39	7,152	-1.47	2,039	28.64	53	127.15
1960	42	8,908	24.55	2,067	1.32	19	-64.15

idents) shows a steady climb in accidents—1960 has almost three times the number of reported accidents as 1953. The number of injuries has also increased at the same rate for this period.

Although it is obvious from the above table that the number of accidents and injuries has increased, the number of people killed each year has fluctuated, so that no pattern is discernable. This is hardly any consolation to those families affected by this tragedy.

We note from this table that:

1. There are still no uniform or complete statistics available on school bus accidents.

2. The number of deaths and injuries incurred in school bus accidents does not follow any pattern other than a steady increase—thus suggesting that more intensive research efforts are needed with an emphasis on the vehicle operator.

The following table compares accident and injuries of New Jersey and national statistics. No tabular presentation is needed for the number killed during this period since school bus deaths in New Jersey for this same period totaled only three. What is particularly interesting in this table is that the number of school bus accidents and injuries have increased at approximately the same rate as the national figures.

TABLE II
A Comparison of National and New Jersey School Bus Accidents and Injuries

Year	No. in N. J.	ACCIDENTS		No. in N. J.	INJURIES	
		Per Cent of Increase	National		Per Cent of Increase	National
1953	46	2.22	47.77	23	52.08	40.22
1954	56	21.72	18.36	33	43.47	24.81
1955	54	3.57	12.92	61	84.84	0.61
1956	73	23.35	2.47	89	45.90	9.07
1957	101	38.35	20.71	69	22.47	34.92
1958	78	22.77	0.47	34	50.72	29.06
1959	123	65.38	24.55	103	202.94	1.32

In terms of percents, it would seem that New Jersey statistics are even more erratic than the national figures. The above comparison will only become meaningful when the licensees under the new program have had sufficient driving exposure to allow for meaningful statistics. Since the new licensing program has gone into effect, the school bus drivers who were processed under this system have had a total of four school bus accidents and only one private car accident, while at the same time, these same drivers have been ticketed for only five moving violations, with none of these

on a school bus. Thus, it seems likely that some aspect of clinic processing is having the desired effect. It would also appear the bulk of the school bus accidents are being contributed to by the drivers who received school bus licenses before the new procedure was put into effect.

One cannot yet draw any final conclusions since sufficient time has not elapsed for these newly licensed drivers to have had sufficient exposure. However, we hope that they will follow a pattern similar to other Accident Prevention Clinic processed subjects.

TABLE III
An Age Comparison of the Accidents and Violations of Three Groups of Drivers

Age	Per Cent of Sample			Per Cent of Violations			Per Cent of Accidents		
	New Jersey	Accid. Prev. Clinic	School Bus Drivers	New Jersey	Accid. Prev. Clinic	School Bus Drivers	New Jersey	Accid. Prev. Clinic	School Bus Drivers
17	1.2	0	0	3.7	0	0	2.9	0	0
18	1.6	2.2	0	3.2	0	0	4.6	1.7	0
19	1.6	4.8	0	2.8	2.3	0	4.8	4.2	0
20-24	8.7	17.0	12.7	12.9	15.2	18.57	18.2	25.9	22.93
25-34	22.9	24.6	22.4	26.9	43.4	45.57	27.6	34.7	28.16
35-44	26.1	22.2	30.2	23.0	28	21.43	20.9	22.9	24
45-54	19.4	10.1	17.1	15.2	6.3	12.14	12.9	3.9	11.24
55-64	11.4	6.3	6.0	8.7	2.9	2.86	6.2	3.9	2.4
65 plus	6.1	1.8	1.6	2.9	1.2	1.4	2.0	.8	.4

Table III is designed to show the accident and violation behavior, in terms of age, of three groups of New Jersey drivers. Columns two, five and eight represent a sample of 303,144 drivers selected randomly from the total population of two and one-half million licensed drivers in New Jersey. Columns three, six and nine represent 1,304 drivers—a sample of the 30,000 Accident Prevention Clinic processed subjects. Columns four, seven and ten deal with the total number of new school bus drivers processed up to October of this year.

No results are recorded for the "under 17" age group—the minimum age for a school bus license in New Jersey is age 21. It is interesting to note that the age range 20-34 of school bus drivers has more accidents and violations than either Accident Prevention Clinic subjects or a sample of all New Jersey Drivers. These facts suggest that:

1. Drivers between the ages of 20-34 ought to be excluded from operating school buses, or

2. More detailed attention should be paid to the past accident and violation history of all applicants, especially 20-34 year olds.

It should be noted that the records recorded for the school bus driver population are for their pre-processing behavior—that is before they received a school bus driver's permit.

The next table presents the pre-licensing records of the newly processed school bus drivers and their post-processing behavior. Table IV indicates, with limitations, a decrease in both accidents and violations. However, we should not be misled by these re-

sults. The time interval between their processing date and the search of their records for post-processing behavior has not been long enough to draw any positive conclusions.

TABLE IV
The Accident and Violation Records of School Bus Drivers: Pre- and Post-Processing
N = 221

ACCIDENTS	
Pre-Processing	46
Post-Processing	8
VIOLATIONS	
Pre-Processing	164
Post-Processing	16

The following four tables compare by per cent of failure, three groups of drivers, on various psychophysical tests. In Tables V (A, B, C, and D) the New Jersey or control group were accident and violation free for a period of three years, before being processed. The Accident Prevention Clinic subjects are a sample of those usually processed for accident involvement. The school bus driver group represents the total number processed, to date.

Each table may be read in the same manner. For example, in Table V A, for subjects aged 36 plus, the controls and school bus drivers had no visual acuity failures, whereas ten per cent of the Accident Prevention Clinic subjects failed on left eye acuity.

The four tables provide some interesting data concerning New Jersey school bus drivers. In terms of visual acuity, field of vision and complex reaction time, the school bus drivers have fewer failures than either of the other two groups. Day depth perception is the one area they fall below the controls and "accident repeaters."

TABLE V A
A Comparison, by Per Cent of Failure, on Visual Acuity, of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	0	0	0	0	0
26-34	0	3.12	0	0	3.12	0
35-41	0	1.56	1.25	1.68	2.17	2.5
42-49	0	3.03	0	1.81	4.54	1.44
50-57	0	2.22	2.45	3.22	8.06	0
58 plus	0	10	0	0	3.33	0

TABLE V B
A Comparison, by Per Cent of Failure, of the Field of Vision of Three Driver Groups

Age	LEFT EYE			RIGHT EYE		
	Controls	Accident Prevention Clinic	School Bus Driver	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	0	0	0	0	0
26-33	1.66	1.66	0	1.54	3.12	0
34-41	.79	1.19	0	1.54	4.34	0
42-48	1.61	4.52	0	1.81	6.43	0
50-57	0	16.32	0	0	16.33	0
58 plus	2.33	12.66	9.09	3.33	11.66	0

TABLE V C
A Comparison, by Per Cent of Failure, of the Complex Reaction Time of Three Driver Groups

Age	Controls	Accident Prevention Clinic	School Bus Driver
18-25	12.50	0	0
26-33	4.6	10.15	2.56
34-41	7.92	12.30	0
42-49	9.09	16.66	1.44
50-57	17.74	24.19	0
58 plus	43.33	46.66	0

TABLE V D
A Comparison, by Per Cent of Failure, of the Day Depth Perception of Three Driver Groups

Age	Controls	Accident Prevention Clinic	School Bus Driver
18-25	0	37.5	39.22
26-33	3.12	34.5	44.87
34-41	7.9	43.65	51.35
42-49	9.09	43.18	62.90
50-57	29.03	38.70	55.17
58 plus	13.33	66.66	54.55

What we may be able to say, if the school bus driver offends at an expected rate, is that their psychophysical characteristics, excluding depth perception, are not necessarily related to their driving behavior. So far, of the over 320 school bus drivers tested and screened, only one has been denied the license on the basis of his failure to meet minimum psychophysical requirements. Therefore, it may be that criteria are either

too low or that only basic psychophysical capabilities are, in fact, necessary.

However, it is more likely a matter of previous screening. Under the new procedure, an applicant has had at least two screenings before receiving his clinic processing. All applicants must first have gone through the usual driver licensing screening and received an operators license. When he or she applies for a school bus driver

permit, he is given a second screening and receives a provisional license for one month; only then does he get the full Accident Prevention Clinic processing.

Conclusions and Hypotheses for Continued Research

It has been generally accepted that there is need for more stringent licensing procedures for school bus drivers. Obviously, if we can prevent applicants who are the greatest risks from operating school buses our accident, injury and death figures should improve. It is also obvious that, in many cases, psychophysical test results give useful information concerning this group of drivers. The need for a high degree of physical fitness is certainly needed. What makes this all the more meaningful, however, is that even with limited pre-licensing counseling, violations and accidents tend to decrease. Thus, we have some basis or logic for *Hypothesis Number One*:

A driver who learns about his psychophysical capabilities and is counseled on the compensatory behavior for any defect tends to have fewer accidents and violations.

As indicated earlier, a start in psychological testing in this area has been made. As yet the number of applicants who have taken these tests is too small for any, even preliminary, analysis. Yet, there is considerable evidence from other studies, that measurement of the psychological and emotional components of a driver provide the best hope for identifying "safety risks." In addition, those applicants who are emotionally disturbed should be screened out since they are operating in an extremely sensitive area. Therefore, *Hypothesis Number Two*:

The inclusion of standardized or custom built psychological instruments in a school bus licensing program has merit, in terms of identifying accident "risks," as well as emotionally unstable applicants.

Although these two hypotheses may seem rather general, their testing holds the key toward reducing school bus accidents.

While the New Jersey research is still in its early stages, it is hoped that studies can be soon initiated to test the above hypotheses and resolve a variety of problems too complicated to deal with in this preliminary paper.

A STRAIGHT LINE ON SAFE DRIVER AWARDS AND INCENTIVES

By E. J. SLINGERLAND
Safety Director, Seattle Transit System, Seattle, Wash.

I think it is safe to assume that every one of us works because he gets paid for it—and no one who works for wages is likely to admit to any other reason. It might seem contradictory, then, to talk about safe driver awards as an incentive for employees when we have already admitted that it is money that talks. Those of you who have tried to sell your management on a driver award program will undoubtedly have met with this argument. What I have been asked to do is discuss some of the criticisms of incentive awards, to see if they are really valid.

When we first suggested a program of driver awards for our operators, we were

met almost instantly with the question "Why should we give a driver a medal for doing the job we hired him to do in the first place?" That may sound like a fairly reasonable argument, but I don't think it will stand much scrutiny. While it is true that when we hire a driver, we make every effort to hire one who will be safe, very few companies can boast that all their drivers are perfect. The latest edition of *Accident Facts* verifies this imperfection by recording over 2,000,000 accidents in 1960 involving commercial vehicles.

So I think that we all recognize that while we might have had high hopes, some of our drivers turn out less than perfect, and will

be involved in accidents. We also know that Tom, the driver who has one or two minor accidents each year, costs us more money, yet draws the same wages as George, who has a perfect record. Is there any reason why we shouldn't publicly recognize George's excellent performance, and at the same time provide an incentive for Tom to improve his record? Though we are all working for money, there are some of us who don't appreciate recognition of a job well done. In the motor transport industry, I believe there is no better recognition than that provided by a safe driver award.

Other critics of our program said "What good is a safe driver award? Only the good drivers will get them, and they won't have any effect on the driver who has the accidents and really needs the help." I wonder if this same critic would refuse to buy fire insurance because when the salesman called, his house wasn't on fire? The inference is the same. Actually, one of the recommendations of a program such as the Council provides is the fact that the benefits reach every driver, good or not so good.

Even the good drivers need a reminder now and then that they are good because they put forth the necessary effort, and not because of luck. Each month we send a letter and booklet or other material to the driver's home, where not only he, but his family as well, reads it. I'm sure that in many cases, the driver's wife has just as much influence on his driving as his company supervisors. One driver told me that after he read the driver-letter, he forwarded it to his son at college, where it was posted on the fraternity bulletin board.

There is another way that the benefits of our program reach nearly every driver. With very few exceptions, the man who has a permanent place on our payroll takes a certain amount of pride in being a good driver. No matter what we're doing, there's a certain competitive spirit that makes us want to be a little bit better than the fellow next to us. If that fellow happens to be wearing a safe driver pin or a shoulder patch, and I'm not, I'm likely to try a little bit harder to get one too. It's possible that I'd never admit it to anyone, but the competition is still there.

This brings up another criticism of incentive awards. Many opponents insist that

incentives for safe driving records, whether they may be in the form of additional pay, merchandise, or a lapel pin, will increase the number of "blind" or "no-report" accidents. I agree that there could be a tendency toward this, but it has been no particular problem to us. Our operators are well aware that while we can possibly excuse an accident, failure to report one is a serious offense which will result in disciplinary action. Last year less than two per cent of our traffic accidents were blind reports.

Some people have told me that an incentive award program requires too much in the way of records—that all I'm doing is making more work for myself. But there is another way of looking at it. No matter what your safety program is, to be effective, it must be based on complete and accurate records. Whether you certify a driver for an award makes very little difference in the amount of work involved; and for any extra work there might be, you are repaid by having available a complete record of each driver's performance. This is essential for any program that produces results in accident prevention.

Of course, the \$64 question, (if such a term can be used) is the one asked by the boss: "How much will it cost?" Unless we are prepared to show that we can save more than the program will cost, we don't stand much chance of selling it. It's easy to calculate the direct expenses, and not much more difficult to add up the indirect costs. There will be the cost per driver in purchasing the material, whether we are giving prizes or shoulder patches. There is the mailing expense if you enter a program that includes such material for the operator.

Some companies pay their drivers for attendance at safety meetings, so these direct expenses would vary according to individual plans, and can usually be figured quite accurately. It is a little more difficult to calculate the money that is saved by such a program. Who can accurately determine the cost of an accident that didn't happen? The best that can be done here is an educated guess, based on your own previous record and the experience of others who have gone into an incentive program. Possibly a few of the facts concerning our own experience in Seattle might be appropriate.

Before we decided to try an award program, we had what we thought was a pretty fair record. Our traffic accident rate was a little better than the national average for comparable properties, and our ratio of claims expense to total revenue had been quite favorable. Our accident frequency rate was more or less stationary, but the cost of accidents was rising rapidly, due to the inflation of claims. In one year alone we had to set aside over \$425,000 for injuries and damages. We felt that if we could reduce our accident costs by as little as one per cent we would save money, as the incentive program that we were considering would cost only about half that amount.

I wish that I could report that immediately after signing up for the Council's driver award program that our accident rate started down, but unfortunately it didn't happen quite that way. It took some time for the program to show effects, and even some of our operators didn't like it at first. However, it wasn't long until even these drivers were showing more enthusiasm for the plan, which they indicated in several ways. More drivers came in to check their records, and ask when their next award was due. Management also took a closer look at these driving records, and we were able to give more attention to the drivers who really needed it. The operators also began to show more concern over their accidents, coming in more frequently to discuss those that were charged preventable. We were always ready to go over these reports with them, using the opportunity to point out the reasons they were considered preventable.

In this way we found the driver award program gave us an excellent opportunity to talk about defensive driving and it seemed

to go over better than when we had to ask the driver to come in.

The driver awards are, of course, only one part of our safety program. We continue to put a great deal of emphasis on training and re-checking. When an operator seems to require it, he is given an additional training period in an effort to help him eliminate any poor driving techniques he may have developed. It is not possible, nor would it be accurate, to say that the incentive awards are solely responsible for the fact that last year we enjoyed the lowest traffic accident rate in the history of our company. Certainly a good portion of the credit for this record, and for the resulting reduction in accident costs is due to this program. It would be hard to find anyone in authority in our company who would not agree that our annual cost of less than \$2000 for the incentive program has not been saved many times over.

In 1960, our cost for injuries and damages was only 40 per cent as high as in 1957, and over the four-year period, the savings were in the neighborhood of half a million dollars. We are not alone in our experience, either. A local trucking concern which introduced an incentive award program reported a 25 per cent reduction in accidents by the second year, and a number of other commercial vehicle operators have made similar reports to our local safety council.

Certainly no one contends that a safe driver award program is a gimmick that will do away with accidents forever, but you will find an increasing number of people who believe that it should be made a part of any well rounded safety program.

A-ROUND THE SCHOOL BUS ROUTE

By WILLIAM B. WOLFE

Asst. Supr. of Transportation, Ohio Department of Education, Columbus, Ohio

It appears that the nation's schools are experiencing such a rapid expansion of pupil transportation today, that schoolmen everywhere are looking for methods of management and control of this growing responsibility.

Pupil transportation is no longer an auxiliary service, but a necessary and important part of the total educational program. Transportation is essential for the operation of most school systems today.

School transportation can be expensive, and it is becoming more so in an increasing amount annually. Many factors are helping to increase the cost of pupil transportation today. School district reorganization and consolidation have expanded this service to a vast number of students who now attend schools in areas far from their homes.

The migration of large masses of city people to the suburbs has increased the number of students transported. Mechanization of the farm has reduced farm population resulting in more sparsely populated farm areas. This, in turn, has caused an increase in the size of rural school attendance areas. The steady increase in our population, coupled with the fact that students attend school more years than in the past, has added to the burden of pupil transportation.

As the size and cost of pupil transportation has grown, so have the number of school bus accidents. In Ohio during the eight year period from 1952 to 1960, school bus accidents increased by 186 per cent. This is a shocking statistic when viewed independent of other facts. During this same eight year period, the number of vehicles transporting school children increased from 7,032 to 8,458, an increase of over 1,000 vehicles. The annual mileage of school vehicles increased by 14,763,516 miles, the number of pupils involved increased by 282,100 during this period. If we consider the growth in all other traffic on our highways during this same period, we can see how the school bus accident problem has been compounded.

It is amazing to note that deaths as a result of school bus accidents increased from two in the 1952-53 school year to five in 1959-60. Injuries, during this same period increased from 65 in 1952-53 to 174 in 1954-55, then declined to 80 in 1959-60.

When one considers the number of buses, pupils, and drivers involved, plus the road, weather, and traffic conditions under which school buses operate, he is surprised that deaths and injuries from school bus accidents, in Ohio, are as low as reported. Even this number is too high; we must work constantly to reduce school bus accidents. The purpose of education is to improve the lives of children, and none of these lives are expendable.

We cannot maintain even one point to a good record. Every parent expects his child to be safely transported to and from school each day. The child should be and can be transported safely. It is the grave responsibility of school officials to provide the people with the safest and most efficient system of school transportation possible for every tax dollar expended.

There are many areas of school transportation in which improvements can be made to add safety and efficiency to the program. We can improve equipment, maintenance, supervision, driver training, and many other facets of the operation of school buses, but the area of concern for this speaker is routing. It is my firm belief that in the area of school bus routing, great strides can be made toward safety and efficiency.

This possibility was recognized by the Ohio Department of Education, and in September of 1960 I began my work as routing consultant and assistant to John Parsons, supervisor of transportation, Ohio Department of Education.

Upon written request from the board of education of any Ohio public school our services are available to help make a survey of the routing plan of the requesting district. It is the purpose of the survey (1) to analyze the routing plan in use at that

time, in light of the four general objectives of safety, adequacy, efficiency, and economy; (2) to determine the needs of the district regarding routing of pupil transportation, being guided by the previously mentioned objectives; and (3) to propose a definite routing plan for pupil transportation that would contribute to the safe, efficient, and economical organization of the school district.

The data for these surveys are drawn from such sources as: the office of the county board of education, county highway department, files of the superintendent or local executive head, building principals, and bus drivers. These data are collected by the superintendent, or the local executive head or their designated assistant, and each district is responsible for the accuracy of its own data.

The information collected and procedure for these surveys involve securing detailed maps of the school district, trip sheets or bus time schedules of the present system, definition of attendance areas, equipment inventory, and school board policy for transportation, if any exists. The existing bus routes are plotted on the map, the school sites are located, boundaries are defined, and students are located along the routes by use of colored map pins, coded to the vertical organization of the school system.

The services of our department are given in the route reorganization process, which involves inspection of roads, route construction, mileage measurement, location of pick-up points, shake-down runs, and driver and/or board of education conferences.

After the survey has been completed, a very detailed report is filed with the local board of education, the county superintendent and one copy is retained by our department. This report contains a complete analysis of the routes of the system in use and those of the plan proposed as a result of the survey. The report also contains a comparison of these two routing plans, plus conclusions drawn from the survey and recommendations for improvement.

Since September, 1960, we have completed some twenty odd surveys in Ohio schools. Most of these have been in districts that have had recent consolidations of rural territory. Although, the local board of education is not obligated to follow the recom-

mendations of our surveys, we have been quite well pleased with the number of districts that have indicated their intention to adopt our proposals this school year. A follow-up of these districts should give some indication of the success of our efforts next year and aid in evaluation of our methods.

You may be interested in the results of these surveys, and I will now present the most numerous conclusions consistently drawn from our studies.

1. The complete lack of board of education policy on school bus routing contributes to the inefficient and uneconomical organization of the present transportation system. This lack of policy also makes the administration of the system difficult and inadequate to meet the needs of the future.

2. The number of buses used in many districts at the present is excessive, and due to the reorganization of the school district, it should be possible to reduce this number by several methods that will be mentioned later.

3. The amount of backtracking on school bus routes can be reduced by proper routing at a considerable savings to the board of education.

4. The number of side spurs to the main bus routes should be reduced in order to save travel time and cost. This would extend the range of the bus and contribute to the safety of all pupils by eliminating some turn-arounds and pick-up stops.

5. The number of pick-up stops should be reduced. This would decrease travel time, extend the range of the bus, and reduce operational cost of fuel and maintenance.

6. Single-trip routing should be eliminated, and double or multi-trip routing used wherever possible to decrease operational cost of drivers and equipment. This would increase the efficiency of equipment used and decrease the number of buses needed.

7. The exclusive use of loop routes limits the range of the buses. They can only pick up pupils within an area limited by one-half the travel time of the route, since they must pick up pupils during the whole travel time. A shoestring route does not pick up on the way out, therefore, it saves travel time and can range farther from school. Not all situations lend themselves to both types of

routes mentioned, and it should be remembered that the loop route can reduce dead-head mileage and should be used wherever possible.

8. Unsafe turn-arounds and stops should be eliminated.

9. The length of routes should be equalized as much as possible to properly utilize drivers and equipment. This may also eliminate some routes altogether, thereby, reducing the number of buses needed.

10. Overloading and underloading could be prevented by constant route revision.

11. Proper assignment of pupils to school and bus route can prevent overloading and underloading, and help equalize length of routes.

12. Small-capacity buses necessitate short routes that are expensive because the number of buses needed increases. When purchasing new buses, larger buses should be considered.

13. When planning routes, dead-head mileage should be eliminated except in cases where shortening routes are needed to extend the range of the bus for scheduling purposes.

14. Travel time on the bus should be equalized for all routes as much as possible. This time should not exceed over one hour for high school pupils and forty-five minutes for elementary students.

15. The long elementary school day caused by transporting the high school and elementary pupils on the same bus should be eliminated. When transporting high school pupils to a different building than the elementary site, dual routing should be used. This decreases the number of buses and drivers needed, and increases the efficiency of equipment.

16. The traditional routing practices and restrictions of the old system should be ignored. New route planning should consider the school district as a whole, and routes and pupil assignment should be made for efficiency of operation.

17. Route revision should be made constantly, and administrator-bus driver conferences should be held periodically.

18. Express routes should be used where possible, especially for high school students. This would decrease travel time, eliminate

pick-up stops, and extend the range of the bus.

19. Feeder cars should be used in areas where the regular route would be too long or an extra route would be underloaded. The feeder car could eliminate unsafe turn-arounds, and long side spurs. The feeder car would also be an aid in scheduling.

20. The average number of pupils transported by a bus in a day should be increased to reduce per pupil cost.

21. Average trips per bus per day should be increased to eliminate the low average mentioned above.

22. Average one-way trip should be lengthened by eliminating excessive stops, side spurs, and turn-arounds.

23. Travel time should be decreased for elementary students and increased for high school students in some cases.

24. Average daily mileage of the buses should be increased to give a lower per mile cost and per pupil cost because of the use of less buses.

25. The extreme range in the composition of the bus load, travel time, and pick-up stops contributes to discipline problems for the drivers and principals and safety hazards for the students.

26. The extreme range in the bus load, stops, and daily mileage contributes to the inefficient use of equipment and driver's time.

27. The use of more buses than needed requires more capital outlay for new bus purchase during the depreciation period of the fleet.

28. The use of more drivers than necessary requires more supervision and salary outlay each year.

29. Maintenance costs should be spread over the smallest fleet necessary.

We do not intend to generalize upon these conclusions at this time, but we believe that another year of such investigation will point the way in which school bus routing should move in the future.

It may be interesting to you to know that in every survey conducted to date, our cost estimates have indicated that a decrease in either the per pupil cost or the per mile cost or both may be expected, as a result of route reorganization. Coupled with this

reduced operational estimate, is another cost reduction in capital outlay for bus purchase because of a reduction in fleet size. The estimated savings in annual operating cost have been as high as \$20,000 in one instance, and the capital outlay savings in this case estimated at \$50,000.

More important than cost have been the indications of improvement in safety such as reduction in stops for a given age group, less or bus. A reduction in side spurs and turn-arounds improves safety, as does the separation of age groups, decreased travel time, and elimination of waiting periods in many cases.

The administrative changes made possible in many cases indicate a better organization of the school day, the curriculum and staff time.

If, after such limited study of the routing situation in only one state, I were asked to state the most urgent needs of school bus routing today, I would suggest the following areas as most important:

Boards of education should consider, write and adopt policy to guide the administration of pupil transportation. This policy should at least be concerned with the following basic questions:

1. The maximum travel time for high school and elementary pupils on school buses.

2. The maximum speed at which buses will be permitted to operate.

3. The maximum time that transported pupils arrive at school before it opens or wait for a bus after school is dismissed.

4. How far normal pupils must live from school in order to be entitled to transportation.

5. The types of physically handicapped pupils entitled to transportation.

School Transportation Sessions

6. How far pupils are required to walk to the main bus line from side roads.

7. Whether the bus will stop in front of each pupil's home on the main route, or only at spaced stops, limited in number by a required minimum distance between stops. It is not suggested that the policies are all-inclusive or that they meet all the needs of all districts. They are presented as essential statements for providing safe, economical, and adequate service.

Boards of education should provide for supervision of pupil transportation in the person of someone other than the head administrator. The problems of pupil transportation today require more time than the head administrator can devote to the job.

Boards of education should adopt the dual routing system for pupil transportation. The high school pupils are transported on separate routes from the elementary pupils. This procedure will free the elementary school from the restrictions of the high school schedule. Dual routing also will reduce the number of buses needed because some of them can be used for more than one route. This is a simple matter of scheduling the start of the high school first in the morning, and elementary school last; this is a matter of board policy.

Boards of education should provide for a public information program to show the need for change in the transportation system. This program should be started long before the actual change is put into effect to avoid public opposition to quick change.

In the final analysis, let us not lose sight of the fact that the purpose of safety, efficiency, and economy in transportation is to make available the better educational program which, after all, is the basis of our existence.

AN OLD AXIOM — SCHOOL BUS ACCIDENT SUMMARY — 1960

By DOUGLAS M. FERGUSON

Superintendent of Safety—Personal Lines,
Nationwide Mutual Insurance Co., Columbus, Ohio

I'm happy to appear here before you again. It's always a pleasure to talk to the leaders in the field of school transportation safety—even when I have to discuss the statistics of our business.

Statistics is never a popular subject—unless they refer to something "vital" and especially interesting, like 38-24-36.

Sir Thomas Browne, an English author of the 17th century, must have had something "vital" in mind when he wrote: "I have often admired . . . the secret magic of numbers."

More to the majority viewpoint, I think, was one of Sir Thomas's compatriots—a bloke named Shakespeare—who noted in his play, "Much Ado About Nothing," that "comparisons are odorous."

The statistics I'm going to review here today may not be as interesting as 38-24-36, but they're every bit as "vital." They pertain to the safe transportation of our "most important cargo"—our school children.

To get into my subject, I cite an excerpt from a report of the 99th Annual Convention of the National Education Association last June. Meeting in Atlantic City, 10,000 N.E.A. members adopted a resolution on the protection of children. That resolution said:

Safety of school children is among the prime concerns of all educators. Yet, despite continuing efforts of school and community groups to prevent accidents and fires, adequate safety remains a serious problem. The National Education Association urges all members of the education profession to continue to use and to expand the day-to-day opportunities for teaching the principles and practices of safe living which are pertinent to their fields of instruction. The N.E.A. calls upon school boards, teaching staffs, and administrators to intensify their efforts to provide physical settings which protect children, to give meaning to the principles of safety, and to enhance the development of safe behavior.

N.E.A. convention resolutions supplement the N.E.A. platform in two ways: (1) by directing the Association's officers and staff

to take specific actions, and (2) by stating the position of the N.E.A. rank-and-file on matters which are educational in nature, national in scope, and of current importance to the teaching profession.

Two things about this particular N.E.A. policy statement are apparent: (1) its scope is greater than the interest of this group here today, and (2) the need for safely transporting an increasing number of children to and from school is the herculean task challenged by the resolution.

Many people, it seems, no longer believe that they can influence actions in their sections of the world. This apathy—this tendency to "let George do it"—may be due to the great international power struggle and the war threats it involves; it may be due to the mighty scientific advances which are announced almost daily; or it may be caused by the world's population explosion and a feeling that one or two people don't count for much anymore.

But whatever the reason for this lack of "go-power," it's up to us—we in this room—to fight it, overcome it, and to pursue the problems of safe transportation with renewed faith and conviction.

We are the leaders—and the manner and methods by which we lead will largely determine the strength and character of those who will follow us, of how many will follow us, and of how good a job we'll all eventually do.

So it's up to us—you and me—to make school transportation safer.

But as I mentioned in this same setting one year ago, we'll see more darkness before we see daylight. With families migrating en masse to suburban homes and with the resulting increase in consolidated school districts, the problems inherent in school transportation have assumed gigantic proportions—and these problems will continue to get worse, instead of better, unless the trends of recent years are reversed.

This is the challenge I throw to you now

Never before have America's school transportation facilities so badly needed the active support and guidance that you can provide. Your demonstrated leadership and experience are absolutely necessary, if the success we all hope for is ever to be realized. That's why I challenge each and everyone of you—in harmony with our colleagues who are absent today—to assume active roles in promoting a safe school transportation system.

Now accident statistics, by themselves, aren't worth much. They're sometimes nice to know, and they may even be nice to look at—but they do not become meaningful unless they are related to a common denominator or inter-related to themselves. For my purposes today, I'm going to inter-relate some statistics through successive years. By doing this, I think I can chart a trend—a trend that should alarm you as much as it has alarmed me.

First, let's look at the progress that's been made in recent years in securing annual school bus statistics from the various states in the U.S.A. In 1953, such data was furnished by 30 states; last year, 48 reported. That's an encouraging increase . . . but before we become sore from mutual back-slapping, allow me to insert a somber note.

Forty-eight states reported last year. That's a fact. But a number of them *still do not separate* their school bus accidents from the total reported for *all* bus accidents. In other words, any accident or fatality involving a passenger-carrying vehicle is recorded in some states. Thus, we safety people don't get all of the information we should to help us plan our attack against accidents. So (if you haven't already done it), I suggest that you acquaint yourself with your state's reporting format and—if it does not conform to procedures recommended by the National Safety Council—I urge you to launch a campaign to bring about adoption of the Safety Council's recommended reporting in your state.

Now, to more accurately measure the size of our school bus safety problems, let's use the reports from the individual states and see how much of an increase there's been in the number of school buses in operation. In 1953, 30 states had 80,000

school buses running. Last year, the number in 50 states was 176,471. I think you'll agree from this comparison that the size of our school bus operation is challenging enough for anyone.

Looking at another angle of our problems, how is the migration to suburbia proceeding? Well, in 1953 five million pupils were transported to and from schools daily. And by 1960—only eight years later—the number had skyrocketed to nearly 12½ million.

Turning to a third area to get the pulse of a rising tide of urgency, let's examine the accident involvement rate of school buses. The figure stood at 2,941 in 1953—and at 8,908 in 1960.

At this point, some of you may be thinking that these advances in numbers transported and accident involvements are not too bad when compared with the increase in school bus usage.

I ask you, though, to please withhold judgment until I make some additional analyses. Because again—this time in the area of school bus accident involvement—some states do not delineate between school buses and public carriers in their annual safety reports. And I don't mean to minimize the tragedy of commercial bus accidents when I indict those states which fail to attach sufficient importance to school bus mishaps to warrant separate accident-reporting data.

When we have accidents, of course, we can anticipate personal injuries. That's as sure as summer and winter, day and night, or flies at a picnic. Statistically, 701 students were hurt in school bus accidents in 1953, and the number had almost tripled by 1960, when 2,067 pupils were injured.

I admit that we might be inclined to look favorably upon these injury figures as they relate to previous data, but again I warn you that such a conclusion will be premature and possibly erroneous.

As long as we have an increasing number of school buses in operation, an increasing number of school children-riders, and an increasing number of injury-producing accidents, we must also expect more fatalities. In 1953, 13 boys and girls were killed while engaged in activities incidental to riding on school buses. In 1960, the number of dead was 50—or approximately four times what it was eight years previously.

My research indicates that previous speakers have given separate treatment to student fatalities which occur on buses and to those which take place while students are going to or from school buses. This separation of information has led to an idea that injuries and deaths occurring while pupils are boarding or dismounting somehow differ from those which take place while the loaded bus is actually moving and transporting its young charges.

I, personally, cannot agree—either with the arbitrary separation of reports of accidents on and accidents off our school buses or with the conclusion that such separation seems to support.

For reasons beyond the intended limits of my presentation, I submit that injuries and fatalities occurring both on and off school buses should be reported together as part of the buses' total operation. I strongly believe this—and I'm exercising the prerogatives of that belief in presenting this accident summary material to you today.

If we now draw the component parts of our problems into one picture, we see what I believe to be a significant, shocking truth. In the period between 1952 and 1961, inclusive, the number of states submitting school bus statistics (but still with some discrepancy), has increased 60 per cent; the number of pupils transported has increased 150 per cent; the number of buses operated has increased 119 per cent; the

number of school bus accidents has increased 203 per cent, and the number of pupils killed has increased 285 per cent.

Now: to those people who have lost confidence in their ability to influence actions in their parts of the world, I ask—what would this school bus safety problem have looked like if every school board could have prevented only one accident or only one injury? How would it look if every state had been able to prevent only one fatality? You know the answers to those questions. But you have to get the questions and the answers to others—and then take them and help us act to solve all of the problems.

Since my assignment is to review the reported school bus statistics for 1960, I can't conclude without going through some more figures. But since you have the same state-by-state data as I (and if you don't, you can get it from the National Safety Council), I'll spare you the agony of a more lengthy report.

Guided by the ancient adage that "the mind can absorb only what the seat can endure," I'm cutting short my part of the program with a tabulation of school bus facts by region. I hope these figures—when compared with the statistics of your state and your neighboring states—will be of interest and value.

In making my tabulation, I have divided the United States into nine regions.

Region	Number of Buses	Number of Accidents	Number of Pupils Transported Daily	Number of Injuries	Number of Fatalities
NEW ENGLAND (Me., N.H., Vt., Mass., R.I., Conn.)	8,351	163	642,543	67	0
MIDDLE ATLANTIC (N.Y., Pa., N.J.)	22,868	1,048	1,971,182	376	7
EAST NORTH CENTRAL (Ohio, Ind., Mich., Ill., Wis.)	32,422	1,079	2,303,890	148	6
WEST NORTH CENTRAL (I.D., S.D., Neb., Kan., Minn., Ia., Mo.)	28,944	1,076	1,041,236	358	2
SOUTH ATLANTIC (Del., Md., W. Va., Va., N.C., S.C., Ga., Fla.)	30,766	2,858	2,453,917	698	14
EAST SOUTH CENTRAL (Ky., Tenn., Miss., Ala.)	18,096	740	1,330,254	160	16
WEST SOUTH CENTRAL (Okla., Tex., Ark., La.)	19,283	414	1,131,216	128	4
MOUNTAIN (Mont., Idaho, Wyo., Nev., Utah, Colo., Ariz., N.M.)	8,502	347	437,948	53	6
PACIFIC (Ore., Wash., Calif.)	12,620	1,186	1,179,190	148	1
CONTINENTAL U.S.	176,471	8,368	12,280,474	2,067	50

In closing, let me say that the picture I've tried to present here today is not a pretty one. I deliberately refrained from using "honey-coated" words or phrases in my presentation with the hope that my words would arouse you—and that you, in turn, would arouse your neighbors and the people of your communities—and that finally all of the citizens and officials of our nation would be awakened—before it is too late.

Active leadership is needed now! Progress is not automatic. The world grows better—not because people wish that it can—but because they know that it can and pitch in and take steps so it can be made better. And we've all got to push and shove and make it better if we're ever going to have the safest transportation possible for school children—"our most priceless cargo."

PUTTING THE RIGHT ANGLE INTO DRIVER SAFETY MEETINGS

By HOWARD R. CHEEK

Supvr. of Transportation, Board of Education of Harford County, Bel Air, Md.

Good safety meetings do not just happen. As a matter of fact, there are far too many school districts in the United States where safety meetings for bus drivers are nonexistent. There are far too many school districts which do not have an organized safety program of any kind in the area of pupil transportation. This is true, not because the administrators in these districts are not concerned about the safe transportation of their pupils, but because this problem gets lost in the multiplicity of problems which cross their desks daily. It is true because they are understaffed and overworked. It is a situation which will continue to exist until the problem is put in its proper perspective and corrective action is taken.

The prevention of accidents is primary among safety considerations and it is my hope that it will not take a series of tragic bus accidents across the nation to impress the people that proper supervision of the bus operation is a vital necessity.

This is exactly what happened in the state in which I live, Maryland. The schools in Maryland are organized on a county system. Since there are 23 counties and Baltimore City, which is a separate political subdivision, in the state there are only 24 school systems. Up until two years ago, one of the county Boards of Education had appointed supervisors of transportation

and some had not. No state aid was made available to help toward the payment of the salary of such a person, and many counties felt that they could not afford such a "luxury."

This situation existed for a number of years, until one morning a train hit a school bus which had stalled on the tracks. Seven high school pupils were killed. Several committees investigated the circumstances surrounding this accident, one of which was appointed by the Governor.

As a result, the Attorney General ruled that expenditures for adequate supervision of school transportation was a legitimate expenditure of state funds. The state Department of Education recommended that each county Board of Education appoint a full-time supervisor of transportation, and one assistant supervisor for each 100 buses in use in the particular county. A full-time state supervisor of transportation was appointed.

A full summer session, yielding six semester hours of credit in the field of pupil transportation, was offered last summer by the University of Maryland. Mr. Wesley Pickle of Tennessee and Mr. Mike Haggerty of Minnesota were obtained as instructors for the two courses offered. I feel that a giant step forward has been taken to assure the safest possible transportation of the school children of Maryland. I deeply

regret, however, that this step was not taken five years ago, and that it had to be purchased with the lives of seven children.

A great deal of time must be spent by someone in planning, organizing, and conducting training programs and safety meetings for bus drivers in school districts from one end of our country to the other. It is just as necessary in Oregon as it is in Virginia. The lives of the pupils in small school districts are just as precious as the lives of pupils in large districts. The first step that must be taken in many school districts is the delegation of the responsibility for pupil transportation to a specific person. The person to whom the responsibility is assigned must have a realistic amount of time to devote to this area.

In my opinion, safety meetings cannot be considered except as a part of the overall safety program for bus drivers. The person whose responsibility this program is must clearly understand what his objectives are and what part the safety meeting plays in meeting these objectives.

Let us consider a total safety program for a few moments. What are our concerns? What do we hope to accomplish? How are we going to go about achieving our objectives?

We are concerned, of course, with the safe transportation of pupils to and from school. That is our objective. We are told by the people who investigate accidents and compile statistics that over 90 per cent of all accidents are the result of driver error. We are, therefore, concerned with the elimination of driving errors by our bus drivers.

I think it axiomatic that the person responsible for the transportation of pupils must select bus drivers with great care. You do not hire someone to drive a school bus whose driving record is loaded with traffic violations.

After the driver is hired, he must be impressed with his responsibility and the urgent need for safe driving at all times. After the first impression, he must be constantly reminded. He must be made "safety conscious." We must change the "it can't happen to me" attitude which all drivers have. The driver must realize that, unless proper precautions are constantly observed, it can happen to him. He must also realize

that whatever happens to him also happens to everyone that is on his bus and who is dependent upon his driving. In essence, we must develop and constantly re-enforce a desirable safety attitude.

The safety meeting is one means of developing and enforcing this attitude. It is not the only means. There are many other things which can be done which will help to achieve this objective.

A safety meeting, however, should not be planned and conducted to develop this desirable attitude. The attitude of which I speak will be developed as a result of the total safety program, which should have a cumulative effect upon the driver.

Safety meetings should be specific in nature, and should treat one topic in detail. It is essential that drivers understand the need for the presentation of the particular topic covered in the meeting. The driver must be properly motivated if he is going to derive any lasting benefit from the meeting.

For instance, suppose a review of your accident reports indicates that several accidents involving school buses have occurred at intersections. Here is a specific problem, which presently exists in your school district, which can effectively be made the topic of a good safety meeting. A presentation of the problem, indicating that 15 per cent, or 20 per cent, or whatever the percentage actually is, of the accidents involving school buses so far this year have occurred at intersections should convince drivers that intersections are dangerous places.

Once the driver has accepted the fact that a dangerous situation does actually exist, he is ready to pay close attention to learning some techniques which will help him to stay out of trouble at intersections. Do not attempt to cover "tail gating" or adjusting to changing weather conditions at the same meeting. These are appropriate subjects for safety meetings on their own. Stick to the one topic which has been selected for presentation and do a good job on that topic.

A poor presentation on the selected topic, or the presentation of a topic which bus drivers do not consider important, can be detrimental to your entire safety program. Bus drivers who attend safety meetings

are attending at a time when they would ordinarily be doing something else. Housewives would be home taking care of their domestic obligations. Service station attendants would be working at their primary job. If they regard safety meetings as important, informative, and helpful they will willingly attend. If they do not, they will not. A poorly organized and conducted safety meeting can be worse than no safety meeting at all.

In organizing safety meetings, careful consideration should be given to the physical arrangements. The time and the place of the meeting should be carefully selected, as these factors will, in part, determine how many of your drivers will be able to attend. Some school districts obtain excellent results by having safety meetings in the evening. I find that, in my own situation, it is best to schedule safety meetings immediately after the morning bus runs, and to schedule them at schools where the majority of the drivers finish their morning runs.

This means that a good number of the drivers scheduled to attend this particular meeting are automatically at the meeting place at the appointed time. It requires less effort for them to stay and attend than it would if they had to make a special trip from their homes at some other time. There is also the advantage of having the educational facilities of the school, such as film projector, motion picture machines, tape recorders, etc., immediately available for use in the meeting. The environment is an educational one and will have some impact upon the drivers.

Careful consideration should be given to which drivers and how many of them attend any given meeting. The meeting will be much more effective if drivers freely participate in an expression of views and/or an exchange of ideas. This will not occur if the number of drivers at the meeting is too large, or if the drivers do not know each other.

In systems which require a large number of drivers, it will be necessary to hold the same meeting a number of times. These meetings should be held in different geographical areas of the system, and should be planned to include not more than about 30 drivers. From the discussions which oc-

cur during the meeting, the conductor of the meeting can often spot misconceptions which drivers have. This will sometimes indicate the need for a meeting devoted specifically to correcting an expressed misconception!

One of the major problems which must be faced in the establishment of a series of safety meetings is that of driver attendance. Bus drivers are just like any other kind of driver, in that they consider themselves considerably better than the average. Many of them have been driving school buses for some period of time, and will not have been involved in an accident of any kind. They consider themselves to be safe drivers, and there is a certain amount of resentment generated when they are asked to attend a safety meeting. The "what can they teach me about driving" attitude must be faced and overcome if safety meetings are going to play an important part in the total safety program.

How do we attack the problem of driver attendance? One way is to make it compulsory. I am sure that this is not the best way. The old adage that "you can drive a horse to water but you can't make him drink" applies to this situation. I think that compulsory in-service training may have some benefits, but I think they are very limited.

Drivers must see that the safety meetings are going to be of some benefit to them if they are to attend willingly. Your job is to make them want to come.

One method of applying gentle pressure in this direction is establishing attendance at safety meetings as one of the requirements for obtaining safe driver awards. This means that drivers who attend safety meetings are recognized on a higher level than those who do not. Drivers like to receive safe driving pins in recognition of the good job they have done. This technique will help to get them to the meetings originally. Whether they return or not depends upon their impression of the actual meetings. If they are helpful, interesting, and informative, they will come back.

The supervisor of transportation in one of the counties of Maryland recently informed me that he had solved the problem of driver attendance. I was rather skeptical, until he explained his problem

and solution. He had been interested in having all bus drivers trained in rudimentary first aid. He was able to obtain a qualified instructor from the regular teaching staff of the county. She was 22 years old, red headed, and had very complimentary measurements. The meetings were held in the evening, and he reported that, not only did the drivers show up, but he sometimes had considerable difficulty getting them to leave. I think his first step in organizing a safety meeting now is to train the red head so that she can be the instructor.

In planning safety meetings, please do not overlook the wealth of expert assistance which is immediately available to you. Be sure, however, that the person that you ask to help you is really qualified in the area in which you need help.

I have never been refused help from people who are knowledgeable in areas which I wish to cover in safety meetings. People throughout the country are concerned with safety on school buses, and will contribute whatever they can toward furthering it if they are asked to do so.

Insurance companies have field safety engineers who are experts in the field. They are more than willing to help, not only from a humanitarian viewpoint, but also because reduced accidents means better business for their employers.

State police are available everywhere and are anxious to help. The American Red Cross welcomes the opportunity to work with drivers in the area of first aid. Safety engineers employed by the government and by private industry have much to offer and are willing to help.

These human resources exist in nearly all communities throughout the country. Not to make use of their talents is a great waste.

Care should be exercised by the person who is responsible for safe transportation, however, that personal contact with bus drivers is not lost. Even when the problem to which the meeting is devoted is being discussed and treated by an appropriate resource person, the supervisor of transportation, if that be his title, should be in attendance at the meeting to introduce the resource person. He should remain throughout the meeting and help to get the discussion and exchange of ideas started.

He should be available after the meeting to talk with the one or two drivers who always have some question which they wish to direct to the supervisor. His presence indicates that the entire school system endorses and approves of the meeting and the concept of an organized safety program. Just as it is hard to visualize an effective faculty meeting without the principal, or an effective board meeting without the president of the board, it is hard to visualize an effective safety meeting without the person responsible for safe transportation in attendance.

There are two cautions to be observed in conducting safety meetings. The person conducting the meeting must realize that he is presenting the topic to a very heterogeneous group. In the group he will have housewives, farmers, retired army officers, service station attendants, and men who work the night shift at a local industrial firm. He will be confronted with educational levels ranging from completion of the third or fourth grade through graduation from college. The members of the group will have vastly different backgrounds. All of these factors must be recognized, and the material must be presented in such a way that it is understandable to everyone. It is always good to use visual aids as much as possible. Such aids might include motion pictures, film strips, overhead projector, and the use of flannel boards or magnetic boards. The last two are particularly valuable for setting up actual and hypothetical traffic situations. Remember that you are after understanding. More understanding will result if the presentation is on a level which is easily understandable by those making up the group. It is not necessary to impress them with our scholarship.

The second caution to be observed concerns the length of the meeting. When the objective of the meeting has been accomplished, stop! Just because the meeting is scheduled to last one hour is not sufficient reason to drag it out. When the appropriate understandings have been developed, everything else is superfluous. Interest will wane quickly, and drivers, when they are finally dismissed, will leave with a bad taste in their mouths. There is nothing sacred about one hour. A good 40-minute meeting is more to be desired than a half dozen poor one-hour ones. As I have stated before, drivers

will not willingly return to be subjected to poorly planned and conducted meetings.

In brief summary, the following must receive careful consideration in organizing and conducting effective safety meetings:

1. Some one person must be delegated the responsibility for school bus safety. This person must have sufficient time to devote to doing this job.
2. Time and place should be selected carefully so that it is easy for drivers to attend.
3. Number of drivers attending each meeting should be controlled so that meetings are not too large.
4. The safety meeting must be specific in nature. The objectives must be clearly defined.
5. The drivers who attend the meeting must be convinced that the topic of the meeting is an important one—one in which they are interested.
6. The presentation must be informative,

interesting, and geared to a level that is readily understood by the members of the group. Human resources in the community should be utilized.

7. Visual and auditory aids should be employed wherever possible.

8. The meeting should be adjourned when the objectives of the meeting have been accomplished.

9. Drivers who regularly attend safety meetings should be rewarded on a higher level than those who do not.

I would again urge that school districts across the nation take the necessary steps to improve the safe operation of their transportation system. I do not mean to imply that travel by school bus is presently extremely hazardous. It is far from it. I do think, however, that increased safety and increased economy can be realized if qualified, trained personnel are appointed to administer this phase of the school program. Do not wait until the horse has been stolen. The time to act is now.

ENCOMPASSING CONTRACT BUS OPERATORS IN THE TRAINING PROGRAM

By BENJAMIN W. NELSON

Supvr. of Transportation, Board of Education of Worcester County, Snow Hill, Md.

In the technological age in which we are living much attention has been focused upon the school system and imploring eyes are watching all of the supporting services which are linked to the total program.

Since transportation is one of the supporting services and we are involved in this endeavor, it is essential that the major purpose of pupil transportation services be defined:

1. To provide educational opportunities for all children regardless of the distance they may live from an appropriate school center of the proper grade level.
2. To provide educational experiences for children above that which might be obtained in a classroom situation.

With the listing of purpose, one needs to add the objectives that have been proven

necessary in the development of any satisfactory program of pupil transportation service. They are as follows:

1. **Safety**
The first objective is to provide maximum safety for all pupils to be transported and in so doing, the following items should be observed by the Board of Education:
 - a. Provide adequate and safe bus equipment.
 - b. Select drivers who are capable of operating large vehicles.
 - c. Make a thorough study of transportation routes in order to eliminate unnecessary hazards in operation.
 - d. Provide for the adequate supervision of drivers and the maintenance of equipment.

3. Economy

The second objective is to provide transportation services at a low cost. In order to maintain a program of pupil transportation within the available funds, it is necessary for a school system to make constant studies and revisions in order to achieve the best service from the funds available for this purpose.

3. Adequacy

The third objective in the operation of a pupil transportation program is based on adequacy of service. In an effort to provide adequate services for all eligible children within a school system, board of education should consider the following items:

a. A sufficient number of buses to provide transportation services on a system-wide basis for all children within a reasonable time limit.

b. Provide express type transportation services for children living in remote areas. This arrangement for services should be made to eliminate the necessity of children being required to remain on a school bus beyond the limit of one and one-half hours.

4. Efficiency

A fourth objective requires efficiency in operation. Since the efficient operation of a transportation program depends upon the placement of responsibility, it is necessary that the following factors be given careful attention prior to and during the school term by all responsible persons connected with the program:

a. Observance of time schedules on a pre-planned basis in order to eliminate inconveniences to those students meeting or waiting for school buses.

b. Selection of appropriate bus stops so as to minimize the danger of accidents on heavily traveled highways.

c. Provide a sufficient number of buses to prevent overcrowding and lengthy routes.

d. Employ capable drivers within the communities to be served.

e. Maintain adequate maintenance facilities to insure minimum expense and maximum safety in operation.

In order to insure that the philosophy and goals of a transportation program may be realized, it is essential that clearly defined policies be passed by the Board of Education.

It is felt by many that the following should be covered:

1. The general philosophy of the transportation program should be stated.

2. A detailed spelling out of operating procedures is required.

3. Consideration must be given to the type and capacity of the buses to be used.

4. There should be plans for routing and scheduling buses.

5. A specific declaration relating to pupil privileges and responsibilities is necessary.

6. Duties of various personnel must be defined.

7. A realistic system is needed for replacing buses in service.

8. A program of maintenance and repair is needed to keep buses in satisfactory operating condition.

9. Outline procedures for the transportation of pupils for field trips and extra curricular functions are required.

10. Proper training of contract drivers is necessary.

Recognizing the importance of the driver in the total transportation program and the objectives previously stated, our Board of Education put into effect a Pre-Service Driver Training Program.

At the present time the Board of Education will not employ any individual to operate a school bus unless he has successfully completed the program consisting of fifty hours of work.

The course consists of actual classroom work, with tests, plus supervised driver training and then the final check out, by the State Police in a bus over a pre-determined route, taking into account the skills learned in the training program.

Enclosed is an outline of the material covered in the course

Pre-Service Course for Bus Drivers, 1960-61

I. Content of course

A. Transportation

1. Importance of training program
2. Importance of transportation in school system

B. Responsibilities and regulations of school bus operation

1. State and county responsibilities for transportation

2. Contractor
3. Driver
4. School bus law
5. School Board regulations

C. The school bus

1. Bus care and maintenance
 - a. Driver's daily checks
 - b. Emergency equipment
2. Bus housekeeping

D. School bus operation—policies and procedures

1. Schedule
2. Loading and unloading
3. Railroad crossings
4. Stops and blinkers
5. Pupil discipline

- a. Types of bus problems
- b. The Principal and bus discipline
- c. Discipline on the bus
- d. School bus rules
- e. The Supervisor and bus discipline

6. Bus drills

- a. Front door
- b. Back door
- c. Two door

School Transportation Sessions

7. Accidents and how to prevent them

- a. Types of accidents
- b. What to do in case an accident happens

8. First aid

- a. The first aid kit
- b. What first aid should a driver use in his situation

E. Public relations

1. What and why
2. Who and how

F. Fire prevention

1. Causes of vehicle fires
2. Use of extinguisher

II. Driving skills

- A. Individual alertness test
 - Person rides in another bus and observes correct and incorrect skills displayed.
- B. Behind wheel test for each person over a prescribed route checking skills of performance.

III. Written tests

- A. Traffic and driving knowledge
- B. Psycho-physical tests
- C. Essay test on materials covered

A HEXAGONAL PROBLEM — SCHOOL BUS SELECTION

By M. R. LIECHTY

Engineering Consultant, International Harvester Co., Chicago

The selection of school bus vehicles is truly a six-sided problem. And even more than a hexagon, we might call it a revolving hexagon. As the six sides of this hexagon, we have selected (1) vehicle life and dependability, (2) vehicle repairs and replacement, (3) maintenance and operating expense, (4) spare units, (5) purchase price, and (6) vehicle application. And when we say that it is a revolving hexagon, you will notice that as your application of vehicles to the intended service is improved, your operating expense will be reduced. You will find that as the dependability of your vehicles rises you will re-

quire fewer spare units. You will find that as you spend more money on the original purchase price for better equipment, you will usually spend less money on repairs and breakdowns. Let's look at each of these items a little bit closer.

1. Safety

As a representative of the School Bus Chassis Committee of the Automobile Manufacturers Association, I can tell you with confidence that the chassis industry feels that we have come a long way up the safety curve, insofar as new vehicles are concerned. There are always things which

can be done. We constantly strive in the direction of added safety and some of the suggestions which we can make at the present time are these:

(a) *Power.* For many years school buses were built with barely enough power to drag the vehicle from its loading source to the school and back home. While other vehicles have been increasing in the power and performance areas, school buses have long been inadequately powered to keep in step with traffic. The new power formula, which was adopted by the national minimum standards for school buses in Lawrence, Kansas, in 1959, is now coming into full play.

It is a good formula for a minimum power standard. Vehicles which meet these standards will have better acceleration than the older buses and, in turn, will tend to help keep traffic moving, especially in congested areas and on high-speed highways. This power standard is a good minimum, but it does not preclude the chance that there are applications which need even more power for proper ability to accelerate and maneuver in traffic.

(b) *The driver's position.* We in the chassis industry feel that the driver's position, visibility, and driving attitude, has a tremendous impact on the safety of the school bus operation. We are not satisfied with the driver's physical position in the present day conventional school bus. Too often, while the driver can see well enough to operate the bus satisfactorily, he does not have the superb vision which he should have if we are to achieve maximum safety.

We, the chassis people, and our school bus technical committee are actively exchanging ideas with the engineers of the body manufacturers through their association, in order to improve on and eliminate this particular problem. We have already offered and are actively engaged in selling transit type units with the driver mounted in the front part of the bus where he has an excellent view, not only of the road ahead, but also of the pupils who are entering the bus itself.

(c) *Brakes.* It would be improper to talk about vehicle safety and not mention brakes, but it is our opinion that the single largest improvement in brakes is in the area of maintenance rather than with new equip-

ment. There are new things being offered, such as the parking brake, which is spring applied and air released and actuates the rear truck brakes when the air is lost on an air brake equipped vehicle, but the majority of school buses are still using hydraulic brakes.

There is a new split-system on hydraulic brakes which will be offered in the near future by various manufacturers to enable the operator to bring the vehicle to a stop on those occasions where a failure with the present system might cause a complete loss of braking. But the best safety factor in any brake system is still good maintenance—preventative maintenance, prior to failure.

(d) *Weight distribution.* When you select a new bus you should consider weight distribution, which is an important factor in achieving good vehicle balance and stability, but normally we in the industry do this for you by offering only those wheelbases on only those passenger sizes which result in satisfactory distribution.

(e) *Seating capacity.* We are sure you will agree, that in making new vehicle purchases, it is necessary to plan a seat for each youngster and at least 10 per cent more if it is economically possible. Natural population growth often forces some routes to pick up more pupils than can be properly seated, but in making any plans for new vehicle selection you will most certainly want to provide enough seats to accommodate all of the pupils and a few extras.

And, one more thing on accidents—we have attempted, for years and years, to avoid school bus accidents by stopping all traffic. In reality, traffic in this day and age on high-speed highways is safest while it is moving uninterrupted. It is our belief that the eventual long range goal in school bus safety must include a program where the school bus does not interrupt high-speed traffic. This may necessitate pull-off areas on congested routes and other new ways of loading and unloading which will allow traffic to move uninterrupted in both ways.

We think it is imperative that plans be started now to keep the school children completely off high-speed multi-lane highways. The very act of stopping traffic, in many instances, directly contributes to the accident. Today's school bus is much like

the Sunday driver—not a menace of himself, but breeding congestion, ill will, and discontent, all of which are safety menaces.

Now, what are the six sides of this problem?

Vehicle Life and Dependability

Certainly if you have any pride in your transportation organization you must have an excellent degree of dependability. Your buses must maintain accurate time schedules to allow a high degree of conformity on the route and thereby enable Mamma to have Johnny on the corner without making it necessary to wait for long periods of time in adverse weather. It is wonderful, for our purpose, that when we select a unit adequate to do the job in a dependable manner, that we normally also get longer life as an added bonus. There is no better bargain in school transportation than an extra year of dependable service built into a school bus.

Spare Units

Across our rotating hexagon, as life and dependability of the selected vehicles go up, the number of spare units you need to maintain rigid schedules will go down. This is a natural reaction.

Application

But dependability is also very closely related to the application of the vehicle in the intended service. Buses have been getting bigger and bigger for good reason. The population of the various areas has been increasing so as to enable the average school bus route to fill a larger bus in the same time. It is rarely practical to buy a school bus which cannot be loaded in one hour. Consequently, we expect that for many years stabilized communities will cause a sizable demand for 48 and 54 passenger units, but the areas where the population is increasing most rapidly are areas of dense population. In these fast growing densely populated areas, it is natural that we should lean more toward the 60 and 66 passenger units.

Using today's methods, the 66 passenger unit is the longest bus which we can build in a conventional type unit and still stay within the overall length limit of 35 feet. Since this bus will be operated in congested areas, and since it requires 256 inches of

wheelbase to properly distribute the load, it is too cumbersome to maneuver properly in congested areas. Further, in congested areas we can fill a bus of even larger size in a short time and this is where we recommend the transit type unit which can accommodate another row of seats. The transit type unit with the engine in the front, and capable of hauling 72 seated pupils, has only a 208-inch wheelbase of the conventional 66 passenger unit. This shorter wheelbase results in much better maneuverability and the driver is "up front" where he can see.

With the engine mounted in the front, the transit type bus needs a beefed-up front axle and front suspension system to carry the extra load, which is suspended ahead of the front axle. The axle entrance way is less than ideal because of the engine cover which uses up a large portion of the floor area in the front of the chassis. The forward control unit does retain an innate identity with normal truck parts. The engine, transmission, radiator, and shift controls are all in positions similar to normal truck operation, allowing a high degree of standardization with other parts and a reasonable purchase price.

To gain the ultimate in application for congested areas, we suggest the pusher bus with the engine mounted in the rear; this bus includes the advantages of short wheelbase, ideal driver location, flat front floor with unlimited aisle room, and ideal load distribution with the 1/3—2/3 front to back load distribution ratio, which allows each tire to carry its proportionate part of the load.

The price goes up a bit because it is designed as a bus instead of a truck, but the application is ideal. In visiting with school bus people over the years, we have often been faced with the question of compromises between a truck chassis and a bus chassis and have been asked to build a vehicle specifically for bus service. The pusher bus unit is such a unit and is designed from the ground up to haul young people.

Other applications, which we must recognize in order to complete the job of getting the pupils to school, are cases which transport the physically handicapped, requiring special driver attention, and many areas are hauling small loads over long distances.

In still other applications, it is ideal to use small vehicles for feeder buses to congregate more pupils in pick-up areas where the larger units can pick them up fast and then make multiple trips to the school. For such an application, a small vehicle, such as the *Troveland*, is gaining popularity and serves a very important purpose. Directly across our hexagon is maintenance and operating expense.

Maintenance and Operating Expense

When it is possible through good application to use five large units instead of six smaller units, then you can save one driver, the housing and greasing expense, and the driver's supervision that goes along with each separate unit. If the six units should be 60 passenger units and the five units should be 72 passenger units, it would result in exactly the same seating area. It is easy to see that when our application is improved, maintenance and operating expenses will go down. But when we talk about the proper application reducing maintenance expense, let us not talk about shoddy maintenance. We sincerely believe in preventative maintenance in school buses, to tear down and inspect, repair and replace all parts before they have a chance to fail in operation.

Other things enter heavily into the particular application and should be considered when making the school bus selection. Such things as cold climate where additional heater capacity is needed. And even time zones such as an area which uses daylight saving time, might use headlights, clearance lights and other lamps sufficiently to warrant buying larger generators. So the selection of the proper equipment to fit the particular application is directly related to the maintenance and operating expense. And what else must be remembered? Repairs and vehicle replacement.

Repairs and Vehicle Replacement

Maintenance and operating expenses are very closely related to repair expenses. For instance, in making recommendations for the national minimum standards, it was the consensus of that group, that a 12-volt 35-amp low-speed cut-in generator was a satisfactory minimum to be used on school buses nationally. The statement has often been made and we repeat it here, that so

often the minimum becomes the maximum. People who select school bus chassis are too often inclined to select components without sufficient analysis, especially on technical capacity of items such as generators.

This can result in a vehicle with inadequate electrical capacity to replace the current drawn from the battery. When this happens, it can only mean trouble. A battery is exactly like a checking account—you cannot draw out more than you put into it. In order to avoid dead batteries, many states are now setting a minimum of 12-volt 50-amp low-speed cut-in generators and even this size is not adequate for all applications. Always compare your generator capacity with the expected current draw.

The wide-spread use of heavier axles, bigger brakes, larger and more powerful engines, in the same application, will reduce the expense of costly repairs and substantially lengthen the vehicle life.

Purchase Price

And to get back to our hexagon—it is not surprising to see that when you take some definite steps to buy adequate components, reduce repairs, and lengthen vehicle life, then the purchase price goes up. Now the purchase price is very important in the vehicle selection and often is the one outstanding factor which is used in determining what the final selection of vehicle should be. We all know that the purchase price is important, but I contend that the price does not warrant the attention which it receives in making a school bus selection because the best is often cheapest in the long run. But price has been over-emphasized to an extent where our hexagon is out of balance. Prices go too low, repairs go up too high and vehicles are replaced more frequently than necessary.

The transportation industry has concentrated its last ten years in large part to the problems centering on economy of operation—cost per mile of units hauled. In coping with this problem, many facets are involved but I would like to make it appear simple by comparing two typical truck users.

The individual, who owns and drives his own vehicle, often faces his biggest obstacle in purchasing new equipment. He must keep the price low because of the money required to finance the deal and

makes his payments out of proceeds earned by the vehicle. Price is important to him, so he buys a highly stressed vehicle and squeezes out every drop of revenue it can produce. It puts him in business but he is not getting a low cost per mile.

The larger operator or company which has better access to capital funds needed to finance the purchase of ideal equipment, is buying more expensive, low stressed equipment. These operators are rewarded with more dependability, longer life per vehicle, less repair expense, and lower cost per mile of units hauled.

Most school buses have long been in the category of high stressed equipment with short vehicle life because of the emphasis on purchase price. I am happy to see bus users taking a good look at the over-all expense of operation and, therefore, leaning farther over to the side of low-stressed long life equipment as an ideal long range way of reducing the cost per mile per pupil hauled.

So there you have it—a six-sided problem of selecting a school bus, but all revolving around safety and written bid specifications; we must never compromise on safety, and we will always have written bid specifications because most buses are owned by public schools—in fact, our last accurate figures indicated that 64 per cent of all school buses are owned by public schools, 10 per cent by private schools, with the remaining 26 per cent by contract haulers.

I am sure that the 26 per cent of the buses which are owned by contract haulers are selected with all the factors which we have discussed here, carefully considered in the vehicle selection. I am confident that the 10 per cent owned by the private schools are carefully selected, based on all six-sides of the hexagon, but very often the 64 per cent which are selected by the public schools, are selected with the purchase price as the prime factor. When the purchase price is the prime factor in school bus selection, an age-old proverb comes into play; namely, that nothing is so bad but that someone else can make it a little worse and sell it a little cheaper.

I am sure that the transportation officials who buy all of their buses on written bid specifications and low bid realize this and

consequently spend almost 100 per cent of their time, which should be devoted to the vehicle selection, to writing bid specifications. It is, consequently, important that we give it some consideration when we talk about selecting a school bus.

On the one side of the ledger we have the people who actually make their vehicle selection based on good and bad experience, and then write their bid specifications so that the vehicle which they have selected will comply and other vehicles will not comply. This gets the job done in a sense, but we could not, in all fairness, contend that this is free and open competition.

Other people tend to set their own arbitrary standards of brake lining area, engine cubic inches and other physical dimensions, which enable the user to select vehicles with components which have previously been found necessary to satisfy his requirements. This also gets the job done in a sense, but this method has some bad side effects which we in the industry do not like. We know that a larger brake will last longer in a school bus operation, but if you buy brakes on their size alone then you destroy the initiative of the engineer who is constantly striving to build a longer life brake in the same size.

We know that an engine with a larger cubic displacement will last longer, but when you start buying engines on size alone, then you destroy the initiative of the industry to build more efficient engines and to build more engine life into engines which are of adequate size and power to do the job. When you specify clutches by diameter because you desire longer clutch life, then you give no credit to the countless number of people who are working on better linings in the same diameter and tremendous strides are being made in this area.

But, generally, when you buy school bus vehicles on price alone, then you are assuming that all of the vehicles offered are exactly equal and you destroy the incentive of individual companies to build more quality and longer life into their specific bus. You must recognize the differences if quality is to be an incentive to the manufacturer.

So it is the recommendation of the chassis industry that written specifications be based

on performance standards rather than physical dimensions. Tell us what you want this vehicle to do and how you want it to react so that we can take the resources which we possess, our efficient staffs of engineers and testing personnel, to build you the vehicle to do the job which you want it to do. Tell us what you expect by way of vehicle performance and vehicle life. Tell us what problems you are encountering which need to be solved and let us help you with them.

When you write bid specifications, take the time to investigate your specific needs

and write specifications which will result in the quality of merchandise that is required in your application. And when you make your selection from those offered, pick the units that are most economical in the long run, buses that will add to the dependability of your time tables and add to your vehicle life, that will reduce repairs, cut down your operating expenses and eliminate accidents.

Let the local chassis people help you with written bid specifications so that this six-sided figure will become balanced and resolve the way it should—around safety.

THE APEX IN SCHOOL BUS MAINTENANCE

By JOHN M. PARSONS

Supervisor of Transportation, Ohio Dept. of Education, Columbus, Ohio

Pupil transportation in the U. S. today is a big business. It is big in size, big in cost, and a big operation to administer. In many schools across the Nation, pupil transportation is the big problem of school boards and school administrators, and this problem is still growing.

A few short years ago pupil transportation was a small auxiliary service to be tacked onto the school budget and to be administered easily by spending a few hours with several bus drivers. Today the cost of pupil transportation is a major item in the school budget, and administrators spend many hours struggling with the problems that accompany this growth.

Pupil transportation is no longer an auxiliary service, but a necessary and important part of the total education program. Transportation is essential for the operation of most school systems today. The school bus has also become an extension of the classroom in many school systems. The use of school buses for educational trips such as field trips, county and state testing programs, county vocational schools, etc., is increasing.

School transportation is being used not only to transport pupils to and from school, but to extend the educational horizon, to help attain the American ideal that every

child, regardless of where he lives, or his physical handicaps, has the right to an adequate educational opportunity.

School transportation can be expensive, and it is becoming more so in an increasing amount annually. Many factors are helping to increase the cost of pupil transportation today. School district reorganization and consolidation have expanded this service to a vast number of students who now attend schools in areas far from their homes. The migration of large masses of city people to the suburbs has increased the number of students to be transported.

Mechanization of the farm has reduced farm population resulting in more sparsely populated farm areas. This, in turn, has caused an increase in the size of rural school attendance areas. The steady increase in our population, coupled with the fact that students attend school more years than in the past has added to the burden of pupil transportation.

School districts in the past have been typically small in area and population, because school districts were small the need for pupil transportation did not create any urgent fiscal consideration by school boards.

School boards were able to operate their pupil transportation program with a small fleet involving very little capital or opera-

tional outlay. These small fleets were usually maintained by local garages and since most schools had small fleets their yearly maintenance cost would be very minor in comparison to other component parts of the school budget.

For instance one district in Ohio ten years ago had a fleet of two school buses. The total operational expenses for the two buses for an average year was \$2,400. Today this district by consolidation inherited 20 additional school buses. The average operational cost ten years ago per bus was \$1,200. Considering the present average operational cost in Ohio for each individual bus at \$2,100 the total operational cost for this district with 22 buses would be \$46,200, not a small item anymore for school boards to consider.

Also, to be considered by school boards is the capital outlay needed to transport all eligible students. Replacing 22 buses at one time would cost a school board approximately \$132,000. Therefore, it is of the utmost importance, due to increasing operational cost and capital outlay, for a district to establish a safe, efficient and economical maintenance program that will insure maximum longevity for their school bus fleet.

I. Developing a Summer Maintenance Program

It is of the utmost importance for school districts to establish a maintenance program, not only for economy and efficiency but also for the safety of our students transported. A maintenance staff dedicated and responsible for a safe operation is the apex of a safe, economical, and efficient maintenance program. We in Ohio feel that during the summer months is the critical period and at this time a maintenance foundation for school buses needs to be established.

In other words, this is the time when mechanics can do a superb preventative maintenance analysis and have the necessary time to make proper repairs. If this foundation is not built strong enough during the summer months, then a maintenance problem is created for the coming school year.

In Ohio our summer issue of the *Pupil Transportation News Letter* is devoted entirely to maintenance. The following are some of the helpful hints and preventative maintenance tips we call "trouble shooting"

that are used to guide mechanics in their preventative maintenance program.

Low Oil Pressure: can indicate clogged oil pump, worn main bearings, worn rings or loose lines—small leaks are not too difficult to spot, and it has been estimated that an oil leak of one drop every 30 ft. will account for a gallon of oil in about 400 miles of driving.

Valves which do not seat properly, or do not have clearances adjusted properly can often be detected by sound, and, of course, can always be detected by the compression test.

Cylinder Head and Block: A defective head gasket or a warped head or block will result in loss of compression. Cracks in the head or block may be indicated by water on the spark plugs or in the oil pan, and may result in loss of compression, water in the fuel mixture or improper lubrication.

Engine Mountings: Visual inspection can be made to see if they are very loose. If the mountings are not kept tight, damage can be done to the clutch and/or drive line parts.

Clutch: In those buses equipped with a conventional transmission, power is transmitted through a clutch. Improper adjustment, i.e., no pedal free travel, will cause a slipping clutch which, of course, can be quite expensive. Improper driving habits, such as driving with the foot on the clutch, can lead to the same result. A dragging clutch is most likely caused by too much pedal free travel and natural wear must be compensated for by adjustment of pedal linkage.

Transmission Noise: Noise which seems to come from the transmission, may be caused by another assembly such as the axle, propeller shaft, universal joint, or clutch. Transmission noise may also result from the use of improper or insufficient lubrication, or from poor driving practices. Of course, if the gears are worn or broken, or the bearings on the shafts are bad, replacement is required. This is expensive.

Propeller Shafts and Universal Joints: Excessive noise or vibration can be caused by lack of lubrication; also if propeller shafts are not assembled with universal joints in the same plane, vibration will result. Worn universal joint bearings or journals or a sprung propeller shaft will cause vibration and noise.

Axles: An unusual noise is usually the first indication of improper functioning of axle driving parts. Noises which seem to come from the axles may be caused by the transmission or tires. If there is a continuous axle noise, drive the vehicle on soft ground. If the noise ceases, it has been caused by the tires and not the axle. If the noise continues on soft ground, it is caused by worn or improperly adjusted wheel bearings, worn or improperly adjusted differential gears and bearings, or insufficient lubrication in the differential. If the axle noise is heard in drive only, or in coast only, this is an indication that the differential pinion and ring gear are out of adjustment or excessively worn.

Wheels, Hubs and Tires: 1. Excessive or unequal tire wear—unequal tire pressure may be responsible. Inflate all tires to the recommended correct pressure. 2. Front wheel misalignment will cause unequal tire wear. Check and correct. 3. Bent wheels or damaged wheel bearings will cause uneven tire wear. Replace if necessary. Hard steering may be caused by under-inflated tires, steering gear in need of adjustment, or lubricant. Front wheels out of alignment or wheel bearings in need of adjustment.

Steering System: Proper operation of the steering system is closely related to other units in the vehicle. Steering difficulties may involve such factors as front axle alignment, front spring suspension, tire inflation, wheel and tire mounting, wheel bearing adjustment, frame alignment and brake adjustment.

Springs: Break of spring leaves is usually the result of overloading the vehicle or driving at excessive speeds over rough routes. The bus carries a plate giving the manufacturer's recommended gross vehicle weight. This recommendation should be followed, or if this is not possible, allowances should be made when driving the vehicle. Loose or missing rebound clips, or loose U-bolts can also cause spring failure. Frozen shackles, due to lack of lubrication, will also cause spring failure, and also cause springs to break.

Shock Absorbers: Where furnished, are an important part of the suspension system with the springs. They should be checked and filled or replaced when they do not serve their function of damping out rebound.

Brakes: Today's modern buses subject their brakes to terrific stresses. Therefore, it is imperative that brakes be kept in adjustment. If linings are allowed to wear too long, or if shoe contact is not true on the face of the brake drums, wear will be far more rapid and brake drums can become egg-shaped or out-of-round. To correct this wearing is far more expensive than the routine inspection. Tightening of connections, slack adjusters and the like and relining—should be part of your standard preventative maintenance program.

Body Maintenance: During the summer all school bus bodies should be checked for rust spots, deteriorating flooring and seats, emergency door operation, replacement of glass, body attachment to chassis frame, first aid kit, all warning devices and lights, fire extinguishers, flares, pots, etc.

Summer months are an ideal time for mechanics to touch up all rust spots or repaint portions of body. Older buses should be repainted. This will add longer life for the body, and will eliminate need to replace a school bus because of body deterioration.

A preventative maintenance summer inspection check sheet should be available for the mechanics and all buses should be checked thoroughly during the summer. We mail a check sheet to all schools early in the spring as a reminder to the maintenance staff that a preventative summer maintenance program should be a complete and thorough analysis and repair of the school bus chassis and body.

II. Developing a Preventative Maintenance Program.

Preventative maintenance is the necessary apex for a successful and economical school bus operation. An efficient and effective preventative maintenance program is the key for dependability; in fact, it is essential that school bus fleets maintain a dependable service. School administrators depend upon the pupil transportation staff for an operation that will deliver the students to school daily and on schedule.

Commercial bus fleets are adequately maintained, not only because road failures must be kept to an irreducible minimum, but because preventative maintenance is the cheapest way to maintain a bus fleet. Railways and airlines practice rigid preventative

maintenance to avoid mechanical failures during scheduled operation and to reduce total operating expenses. School buses must also be maintained properly if reliable and low operation costs are to be achieved. Safety of bus equipment is almost wholly dependent on preventative maintenance because even the finest bus becomes unsafe if proper inspections and preventative services are not provided.

Preventative maintenance differs from regular repair or replacement maintenance. In comparison, a preventative maintenance analysis or inspection is similar to an annual physical examination. Doctors evaluate and analyze the working parts of the human body to ascertain the need for a preventative medical program before the body has a serious major breakdown. This preventative program for human beings tends to extend the length of our life expectancy.

It is imperative to have a staff trained in proper methods and procedures for diagnosing trouble. Just as a doctor is trained for diagnosing human sickness so should the maintenance staff be trained in diagnosing mechanical sickness. A superb preventative maintenance program will extend the longevity, prevent major breakdown, and provide a safe, efficient and economical school bus fleet.

Developing and administering a good program of preventative maintenance for school buses is a cooperative undertaking that begins with the top level policy-forming officials and runs throughout the entire organization. Failure to place maintenance on a policy-forming level is a mistake that often results in inadequate care for school buses. A good maintenance program must be planned and executed, at the level of organization responsible for the transportation system.

III. Developing a Dedicated Maintenance Staff.

Developing a basic fundamental attitude and dedication toward preventative maintenance is one of the most difficult things to

accomplish. The development of a proper attitude by the maintenance staff is one of the basic goals that needs to be achieved if a good program of preventative maintenance is to be established. The maintenance staff should constantly be looking for new methods of improvement and dedicate themselves to perfection.

This is often difficult to develop since looking for work to do and its perfection is a concept not always easily acceptable.

The men who drive and service buses must fully believe that every bolt and screw has a definite function to perform, and unless each is in its place, the bus is not complete. Maintenance cannot effectively function where drivers and servicemen do not value the little things that do not immediately impair bus functions. A driver who is genuinely concerned when he knows that the slightest thing is wrong with a bus has a good maintenance attitude. He simply cannot let minor ailments go without attention.

A maintenance staff dedicated to an efficient and safe program of preventative maintenance needs to have many qualifications, but basically they should be dedicated to the following fundamental requirements:

1. Knowledge of all parts of a school bus, and especially the correct function and location of each part.

2. A pride or satisfaction in good workmanship. A good maintenance attitude can be satisfied only by doing things the right way all the time.

This kind of attitude toward preventative maintenance can be developed only through long and careful training. The need for careful attention to small details and the need for exact workmanship must be emphasized by school administrators, training and supervisory personnel, and by everyone having anything to do with school bus operations. Without this emphasis, it is impossible to develop a preventative maintenance program sufficient to insure long, dependable service, and economical operation.

**OFFICERS OF THE
SCHOOL AND COLLEGE CONFERENCE,
SECTIONS AND COMMITTEES
NATIONAL SAFETY COUNCIL 1961-62**

Vice-President for Schools and Colleges—LOWELL B. FISHER, Chairman, National Association for Colleges and Secondary Schools, University of Illinois, Urbana, Ill.
Chairman of the Conference—HAROLD K. JACK, Dir., Health, Physical Education and Recreation, Temple University, Philadelphia, Pa.
Vice-Chairman for Elementary Education—OLIVE BERG, Elementary Supervisor, State Department of Public Instruction, Pierre, S. D.
Vice-Chairman for Secondary Education—Cecil G. ZAHN, Supervisor in Charge of Safety and Driver Instruction, Los Angeles City Board of Education, Los Angeles, Calif.
Vice-Chairman for Higher Education—CHARLES P. YOST, Department of Safety Education, West Virginia University, Morgantown, W. Va.
Vice-Chairman for Driver Education—FOREST R. ROFFSINGER, Course Development, Northwestern Traffic Institute, Evanston, Ill.
Vice-Chairman for Supervision and Special Areas—LEWIS SPEARS, Consultant in Safety, Texas Education Agency, Austin, Texas.
Secretary—WAYNE P. HUGHES, Dir., School and College Dept., National Safety Council, Chicago, Ill.

1961 CONGRESS PROGRAM COMMITTEE

Chairman—MARLAND K. STRASSER, San Jose, Calif.
Secretary and Staff Representative—LAWTON K. SMITH, National Safety Council, Chicago, Ill.
Members—WILLIAM L. BECKER, St. Paul, Minn.; IVAN L. ELAND, Cedar Falls, Iowa; RUTH HIGGINS, Louisville, Ky.; WARREN J. HUFFMAN, Urbana, Ill.; MARGARET L. JOHNSON, Northbrook, Ill.; JOHN G. LEWIS, Atlanta, Ga.; BERNARD I. LOFT, Bloomington, Ind.; DAVID McMURRAY, Toledo, Ohio; ELIZABETH BARTON, Washington, D. C.; REV. JAMES J. SCHLAFLEY, Kansas City, Mo.; TOM SEALS, Washington, D. C.; W. H. TAYLOR, Nashville, Tenn.; HOWARD O. THIEROLD, Jr., University Park, Pa.; GELINDA E. VENCOLANI, Wauwatosa, Wis.; MARY MAY WYMAN, Louisville, Ky.

1962 CONGRESS PROGRAM COMMITTEE

Chairman—HARRY M. LODGE, Brookfield, Ill.
Secretary—MRS. EARL R. KNUTSON, Grand Rapids, Mich.
Members—RALPH E. BECKER, Dayton, Ohio; RICHARD W. BISHOP, E. Lansing, Mich.; ROBERT D. BOND, Dearborn, Mich.; HAMILTON CROSS, Chicago, Ill.; A. L. CUNNINGHAM, Gary, Ind.; JAMES E. GOETCH, Cresco, Iowa; NORMAN KORN, Middletown, Ohio; HENRY MORGAN, Baton Rouge, La.; OROTHO QUICK, DeKalb, Ill.; CHARLES S. RUNT, Hartford, Conn.; J. J. SMALTY, Manhattan, Kan.; RAY E. SMITH, Moline, Ill.; THEODORE A. TOMPKINS, College Park, Md.; MARIE TRAUFLER, Minneapolis, Minn.; MRS. R. C. WALLACE, Chicago, Ill.; R. C. MERRIMAN, Ft. Atkinson, Wis.
Staff Representative—VIVIAN WEEDON, National Safety Council, Chicago, Ill.

1961 CONGRESS PROGRAM COMMITTEE

Chairman—LILLIAN C. SCHWENK, Iowa State University
Secretary—RUTH M. JURA, R.N., Grand Rapids Public Schools, Mich.
Members—DORIS J. KIGIN, Arizona State University; CORNELIA MULDER, Flint Public Schools, Mich.; LADNARD T. ROLLINS, Quincy Public Schools, Ill.; FRANK ULLSAS, Iowa Dept. of Public Safety; MALCOLM D. WHALE, State Dept. of Public Instruction, Michigan
Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

DRIVER EDUCATION SECTION

General Chairman—FOREST R. ROFFSINGER, Evanston, Ill.
Immediate Past General Chairman—CHARLES R. LEMMEL, Dover, Del.
Vice-Chairman—MARLAND K. STRASSER, San Jose, Calif.
Secretary—IVAN ELAND, Cedar Falls, Iowa
Staff Representative—LAWTON K. SMITH, National Safety Council, Chicago, Ill.

ELEMENTARY SCHOOL SECTION

General Chairman—OLIVE BERG, Pierre, S. Dakota
Immediate Past General Chairman—LESLIE R. SILVERNALE, E. Lansing, Mich.
Vice-Chairman—RUTH HIGGINS, Louisville, Ky.
Secretary—MARY MAY WYMAN, Louisville, Ky.
Staff Representative—VIVIAN WEEDON, National Safety Council, Chicago, Ill.

HIGHER EDUCATION SECTION

General Chairman—CHARLES P. YOST, West Virginia University
Immediate Past General Chairman—BERNARD I. LOFT, Indiana University
Vice-Chairman—JAMES E. AARON, Southern Illinois University
Secretary—C. FRAZIER DAMBON, University of Wisconsin
Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

CAMPUS SAFETY ASSOCIATION

Chairman—CHARLES W. EASLEY, California Institute of Technology
Immediate Past Chairman—MARK J. DONDERO, Massachusetts Institute of Technology
Vice-Chairman—GUSTAVE L. SCHEFFLER, University of Minnesota
Secretary—GLENN F. SHUPE, Wittenberg University
Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

DIVISION OF COLLEGE SAFETY EDUCATION

Chairman—IVAN L. ELAND, State College of Iowa
Immediate Past Chairman—JAMES F. NIHAN, State University of New York
Vice-Chairman—SHELBY GALLIEN, Purdue University
Secretary—C. FRAZIER DAMBON, University of Wisconsin
Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

DIVISION OF COLLEGE SAFETY CENTERS

Chairman—GORDON H. SHEERE, Michigan State University

Immediate Past Chairman—SHELBY GALLIEN, Purdue University

Vice-Chairman—A. E. FLORIO, University of Illinois

Secretary—JAMES E. AARON, Southern Illinois University

Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

DIVISION OF RESEARCH IN SAFETY EDUCATION

Chairman—WARREN J. HUFFMAN, University of Illinois

Immediate Past Chairman—CHARLES PETER YOST, West Virginia University

Vice-Chairman—EDWIN B. ANGIER, Los Angeles City Bd. of Education

Secretary—FRANK BENNETT, Baltimore Public Schools

Staff Representative—DANIEL P. WEBSTER, National Safety Council, Chicago, Ill.

SAFETY EDUCATION SUPERVISORS SECTION

General Chairman—LEWIS SPEARS, Austin, Texas

Immediate Past General Chairman—DALINOR KRALOVIC, Philadelphia, Pa.

Vice-Chairman—FRANK BENNETT, Baltimore, Maryland

Secretary—RONALD PATTERSON, Detroit, Mich.

Staff Representative—KENNETH HOOK, National Safety Council, Chicago, Ill.

AMERICAN INDUSTRIAL ARTS ASSOCIATION-NATIONAL SAFETY COUNCIL SAFETY COMMITTEE

Chairman—EDMUND CROSBY, College Park, Md.

NATIONAL SCHOOL SAFETY HONOR ROLL COMMITTEE

Chairman—RUTH JEWELL, Raleigh, N. C.

Judges—CLINT DRYER, Oakland, Cal.; RUTH JEWELL, Raleigh, N. C.; JOHN G. LEWIS, Atlanta, Ga.; ALFRED L. PAPILLON, Chicago, Ill.; EDWARD WILLIAMSON, Tallahassee, Fla.; MAY F. HAZARD, Detroit, Mich.

Staff Representative—MARVELINE KOPENHAFER, National Safety Council, Chicago, Ill.

SAFETY EDUCATION MAGAZINE ADVISORY COMMITTEE

Chairman—JOHN W. HULL, Texas A. & M. College System.

Members—HOMER D. BRONSON, Chico State College, Calif.; RICHARD ECKERT, Arlington High School, Arlington Heights, Ill.; R. W. JONES, Keokuk Iowa Community High School; JOSEPH M. KAPLAN, Greater Los Angeles Chapter, N.S.C.; MARY B. RAPAPORT, New York State Dept. of Education; MRS. YVONNE JONES SLOVER, Meadowbrook Elementary School, Ft. Lauderdale, Fla.; IVAN J. STEHMAN, Pennsylvania Dept. of Public Instruction; BERNARD I. LOFF, Indiana University.

Editor—THEA FLAUM, National Safety Council, Chicago, Ill.

STANDARD STUDENT ACCIDENT REPORTING COMMITTEE

Chairman—FRANK SVARC, Chicago, Ill.

Secretary—MARIE TRAUFLER, Minneapolis, Minn.

Staff Representative—VIVIAN WEDDON, National Safety Council, Chicago, Ill.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

WHERE ARE WE? — WHERE ARE WE GOING?

By FRANKLIN M. KREML

Dir., The Transportation Center, Northwestern University, Evanston, Ill.

Where Are We? The Plus Side and the Minus Side.

1. Reduction in the death rate from 16 in 1935 to 4 in 1961. (If we had continued at the old rate we would today be killing over 150,000 people a year.)

However, personal injury and property damage accidents continue to rise and the cost thereof continues to mount steeply. The reduction in the death rate results in part, at least, from better handling of the injured at the scene of the accident and improved medical care in our hospitals.

2. Despite the fact of congestion, which is, of course, undeniable, we are moving at better speeds than ever before almost everywhere. But, with billions of dollars invested in facilities for movement and storage, we fall substantially short of the high level of potential efficiency present in these facilities, because we are unwilling to expend a greater sum—but still a very small percentage of the total—for adequate control, supervision, regulation and official personnel, necessary therein.

3. There is a greater public awareness of the problem than ever before, resulting from the great attention given by the mass media, but little of what appears in the public press informs with sufficient instructiveness to result either in better individual practices or in better individual or organized citizen activity. And beyond this, we cannot help ponder whether, after two decades of killing between 30,000 and 40,000 people a year on our streets and highways, the American people have not, by and large, come to accept this as a part of the American scene.

4. Accident prevention operations at all levels, both governmental and civic, have been generally improved, ranging from the prosaic though fundamentally important work of accident investigation, which now is being done intelligently if not scientifically in most American police departments, to more effective planning, both substantive and administrative for dealing with the problem.

On the other hand, one is dismayed by the time that it takes to get acceptance of application of these new operational methods and techniques. The worth of accident investigation and the basic methodology of carrying it forward was developed in this country in 1929, for example, but there are still many police departments which do not apply the modern, efficient version of this technique, despite the ready availability of texts, manuals and training schools.

5. Speaking of schools, training and education in all areas of traffic accident prevention is at an all-time high. Only a few short years ago—to, at least—there was but one such school, this being the then Harvard Bureau of Street and Highway Traffic Research, established in 1926—six students. But with the coming of the Automotive Safety Foundation on the scene, followed almost immediately by the Kemper Foundation for Traffic Safety, subsequently other substantial casualty insurance support, and finally the Insurance Institute for Traffic Safety, many other schools sprang up, including California, New York University and Northwestern University, to name but a few of the literally scores of institutions engaging in training and education in this field.

6. Yet, one cannot but be concerned over the superficiality of much of this training and the relatively few people trained, measured against the country's need, particularly since this springs in large part from our failure to develop a corps of teachers and instructors.

7. Research is going forward in an amount only dreamed of by my colleague and good friend, Sidney Williams, long-time director of public safety division, National Safety Council. Some of this research, particularly such as that going on at Cornell, has been most encouraging in that it has made a substantial, fundamental contribution to improved safety—in this case (Cornell) in the automobile itself. Heartening, too, is the substantial interest, supported by quite large sums of money, of the Department of Health, Education and Welfare and the National Councils of Health.

On the other hand, by way of a single, pertinent example, the apathy of the public towards the adoption and use of seat belts—though their usefulness has been irrefutably established by Cornell—is appalling. And I fear that at least some of the research supported by the National Councils of Health is more concerned with meeting academic standards of research than the urgent public need.

8. More money, both public and private, is being spent than ever before in the cause of traffic accident prevention—even excluding the great multi-billion dollar highway program—and this is important, of course; for the work cannot go forward without financial support. But even so, in relation to the size of the problem, the amounts being spent at all levels of American life, are almost completely inadequate. Thus, to quote from Justice Clark's speech at the Traffic Institute's 25th Anniversary Dinner, of the 80 billion dollars spent annually for automotive transportation, only one billion is spent in the area of traffic accident prevention—that is, only 1/80th of our total expenditure is devoted to insuring safe operation and use.

9. As a result of this added support, we have today more good people in the professional ranks of traffic accident prevention than we have ever had, but they are still too few and we have failed to get our share of the bright young lawyers, sociologists, political scientists, economists and even engineers. Our professionals, in the main, still come out of the work background of our enforcement agencies, engineering bureaus, motor vehicle departments, etc. It is good, of course, to have people of practical experience, but it would be even better had they had also a fine academic preparation that would help to give them the breadth of basic comprehension, the vision and the competences for the solving of new problems that we today continue to cope with on mainly the basis of the "best practice in the field."

10. Coordination between the professional safety people and the organizations which they make up at the national, regional, state and local levels, is better, I believe, than at any point in the past. This has been brought about, particularly at the national level, by the efforts of the ASF and the NHTS, and by the Bureau of Public Roads, which, with

their central control of funds and an appreciation of the truly important objectives, have brought about cooperation by the careful—and in many cases stipulated—allocation of monies.

However, individual and organization prestige program area prerogatives, and ordinary human jealousies have kept the field from presenting the kind of unified, coordinated front that makes the best use of all of our resources in dealing with the common problem. This situation is aggravated by the fact that some of our programs at all levels, including the national, are still largely, if not wholly, inadequate to the task to which they address themselves.

I am idealistic enough to suppose that this can be largely overcome, particularly if, as indicated earlier, we were to get our share of the bright young graduates of the country's university system.

In summary, we have progressed; we continue to progress but not enough or nearly fast enough and in a fashion that is, in my considered professional judgment, substantially wasteful of the resources of money and people available to us.

Where Are We Going?

1. The U. S. population by 1975 will be 225 million; 80 per cent will be concentrated in our great metropolitan centers. It is estimated that we will have in operation 113,642,000 motor vehicles that year. The only comment I wish to make here is that every such estimate we have made in the past has been low. These vehicles will not only be operating throughout the great metropolitan areas, but will, increasingly, be moving over the 41,000-mile interstate highway network which should be about completed by then.

Other forms of personal transportation, taking advantage of developments in jet propulsion, ground effects vehicles and electronic control systems based upon our missile tracking and guidance system principles, will be emerging—may, in fact, be numerous—may result in the obsolescence of the then recently completed highway system!

The capacity of state and local governments, as now constituted, to cope with the problems resulting from such growth and change in personal transportation is doubtful, and the contemplation of the cost of

the assumption of this responsibility by the federal government is horrifying.

Thus, we are going forward with programs, personnel, administrative machinery and governmental structure that are not adequate to cope effectively with our present problems into an era of larger, compounded, more complex and difficult problems than ever before—with no real plans to make our programs, personnel, etc., adequate.

What Do We Need to Do?

1. We need, as Sidney Williams so frequently pointed out, to mature; to grow up to our machines, to cause them to serve us—not victimize us—from the automobile to atomic energy. This is easily said, but not easily done, and is a responsibility of all people—not just Americans and certainly not just people engaged in the work of street and highway traffic accident prevention.

2. We need, to make our total national traffic accident prevention program much more effective than it is now. To this end, we need:

a. As I said earlier, a greater share of young college-educated people with an orientation to this field. If this means the encouragement—even support—of special fellowships to the baccalaureate and graduate level for likely young students as a part of a program of positive recruitment, we should do this, for the field will, after all, be no better than the people.

b. More substantial and long-term funding is needed, for we are, I think, still trying to bring down the bear with an air rifle. Even more important than this, we must develop, beginning at the level of the national organizations, a degree of operational coordination that will insure the best use of available resources. Unless we, who

are quick to assert the prerogatives of our leadership, accept the responsibility of it as fully, we shall court catastrophe in the years ahead, even as we did during the 20's and early 30's as a result of our inability to deal with the first great growth in the use of the automobile.

c. State, county and municipal government reorganization must be undertaken. It is patent that present governmental organization below the federal level is inadequate to the problems developing with the growth of huge metropolitan concentrations over large areas: the magalopoleis of tomorrow which are practically here.

d. I believe that one of the constraints within which we in accident prevention now operate is the deep concern of every one with the all-important question of war or peace. We must, of course, be concerned; and we must be ready morally and militarily for whatever lies ahead.

However, a very important part of our military and moral preparation is the conservation of American life and hands, which will be sorely needed if we pit ourselves finally against the great population masses of Russia and China. Beyond this, and in my view more important in the long run than the military consideration, is the fight for men's minds on the fundamental proposition of the importance of the human being versus the importance of the state.

We can contribute greatly to the winning of this—the real war—if, through our free, representative processes we deal as effectively and decisively with traffic accident prevention as I know we can, thus demonstrating our humanity, our sanity, our capacity, as a people, to effectively govern ourselves. To do less weakens us ideologically, morally, and militarily, and may cost us our freedoms, our lives, our world.

WHAT OFFICIALS WANT FROM CITIZENS' SUPPORT GROUPS

By HON. BEN WEST
Mayor of Nashville, Tenn.

I endorse and encourage the formation of citizens support groups for our traffic safety programs. I think we should encourage them, keep them informed on the overall picture of traffic safety, and foster a closer relationship not only between each group and their local government, but also between the various groups themselves. If there is more than one, it is evident that they often work at cross-purposes with one another, although all have the same ideals. I consider those thoughts worthy of repetition here with, perhaps, some elaboration.

The first thing an official wants from support groups is their cooperation. I have in mind the type and sort of cooperation which would cause them to clear with the proper department any project they might have in mind undertaking before actually embarking upon it.

I would want the degree of cooperation from them which would make them seek and then use the advice and counsel of responsible officials.

I would encourage them to establish criteria which would engender recommendations to their officials which were based on facts, not on hysteria, or selfishness, or because "it worked somewhere else."

Next, I would want them to exercise reasonableness in the sense of advocating projects which have a possibility of being successfully completed. A lot of effort, both public and private, go into the promotion of projects which have only remote chances of success. This energy channeled elsewhere would not be wasted.

Reasonableness also would keep their activities aimed at traffic safety and disconnected from the realm of partisan politics.

Reasonableness would see the elimination of petty, personal complaints, and the arbitrary advancement of "pet projects."

What sort of support should be expected? I do not know of any responsible public official who would not welcome the support

of good, constructive criticism. This criticism, however, ought to be made directly to the official involved and not to the news media for publicity's sake alone. Many good ideas have died in their infancy because of premature publicity and a lack of information given to public officials on the purposes of the program.

Along with the criticism should come positive suggestions from the group designed to sincerely correct the criticized action or lack of action.

Issues which are controversial need grassroots support. This could easily come from support groups if done in the right way. Community peace and harmony might be shored up and a higher degree of working relationship established if the support group laid the true facts before the official in the initial stages and afforded him an opportunity to evaluate the facts and determine the validity of the project. I am confident every official would enthusiastically promote any issue which possesses a reasonable chance for success. If issues which are not probable receive all the full attention of the support group, and the official is in the position of having to oppose such measure, then his and the support group's stand are both weakened in the eyes of the public.

In our own organizations, yours as well as mine, we should not view a new idea with skepticism simply because its author is not a traffic safety expert. An idea is good, if it is good, no matter what its origin might be. If the idea has merit, steps should be taken to develop and exploit it, even though it came from the newsboy on the corner.

I am not a traffic expert. Neither are most of the others actively interested in traffic safety. But we can all be public relations experts in this field if we want to.

Demographers, the population experts, predict an increase of some sixty million people by 1975, which shows that the American people have not been entirely asleep.

Figures submitted to my subcommittee by the Bureau of Employees' Compensation show that for 1959 we had 3,912 federal civilian employees injured in motor vehicle accidents, and 50 deaths. These employees lost 421,010 days from work as a result of these accidents, for a total direct cost to the government of \$4,335,307.

I have pending in the Committee on Interstate and Foreign Commerce, a bill which would do something about this. This bill, H.R. 1341, would establish safety standards for government-owned passenger-carrying motor vehicles. Extensive hearings have been held on this measure and have accumulated an impressive amount of favorable testimony from doctors, engineers, scientists and safety experts.

My bill not only would help to reduce the cost of highway accidents to the government but also would promote the building of safer automobiles for the public. Forced to meet safety standards set by the government, manufacturers would be encouraged to offer these same features as optional equipment or, perhaps, as standard equipment. Furthermore, government approval of certain safety features no doubt would lead to widespread public demands for the inclusion of these features on models offered the public.

That is what happened in the case of seat belts. When federal agencies, led by the Public Health Service, began installing and using seat belts, the public began to take interest. The states began to take interest. State legislatures passed laws requiring seat belt attachments on new automobiles. The industry then began offering front seat attachments on 1962 models.

In our hearings on motor vehicle safety, the American Medical Association submitted a list of safety features repeatedly recommended by physicians, researchers, and safety engineers with little success. These included seat belt anchorages, crash padding, improved steering wheel, safety door locks, removal of dangerous knobs, securely anchored seats, the elimination of pointed hood ornaments, and other hazardous exterior design features.

My bill, which passed the House in 1959, has been reintroduced and is now pending before my subcommittee. Hearings have been held but some question has been raised as to which agency should set safety stand-

ards and we have not worked out that problem.

The bill was bitterly opposed on the floor of the House on the grounds that it would increase the cost of automobiles bought by the government. Even if it did, I say the increased cost would be justified. But cutting down on deaths and injuries will save money, even if we could measure the worth of human life in dollars.

Furthermore, many or all of these essential safety features could be paid for by eliminating chrome and frills which serve no useful purpose. But, you will note that some of these recommendations such as eliminating hazardous knobs and gadgets, would cut costs. So economy cannot be the whole reason. There seems to be pride of authorship factor working here which makes any suggestion from a mere Congressman offensive to a professional designer of automobiles.

Be that as it may, the federal government has a responsibility to its civilian employees and military personnel to provide them with the safest passenger vehicles possible. There is no question of states' rights here. It is just a question of saving human lives and reducing expenses for disability pensions and death benefits.

At the same time, by putting safer cars on the market we will be making a real contribution to safety.

Earlier, I mentioned the growing demands from the public that the federal government do more to promote highway safety. Pressure increases each year for more drastic remedies to meet this problem.

Now, I am not one who believes that passing a law is the ideal way to solve any or all of our problems.

As a nation, we abhor regulations, and rightly so—especially regulation at long range from Washington. We like to see things which must be done accomplished voluntarily. But the fact that we have food and drug laws is proof that things, even essential things, cannot always be done voluntarily. The fact that we have federal regulation of aviation is proof that business, even big business, cannot always regulate itself.

Traditionally, we have relied on the states to set safety standards for passenger automobiles.

The states could force the industry to build safer vehicles and to provide the minimum safety features our doctors think are essential. This was suggested in a report to Congress in 1959 by the Department of Commerce.

That report said: "There are residues of weakness in automotive design and function, however, to which manufacturers and public officers alike need to give further attention."

Now, this is the Department of Commerce speaking and Lewis L. Strauss, the Secretary who submitted the report, cannot be accused of being a wild-eyed visionary or an enemy of business.

Continuing, the report had this to say: "Many states require certification through their motor vehicle departments that these standards have been met. An expansion of such standards, and a more widespread use of the certification process by the states, would lead to quicker adoption of desirable vehicle safety features."

A very good example of where the states could and should tighten up laws to protect the public is found in the situation facing a motorist who wants to buy some automobile brake fluid.

Last year, when Chrysler found that 28 per cent of the brake fluid sold in the Detroit area was substandard, I checked up and was surprised to learn that although 27 states and the District of Columbia had regulations covering the sale of brake fluid, in only about ten instances were the regulations really effective.

Now, an ordinary motorist just has no way of knowing when he has been sold substandard brake fluid and may not find out until his brakes fail at some crucial moment.

I understand that some of the states have tightened up their laws since I introduced my bill to establish federal standards for brake fluid but if the situation is not a whole lot better when Congress convenes again in January, I am going to press for early action on my bill.

In another area, the federal government may be forced to take action. That is in trying to curb the smog menace.

More than a year ago my subcommittee held a hearing on methods of controlling so-called blow-by gases, which we are told

account for 40 per cent of the smog-producing fumes caused by automobiles.

An inexpensive device for piping these unburned gases back into the engine will eliminate these blow-by fumes. Secretary Flemming, head of the Department of Health, Education, and Welfare, in the last administration, recommended the voluntary installation of these devices as standard equipment. The present secretary has joined in that recommendation.

Federal legislation may be necessary to force the installation of this device. We will have to wait and see. But air pollution is one of our major health problems and the public is demanding action.

I have introduced a bill to require that drivers in interstate commerce hold permits from states which have permit laws substantially in conformance with the Uniform Code. Perhaps this should be amended to require physical examinations. I understand that Pennsylvania now is the only state which has a physical examination requirement stringent enough to weed out all those unfit to drive.

I would go further than forcing the states to meet the minimum requirements of the Code regarding permits. We might even amend the law to cut off federal highway funds to states which do not adopt the uniform code.

I think we will all agree that most of the states are lagging in setting minimum requirements for drivers. Serious violations, such as driving while drunk, are being winked at. Potential killers are being left on the highways. There is too much ticket-fixing. In some of the states driver licensing laws are little more than revenue measures. Permits are renewed by mail on payment of a fee. Persons retired for physical disabilities are permitted to drive without physical examinations.

The federal government has not hesitated to require strict physical examinations for all airplane pilots. Why should we hesitate to require the same high standards for motor vehicle operators? It is a well-known fact that there are 75 million drivers of trucks and automobiles who constantly move over Uncle Sam's highways. Yet, our highways are literally filled with drivers who are color blind, partially blind, drug addicts, alcoholics and people subject to black-outs.

Persons with mental deficiencies and physical defects which should disqualify them from operating cars drive on high-speed interstate highways.

There is a great difference in dear old Uncle Zeke who drives from the farm to the country store in a small rural community and the same man driving on U.S. Highway Number 1 from Washington to New York.

While I have been an advocate of the construction of safer automobiles and still am convinced that industry can do a better job, I am perfectly willing to admit that one cause of our heavy accident toll is that operating the modern automobile calls for better physical and mental equipment than many states require.

I am constantly amazed at the tenacity with which many people fight to keep their drivers licenses as if driving were a God-given, heaven-endowed, or contractual right. To drive is a privilege, not a right.

People who would not dream of harming a neighbor by fostering a nuisance which endangers public health, think nothing of loading a car with the grandchildren and children of a neighbor even though they may require a magnifying glass to read a newspaper.

If the states cannot or will not do something about these potential killers, it is time for the federal government to take action.

I have not covered all of the areas in which my subcommittee has taken an interest but I have tried to hit the high points and give you an indication of the way things are going in Washington. Your comments and suggestions will be deeply appreciated by all members of the Subcommittee on Health and Safety, which has the responsibility of developing and considering plans and programs.

We welcome the counsel and advice of all those interested in this problem of highway safety.

THE INTERSTATE HIGHWAY SYSTEM

By ELLIS L. ARMSTRONG

Pres., Better Highways Information Foundation, Washington, D. C.

Perhaps our present most challenging problem in safety is that connected with highway traffic. The nearly 40,000 people killed and one and one-half to two million injured each year in accidents on our highways, with economic losses now totaling seven billion dollars a year or more, emphatically demonstrate the magnitude of this problem.

While we are making progress in reducing the accident rate, the continually increasing number of cars on our highways and the increasing miles of travel justify intensifying all efforts to reduce this great loss to our society. All three E's of making highway travel safer—engineering, education and enforcement—must each receive increasing attention. We must not become hardened into accepting death on the highways as death by natural causes.

Over a couple of holiday weekends each year we do get quite concerned over the

terrible rising score of deaths as the weekend draws to a close—as this ghastly rising number is hourly drawn to our attention by the news media. We don't always appreciate that this score is not much different from that which we chalk up day after day, week after week, every month of the year. On an average, over 100 people are killed every day on our highways.

Education and enforcement apply to the important element of the problem, which is people, and the way they act and react. Engineering applies primarily to the other two elements, the vehicle and the road. And progress is being made in engineering vehicles and roads for greater safety. No doubt, this progress also has a good effect on the driver's attitude and actions.

I was interested in a statement made in a recent report on highway construction in Italy and on their accident problems: "In 80 per cent of the cases casualties can

be traced back to violations of traffic regulations and carelessness; however, it is known this type of behavior is seldom observed with an efficient road system." The three elements of the problem, and the three E's of the solution are extensively interrelated.

Our modern highways incorporate numerous features which improve the safety of travel on our roads. One of the big problems is catching up with the needs. We now have an accelerated highway improvement program underway and are beginning to make progress, but we still have a long way to go. One of the most important parts of our present program is the National System of Interstate and Defense Highways.

The 41,000-mile Interstate is actually the backbone of our entire nationwide highway system. It is the basic network of controlled access, high capacity highways, with no grade intersections, generally divided roadways, and entrances or exits only at carefully controlled and engineered access points. It is a single purpose system, designed for the free flow of high volumes of through traffic with maximum safety. It is being designed and constructed to meet the traffic needs of 1975.

Traditionally, roadways have provided access and service to abutting land, and have served as parking areas, as well as providing for traffic movement. With increasing traffic volumes and speeds, new concepts were forced to meet the needs. The freeway concept, which the Interstate reflects, received its first big tryout with the Reichsautobahnen in Germany, on which construction began in 1933. Its prime function was to provide fast, uninterrupted movement of military traffic. The principle had been established by the Autostrada toll roads in Italy built a few years earlier.

Nationwide investigation was ordered by Congress in the Federal Aid Highway Act of 1938. "... with respect to the feasibility of building, and the cost of, superhighways not exceeding three in number, running in a general direction from the eastern to the western portion of the United States, and not exceeding three in number, running in a general direction from the northern to the southern portion of the United States. . . ." There no doubt were differences of opinion as to just what constituted a "superhighway" but the Bureau

of Public Roads in preparing the study used standards very similar to those now being applied to the Interstate System.

This study was the first complete assembly of data on the use being made of our national highway network and emphasized the need for a special system of direct inter-regional highways, with all necessary connections through and around cities. A number of other extensive studies followed, along with lengthy Congressional hearings, and finally culminated in the Federal-Aid Highway Act of 1956 which launched our present accelerated 15-year highway construction program, including the National Interstate System designed to catch up with present-day needs.

The Interstate is a logical development of our automobile age. The concept of access control is the first significant change in essential characteristics of road layout since the days of the Romans. It provides for our present-day needs for arteries carrying large-volume, high-speed traffic safely and efficiently and insures against obsolescence.

Need for Interstate System

The mobility of a population is a basic criterion of the growth, development and economic well-being of the citizenry. The freedom of movement in our modern-day America is unique, and has come about because of our rubber-tired automobile and our highways, and has actually created our present way of life. Early in America's history, the main arteries for movement of people and goods were the waterways. In fact, our first President had a 'grand plan' for a great interstate system of canals, and canal building was the first big public works construction program of the nation.

During the first half of the nineteenth century, construction of roads and trails progressed, but the growth was short-lived with the coming of the railroads, which took over most long distance movements of people and goods. Great economic growth and development followed the railroads. The railroad construction era was one of the great epics of America.

However, by 1900 travel for the average citizen was still unusual. One writer commented concerning the low excursion rates coming into vogue for special railroad or steamboat trips and stated that even travel was becoming possible for the common man.

This was only 60 years ago and is quite a contrast from the present average citizen who travels 10,000 miles per year in his automobile.

The invention of the self-powered, horseless carriage in 1893, followed by the development of mass-production methods, resulted in an ever-increasing number of automobiles on America's highways. This, in turn, brought about the development of our highway network; during the 1920's and the 1930's great progress was made in highway construction and betterment. However, most of these roads were built for low-volume, low speed traffic.

Following World War II the accelerating number of automobiles on our highways aggravated the highway neglect during the war and resulted in highway improvements getting further and further behind the needs. Highways and city and town streets were not designed for the traffic which tried to use them, and traffic accidents increased their deadly toll. The potential of the motor vehicle was limited and in some urban areas severely curtailed by congestion.

Road widening was accomplished and bypass routes were constructed, but generally to meet existing emergencies, and usually became overloaded when the ribbons were cut. Without access control, good bypass highways deteriorated to city streets as businesses moved out and set up along the roads. Many were, and still are, pessimistic about being able to provide for the highway needs of the present age.

However, the individual freedom of movement and of choice provided by our automobiles and highways, the widening of opportunity for employment, social contacts, better living environment, recreational and all aspects of modern life is something we like and is basic and we must realistically accept that it is here to stay. Transportation is consumed in production; the relationship between highway travel and the values of the total goods and services we produce each year is quite constant: 1.4 miles of travel for each dollar of goods and services. We now have over 75 million motor vehicles on our roads and we expect that in 1975 this will increase to about 115 million.

Traffic is the very lifeblood of our entire economy; and this is particularly true

of our cities. The requirement is for a varied, unimpeded flow of cars from area to area and from function to function. And it is this need that the Interstate meets, as the basic high-capacity, free-flowing part of the overall highway system.

To be most effective, a well integrated, balanced system of feeder and service streets and highways is required, along with the necessary freeways to supplement the Interstate, to make up the entire highway system. And in some of our more densely populated urban areas, the highway system requires supplemental rapid transit facilities to satisfy the transportation needs.

Purpose of the Interstate System

Federal law concerning the Interstate System provides that:

"It is hereby declared to be in the national interest to accelerate the construction of the federal-aid highway system, including the National System of Interstate and Defense Highways, since many of such highways, or portions thereof, are in fact inadequate to meet the needs of local and interstate commerce, for the national and civil defense.

"It is hereby declared that the prompt and early completion of the National System of Interstate and Defense Highways, so named because of its primary importance to the national defense and hereafter referred to as the Interstate System is essential to the national interest and is one of the most important objectives of this Act. . . . Insofar as possible in consonance with this objective, existing highways located on an interstate route shall be used to the extent that such use is practicable, suitable and feasible. It being the intent that local needs, to the extent practicable, suitable and feasible, shall be given equal consideration with the needs of interstate commerce.

" . . . The Interstate System shall be designated within the United States, including the District of Columbia, and it shall not exceed forty-one thousand miles in total extent. It shall be so located as to connect by routes, as direct as practicable, the principal metropolitan areas, cities, and industrial centers to serve the national defense and, to the greatest extent possible, to connect at suitable border points with routes of continental importance in the Dominion of Canada and the Republic of Mexico.

" . . . The geometric and construction standards to be adopted for the Interstate System shall be those approved by the Secretary in cooperation with the State highway departments. Such standards shall be adequate to accommodate the types and volumes of traffic forecast for the year 1975."

The geometric and construction standards adopted by the various states and approved by the Secretary of Commerce state that " . . . The highways of this system must be designed in keeping with their importance

as the backbone of the Nation's highway systems . . . they must be designed with control of access to insure their safety, permanence, and utility and with flexibility to provide for possible future expansion. . . . All known features of safety and utility shall be incorporated in each design to result in a . . . system . . . which will be a credit to the Nation." Minimum standards are outlined with the statement that it is expected that designs will generally be made to values as high as are commensurate with conditions.

Thus, by law, the present 41,000 mile system is a high quality, high capacity freeway network providing for efficient, safe, smooth-flowing traffic. It will compose 1.2 per cent of the total highway mileage but is expected to carry in 1975 over 30 per cent of the total traffic. Of the total mileage, 6,700 miles have been designated in urban areas. This urban mileage when completed will carry about one-half the traffic on the Interstate, and according to present estimates will involve 42 per cent of the total cost.

The Interstate incorporates 2,274 miles of toll roads and bridges as a part of the system. To supplement the Interstate System, additional freeways have been built and more are in the planning and construction stage. The general practice today is to design and construct new highway facilities to meet the traffic demands and the freeway is the answer where heavy traffic needs exist. California, for example, has a 20-year plan for about 10,000 miles of freeways in addition to the State's 2,100-mile Interstate System, to meet the needs of the increasing traffic ahead.

Cost of the Interstate System

The estimate of 1960 of the Interstate shows an average cost for the 41,000-mile system of about one million dollars per mile, the same as the 1957 estimate. This breaks down to approximately four million dollars per mile for the urban sections and 680,000 dollars per mile in the rural sections. Right-of-way costs average about 15 per cent, being six per cent in rural areas and 25 per cent in urban areas.

The real measure of costs, however, is the cost per unit of service, the vehicle mile, that the facilities provide. A detailed analysis of the cost of ownership of the

Interstate System, compared to other federal-aid highways was recently made by the Bureau of Public Roads. These costs include capitalization of the construction costs including right-of-way, and the costs of maintenance, operation and administration.

The study shows that the unit cost of service provided by the Interstate System is approximately 0.4 cent and is the same for both rural and urban as compared to about 0.7 cent on the remainder of the federal-aid primary system and three times as much on the federal-aid secondary system—approximately 1.2 cents. While the cost per mile of Interstate is high, it is by far the most economical way to provide for motor vehicle traffic when sufficient travel demand exists.

Because of the national importance of the Interstate System, the federal-aid matching ratio is 90 per cent federal funds and 10 per cent state funds, as compared to the normal 50-50 matching federal-aid ratio. The federal funds came from the special highway trust fund built up by Federal taxes on gasoline, rubber and trucks. Present legislation provides sufficient revenues for the trust fund to complete the Interstate by 1972.

Savings on the Interstate System

A large number of studies have been made of the savings in cost to the motorist of using the Interstate System. Wilbur Smith and Associates' analyzed the various studies made and arrived at the values shown in Table 1 as recommended values to use in evaluating cost savings. These are broken down into vehicle operating costs, accident costs, and time savings, and are the direct savings to the motorists. I am in general agreement with these estimates.

Two specific examples of Interstate savings, although there are a host of others, are the Schuylkill Expressway in Philadelphia and the Los Angeles freeways. Detailed studies of the Schuylkill Expressway show motorists are saving 18 million dollars a year in direct commuting costs. These savings alone will repay the construction costs of this expensive new facility in three years. The original 40 miles of freeways in Los Angeles completed by 1953 cost 130 million dollars. Studies by the Southern California Automobile Club show that in the seven-year period since then, the direct

savings of motoring costs have been twice that amount.

It should be emphasized that these savings are the direct savings to the motorist. In addition, such items as the saving of human lives and reduction in human suffering from accident reduction, the creation of new opportunities for growth and development, the rejuvenating effect on existing areas, the increase in land values, the overall upgrading of the economy as a whole, the triggering of new investment and construction, the easier access to cultural functions, schools and recreation facilities, the relief from driving tensions and the joy and pleasure of motoring on an adequate highway facility are all extra dividends.

TABLE I
Estimated Interstate Cost Savings in
Recommended Priority Cost Savings in
Urban Areas¹

Item	Cents per Vehicle Mile ²	1960	1975-1980
Operating Costs	0.97	1.12	
Accident Costs	0.73*	1.00*	
Sub-Total	1.69	2.12	
Time Savings for Commercial and Passenger Vehicles ³	2.58*	2.92*	
TOTAL	4.35	5.04	

Item	Cents per Vehicle Mile ²	1960	1975-1980
Operating Costs	0.00	0.00	
Accident Costs	0.72	1.00	
Sub-Total	0.72	1.00	
Time Savings for Commercial and Passenger Vehicles	0.98*	0.98*	
TOTAL	1.70	1.98	

1. "Future Highways and Urban Growth," Wilbur Smith and Associates—Estimates from analysis of various cost studies, February, 1961.
2. On basis of 15 per cent commercial vehicles.
3. Adjusted to reflect 15 per cent increase in operating costs 1960-1975.
4. 0.8 of assumed 1960 accident cost of 0.90 cents per vehicle mile.
5. Average savings 1975-1980.
6. Time savings for commercial and passenger vehicles prorated to all traffic and then totaled.
7. On basis all vehicles save 10 minutes per mile.
8. On basis all vehicles save 1.0 minute per mile.
9. On basis of 20 per cent commercial vehicles in rural traffic.
10. On basis all vehicles save 0.33 minutes per mile.

Safety and the Interstate System

The Interstate reduces accidents by reducing and eliminating conflict areas and minimizing decisions that must be made by the motorist. Records to date indicate the accident rate is reduced to one third or less of the average of all roads and the death rate is reduced to at least one-half of the average. Total savings of lives by completion of the Interstate alone has been estimated to save at least 4,000 lives per year,⁴ and more recent studies have increased this estimate to as high as 9,000 lives per year.⁵

The physical separation of lanes for travel in opposite directions, which is standard for most of the Interstate, minimizes the possibility of head-on collisions, usually the most severe type of highway accident. The modern design provides not only for broad medians between opposing lanes but, where possible, for the two separate roadways to follow different centerlines. They are placed on different sides of a hill or a stream, at different levels on a slope, and with separately varying curvatures to avoid long stretches of straight highway with constant medians.

This flowing design has produced some beautiful highways that are a joy to ride upon. They promote alertness and lend interest; the driver stays awake, enjoys his trip, and travels safely.

Control of access on the Interstate eliminates side-traffic friction, which causes many accidents. You may have in your area a "death mile" or "bloody boulevard," where a heavily traveled highway probably "modernized" to four lanes 10 years or so ago is continuously lined with roadside businesses with their accompanying driveways, pull-offs and parking areas, such that the traffic weaves in and out to suit each driver's whim. The providing for entrances and exits only at planned, safe access locations protects both the through traveler and the local driver.

Grade separations to eliminate cross-traffic problems is an accident-reducing feature. Provisions for accelerations and decelerations outside the regular lanes of traffic, and adequate weaving areas, minimize conflicts. The grades and curves used provide for maximum travel speed without hindrance from these factors. The 12-foot width of

lane is a feature that provides for increasing carrying capacity as well as increased comfort and safety.

Signing on the Interstate is an important feature that receives careful attention. The design of signing is an important part of the initial overall study. The most elaborate layout will be a failure if the motorist doesn't know what to do, and it becomes a death trap if he stops to find out.

The Interstate incorporates the best and safest features of design derived from long experience and research. As sections of the system are completed, they are under constant surveillance for improvements. A nationwide analysis of the sections of Interstate in operation was made about a year ago by a select group of Highway Engineers with general high praise for the standards being used and the resulting safety of traffic movement.

Savings from accident reduction alone, in many instances, are enough to pay for the construction of the Interstate. While Commissioner of Public Roads, I had an extensive analysis made of the Interstate in eight western states. The estimated cost of building the multi-lane Interstate was compared with the cost of maintaining the mileage in its present conventional form. The difference in cost in providing the separated lanes was nearly equalled by the saving in accidents by 1975.

Status of the Interstate System

At present over 11,000 miles of the 41,000-mile system are open to traffic, and construction is underway on about 5,000 additional miles. Motorists will be able to travel on approximately 3,000 miles of new Interstate per year for the next ten years on the basis of the present schedule.

The effect of the Interstate is going to be increasingly evident as longer stretches of this modern facility come into operation. The general approach has been to build first in those areas where needs are greatest, and this is now beginning to pay good dividends in relieving congestion in some areas.

One big problem in urban areas is that as yet no major urban area has the full system completed. As segments are opened for traffic, motorists are drawn from quite a distance in all directions, and as a re-

sult the section may get overloaded, with resulting criticism that new highways can't solve the problems. As the full system is completed, and it operates as a system along with the required improvements of the other streets, it is believed such criticisms will disappear.

On the basis of present legislation it is expected that the Interstate will be completed by 1972 or 1973. This completion date will be insured by continuing understanding by the general public of the needs and benefits of the system. For a public works program of this magnitude requires strong support, which this understanding will generate, for it to proceed on schedule to its completion date.

One of those areas of difficulty in keeping a program of this size underway is proper perspective. Even with the present program of improvement we are only spending 12 cents of our highway transportation dollar on our highways, as compared with 14 to 15 cents from 1920 to World War II.

Future Problems

Of course, the Interstate System won't solve all the problems of traffic or of highway accidents. It is only a part of the overall system of highways, even though a very important part, and the entire highway system must be made adequate for the traffic each segment carries, if we are to obtain a truly effective safe-operating system. While the Interstate will carry large volumes of traffic, that will be still over 75 per cent of the total traffic on other highways and streets.

The 1956 Act envisioned keeping the other highway construction in phase with the Interstate construction. This needs to be understood, appreciated and pushed. So far progress has been generally good.

While the Interstate is designed for 1975 traffic it won't become obsolete when that date is reached. With control of access the full carrying capacity of the system will be preserved. Generally right-of-way provides for expansion when additional needs develop. Further the major portion of the system will not reach its maximum carrying capacity for many years beyond 1975.

Needs in other areas not in the vicinity of the Interstate routes will require additional miles of freeways or Interstate

design standards. It is estimated that traffic needs in urban areas by 1980 will require 5,000 to 6,000 miles of freeways in addition to the 6,700 miles provided by the Interstate.

From the standpoint of safety, driving on the Interstate will require special attention. It is a high-speed facility and alertness must match speed. Hypnotic effects of high speed, steady driving needs special attention. Rear-end collisions and single car accidents by driving off the roadway are the principal accidents on the freeways. However, it appears that as drivers become acquainted with freeway driving, accidents decrease still further and some of our toll roads have chalked up amazing records for accident-free driving.

I think we're making progress on this problem of highway accidents. However,

we need to continually, realistically, face up to the problems, carefully evaluate various solutions, and carry out a program that can be accomplished. The improvement of all our highways adequate for the traffic they carry, will go a long way towards saving of accidents, lives and suffering.

EFFECTS OF ENFORCEMENT ON QUANTITY AND SEVERITY OF TRAFFIC ACCIDENTS

By MAJOR GLENN KISSINGER
Asst. Dir., Enforcement Div., Motor Vehicle Dept.
Wisconsin State Patrol, Madison, Wis.

I hope that none of you here today came to this meeting hoping to hear me make this emphatic statement: "Yes, traffic law enforcement definitely does reduce the quantity and severity of traffic accidents," and then provide unchallengeable facts and figures to support my claim. You would be disappointed, for I do not have the conclusive statistics you are looking for.

But I will make this statement: "Traffic law enforcement reduces the quantity and severity of traffic accidents," and I will support my argument with logic and available statistics from my own state of Wisconsin.

To my knowledge, there has been very little research on the relationship between enforcement and accidents. The reason for this, I'm sure, lies in the very magnitude of the problem. There are so many variables to measure, that to do a thorough and conclusive job would require resources not available to most agencies.

It is easy enough to keep severity records on sections of highways in a police agency's jurisdiction. The Wisconsin State Patrol keeps such ratings based on accident reports filed by drivers involved. And it's easy enough to segregate those sections of highway where enforcement is concentrated, in order to compare the severity ratings on those roads with the severity ratings of roads where enforcement activity is sporadic or nonexistent.

But severity ratings do not take into consideration such factors as changes in the character of the highway, the elimination or creation of particularly troublesome intersections. They do not take into consideration shifting traffic patterns caused, for example, by construction of freeways or expressways. They do not take into consideration changes in the court system, with a lenient local judge being replaced by one who hands out stiff sentences to convicted traffic violators.

What constitutes a personal injury accident may be subject to variation. Some may define it as one which requires physician's treatment of one or more drivers or passengers. Others would call a scratched finger a personal injury. Severity ratings do not take this variable factor into account.

The quality of enforcement is another variable factor, even more difficult to measure. The mere fact that a patrol officer is assigned to a piece of highway for eight hours a day does not mean the section of roadway is receiving proper enforcement effort. How he operates in his sector while on duty—whether he spends too much time in the coffee shop—will influence the effect of enforcement. This is almost impossible to measure, since in the best of organizations it is bound to vary from supervisor to supervisor, and from man to man.

The only research on the subject with which I am familiar was done in 1957 by Mr. Robert P. Shumate, then of Northwestern University Traffic Institute and now of Indiana University, Department of Police Administration. This research project was carried out with the cooperation of the Wisconsin State Patrol and the U. S. Bureau of Public Roads, and is identified as Research Project R13.

In this project Mr. Shumate compared traffic accident severity on four routes in Wisconsin before and after the assignment of Wisconsin State Patrol officers to the routes on a line patrol basis. The routes were 26, 52, 104 and 208 miles long, and included both two and four-lane highways. Intensity of enforcement was measured not by the number of officer-motorist contacts made, but by the number of times a motorist should have seen a moving or stopped patrol car, conspicuously marked. Some pertinent conclusions from this study include:

1. The addition of patrol units to a given stretch of highway reduces the frequency of fatal and personal injury accidents up to the point where the quantity of patrol units reaches a ratio of one unit for each 13 miles of highway. When a ratio of one enforcement unit to 26 miles of highway is reached the frequency of accident occurrence shows no significant change.
2. Reductions in frequency of accidents tend to be more pronounced during the second

and year of effort indicating a possible cumulative effect.

3. Property damage accidents do not show as consistent reductions as fatal and personal injury accidents. This may be attributed to the fact that property damage accidents are more susceptible to changes in the completeness with which they are reported.

4. Substantial increases in the number of patrol units assigned to a given stretch of highway does not cause an appreciable proportion of motorists to change their travel habits even though there is an alternative route available.

The Wisconsin State Patrol, as it exists with 250 uniformed officers today, has been actively engaged in rural traffic law enforcement for about six years. During that time we have devoted our efforts toward accident reduction by employing the principles of selective enforcement whenever practicable. We have concentrated our forces where and when the accidents, fatal and personal injury, have been occurring. We are satisfied that our all-out program of concentrated enforcement has been successful in reducing the number of severe accidents on the highways patrolled.

What indications have we that our program is succeeding? Most of our statistics. Last year there were 4,144 accidents on state and federal highways under line patrol by the Wisconsin State Patrol. On those same roads in 1957, some of which were under line patrol at the time and some not, there were 114 fatal accidents. That's a reduction of some 25 per cent. During that same period of time, fatal accidents on all other state and federal highways in Wisconsin increased by 2.3 per cent. You may argue that these figures are not conclusive. Perhaps they are not, but they give us some indication of what is taking place on the highways placed under line patrol.

I am a traffic police administrator, not a researcher. I outlined earlier some of the reasons why I believe there has been little scientific study of the effect of enforcement on the quantity and severity of accidents. But I submit that any sound research that would be done on the subject would only underline what the bulk of traffic safety authorities have believed for years—that en-

forcement does indeed have a significant effect in reducing accidents.

Statistics show us that only an insignificant percentage of traffic accidents are caused by vehicle or road defects. The great majority is caused by human error, in short, violations, either unintentional or willful, of the basic rules of the road.

All states have traffic laws to cover virtually every conceivable driving situation. Can anyone challenge the assertion that if everyone obeyed every traffic law there would be few accidents, except, perhaps, those few caused by road or mechanical defects? I don't believe they can.

Once we have established that traffic law violations cause accidents, isn't it safe to assume that by reducing the number of violations we will reduce the number of accidents? If there are fewer violations there will be less potential for accidents to happen. Hence, there should be fewer accidents.

The next logical question would be: "Does enforcement reduce the number of violations, thereby reducing the number of accidents?"

For most drivers, there is probably no need for enforcement. They probably obey traffic laws because they realize their significance. They know that laws are written for the protection of everyone who uses the highways.

Some drivers, though, have to see a squad car or know that a policeman is or might be in the area before they behave. They are legal as long as they suspect they are being watched. Here enforcement is affecting their driving manner and is preventing the accident-causing violations.

Other drivers have to be arrested once or twice, pay the fine and realize they are just a few points from losing their licenses before they drive safely. Or, they may be in no fear of losing their licenses, but they may not be able to afford a fine. They may fear the publicity resulting from a traffic conviction. Whatever their motives, they still obey the traffic laws, not because they realize their importance, but because they shun the legal and social consequences of conviction. Nevertheless they still obey the

law and do not endanger themselves or others by improper driving behavior.

Finally, there is a small number of drivers who wilfully and wantonly disobey the law constantly. Take the chronic reckless driver; for example, the one who speeds down residential streets at 40 or 50 miles an hour, or down winding country roads at 80 and 90 miles an hour. Is he going to do this once or twice and then stop, forever after to drive safely and courteously? I doubt it very much. He's going to keep it up until one of three things happens: He kills himself, he kills someone else, or he is arrested enough times to lose his driving privileges. The hope of enforcement is that we can get to him soon enough, so that he stops driving before the accident happens. Then we have reduced the quantity of accidents by at least one.

I think, then, there should be little doubt that enforcement reduces the number of accidents. There is less reason to believe, however, that enforcement reduces the severity of accidents except in this respect—granted that there is a fairly constant ratio between fatal, personal injury and property damage accidents, any reduction in the total number of accidents is bound to bring a reduction in the number of fatal and personal injury accidents.

Mr. Shumate in his study noted that property damage accidents do not show as consistent reductions as fatal and personal injury accidents. If this is true, then enforcement is reducing the severity. However, Mr. Shumate pointed out that this may be attributed to the fact that property damage accidents are more susceptible to changes in the completeness with which they are reported.

In the short time allotted me, I have told you why I believe enforcement reduces the severity of traffic accidents. I have told you there is little statistical evidence why this may be so, and I have explained why I think the evidence is sparse. But can we who are engaged in traffic law enforcement sweep away the logical conclusion that enforcement does have a salutary effect on both the quantity and severity of traffic accidents?

ENFORCEMENT EFFECTS ON QUANTITY AND SEVERITY OF ACCIDENTS (RURAL)

By MAJOR J. M. THAXTON
Asst. Chief, Oklahoma Highway Patrol, Oklahoma City

Law enforcement is a vital part of our democratic way of life. To eliminate enforcement would be the only method of ascertaining the full impact of its effectiveness. With positive assurance that we cannot take such a drastic step, it is imperative that we use other methods of measurement to determine the effects of enforcement on severity and quantity of accidents.

If we in the field of law enforcement are to discover significant relationships between enforcement and accidents, we must continue to enlarge our area of research to a point where we understand more about the effect of the activities of related agencies such as highway engineers, educators, climatologist, automobile engineers and others associated with the modes, vehicles and conditions of traffic.

Since we have been unable to devise such a tell-all measuring stick and its foreseeable development is most remote, if for no reason other than this thing called driver attitude, our attention must continue to be directed toward enforcement. Each law enforcement officer is in the first line of America's defense against traffic accidents. I contend that it is his solemn obligation to perform his duties in such a manner—and this encompasses quality as a part of quantity—that the effectiveness of enforcement on this scourge of our nation, quantity and severity of accidents, will awaken the American motoring public to the fact that it is killing itself on the highways of this country.

Statistics reveal that enforcement per se does not produce results which are readily distinguishable from the effects of other contributing factors. Generally, this is true although a very noticeable effect of enforcement is evident when enforcement suddenly drops to a point near the normal increase in vehicle miles traveled. This situation adds weight to the general belief that a certain level of consistent enforcement is essential to maintaining a progressive traffic safety program.

There are many contributing factors which control the increase or decrease in traffic accidents. If there is a decrease in accidents, enforcement officials may be prone to say, "We did it." Highway engineers are ready and willing to take a large share of the credit while safety education authorities believe that they have finally changed the drivers' attitude. The automobile manufacturer lays claims to the decrease in severity although they are not so eager to talk about total number of accidents.

I know of no studies conducted by any group to determine the effectiveness of enforcement (or the presence of officers) on accidents. Despite the alleged effects and results adduced from such studies, the experience in my home state will not substantiate their findings in whole.

Much has been said about amount of enforcement but for the purpose of discussion, I would like you to think of it as the amount of enforcement which will create greater compliance with the traffic laws and will bring about a decrease in the quantity and severity of accidents. The deterrent effect on drivers, generated by the enforcement of traffic laws and the ultimate prevention of accidents, is to be desired.

When we speak of the "enforcement effects on quantity and severity of accidents," many relevant factors are involved. Placed high in importance among these factors is the quality of enforcement. Good enforcement means attaining maximum effectiveness in each instance as a deterrent to violations of the law. It means accomplishment of objectives which justify enforcement—preventing accidents. Furthermore, it means obtaining the best possible results through increased efficiency.

Additionally, it has been stated that there is a point below which the amount of enforcement is too small to have any appreciable effect, and our experience lends support to this statement. It has also been

stated that it is possible for the amount of enforcement to go beyond the point where additional desired results will be obtained. In other words, when the number of traffic arrests goes beyond the point where the deterrent effect is increased, additional arrests will not aid materially in reducing the number of accidents. No doubt this statement has some merit; however, we have never been able to get our quantity (with quality) up to this point. We, therefore, have never fretted about reaching this so-called "point of diminishing returns."

Selectivity of enforcement is one of the means of obtaining quality. Quality, however, is dependent upon many other factors. The caliber of enforcement personnel and the type, as well as amount, of training they receive is vital. Good enforcement procedures, good equipment and many other factors are involved. Selectivity is one of the means of obtaining quality.

Up to this point we have been speaking in generalities. This is fine, but I am sure that we are more interested in what to do about our common problem. What works best? I shall point out, with the aid of statistics, what our experience has been.

In Oklahoma, ten years of statistics were compiled in graphic form in order that an analytical study could be made and, if possible, to determine both the long range and the short range effect of enforcement on the quantity and severity of rural traffic accidents. At the same time, a study was made to determine the relationship between speed and the quantity and severity of rural accidents.

First, I must say that we are unable to determine from the so-called control studies of one or two years' duration a great deal more than speculative conclusions. Most of these studies have been conducted on roadways where enforcement has been greatest for a number of years. Does this give a true picture of the effect of enforcement? We do not think so because the maximum effective enforcement may have already been reached before the controlled study began, especially when most of these studies were conducted on trunk highways.

Through our method of selective enforcement, we were convinced that increased enforcement, applied in certain areas, provided the desired results, although we were

more concerned about the overall effects—statewide. We believe the statistical picture of the effect of our statewide program, during the past ten years, has shown us the overall effects of our program, and bettered our understanding of statistics. When compiled for a long period of time, they tend to disprove some of the short-period conclusions which may have been pulled out of the same statistical array.

Year by year, we compared statistics of accidents and enforcement activities and we were unable to correlate direct, immediate relationship of any of the changes year by year except in two areas.

1. A year of low enforcement activity is followed by a general increase in quantity and severity of accidents.

2. There is a direct relationship between speed and quantity, and especially severity, of accidents.

Again, I am reminded that to eliminate enforcement would be the only method of ascertaining the full impact of its effectiveness. We know that this will not be done although we got a fair sampling of this in Oklahoma in 1955, when, for a number of reasons, arrest activity dropped 37 per cent and warning activity dropped 65 per cent. Yes, the expected happened—a sharp rise in accident activity followed the next year—1956.

Since the year 1955, there has been a steady increase in enforcement activity.

1. The steady increase in the overall enforcement program was most effective on the federal highway system. This was the area where a greater portion of manpower and enforcement was applied; although it must be noted that engineering plays an important part, in providing more uniformity of construction, than is found in either the state or county highway system.

It is noteworthy, and probably significant to this topic, that accidents on the federal highway system have not shown a general increase during the past ten years even though the vehicle miles traveled have increased 35 per cent.

2. A lesser degree of enforcement has been applied to the state highway system; therefore, this could be the reason for a general increase in the accident trend, which appears to be in line with the continuous increase in vehicle miles traveled on trunk

highways, and the proportionate number of enforcement personnel patrolling this roadway.

3. The most significant pattern which has developed from this study is that of county highway-system accidents. Accidents are increasing at an alarming rate, not in proportion to the increase in vehicle miles traveled on this roadway network. The severity of accidents, especially personal injury, has increased 74 per cent during the past ten years. Compare this with a normal increase of 32 per cent on state highways and no general increase on federal highways. (The reference of the norm on state highways is a comparison with the increase in vehicle miles traveled.) The percentage as shown reflects, in reverse order, the approximate degree of enforcement applied to each of the highway systems and the degree of uniformity of engineering on these roadways.

There are strong indications that we have not materially changed the attitude of the drivers, but it is our belief that through selective enforcement, we do change their driving habits temporarily (a matter of weeks or months) at a given location, provided we are dealing with local people and a local problem. To this extent selective enforcement is most effective in the rural areas. It is also believed that enforcement, not unlike advertising, attains its greatest effect not by becoming monotonous, but by periodic changes in the programs (as evidenced by accident experience), which in turn creates renewed attention.

This leads up to the question of speed. A speed check was conducted at 35 locations throughout the state on federal and state highways. These checks established that as the speed decreased, during the years 1959-1960, there was not a single case where the severity of accidents showed an increase. Checks were conducted on a four-mile length of roadway two miles on either side of the radar speed check point. All of these sections of the highway system had been given maximum enforcement. It is also

noteworthy that there was no appreciable decrease in accidents or severity. Significantly, the total vehicle count did increase and the vehicle miles traveled showed an increase.

Does enforcement materially change the average speed? There are indications that it does for a period of time, then without any apparent reason, the speed increases even with added enforcement. Moreover, it appears to follow a regional trend. This leads us to believe that forces other than enforcement and engineering are temporarily stronger. I present this as a part of our enforcement problem. What are these forces and what do we do to combat them?

Can we for one moment afford to even relax our diligence on enforcement? Furthermore, with the stakes so high, can we afford to gamble, or even toy with the idea, that enforcement is not effective against quantity and severity of accidents? Is there an area of doubt which will justify compromises involving human life? Our dedication to duty, enforcement, and if you please, to truth and to humanity, will continue to carve wider paths to traffic safety.

Our greatest degree of uniformity, nationwide, is on the federal highway system. In our state we are, generally speaking, pleased with our enforcement and accident picture on this highway system.

Our future goal is to create a similar situation on the state and county highways. To do this, we must have added manpower (our troopers average 432 miles each or 950 miles per patrol unit) and we believe in continuously rejuvenated selective enforcement program; plus, of course, a closer working relationship with our highway engineers.

As the overall problem, month by month and year by year, becomes more acute and more complex, the challenge appears to be one of accomplishment and purpose. In closing on this somber note, I hasten to remind you that great challenges have always produced great champions.

Should traffic patrolling be increased?

THE EFFECTS OF ENFORCEMENT ON THE QUANTITY AND SEVERITY OF TRAFFIC ACCIDENTS

By **TERRENCE T. DOHERTY**
Chief of Traffic, Police Dept., Chicago

My contribution to this discussion of the effects of enforcement on quantity and severity of accidents will consist of relating an experience in the city of Chicago this year. I believe you will find that the experience I relate will bear specifically on the issue proposed here today.

In early 1961 the fatal accident experience in Chicago began to rise. The extremely low fatality figure of 270 for the year of 1960 was a challenge that was hard to meet. In planning a program to meet this rising trend it was decided to analyze the accident experience for Chicago for a period long enough to give significance to any trends developed from such analysis. Two years experience—1959 and 1960—provided the necessary volumes of accident statistics for this study.

It seemed logical to make an hour-of-day breakdown which would separate the week-day experience from the week-end experience. Therefore, one study was made of the five days from Monday through Friday and the other for Saturday and Sunday. The most outstanding fact discovered was that the hourly fatal trend conformed pretty closely to the injury trend, the property damage trend and the "all" accident trend. The only exception were two week-end hours, two AM and four AM which showed an exceptionally high fatal trend. A parallel to this was that injury accidents were significantly higher from about 12 midnight to three AM on week-ends. There were those who doubted the reliability of the two AM and four AM trends, pointing out that they contained only a small number of the fatal accidents. But the extraordinary injury trend of these hours answered this objection.

People in our field are all familiar with selective assignments by hour of day in which the staggering of five or six or seven shifts is arranged to match the entire 24-hour experience. But, why resort to this

refined, hour-by-hour, system when a concentrated attack on trends by eight-hour groups pointed the way to a chance to reduce the bulk of the accidents? Why not just pick out those hours which contained most of the accidents of the day and try to reduce this large number? Thus was born the idea of the "power" shifts which brought most of our enforcement efforts into short, eight-hour periods, almost to the neglect of the other hours of the day.

As might be expected the week-day hourly accident experience concentrated most accidents—fatal, injury and property damage—into the hours between three PM and eleven PM, a familiar pattern in cities. So the week-day power shift was three PM to eleven PM, with a smaller group working seven AM to three PM and a bare skeleton force on the eleven PM to seven AM shift. Matching the week-end trend was not so easy. Enough experience remained between three PM and eleven PM that these hours could not be neglected. The extremely high incidence of fatalities and serious injuries from nine PM Friday until five AM Saturday and from nine PM Saturday until five AM Sunday called for attention. In fact, the mere numbers of accidents did not seem to tell the whole story. There was a prevalent feeling that these were really the most dangerous hours of the entire week!

The problem was solved in this manner: The very large group assigned to the three PM to eleven PM shift was divided into three units. One of these units was designated as the "swing" unit because its hours were changed on week-ends. This group would not report for work at three PM Friday afternoon but would come out instead at nine PM. They would then work until five AM Saturday morning, reporting again at nine PM Saturday night for the tour until five AM Sunday.

Two minor difficulties developed with the swing unit: First, it was difficult for them

to resume duty at three PM Sunday after having worked until five AM Sunday morning. Secondly, this group encountered more than their share of drunken and reckless drivers, who had to be physically arrested instead of receiving summonses. Many of these had to appear in our "week-end and holiday" court because they could not make bail. This forced a morning court appearance on the already hard-pressed men of the "swing" unit. We believe that this factor discouraged some very important arrests in the early days of the program.

The court problem was solved when the courts agreed to allow a sergeant to represent all traffic cases in the week-end court, because they were mostly continuances anyhow. The fact that the Sunday afternoon accident experience was not serious led to a day off and "time due" system which relieved the hardship of doubling back on Sunday afternoons.

If the power shift idea consisted of nothing but the technique of assigning the most men to a certain set of hours, it would be so basic as to be not worthy of mention to a group of people who already understand this principle. But there was an important additional factor. The large groups assigned to these shifts also had to produce a higher "per-man-per-day" volume of work than men on the other shifts. We wanted the concept of the power shifts as "work" shifts. We wanted such an extraordinarily large number of traffic arrests during those hours that it would be noticed by the public.

In these hours there exists a number of accidents and violations out of all proportion to the other hours of the day. To put it another way, no other combinations of hours even approach the great volumes of accidents and accident-causing violations which exist during these hours. This is not a refined, detailed, selective enforcement program. This is a sledgehammer attack against accidents in volume, in order to obtain a maximum reduction in all kinds of accidents.

There was little encouragement in the early days of the program. It was instituted March 1, 1961, and one month later we had an actual rise in the fatal figures which brought the 1961 figures above the 1960 figures, so bad that at one time we

were running 41 deaths more than the previous year. Worse yet, all of the fatal accidents of April, 1961 occurred during the hours of the "power" shifts. Instead of then abandoning the program we decided that these shocking figures were a perfect corroboration of the correctness of our hourly assignments and that it was more important than ever to continue our efforts. Furthermore, it must be remembered that two years of accident experience was used to obtain our information, therefore quick results were not to be expected. We had to work for a long-term effect.

However, results were not so very long in coming. Early in May, two months after the introduction of the power shifts, the monthly comparison of the "ALL" accident trend, the injury trend and the property damage trend showed a slight reduction. At that time the fatal trend had not yet responded. At the end of May, they did respond slightly and we ended the month with lower figures than the corresponding month in 1960. In July the yearly comparisons went into the "minus" column on injury accidents, property damage accidents and total accidents. May, June, July, August and September also had fewer fatalities than the corresponding months of 1960 and our "deficit" in fatalities was down to 23 by the end of August, 20 by the end of September and 15 as of October 16th.

From the experience with the "power shifts" the following effects of enforcement on accidents is derived:

1. A level of enforcement, high or low, affects the accident experience a certain period of time later, depending, apparently, upon the size of the community involved. No change in the accident experience can be connected with enforcement being done at the same time the change occurs. This is the well-known "lag" principle.
2. Notice that the level of enforcement must be sustained over several months in order to produce any effect. Short period of "up and down" enforcement produce no measurable changes either way.
3. Increased enforcement reduces the accidents sooner than reduced enforcement allows accidents to increase. In Chicago eight months elapsed before the motorists sensed a decrease in enforcement and began to have accidents. But when enforce-

cent. In 1960 enforcement went up 119 per cent and accidents went up 103 per cent.

These effects are caused by several things. Number one, we admit, we are not as selective as we should be. Number two, public information and safety education activities are not as constant and as vigorous in the enforcement effort as they should be. In other words, our efforts are not adequately supplemented by public information and safety programs. However, progress has been made in this respect by the use of safety posters. Each year the police and safety officials meet and decide on what type of violations are causing the most accidents, then we come up with ten point programs. Posters are then made and distributed throughout the state of Michigan, so that a driver in Kalamazoo going to Lansing will see the same posters, calling to his attention, for example, that "following too

closely" is a problem throughout the state. In summary, it is my contention that we in the police field need more training for uniformity of action.

Public education is the most important tool in traffic safety. Keeping citizens informed as to what we, the official agencies, expect of them is very important. They must be educated, not policed.

Judges and prosecutors must come to an agreement on the problem of issuing citations in accident cases. Laws requiring the reporting of accidents and driving regulations should be uniform throughout the entire nation.

If it is a violation of the law to commit an unsafe driving practice in one section of our country, then it must be a violation in any other section, if we are to become a united fighting force in the control of our accident problem.

THE EFFECTIVENESS AND USE OF SEAT BELTS IN THE UNITED STATES

By ROBERT A. WOLF

Dir., Automotive Crash Injury Research, Cornell University, New York City

Many of you are familiar with the work of the Cornell Automotive Crash Injury Research project (ACIR), but a few words about the nature of its work may be appropriate as a backdrop to this paper. The project has been sponsored variously by the Armed Forces Epidemiological Board, the Ford Motor Co., the Chrysler Corp. and at present is supported by the Automobile Manufacturers Association and the National Institutes of Health.

ACIR has been in existence for about eight years and during this time has, with the voluntary aid of police, physicians and public health services, collected more than 45,000 automobile accident cases from 21 states throughout the nation. This massive data, as it grew through the years, has been analyzed with the principal objective of trying to determine the causes of injury to passengers in the hope that—if "causes" could be identified and understood, then "cures" could be brought about.

Many "causes" such as flying glass, ejection, steering wheels, etc., have been identified during the years, and the "cause-cure" interplay has been under continual observation and analysis by ACIR. As time progresses, evaluation of "cures" such as safety belts which began to appear in a few of our cars in the mid-fifties, has become a growing part of ACIR's activity. During the past few years this group has gathered convincing evidence that the lap type safety belt is indeed a powerful device for reducing death and injury on our highways.

I shall try to report on the general state of knowledge concerning the seat belt and especially what we at ACIR know about its functioning and its effectiveness—based on our own research.

Many years before the seat belt became the byword that it is today, a small group of engineers, doctors, airmen and safety minded persons began to experiment with various aspects of this device, borrowed

from the aviation industry, to determine if it could help to reduce the mounting toll of injury from automobile accidents. Names like DeHaven, Dye, Stapp became synonymous with this movement. The group became convinced that they had a powerful life saving device within their grasp—if only the public could be persuaded to use it. Laboratory tests pointed out the potential advantages—but this was not enough. What was needed was more convincing evidence that seat belts actually worked in real accidents.

By 1956, Cornell's crash injury research program had collected enough data on automobile accidents in several states to make one of the first studies of the effectiveness of the seat belt in actual practice. The first results were indeed startling. Could such a simple device really prevent almost two-thirds of the fatalities occurring in passenger car accidents? Incredible! Well, as it turned out later, this early result was somewhat optimistic; the sample was small and there were some inconsistencies in data. As accident data and methods of analysis improved, we began to converge on a fuller understanding of the action of the seat belt and a more realistic measure of its actual effectiveness was developed.

In addition to what we are doing at Cornell by means of accident analysis, a great deal of important experimental crash injury research is being conducted by others such as the University of California, University of Minnesota and the automobile industry. This research is generally of a laboratory nature, in contrast to ACIR's approach by means of statistical analysis of many highway accidents. The two forms of crash injury research, however, are complementary in that each supplies knowledge of different aspects of the problem which are vital to a complete understanding of the action and effectiveness of the seat belt. Experimental laboratory type crash tests with anthropomorphic dummies produce force measurements and observable motions of the dummies under controlled conditions of speed and direction of impact.

The experimenters also try to estimate the physiological damage which could result from the tests. High speed photography is used to observe the split second impact action and is essential to this type of investigation. The number of tests, however,

is generally limited by cost and time, so only a few of the situations encountered in real accidents can be simulated. Statistical analysis of injury which occurs in actual accidents such as done by ACIR examines the results of a great number and variety of factors by working backwards from evidence gathered during on-the-spot accident investigation.

I shall deal principally with lap-type safety belts, as this is the only type used extensively enough in this country to be evaluated by our method. Development and use of the safety belt is also proceeding in Europe where the diagonal shoulder strap type has gained prominence. I shall discuss the function and effectiveness of the lap belt and shall also make some estimates concerning present public acceptance of seat belts in order to show how the current upsurge in popularity may influence the national fatality picture during the next few years.

The public acceptance aspect should be of particular interest to those of you who have been engaged in seat belt promotional work during the past years and have begun to observe the upswing in public reception. It is astounding and very gratifying to witness this trend and I am certain that "explaining" the phenomenon will keep motivation researchers and sociologists occupied for many years.

The ability of the safety belt to influence the toll of death and injury on our highways depends on two main factors:

EFFECTIVENESS

The effectiveness of the device, itself, as a safety control measure—our research at Cornell produces the factual evidence.

USE

The extent to which this measure is used by the motoring public—your educational efforts influence this factor.

Knowledge of a marvelous cure for a disease is not enough—to be effective, it must be used.

What ACIR Has Found Out About Effectiveness

Since 1957 we have made several studies of the effectiveness of belts based on thou-

sands of persons involved in automobile accidents and we are coming closer each day to a true understanding of how the seat belt functions.

Even though our results in measuring the degree of effectiveness vary somewhat from study to study, the trend is always the same—seat belts really work. They are a powerful and effective means of saving lives and reducing injury but they are not "cure-alls." The belt appears to be very effective in controlling severe injury near the fatal end of the injury scale whereas its role in mitigating injury at the minor end of the scale is still obscure.

Our latest and, we believe, most reliable study, published in 1960, shows that "major to fatal" grades of injury are reduced about 35 per cent by wearing lap-type safety belts. Translating this result into a national goal for saving lives, it means that if all passenger cars on the road were equipped with at least two seat belts and they were used all of the time, about 6000 to 8000 lives could be saved each year; also, many other injuries resulting from ejection and impact could be eliminated.

This is a theoretical goal—obviously all motorists have not bought and are not wearing safety belts. A nationwide poll made in May-June of 1961 by the Auto Industries Highway Safety Committee indicated that only about 3.3 per cent of the passenger cars in the United States were equipped with belts at that time—so you can see how far we have yet to go to reach an effective goal. I am going to use the results of this survey later on in this paper to help make a forecast of public acceptance.

How does the seat belt function? In our analyses, we divide its functioning into two categories—Ejection Control and Buffeting Control.

It reduces EJECTION of passengers from the car; this is the major effect and accounts for about two-thirds of its control action.

It reduces violent BUFFETING of the passenger inside of the car; this accounts for the other one-third of its action.

Each of these functional categories influences a wide range of severities of injury. For example, if ejection and buffeting

could be completely eliminated as sources of fatalities, we would be very close to the goal of saving 8000 lives annually, whereas if only ejection is controlled, the number will be closer to 6000. The number of lesser injuries which may be mitigated by belts is unknown, but is very large.

Thus far in our research we have approximately "pinned down" the fraction of the effect due to control of ejection and have a good understanding of the injury patterns caused by ejection. We have, however, much more to learn about the detail effects of buffeting as they influence injury. Ejection, that is being violently thrown from the car, was shown in an early ACIR study made in 1954 to be a surprisingly frequent event.

A study made in 1958 showed that before safety door locks were introduced in American cars, about 14 per cent of the occupants of ACIR's injury-producing sample were ejected. These early studies proved that the popular belief that it was good to be "thrown clear" of an accident was a fallacy. Indeed, it has been proved that the ejection is more likely to be "thrown clear" to eternity.

The seat belt, if properly used, will hold the passenger in the car and prevent ejection. Although ejection generally occurs in medium to high speed accidents, it is by no means limited to this class of impacts. Many persons are ejected and killed in low speed accidents due to striking their heads on pavement, being dragged or run over, sometimes by their own car.

Let us now consider the other third of the belt's effectiveness—buffeting control. Unfortunately, ACIR has not yet been able to separate in a quantitative manner the various antibuffeting effects of the seat belt in forward, side, rear and rollover types of accidents, so these effects must all be lumped together under the single heading—buffeting.

This part of the discussion must, because of the lack of factual analysis, be limited to a more qualitative form than that of the preceding phase concerning ejection. Buffeting is used here to define the violent flailing of the passenger inside of the car under the overwhelming forces of impact as the automobile crashes, is decelerated and brought to rest. Control of buffeting probably has influence on all degrees of

injury varying from minor to fatal. It has been amply demonstrated, as one of the purposes of safe "jackknifing" that the passenger will have better chances of survival if he can be held tightly to the car so that he can be made to decelerate with rather than be thrown violently and uncontrollably against its interior surfaces.

What actually happens, if the passenger is restrained, is that the car stops suddenly whereas the passenger keeps on moving with his initial momentum until he laterally collides with the interior of the "upping" car. This is the critical "collision" which tends to make the passenger an integral part of the car and avoids the second, or inside, collision. Although the lap-type safety belt is now known to be an excellent ejection control device, we are not yet certain whether it is a completely effective antibuffeting control in all types of accidents.

Our rather meager data on antibuffeting action seems to indicate that in side impacts and in rearward collisions, the lap belt does a creditable job of holding the passenger because the interior side surfaces and the seat back also help to restrain the body. The belt's antibuffeting control is also quite effective in the rollover type of accident where, without a belt, the passenger is tumbled about in a most frightful manner as shown by motion picture studies of anthropomorphic dummies in rollover crash tests.

In the forward impact type of accident, the lap belt may be found wanting; the stretch in the belt and its fastening, coupled with the "jackknifing" of the passenger's body may allow the head to strike the windshield or instrument panel. In forward impacts there is a considerable forward translation of the body which may amount to 18 inches, coupled with the typical U-shaped "jackknifing" forward of the torso and forward extension of the legs and arms as the passenger bends around the belt. In the right front seat position even most full-sized American automobiles do not have enough space between the front seat and the instrument panel to avoid collision of the average passenger's head or knees. This characteristic is further emphasized by the smaller space of the European car and the American compact.

Bucket seats appearing in "sports" versions and recessed dash panels in some big American cars may be harbingers of a trend toward design for seat belt compatibility.

This area needs further clarification and ACIR hopes to do more probing into the injury effects of the front seat position. It may be well that especially in this position, the shoulder harness or diagonal belt is a better solution than the lap belt. Intrusion and observation of test crashes prompts the conclusion that there is a pregnant opportunity for applying real engineering ingenuity to redesign of the right front seat position in the American automobile. Such effort could be directed either toward local elimination of the instrument panel and provision of plenty of forward clearance to accommodate "jackknifing" or it could point toward development of a special type of safety harness to prevent "jackknifing."

In the latter direction, much of the "hardware" could be incorporated in the seat design. If we in this country are going to adopt exclusively the lap type safety belt, we must learn to redesign passenger compartments and provide our car interiors with the necessary clearances to be compatible with the known action of this type of belt.

As use of seat belts becomes more prevalent, questions are certain to arise concerning the belt itself as a "cause" of injury. Some cases of internal injury attributed to the action of European type diagonal belts have been reported in Sweden but it is too early to say whether the design of the harness itself is at fault, whether the diagonal is being improperly worn, or whether the severity and nature of the accidents were such that no form of harness would have prevented injury.

There is no doubt that, as passenger restraint is improved to the point where buffeting impact is prevented, a threshold of human tolerance to non-impact but very high acceleration forces will be reached; internal injury may then become prominent as a problem in certain accidents of great severity. There are, of course, limits to human tolerance of acceleration forces but there are many lives to be saved by present means before this threshold is reached.

ACIR has started to study the problem of injury caused by belts themselves but

thus far there is no conclusive evidence of a major problem. More data is needed which can only be obtained as belt usage increases. Results of this preliminary investigation are reported in a recent paper by John Garrett and Dr. Paul Braunstein—"The Seat Belt Syndrome." This paper also examined seat belt structural failures and found that failures occurred in less than one per cent of the thousands of cases examined.

In closing this part of the report on the status of research on safety belts, it is appropriate to point out that there are other types of belts receiving attention in different parts of the world. In Europe, for example, the diagonal shoulder strap sometimes combined with a lap belt is very prominent. The European engineers, in defining the original requirements for belts to be applied to their smaller cars, placed heavy emphasis on the antibuffeting requirements and reasoned that, because of the generally small compartment sizes and especially the short distance between seats, windshields and instrument panels, they must eliminate "jackknifing" and flailing of the torso—hence they specified the need for shoulder restraint. These factors started the public use of safety harness in Europe off in an entirely different direction from that in the United States.

Apparently ejection is not encountered as frequently as it is in the United States, so there is less emphasis on its control. The extent of public acceptability of this type of belt in some countries is astounding. For example, it is reported that by 1960, in Sweden, safety harnesses were installed in over 60 per cent of their cars compared with seat belts to the extent of about two to three per cent in the United States at that time—and they started later.⁴

A recent article from Sweden, concerned with the injury effects of safety belts, mentions that belt installations may be in 70 to 80 per cent of the Swedish cars by early 1961.⁵ Unfortunately, a study of the effectiveness of the European type of belt or harness, equivalent to ACIR's study of the American type of seat belt has not been made so there is no direct way of comparing the two types by means of accident-injury analysis. We are opening discussions with Swedish authorities to ex-

change information and determine whether comparison studies are feasible. Several designs of shoulder restraining harnesses are being offered at present by American belt manufacturers but their acceptance is very limited; it is reasonable, however, to expect more of these to appear in the future as their popularity increases.

Seat Belt Usage

In this part of the discussion I shall deviate from the role of the factual reporter of scientific evidence and take on the garb of a clairvoyant. I shall use the crystal ball to assemble a view of the future using some results from ACIR's research, some from the recent Auto Industries Highway Safety Committee Survey and some personal conjecture. This may help to give you some new perspective on the potential influence of the safety belt in the national highway safety program.

There is growing evidence that a real breakthrough in public acceptance of safety belts is occurring in this country. The tide has been slowly rising and ebbing for about five years and it now appears that the wave-front of the flood is about to deluge the country. Those of us who have been observing this surge are aware of its occurrence but find it surprisingly difficult to determine its magnitude; it appears that a sudden change began to take place during the Fall of 1960.

What is the actual trend of seat belt installation and usage? It is not easy to answer this question but some insight into public acceptance may be gained by examining seat belt sales throughout the country. ACIR is conducting an informal survey of seat belt sales with the cooperation of some American manufacturers of seat belts.

Response to ACIR's inquiry has been very gratifying, and although only a fraction of the industry is represented at this time, we hope the data is fairly representative of the national trend. It is planned to issue a separate report of findings on sales trends to the cooperating belt manufacturers and to continue the survey as more manufacturers join the effort.

This report has just recently been initiated and is of a preliminary nature. Figure 1 shows a composite curve of the industry's sales trend which, incidentally, has been

considerably smoothed. Each of seven manufacturer's sales data has been proportioned over the years to his own total sales, then combined with the total group and averaged; this produces a curve which represents the trend of sales growth over a five year period. This curve provides only the general shape of the sales trend but is not capable of showing total sales volume because it represents only a part of the industry's volume.

How then can we estimate total volume of sales? It so happens that the recent survey of seat belt installations made by the Auto Industries Highway Safety Committee in May-June of 1961 provides a bit of information which allows us to combine the sales trend curve of Figure 1 with the measured national installation of 33 per cent found by the AIHSC survey. We, thus, have a curve of typical form and a point on the curve. From this limited data Figure 2 is developed; this shows the estimated cumulative number of seat belts in American passenger cars for the five year period. Projections of future volume indicated by the dotted line are based on the established trend.

An additional assumption had to be made to formulate this curve; an "educated guess" is made that an average of 2.5 belts per car are being installed at the present time. On Figure 1 and Figure 2 the data collected up to mid-1961 is shown by the heavy lines; whereas the future projections are purely conjectural. It will be interesting to check the actual figures as they develop during the next few years.

FIGURE 2
NUMBER OF SEAT BELTS INSTALLED
(NATIONAL ESTIMATE)

In rationalizing the projected trend on Figure 2 for the year 1962 and beyond, it is believed that due to the increased convenience of installing belts in new cars as provided by built-in anchor points, in addition to mandatory regulation in some states, and the generally increasing public awareness of the value of safety belts, the rate of installation will actually continue to accelerate but, to be conservative, the acceleration is not incorporated in the projection.

To indicate this conservatism, a straight line projection is used rather than an accelerating slope and is extended until 35,000,000 belts are reached. At this point it is assumed that market saturation starts to enter and the installation rate begins to "slough off" in some fashion as indicated. The exact point at which the rate begins to fall off is not predictable; it is shown here merely to express an awareness of the possibility—only experience will tell.

Lives Theoretically Savable versus Lives Actually Being Saved

There are various possible ways of expressing goals for a national seat belt promotional effort. One way would be to aim for at least two seat belts in each of the 61,000,000 passenger cars in the national registration on the assumption that this is the best one could hope to achieve. The Federation of Women's Clubs has chosen the very "catchy" slogan, "A Million and One in '61," and are working hard to achieve it.

I have selected a different way of stating a goal and outlining a method of measuring progress toward it by casting the seat belt in terms of its potential life-saving role. This choice may be less glamorous than others but it has the virtue of including a measure of effectiveness of the seat belt, an installation growth factor and a usage factor. All of these factors are important ingredients of the problem and may change with time and the changing habits of people. This scheme, therefore, provides us with a means for "keeping track" of the influence of the seat belt in the coming years and allows us to modify the major ingredients as they may shift about in the future.

ACIR has made two studies which may be used to estimate goals of "lives savable." The California seat belt study indicated a potential reduction of major fatal injuries of 35 per cent through combined control of ejection and buffering; the ejection study found that fatalities could be reduced by 25 per cent by means of complete control of ejection. Applying these results to "applicable" national fatalities produces the two upper curves in Figure 3 labeled "lives theoretically savable."

The top curves of Figure 3 show the lives savable annually by means of seat belts (ejection and buffering control); it is extended to 1963 and this may be considered as representing a maximum goal

of saving about 8000 lives per year. Notice that about 1962 the projected slopes of the curves start to slip downward at a faster rate; this reflects the fact that if the expected lives are indeed being saved, the total number of lives savable should also reduce.

The lower of the two curves (marked ejection) represents an approximation to a boundary of lives savable by means of ejection control alone; it indicates about 6000 lives per year as a lower goal. Consider these curves as being related to each other and that the region lying between them is a band of uncertainty which describes a wide "broad brushed" curve.

The up-sweeping curve at the bottom of the graph is the estimate of lives being saved annually by means of seat belts; this is based on the trend of belt installation developed through the sales survey shown in Figure 2. Since the theoretically "savable" curves and the actually "being saved" curves are dependent on each other, any intersection of the two would represent a simultaneous solution and would indicate the time when the theoretical goal would be reached.

The lower curve of Figure 3 indicates the estimated number of lives being saved for usage factors of .345 and .50 where "usage" is the per cent of time passengers wear belts. The fanning effect plotted about the .345 curve represents $\pm 20\%$ deviation about the mean; this device is used to indicate some of the uncertainty of the projection process.

The point on the lower curve at which the curve starts to break upward in 1961 marks the estimate of 92 lives actually being saved per year at the present time and gives us some indication of the distance we have yet to go to reach the theoretical goal of saving 6000 to 8000 lives per year. Note that the projected increase for 1962 is about 7-9 times that of 1961 and that of 1963 is about 20-30 times that of 1961.

The method used to estimate the number of lives actually being saved by belts is shown here in the event that some readers may wish to plot actual progress of events as some of the values change. Several ingredients are needed: number of annual fatalities; theoretical effectiveness of belts; number of belts installed in cars and the

percentage of times they are used; these and the available data are indicated below.

Number of Applicable Annual Fatalities (National Safety Council data) = Of about 38,000 fatalities, 60 per cent are "applicable" to the ACIR type of sample.

Theoretical Effectiveness (from ACIR Research) = 35 per cent reduction in major-fatal injury. Applied in this case only to fatal portion of national injury as an approximation.

Per Cent of Time Belts are Used (33 per cent from ACIR research 1958)¹ (34.5 per cent from NHTSA poll 1961)² = Use 34.5 per cent for this computation.

Number of Belts Installed (from NHTSA poll 1961)³ = 3.3 per cent of passenger cars in national registration.

The computation for estimating the probable number of lives being saved by seat belts in any year, for example 1961, is made as follows:

$38,000 \times 60 \times 35 \times 34.5 \times 0.33 = 92$ lives. It is interesting to note that earlier in 1961, the author made an estimate of 64 lives being saved by seat belts.⁴

38,000 = estimated annual highway fatalities for 1961.

60 = portion of annual highway fatalities applicable to ACIR sample.

35 = theoretical effectiveness of seat belts.

34.5 = usage factor, the per cent of time installed belts are used by passengers.

0.33 = per cent of passenger cars having two or more belts.

When the term "major to fatal grades of injury" is used, it does not include all grades of injury encountered in accidents. "Major" is used in the California seat belt study⁵ to identify two gradations in a scale of four grades: "complaint of pain" - "minor" - "major" - "fatal," so it applies to only a part of the whole injury spectrum.

Therefore, the 35 per cent reduction found by the study may be applied to only the fatal or near fatal fraction of the national injuries reported each year.

How Realistic is this Projection?

Can we actually reach these goals? I cannot, of course, guarantee when the goal will be reached or if it will be reached but if

everyone continues to work at seat belt promotion with the present zeal, it appears to be a distinct possibility. The "lives savable" and "lives being saved" curves will, of course, probably never really intersect as all automobile owners are not likely to install belts and people will not always use belts all of the time.

If the assumptions of this analysis prove to be reasonable, however, and the projected trends of belt installation and usage are maintained, it appears that somewhere about 1964 to 1966 the influence of the seat belt will have reached its potential influence in controlling fatal injuries from ejection and a year or two later will reach the limit of combined ejection and buffering control. From that time onward, it will be a matter of "holding the line" against other changes which may be occurring in public attitudes and traffic injury patterns.

Many factors may influence the accuracy of this projection to make it more or less optimistic. Probably one of the greatest negative disturbances could occur from the type of unpredictable sociological effect known as "sales resistance." For example, if the surprising surge in public acceptability which is occurring now is being produced by a small segment of the public who were pre-conditioned to be very receptive to the seat belt and were "ready" to buy anyway, we may be receiving a false signal about the total public's attitude.

There may be a large segment of "die-hards" lurking in the wings who will resist the use of belts and we will not encounter them until the "ready" group has played out its part. Such a factor would cause the "lives being saved" curve to fall off at a lower level and a lower slope from that which is indicated. Several factors may modify the slope of the curve which, in effect, determines the time period when the maximum life saving influence will be reached.

The effect of differing "usage" may be seen by comparing on Figure 3 the two values of .345 which represents present usage with .50 which represents an improving public habit pattern and produces a much steeper slope.

The projected slope of sales on Figure 1 which determines the basic trend used in the rest of the analysis contains a large

uncertainty. We have factual data on seat belt sales only up to mid-1961—beyond that the trend is pure conjecture. It is particularly difficult to determine a representative slope of the upswelling trend because we are at the beginning of the transition phase. The sudden rise started in the Fall of 1960 and data was available only to mid-1961—not enough to firmly establish a slope for the future. ACIR plans to gather future seat belt sales data and perhaps in a year we shall have a better "fix" on the projected trend.

On the other side of the picture are several factors which indicate that a fairly high degree of optimism is warranted. There are several "islands" of probable public acceptance of safety harnesses or belts which indicate that installations can indeed approach a very large portion of total car population. The Swedish experience indicates that safety harnesses are installed in 70-80 per cent of their cars.

In the United States a recent survey of 531 doctors, made by the American Medical Association, indicates that 32.8 per cent of the group have and use safety belts. Consumers Union recently reported that about 17 per cent of their readers of *Consumer Reports* have safety belts and some commercial automobile fleets have very high records of installation and use of belts. Other factors which are at work to stimulate public acceptance are: the promotional campaigns jointly sponsored by the National Safety Council, American Medical Association and the United States Public Health Service, the campaign of the General Federation of Women's Clubs, the provision of convenient seat belt anchor points in the 1962 model cars, legislation to make installation of seat belts mandatory—such as Wisconsin's new law, and general support of hundreds of safety groups, the automobile industry, the press, the radio and television industries.

I also have a suspicion that having seat belts may be acquiring a status symbol and, if this is so, there should be a strong "following the crowd" effect.

Before closing I must point out that I have presented a somewhat oversimplified view of the projected influence of the seat belt as a "cure" to ejection. We must realize that there is another "cure" work-

ing on control of ejection at the present time, the safety door lock, and it has had a head start on seat belts in the role of a life saver. Very effective safety door locks were introduced by the American automobile industry in 1956 models and current designs include further improvements.

I have avoided putting a "door lock" curve on Figure 3 because of the technical complication of comparing it with seat belts and the confusion it would undoubtedly cause at this point. A curve of lives being saved by door locks would begin to appear about 1957 and would rise slowly to a value of about 800 in 1961.

I have discussed the relative positions of the lock and belt as life savers in a paper earlier in 1961 at which time it was estimated that on a national basis door locks were saving about 800 lives per year while seat belts were saving 64 lives. The 64 rate has, with the passage of time now become the 92 rate of this paper and is rapidly increasing. The important point to remember is that both of the devices are working toward the same end—saving lives and reducing serious injury.

It would be a most gratifying experience to have one of the National Safety Council's statisticians knock on ACIR's door sometime about 1964 or '65 and excitedly proclaim—"We have been noting a mysterious downward break in our annual automobile fatality curves for several years and we're at a loss to explain it!" I would then ask—did it start to break about 1960-61?

WHAT MAKES EFFECTIVE SEAT BELT PROMOTION

By HOWARD N. SCHULZ
Committee on Medical Aspects of Automotive Safety
American Medical Association, Chicago

In discussing this topic from the viewpoint of the medical profession and the American Medical Association, I plan to briefly outline what results have been shown by surveys and to discuss what we have done to promote the use of seat belts.

This summer our advertising department conducted a survey on automobile preferences among physicians. The questionnaire was sent to 1,000 doctors selected by the records department as a random sample of the physicians in private practice. There were 11 questions asked. Only one question with five parts concerned seat belts.

Answers were received from 531 physicians. The questions were as follows:

1a. Do you have safety belts installed in your car(s) at present?

32.8 per cent have safety belts installed in their cars at present—99.5 per cent do not—7.7 per cent did not designate.

1b. Do you intend to install safety belts in your car(s)?

46.9 per cent intend to install safety belts in their cars—23.8 per cent do not—27.3 per cent did not designate.

1c. Do you recommend the installation of safety belts to others?

81.5 per cent recommend the installation of safety belts to others—12.8 per cent do not—5.6 per cent did not designate.

1d. Do you favor making safety belt anchorages (front and rear) standard equipment?

88.1 per cent favor making safety belt anchorages (front and rear) standard equipment—7.9 per cent do not—4.0 per cent did not designate.

1e. Do you favor extending standard safety equipment to include crash padding, improved steering wheel and recessed post, etc.?

92.5 per cent favor extending safety equipment to include crash padding, im-

proved steering wheel and recessed post, etc.—3.6 per cent do not—4.0 per cent did not designate.

This seemed to be an extremely high percentage. Even if all of the 469 who did not reply did not have seat belts, the results still would show that at least 17.5 per cent of the 1,000 physicians who were queried had seat belts.

Within a very few days of this survey a letter was received, reporting another survey from Jefferson County, in which 500 physicians received a letter and a reply card. The response was 66 per cent and the data indicated that 34 per cent of those replying used seat belts, and 92 per cent believed in the value of seat belts.

These results have been achieved almost entirely by means of the written word. The AMA News which goes to all physicians as one of the benefits of membership in the AMA, has carried out a continuing campaign. Rarely does an issue come out without some story, editorial or reference to seat belts. We feel that this has been effective.

The publication *Today's Health* also goes to all physicians. In addition, about 600,000 subscriptions are sold to the public. Feature stories on seat belts have helped the campaign.

Very often, physicians write in to inquire what they can do as individuals to help in the seat belt campaign. A good answer to them is in the forms of a series of questions. Do you have some community leaders as your patients—the mayor, a congressman, judge, chief of police? Do they now have seat belts in their cars? Can you use your influence as a personal physician to get them to use seat belts? This approach which can be carried out on an individual basis is only one of many. The main thing is to encourage people to make their contribution to this program, whether it's an individual effort or community project.

ened not only to bring additional motorists to install seat belts but to pound away at the theme that a seat belt is of no use unless it is worn. Complementing these efforts must be the continuation of all of the other traffic safety measures outlined in the balanced program of the President's Committee for Traffic Safety.

The old adage, you can lead a horse to water but you can't make him drink, is certainly true in the case of seat belts. A recent national poll revealed that, of the estimated two million motorists who have voluntarily equipped their cars with seat belts, only one-third use them at all times in their driving. These are drivers who at one time obviously recognized the benefits of seat belt use but now only a third will take the few seconds necessary every time they enter their car to fasten their seat belts.

This is one of the reasons why we do not feel that the answer to the problem of increasing seat belt use lies in legislation requiring their installation. The answer, as I see it, will be found in education on a distinctly personal level. Arguments for seat belt use must be presented to drivers on a "benefits to you" basis.

Let's face it, the average driver is not particularly concerned with accidents involving the other fellow. He is concerned with accidents as they affect him or his family. When he reads that so many millions of accidents occurred during the year—this is the result of the other guy—the bad driver—the one who needs seat belts. But when he reads that accident rates are down two per cent over last year, this is a result of his own superior driving ability.

In promoting seat belt use, we must find means to take advantage of this feeling of superiority by associating seat belt use with above average drivers. I believe the insurance industry touched on this philosophy somewhat when they reduced rates for drivers who equipped their cars with seat belts.

Speaking of insurance, I think we would do well to encourage drivers to view seat belt use just as they do their auto insurance. They don't take out a policy to protect the other fellow but to protect themselves. Most drivers know from experience that their chances are something like one in seven of having an auto insurance claim in any given year, yet they continue to renew their policies year after year. Seat belt use follows this pattern and, like auto insurance, should be there when needed. Failure to fasten a seat belt should be regarded just as seriously as failure to renew an insurance policy.

I also believe that this classroom, most particularly the driver education classroom, can be instrumental in effectively promoting seat belts. Many of the training aids, publications, and films distributed to schools by companies within the auto industry do contain information on seat belts and all cars loaned to schools for driver education through the manufacturer-dealer cooperative programs are equipped with seat belts to encourage their continued use after graduation.

We feel that such measures as these will have increasing impact in the safety picture as time progresses. Thank you.

MANDATORY PERSONAL APPEARANCES IN TRAFFIC COURT

By JAMES A. RAVELLA
Municipal Court Judge, Warren, Ohio

This is a very important matter and we have all heard it said, and we've said it ourselves, that all moving violators should be made to appear in traffic court. Why?

That is the basic question.

For what purpose or purposes should moving violators appear in traffic court? What do we hope to accomplish thereby?

For convenience and expedience these cases could be handled in a traffic violations bureau. But should they?

I think we are going to come up with some valid reasons for bringing these moving violators before a judge in a court of justice.

But we are going to be faced with a second question. That question is whether or not the time, trouble and expense involved, in bringing these cases to court, is justified by the result that will be attained.

Basically these two questions merge into one:

What can the judge do better in the courtroom than the cash register does in the violations bureau, and how much savings in human life is going to result, if any?

Our basic premise is that all moving

traffic violators should appear in traffic court. We know, however, as a practical matter, that there aren't enough judges and traffic courts in the land to handle all these cases, and not enough hours in the day to review the citations of the approximately 10 million moving traffic violations which occur annually in the nation.

So as a matter of expediency shall we amend our goal and have it only require that "all hazardous moving violators appear in traffic court"? What, then, about the contention that many penalties, as permitted in some violation bureaus, are ineffectual in reducing the shocking automobile accident rate, especially where the offenders are persons who can afford the luxury of breaking traffic laws and thus become "violators for a price."

MANDATORY PERSONAL APPEARANCE IN TRAFFIC COURT

By EARLE W. FROST
Judge, Municipal Court, Kansas City, Mo.

Most traffic courts now require personal appearance in traffic cases except as, to first, second, or even third moving violations within a certain time limit. Therein, as to these moving violations, lies the problem posed by the subject of this discussion.

It was recognized, even in the early years of the program for traffic safety and the improvement of traffic courts, that "a traffic violation bureau should be considered a legal expedient rather than a safety measure" (Enforcement for Traffic Safety, page 41).

Warren, in *Traffic Courts*, 1942, pages 57 and 58 said:

The theory which lies behind violations bureaus is the establishment of a method for disposing of some of the traffic offenses when their number begins to overwhelm the regular court. The effective use of these bureaus avoids badly overcrowding traffic dockets and permits the bench to exercise thorough judicial consideration of the more serious traffic cases. But the use of such bureaus is to be weighed against the purpose of the traffic court—to enforce the traffic law effectively and promote safety—and when utilization of this device does not or will not promote these

ends a violations bureau is out of place. For this reason "inferior court" jurisdiction should be limited to offenses against public convenience and should not include those which involve public safety to a serious extent. It is most desirable that all traffic offenders be brought before the judge for corrective as well as punitive action.

The predecessor to the Traffic Court Division, the Traffic Court Committee of the National Safety Council, in 1943 recommended specific proposals for the improvement of traffic courts, including the recommendation that "a traffic violations bureau, set up under the direct jurisdiction of the court, should be in operation to receive cases of minor nature—ordinary parking violations and possibly a few minor moving violations."

The 1946 President's Highway Safety Conference Committee on Enforcement recommended:

The bureau should handle the least hazardous violations and should deal with moving violations only when they respond to treatment outside the courtroom. Major traffic law violations should never be handled in a violations bureau. (1946 Report, page 26).

Obviously, if hazardous moving violations are actually major traffic law violations, as we are more and more inclined to conclude, then there is no place in a traffic violations bureau for any hazardous moving violations.

There is, of course, a logical basis for the use of the term "hazardous" in connection with any discussion and treatment of moving violations, since the traffic codes of some states include as moving violations some violations that cannot be classed as hazardous moving violations and which have no direct relationship to traffic safety.

Judge Edward C. Fisher, now of the legal staff of the Northwestern University Traffic Institute, said in his book *People's Court* in 1947, page 38:

These violations bureaus are simply an expedient, not a solution of the traffic problem. They are adopted when the volume of business begins to overwhelm the court and are merely a development of the ancient system of bail forfeiture. The customer never sees the court, but simply pays his money over the counter, a stipulated sum for each violation and the whole transaction is purely on a financial basis. . . . Under no circumstances should violators charged with hazardous moving violations be permitted to pay their penalties at a violations bureau.

In 1949 Chief Justice Vanderbilt, in speaking of the New Jersey record of the first year following their new judicial establishment said:

The most significant aspect of the work of these courts (referring to the new municipal courts) is the increased respect now accorded them in the public eye. . . . The resultant increase in respect for law in the part of hundreds of thousands of defendants and witnesses who are brought into the municipal courts is quite as important as the improvement in the enforcement of the traffic laws. . . . (Annual Judicial Conference, Sept. 1949).

In 1953 the Conference of Chief Justices adopted sixteen resolutions concerning traffic law enforcement. One of these resolutions, No. 10, referred directly to the subject of this discussion, as follows:

RESOLVED, That because of the increasing toll of highway accidents, trial courts of first instance should require all persons charged with moving violations to appear in court in person and the traffic judges should increase the amount of individual attention given to each case of such nature for the purpose of assessing adequate corrective penalties and that, if necessary, steps be taken to add additional judges and prosecutors to accomplish this end.

Of this resolution Chief Justice Vanderbilt said:

This resolution is to be read with Resolution 15 providing for a violations bureau to

handle nonmoving traffic offenses so as to give the traffic judge more time to deal in person with moving violations. Given such personal attention will not solve the problem of handling moving violations satisfactorily unless he can give each case the amount of time necessary to master it thoroughly, a prerequisite to a wise decision. Accordingly, the most important part of the resolution is the last clause calling for more judges and prosecutors if needed to enable each judge to give each case as much time as it may reasonably require. Hurried justice is likely to be the reverse of justice.

The citation of authorities on this subject would, of course, not be complete without the word of the supreme authority, the expert to end all experts, Mr. Traffic Court himself, James P. Ecomomos, who stated his views in the "Administration of Traffic Courts," page 36 of *Judge and Prosecutor in Traffic Court* as follows:

Only those violators of the traffic laws designed to promote public convenience, such as parking and standing regulations, should be processed through a traffic violations bureau. This means violations of regulations designed to promote public safety—moving violations—should be heard by the judge.

The primary aim and objective of a traffic court is not to punish the violator for the sake of the punishment alone, although, unfortunately, we must recognize that there are some violators, we hope a very limited number, who do not understand any other language.

The Traffic Court Committee of the National Safety Council stated in 1943 the recognized primary objective of the traffic court, as follows:

The primary aim of the traffic court should be to impress defendants with the need for traffic law observance rather than to penalize. This may be stated as a simple objective, but as can be gathered from the few standards we have been discussing, it requires application of some rather important principles if it is to be achieved. (Specific Proposals for the Improvement of Traffic Courts, 1943).

Now, obviously, this objective can never be achieved through payment of fines in a violations bureau. The only way it can be achieved, if at all, is in the traffic court and the first requirement must be that the violator be required to appear personally in the traffic court.

Traffic court judges are fully aware of the desirability of requiring all hazardous moving violators to appear in court, however, the great increase in traffic cases in metropolitan areas has far-surpassed the present capacity of traffic courts to handle

all hazardous moving violations in the courts. Of course the resolution of the Chief Justices supplies the theoretically correct answer, that is, obtain more judges and prosecutors.

As a practical matter, however, officials of cities, hard pressed financially, are sometimes the first to suggest letting all moving violators, including speeders, pay at a violations bureau, arguing for public consumption the convenience to the violators, but no doubt thinking about all the increased revenue the city may obtain when the violators can conveniently and guiltlessly pay for their violations for a price at the bureau.

Moving violators, if not corrected, become repeaters and ultimately reach the court after the damage, injury or death has occurred. Prevention, at the cost of additional judges, would be much cheaper and more compassionate to the victims.

A captive audience, such as traffic violators compelled to be present and listen, may quite understandably be inclined to be a hostile and an antagonistic audience. Yet all judges who make appropriate opening remarks before traffic sessions will, I am sure, verify my experience that the making of such remarks invariably and very noticeably increases the cooperation and respect of all violators. Even the repeaters often express regrets and apologies for returning and promise never to be there again instead of arguing about what a bum rap the cop gave them.

All judges are aware of the fact that many violators in court, charged with carelessness after having had a collision, who vehemently protest they are good drivers and never had a collision before, are found, on checking the records, to have a long record of many moving violations, paid over the years at the violations bureau.

They have never been in court and it quickly becomes apparent they do not know the right-of-way rules. It is utterly astounding how many drivers, of many years driving experience, have not even the faintest conception of the fact that there is a right-of-way rule for every traffic situation, much less what the rule is. Good defensive drivers, of which fortunately there are many, have saved them in the past but finally their luck runs out.

How many times have you judges had

such drivers before you, who blandly tell you, even though you may be a traffic judge of long experience, even as much as over 20 years, how right they are and how wrong the other driver is, and you also, if you decide against them. In addition they magnanimously proceed to give you the benefit of their solution of the whole traffic problem.

These are the drivers who cause many "accidents" by their carelessness, inattention, failure to yield right of way, downright discourtesy and the almost psychopathic attitude of many drivers whose inflated ego behind the wheel leads them to believe they are perfect drivers instead of rank amateurs; that all the rules, many of which are unknown to them, apply to the other driver but not to them; that it could never happen to them to be involved in a so-called accident; that if it does it is always the other driver's fault; and that if the judge decides against them he is just a confused old man and doesn't know what he is doing or is just picking on them.

If ever education is needed it is for these egotistical but thoroughly ignorant, almost morose, drivers who endanger themselves and their innocent victims every second they are behind the wheel, and the time it is needed is when they are busy committing the moving violations and before the so-called accident occurs. True, a regrettably large number of drivers cannot or will not assimilate the needed education but that, too, becomes quickly apparent to the experienced judge and then the answer must be to speak to them in the only language they can or will understand—heavy penalties to deter future moving violations that will lead to the inevitable collision.

Many years of traffic court experience has caused me to conclude that the greatest failure and fault of even the better-type driver, as well as the inferior types, is lack of education, understanding and application of right-of-way rules. This becomes self-evident when we realize that if right-of-way rules were known and followed by all drivers, assuming proper driving habits to enable them to do so, we would never have an intersection collision!

Preventive education of moving violators by means of required court appearance might well be the answer to the education and

understanding necessary to secure voluntary compliance with right-of-way rules, provided we also simplify our right-of-way rules and definitely place the continued responsibility of yielding on one of the two drivers without permitting any exercise of opinion or judgment by the driver. Other bad driving habits and faults, including those which frequently make it impossible for the driver to yield right of way, could be spotted in time, by requiring court ap-

pearance, so that many tragic collisions of the future might be avoided.

Thus the need for specialization in the handling and in the education of moving traffic violators is of the greatest importance if we are ever to solve or even greatly improve the traffic problem. This cannot be done unless the hazardous moving violators are required to come to court, so the court can educate and impose selective judgment on such violators.

REPORT ON AMERICAN BAR ASSOCIATION NATIONAL SYMPOSIUM ON CORRECTING THE VIOLATOR, AND THE NEED FOR RESEARCH

By THOMAS M. POWERS
Presiding Judge, Municipal Court, Akron, Ohio

I have long felt that all traffic violators should appear personally before the traffic judge unless there are compelling reasons that make such appearance impossible or impracticable.

Now it is my assignment to report on the National Symposium on Correcting the Violator panel program at the recent annual meeting of the American Bar Association held at St. Louis and jointly sponsored by the Standing Committee on Traffic Court Programs of the American Bar Association and the National Association of Municipal Judges. Also, after the report I shall say a few words concerning the need for further exploration and research in this field of correcting and penalizing the violator.

There may be some here who were fortunate enough to hear the interesting and able speakers at that symposium but for those of you who were unable to attend, let me say that you missed a real treat because never in the many meetings that I have attended where this subject has been discussed have I heard such complete and enlightened discussion of it.

One speaker ably concluded his remarks by stating:

Traffic courts should at all times be firm and forward in the imposition of proper

penalties as long as justice is meted out and with the thought in mind of serving the following purposes: penalizing the violator so that the penalty will act as a deterrent, educating the violator, making the proper impact upon the community, and last, but not least, instilling in the violator a voluntary desire to be a good, careful driver and to respect and obey the traffic laws so that the streets and highways will be safe for everybody, motorists and pedestrians alike.

Another speaker reminded us of the difference in intent and in the type of individual involved in the traffic violation as opposed to the person who is regarded as a criminal in the usual sense of the word, emphasizing that the methods of handling actual criminals cannot satisfactorily be applied to traffic violators.

Another speaker carefully analyzed the different types of traffic violators, the "can'ts," the "don'ts" and the "won'ts," pointing out that if correcting the violator and getting voluntary compliance with the law are the central objectives of the traffic court then we should treat these three different types of violators more understandingly and with the view to attaining desired objectives.

Another speaker emphasized the importance of the judge, proper court facilities and proper atmosphere and concluded with some pertinent remarks by the Honorable Tom Clark, Associate Justice, United States

Supreme Court on the importance of the Traffic Court in our judicial system:

In saying that the traffic court is the closest court to the people in pointing out the millions of people that come there every year, and then saying that respect for law and respect for court indeed begins right at this level—the traffic court—we are pointing out something that is vital in our judicial system. Those who are charged, or who go into our traffic courts not being charged but just as visitors, see in action perhaps the only court they know anything about. The condition of that courtroom, the manner in which its procedures are carried out, the demeanor of the judge and the attitudes of the court, the method in which the court is carried on, and the time, perhaps, one has to wait in order to have his case called, all these things are impressed indelibly upon those people who come and sit in that courtroom. This is true whether or not they take part in the proceedings. There can be no more important court in this whole land than the traffic courts of the various states, of the various counties, of the various municipalities. Here is where respect or disrespect for law, for order, for the courts, and for government is fostered.

Finally, another speaker pointed up the unbecoming motivation of revenue-raising that permeates too many traffic courts, deploring the violations bureau and its posted schedules of fines for different offenses, deploring the growing tendency toward resort to this type of push-button justice rather than the individual consideration of the facts and circumstances of each case; and deploring, finally, the growing disrespect for law observance when the public feels that by "paying the price" there is a full acquittance for the violation.

So much for a summary report of the symposium to you. It would be impossible, because of time limitation, to do justice to all the good points brought out by the different speakers.

Let me in conclusion make a plea for more such symposiums and may I add thereto a plea for further exploration and research in this field of correcting the violator.

It is axiomatic that no person's judgment is better than the facts on which it is based. There is a great disparity and a great lack of uniformity among the traffic courts of the nation in treating, in handling and penalizing, traffic violators. As an example, in some places a D. W. I. defendant gets off with a \$23.00 or \$30.00 fine and no jail sentence or loss of driver's license, while in other places the same defendant under the same facts and circumstances would get a \$100.00 fine, thirty days in jail and lose his license for one year.

I do not believe in uniform fines or penalties because I do not believe they make for justice in the individual case, which should be considered in the light of all the attendant facts and circumstances. However, I do believe in the uniform approach of considering and weighing the proper penalty to be meted out in the light of the objectives to be obtained and considering the tested and proven techniques and tools available to the court for treating the violator.

In summary, concerning this matter of research, I feel that what is meant by correct penalization and the methods and techniques of achieving same should not be just something that we ourselves discuss and accept and believe to be efficient methods, but rather should be discussed and explored more publicly at the national and state levels, to the end that there will be a better public understanding of what we are trying to do and why we are trying to do it, and what we believe the objective should be in the penalizing process.

Without this understanding, we will never get the public support that we should have for better traffic courts; and in this respect we are making the same plea that years ago was made to the public when gradually and finally there was understanding and support given for the enlightened and humane treatment of juveniles, rather than having them herded together with hardened criminals, and treated and penalized under the criminal code as adult criminal offenders.

I am not saying that traffic violators are juveniles. The vast majority of them are not, nor are they criminals in the usual sense of the word.

Research, education and understanding are needed for everyone, judges included.

As the matter stands now the Traffic Court Program of the American Bar Association is practically the sole agency trying to bring understanding and order out of chaos in this field of corrective and enlightened penalization for traffic violators.

However, they are handicapped because of lack of funds and personnel to raise the torch in the darkened areas throughout the nation—a torch that is sorely needed in every state of this nation because there is no spot so remote today that the motor vehicle does not reach it, and where traffic violators are not processed.

IS DRIVER LICENSE SUSPENSION FULFILLING ITS ROLE: DRIVER LICENSING VIEWPOINT

By EDWARD SCHEIDT

Commissioner, North Carolina Department of Motor Vehicles, Raleigh, N. C.

In discussing the question of whether driver license suspension is fulfilling its role, it is first necessary to define what its role is. Suspensions, as carried out under the authority of driver license administrators, should have the objective of making safer drivers, and therefore suspensions should be regarded as a part of the driver improvement procedure. The term "driver improvement," in the parlance of the administrator, has a special meaning rather than merely a general meaning; it refers to the improvement or correction of dangerous driving practices or habits by changing the attitude of drivers through procedures available to the Department of Motor Vehicles such as advisory letters, conferences, driver improvement clinics, or suspensions and revocations.

The authority of the driver license administrator to suspend a license or to put into effect other driver improvement measures is, for the most part, limited to situations involving the conviction of drivers for violations of the motor vehicle laws. There are some exceptions to this but mainly suspensions are based upon convictions.

To justify driver license suspensions as a "driver improvement" technique, it is necessary to demonstrate that there is some relationship between violations of law and accidents. Motor vehicle administrators and safety experts have long been convinced that there is a very close correlation between violations of the traffic laws and accidents; and, therefore, if violations are decreased through driver improvement procedures the likelihood of drivers having accidents would also be decreased. Another strong belief or assumption by administrators has been that existing driver improvement procedures actually have a beneficial effect.

Both of these assumptions, namely, that there is a close correlation between violations and accidents and that there is a likelihood that violations and accidents can be decreased by driver improvement procedures, were given strong support by a very significant study made in the years 1956-58 under

the auspices of the American Association of Motor Vehicle Administrators.

This study was made possible through a grant from the Esso Safety Foundation and was supervised by a committee of motor vehicle administrators of which I had the privilege of serving as chairman. The staff work of this study was done by the Institute of Government of the University of North Carolina at Chapel Hill. This study covered the operations of point systems in driver licensing and other driver improvement measures throughout the entire United States and the Dominion of Canada.

One of the most interesting and revealing disclosures of the study was the conclusive relationship between violations and accidents, as shown by a scientific sampling involving 40,000 drivers in the state of North Carolina. I understand that the sampling methods were such that the results would not have been materially different if it had been possible to examine all the drivers files in the department.

The 40,000 drivers whose files were tabulated were classified as to whether they had no violation of traffic laws charged against them, one violation, two, and on up to five or more violations. This related to violations which did not involve accidents. The tabulation then showed how many accidents subsequently occurred involving drivers in each of the categories.

The results shown were that drivers who had no violations had very little likelihood of having subsequent accidents; those with one violation had a greater probability of an accident, and so on up to the point where it was a virtual certainty that drivers having as many as five violations would have subsequent accidents. To put it another way, the more violations committed by a driver, the more likely he was to have an accident later.

The same study also contained considerable information to support the thesis that driver improvement procedures, such as advisory letters, conferences, or re-examina-

tions, result in fewer violations and accidents involving the recipients of the driver improvement action than by individuals not receiving such action. These conclusions were made possible by the existence of control groups which had the same characteristics and experience, the only difference being that one group received driver improvement attention and the other did not.

In a sense it might be said that license suspensions represent a failure of the other driver improvement measures which preceded the suspension, for presumably if the other driver improvement procedures had been effective, it would never have been necessary to suspend the license.

To the average individual the suspension of his driver license represents a much sterner action than warnings, conferences, or other measures which do not actually interfere with his privilege to operate a motor vehicle. It follows that properly administered and properly understood the suspension power can play a very vital role in highway safety. It is, therefore, well that all those to whom this authority is entrusted take every precaution to insure that the suspension power is utilized to its greatest possible advantage.

There is no question about the fact that tremendous progress has been made and is being made in "driver improvement" in its various phases, including that of suspension of the driving privilege. Noteworthy work is being done by the American Association of Motor Vehicle Administrators in helping to upgrade the driver licensing function in all of its facets. Particular tribute should be paid to the interest shown and financial assistance rendered by the Insurance Institute for Highway Safety in supporting the efforts of the American Association of Motor Vehicle Administrators in this vital area.

Since performance should always be measured in terms of its potential, it can be stated that at the present time driver license suspension is not entirely fulfilling its role, although tremendous strides have been made throughout the years. Administrators are generally and basically doing a good job in carrying out their responsibilities but there is always room for improvement. In my judgment, the most urgent needs in the way of driver license suspension fulfilling its role are not matters within the immediate author-

ity or jurisdiction of the licensing authorities, but relate to the assistance and cooperation of other agencies who also have vital and indispensable functions and responsibilities with respect to driver licenses.

The first such agency is, of course, the police. Unless individuals who commit violations of the safety laws are arrested in the first place, their licenses will never be suspended for the violations which, if unchecked, cause accidents. Therefore, the truly effective driver improvement program begins with effective policing on the front line.

Another area in which the police are indispensable is in the apprehension of individuals who violate suspension orders. If drivers can, with impunity, ignore their suspensions and continue to drive in violation of suspension orders, it makes suspensions impotent and valueless. This suggests that all police should consider the detection of violations of suspension orders as an important police responsibility and not merely a matter for licensing authorities as, unfortunately, the attitude has sometimes been.

The cooperation of the courts is also indispensable for driver license suspension to fulfill its role. Some of the things which courts can do in this connection include:

1. Forwarding conviction notices to the Department of Motor Vehicles as soon as possible. While courts generally send these notices in promptly, occasionally there is some delay in doing so and, of course, the greater the delay the less effective or weaker is the driver improvement action of the Department.

2. Careful consideration by the courts as to whether the judgment rendered is one which will enable the Department to take driver improvement action. The Department can only act upon convictions which are valid under the driver license laws and any instance where the judgment does not constitute such a conviction and final judgment, the Department is powerless to carry out any of the driver improvement procedures affecting the individual, thus depriving him of the possible benefits of such actions.

3. Recognition by the courts of the difference between the function of the courts to administer punishment to individuals convicted of law violations and the function of the driver license officials in carrying out

the provisions of suspension orders or other driver improvement procedures which relate to the conditions under which the state grants or withdraws the driving privilege and are not to be confused with the concept of punishment for an offense.

Finally, for driver license suspension or driver improvement measures to achieve their potential, greater interest on the part of all public-spirited citizens is needed. The driver licensing authorities should be sup-

ported wholeheartedly by individual citizens and by all organizations having any direct or indirect interest in highway safety in their efforts to derive the most benefit from driver improvement procedures. Citizen support is a necessary ingredient whether a program of vigorous enforcement of the traffic laws is to be sustained or whether suspension provisions and other driver improvement measures are to achieve their potentialities.

IS DRIVER LICENSE SUSPENSION FULFILLING ITS ROLE?—CITIZEN VIEWPOINT

By A. E. HUBER

Executive Dir., Indiana Traffic Safety Foundation, Inc., Indianapolis, Ind.

It would appear there exists some difference of opinion regarding who actually should have (or does have) the authority to suspend the driving privilege. Unfortunately, these differing views are representative of the situations which exist in most of our states.

As a citizen, I am not as concerned about who has the vested authority to suspend a driver's license as I am who has the authority and the responsibility for making a driver license suspension program effective.

I feel most informed citizens accept driver license suspension as an essential tool in our nationwide effort to reduce traffic losses. Most citizens accept the logic of the safety authorities reasoning that, in order to protect the general public from a potentially dangerous driver, it is sometimes necessary to suspend an individual's driving privilege until his condition can be examined and serious defects corrected.

I'm sure most citizens feel that, in other instances, it is necessary to suspend the license of an individual in an effort to impress upon him the real value of the motor vehicle and of the license to operate. But there is ample evidence that license suspensions are not being used to their fullest extent and that even where the suspension is used, all is not going as well as it might.

Far too frequently we read headlines such as "Suspended Driver Nabbed in Police

Chase," "Suspended Driver Held in Fatal Crash," or "Suspended Driver Attempts to Elude Police." Frankly, I sometimes feel that the only drivers apprehended for driving while under suspension are those who become involved in accidents or serious violations while ignoring a current suspension. From the frequency of such occurrences in our part of the country, I have become quite concerned about the number of drivers under suspension who obviously continue to drive.

One of our Indiana judges indicated that he believed as many as 25 to 30 per cent of the drivers receiving suspensions violate their suspension. One of our deputy attorney generals, who handles appeal cases for our Motor Vehicle Bureau, estimated that based upon his conversations with drivers and attorneys involved in appeals from suspension action, he believes that as many as 50 per cent of the suspended drivers will ignore their suspension orders. (This would mean, in our state alone, 10 to 20,000.)

To me this is shocking evidence that many offenders are openly contemptuous of our traffic courts and license administrators efforts to reduce traffic losses and that a completely inadequate job is being done to make suspensions effective.

This is even more serious when you consider that many individuals elected or appointed to serve as traffic judges are reluc-

tant to recommend suspensions in almost any case, regardless of its severity. Certainly when suspensions are recommended and placed in effect they should be rigidly enforced. I feel we are most fortunate, in our state, to have mandatory suspensions for some of the more serious driving offenses. Otherwise, I feel suspensions would never be effected in many of our communities.

Other courts are tardy in forwarding abstracts of conviction and recommendations for suspension to the license administrator. This results in long periods of time elapsing between arrest for the violation and action by the driver license administrator. This lag in direct and positive action may be responsible, in part, for growing disrespect for suspension orders. It most certainly must tend to lessen the seriousness of the original offense in the mind of the violator.

It seems to me these conditions should be matters of grave concern to every jurist handling traffic cases, to every public official with responsibilities in traffic and to every citizen interested in a law-abiding society.

I fully recognize that in most instances

neither the courts nor the driver license administrators presently have the personnel to conduct periodic follow-ups on the large number of suspended drivers to insist upon compliance with suspension orders. However, it seems to me that some agency or official body must conduct such follow-ups if the driver license suspension is to serve as an effective means for improving safety on our streets and highways.

In view of general conditions in this area, I feel as citizens we have every right to ask not only—

"Is driver license suspension fulfilling its role?" But, more directly to ask—

"How can license suspensions be made more effective?"

"Which agency shall be directly responsible for performing the follow-up to insure that suspended drivers respect their suspension?"

I fear that if we permit the continuation of what obviously is widespread disrespect for suspension action, we are tolerating a condition which will seriously undermine our entire system of traffic law enforcement.

THE AGING DRIVER

By E. R. KLAMM

Accident Prevention Dir., Allstate Insurance Co., Skokie, Ill.

The matter of the aging driver is receiving greater attention today. It is replete with many angles and I would like to discuss just a few.

In reviewing material previously written on this subject matter, the following major thought prevails. "Driving performance, not age, should be the determining factor in permitting any person to drive." Burt Marsh of the American Automobile Association did a very comprehensive study "Aging and Driving" last year.

In further reviewing this situation, it seemed paramount to me that I personally review the situation with our senior citizens. This was a revealing experience and certainly one that was extremely educational to me. First and foremost, we must recog-

nize that the senior citizen will not accept driving restrictions without a struggle. In fact, the senior citizen can assemble quite a force to prevent any restrictions from being administered if he so desires.

These were some of the highlights that "Mr. Senior Citizen" stressed to me.

1. After age 60, 65 or 75, he still has an imperative need for his operator's license. He indicates that he will be probably traveling more if he has sufficient funds to retire than he did prior to retirement age. If he retires, he and his wife would plan to travel considerably by car. Such travel is educational, less expensive and more convenient. He will also be in a position to visit his children and their families and, for the most part, they will be spread throughout the

U.S.A. Oftentimes, he and his wife, who may be his junior by a few years and in better physical condition, will share the driving chores. So, Mr. Senior Citizen does stress the vital need for keeping his driver's license.

2. If any restrictions are to be imposed, he will rebel to his political friends. Or, he may employ a lawyer to protect his "so-called rights." Some indicate they will even go directly to the "governor's office" to prevent any injustice from being imposed upon themselves as far as their driving privileges are concerned.

3. They will protect their constitutional rights and prevent any discrimination against their freedom.

So, it seems essential that any planned program dealing with the senior citizen as a motorist should be planned and administered slowly. The aging driver also stresses that any decisions involving his own group should include some of his own type on any committee making such decisions. That is, he wants to "voice his opinion" and be in on decisions rather than having "some young whipper-snappers passing laws or administrative acts restricting the senior citizens' own use of the vehicle."

The senior citizen did agree that there were certain physical shortcomings that did affect their operation of a vehicle. His physical condition deteriorates, his mental processes work more slowly, vision slackens, perception declines, coordination is oftentimes adversely affected, his response to emergencies may be somewhat curtailed. Nevertheless, he feels these are all factors he can compensate for in his driving so that he does not feel that his license should be placed in any jeopardy because of any physical shortcomings. He does not concur that a mandatory physical examination should be completed by every person as he reaches age 65, 70 or any other age. Driving ability is far more important than age. Age is relative and he will certainly stress this fact.

In asking for suggestions from our senior citizens, the following points were stressed by them to me.

1. The senior citizen should be remembered among any committee considering this problem.

2. Representatives from the American Medical Association and/or state and local

medical associations should be included on any committee dealing with this matter.

3. The Department of Health, Education and Welfare is vitally concerned with the senior citizen problem and so they should be involved in any matters referring to the senior citizen in traffic—both as a driver and a pedestrian.

4. Driver training is essential for all, not just senior citizens. Nevertheless, senior citizens are anxious to attend driver training sessions where convenient for them. This is extremely important in staying abreast of the traffic situation. They single out that the senior citizen who drives should take driver training.

5. Where driving ability is questionable, then a request for a re-examination is in order for recertification of the operator's license.

6. The use of driving simulators should be encouraged in training programs available for senior citizens particularly in reference to driving on expressways and under emergency conditions.

7. Newspapers and media can devote more time and space to safe driving for aging drivers. Also, that the press widely publicize any senior citizen "voluntarily giving up his license." They are insistent that they are "matured."

8. All drivers should recognize that senior citizens have a right to drive as much as anyone and so, "other drivers must adjust to the driving of senior citizens." If a senior citizen is driving slowly, he is driving at the maximum speed capable for his ability and so, he should not be forced or coerced to drive faster or "forced off the road." The senior citizen states he has paid considerable tax dollars to support the building of roads so he is entitled to the use of them.

9. Driver training schools established by the courts, police, or motor vehicle departments should be available for the senior citizen. Also, there should be special hand-out pieces for safe driving for senior citizens. They do stress that the official government should give greater consideration to this matter and be able to expand their services to the senior citizen so that he or she will be better informed to properly adjust themselves to driving situations. They are anxious to learn and they are anxious to "stay out of accidents." So, like in many

other areas, the official government should consider "ways and means" of properly serving the senior citizen so that he can properly adjust himself to all driving situations.

Senior citizens who are competent drivers to begin with and who learn to compensate for the toll of the passing years need not be a problem just because of advancing age. This means those who avoid serious disabilities, who restrict their driving as to amount and time of day, and who keep pace with driving knowledge.

Last year, the total number of fatal traffic victims over 65 years old amounted to approximately 6,000. Of these, more than half were drivers and most of the balance were pedestrians who were never drivers. In the years to come, the number of drivers in this age group is expected to skyrocket, thus aggravating the problem.

Of the many circumstances that contribute to accidents among aging drivers, the inability to properly adjust to constantly changing driving situations and failure to acknowledge their physical limitations stand out as the principal ones. Loss of ability to judge speed and to discern audible and visual clues are also prime factors. In addition, older people are often absentminded and totally unprepared for emergencies, which under stress renders them indecisive, erratic or just too late in responding.

Here is what the driver must cope with as he ages. Physical condition deteriorates. The mental processes work more slowly. Vigor slackens. Perception declines. Side vision in particular is reduced, underlining the need for an older driver to compensate for his narrowed field of vision by turning his head from side to side so that he can take full advantage of all the vision he has. The capacity to manipulate the car, especially

in emergencies, is curtailed but can be improved somewhat by the use of power equipment in the car. Coordination is oftentimes adversely affected.

Failure to yield the right of way ranks as the most frequent accident-producing error among older drivers. Inattention and an unwillingness to adjust (the one-track mind) is mainly responsible. A California study has shown that right of way conflicts increase sharply with the driver's age.

Exceeding speed limits is not prevalent among older drivers, but there is a speed problem. Elderly drivers often fail to drive at speeds at which they can maneuver their car under control when adjustments are called for.

Improper turning is a problem with older drivers. Forgetting where they are in relation to traffic appears to be behind most of it, probably due to poor vision or hearing and misjudging speed. They often turn from or into the wrong lane and afterward lose control of the car. This problem is compounded by the fact that older drivers have trouble correcting their mistakes. Even a small mistake may not be corrected in time.

Older drivers need more supervision conducted under the driver licensing authority. Close tabs on their mental and physical fitness (particularly vision) must be maintained. Senility and other competence-debilitating disorders of old age must be detected as quickly as possible and be automatic grounds for license revocation.

The medical profession has a serious responsibility to effectively cope with this "individual" problem. Opportunities for the senior driver to improve his driving and keep up to date, as long as he is able, should be readily accessible.

THE AGING DRIVER

By O. D. SHIPLEY

Commissioner, Bureau of Traffic Safety, Harrisburg, Pa.

I feel safe in assuring Ed Klammer and other senior drivers that motor vehicle administrators, by and large, are not "out to get" them. At best we would be fools and

at worst tyrants to attempt to deny driving privileges to any group on the purely arbitrary basis of age. The motor vehicle is a much too important economic and

social factor in this day and age to deny its use to anyone without justification.

A person's chronological age is of no importance by itself when we're talking about competency behind the wheel. The ability to operate a motor vehicle safely on today's high-speed highways and in modern traffic conditions should be the only justifiable criterion for determining whether an individual should be granted the legal privilege of obtaining as well as retaining a driver's license. Our American sense of fair play and just plain logic and common sense rule out any other approach.

This is not to say that the senior driver does not have problems which are related directly to his years. As human beings reach their later years, their physical faculties inevitably tend to deteriorate to some degree. This may or may not effect their ability to handle a vehicle safely in traffic. Persons who began driving in the early decades of this century may need help in adjusting mentally to the ever-changing traffic environment of today.

Neither the senior citizen nor the licensing authorities can afford to ignore such problems. To do so would endanger the lives of all highway users in general, and of the aging driver in particular.

But there is a right way and a wrong way to handle these problems. The wrong way, in my opinion, is to question the aging driver's ability solely on the basis of advanced age. Such an approach is a form of discrimination not in keeping with our democratic traditions. It implies a biased attitude toward a particular group of our citizens that can only tend to prejudice any subsequent judgments of actual driving ability.

Any program which singles out the aging driver is bound to be self-defeating. No matter what the merits or good intentions of the program may be, the older licensed operator almost invariably sees himself as a "victim of persecution." The resulting psychological effect on the aging driver can only be detrimental to the cause of traffic safety.

I firmly believe that the most effective way to meet the problem of the senior driver is to question the competency of ALL licensed operators, regardless of age. After all, we have far too many young

and middle-aged persons who are menaces on our highways because of extreme physical or mental deficiencies. Do they have any more right to cover our roads with innocent blood than the aging driver who may or may not be incompetent?

As you know, Pennsylvania has undertaken a pioneering program which calls for the periodic visual, mental and physical re-examination of all of its five and a half million licensed drivers.

After more than a year of operation, I can tell you frankly that this is an effort of colossal proportions. But even at this early stage, hundreds of drivers with extreme physical and mental disabilities have been eliminated from the streets and highways.

Quite naturally and inevitably, this program initially alarmed some of our elder operators who saw it as directed at them primarily.

This fear was groundless. Before the re-examination program was inaugurated in June, 1960, Dr. Charles L. Wilbur, our Secretary of Health sent a lengthy memorandum to the more than 20,000 physicians in the Commonwealth. It was intended as a guide in the performing of driver physical examinations. In his concluding statement, he said:

"The physical standards (for obtaining or retaining a license) do not specifically single out the aging driver, because the common view that older drivers are more likely to have accidents has been contradicted by the facts. No one in Pennsylvania will lose his operating permit if he is physically and mentally competent to operate a motor vehicle, regardless of age. The important yardstick is not the chronological age, but the functional age of an individual. The physician, of course, by virtue of his training and knowledge, is the best qualified to make the essential determination."

I'm sure Dr. Wilbur was neither surprised nor alarmed when a 91 year-old driver was pronounced physically fit to drive, or when a 16 year-old was grounded because of mental incompetence.

In selecting the drivers to be called for examination each week, we use a letter-

type system based on the permanent plate numbers appearing on our operator's license. This does two things. It gives us a cross-section of all age groups each week and assures the older drivers that they are not being singled out.

Incidentally, our re-examination program is yielding several important by-products in the field of preventive medicine. Many individuals are benefited by the visual and physical check-up in terms of their personal health.

Individuals who haven't visited a doctor in years have been informed by the examining physician that they are suffering from dangerously high blood pressure, glaucoma, extremely poor vision and other serious disorders.

The value of this diagnosis and treatment is obvious.

The Pennsylvania Medical Society has given outstanding cooperation to every phase of the program. In the light of time-worn problems involving doctor-patient relationship, this cooperation assumes extreme significance to the success of the program.

The public reaction to this unprecedented program of ours has been overwhelmingly favorable. But, perhaps the most gratifying reaction of all came from our senior operators.

Shortly after the first group of 200,000 physical examination notices were sent out last year, we began receiving letters from elderly persons voluntarily surrendering their operator's license.

One elderly man wrote: "Having reached the age of 84, I think the sensible thing for me to do is to stop driving and will ask you to cancel my license application."

Another man, 72, stated: "After returning from the hospital following a critical illness, I realized that I will never be able to drive an auto again, so I am returning my 1960 driver's license."

A 63 year-old operator declared: "I do hope everyone feels the same way I do about physical conditions. I know I am not able to drive like I used to and will not venture out on the highways anymore, because I might be the cause of an accident. The method of physical examination is a wonderful thing, as I see so many people in our community who should never

drive again due to their age and physical defects."

From a male driver in his 67th year came a letter which read: "For my health and perhaps someone else's, this is the best thing you've ever done for safety on the highways."

I could go on quoting from more letters of this sort, but I think the point has been made. When confronted with the physical fitness requirements embodied in our new licensing program, many of our older citizens took stock of their own deficiencies behind the wheel. And many of them faced up to the fact that continued operation of a motor vehicle endangered their own lives and the lives of others. This is a tribute to their intelligence and honesty.

In terms of our discussion here today, I doubt very much whether our older drivers would have responded in this manner if we had instituted a licensing program aimed exclusively at them. By launching our attack against incompetent operators of all ages, we made the older people feel that we held no particular bias toward them solely because of their age.

Our new physical standards deny licenses to persons suffering from inadequate vision, severe cardiac conditions, circulatory and neurological disorders, uncontrolled epilepsy and diabetes, chronic alcoholism, narcotics addiction, and other severe physical and mental disorders that can, and do, cause them to lose control of their vehicles on crowded city streets or high-speed highways.

Would a program aimed only at older drivers eliminate such menaces from the highway? Some, of course. But what about the mentally unbalanced Kenneth M. Shelley, who sped down the Pennsylvania Turnpike at 90 miles per hour in the wrong lane? He was only 37. Or the middle-aged gasoline tank truck driver who had nine accidents all at the wheel of his mobile Molotov cocktail, before it was discovered that he was subject to epileptic seizures?

During the years of 1957, 58 and 59, the Classified Operators Section of our Bureau of Traffic Safety, removed the operators' licenses of 6,567 persons for the following reasons:

Mentally Ill—1713
Uncontrolled Convulsive Seizures—1206

Chronic Alcoholism—460
Narcotics Addiction—580

Failed to pass or declined to take the offer of a re-examination—2111

Voluntarily surrendered their licenses in lieu of the re-examination—291

All of this was accomplished prior to our re-examination program. How did we find these people? Reports from doctors, hospitals, relatives, police officials and other safety-minded people. At best, this amounts to a scratch-the-surface technique,—however, the results definitely highlight the need for periodic re-examination.

It is hard to believe that people of all ages with such disabilities are being licensed all over the United States, and will continue to be licensed until other states lay down physical and mental standards for granting a license such as has been done in Pennsylvania.

On a nationwide basis we license more than 1,300,000 drivers each year who are physically, mentally or visually unqualified to handle a motor vehicle safely. This figure is an estimate based on minimum medical standards and was arrived at by projecting the results of our examinations of over 600,000 drivers in Pennsylvania during the past 15 months.

I am of the firm opinion that unless the various states show by positive action a willingness to cope with this appalling problem, the Federal Government will step in with a program of federal control of driver licensing. I, also, firmly believe that driver licensing should remain the prerogative of the states.

The adoption of an effective, comprehensive driver licensing program is no easy task. If it would be, Pennsylvania would not stand alone today with its re-examination effort.

I have been most fortunate in my efforts in having a Governor who recognized the full tragic extent of the driver improvement problem and has been willing to risk political unpopularity to push the cause of traffic safety so that lives may be saved, even if votes are lost.

The legislature is a horse of another color. The hard, bare fact is that no overall traffic safety effort can be truly effective

without enabling laws. And legislatures across the land have, with terrifying consistency, refused to risk their political necks on legislation urgently required to toughen our licensing procedures.

There is documentation—if these lawmakers would make the effort to seek it—that for every vote they lose through supporting sound traffic legislation, they will gain ten.

We sorely need leadership on the part of Motor Vehicle Administrators and Chief Executives coupled with some legislative foresight if we are to make substantial progress in eliminating carnage from our streets and highways.

The aging driver has a higher stake than most in sound traffic safety legislation and comprehensive, fair driver licensing programs. He needs two things basically: fair treatment in the judging of his competency to drive, and help in adjusting to modern traffic conditions. I am sure that he would not ask for more than this.

It is the responsibility of motor vehicle administrators and legislators to see to it that he gets both. In the end, the entire cause of traffic safety in this age of the motor vehicle will be served to the benefit of everyone.

I have indicated the need for careful handling of problems involving the advanced age driver and his acceptance of the program.

Obviously, this acceptance is not universal, and frequently it is necessary to handle some extremely delicate situations in a firm manner. It isn't easy to tell a 75 year-old driver that his driving days are over, but, in the interest of public safety, it is necessary.

A few months ago, a very feeble senior citizen came into my office in an extremely belligerent state of mind. "Look here, you young whippersnapper," he said, "I can drive as well as I ever could. Much better than you can, so why are you taking my driver's license?"

I carefully explained why it would be extremely hazardous for him to continue driving and suggested that he hand me his operator's card.

I failed to convince him. In fact, his belligerence increased, and he said, "Neither

you, the Governor nor the State Police are going to stop me from driving. If you take my license, it will have to be by force, and even after you do this, I'll just drive without it."

In the calmest manner I could muster, I attempted to reason with him, but he shuffled out of my office mumbling under his breath some invectives that I assume were uncomplimentary.

In less than five minutes he was back. "Mr. Shipley," he said, "I want to apologize

to you. You are right. I know you are right. I know I shouldn't be driving, but I felt I had to make one last effort to keep my driver's license."

Then, with tears in his eyes, he put a trembling hand on my shoulder, handed me his driver's license and said, "Thank you for being so patient with an old man. Your program is good. God bless you for having the courage to do what is right."

Not it isn't easy to take away the very precious privilege of driving a motor vehicle.

SHOULD ALL MOTOR VEHICLE ACCIDENTS BE INVESTIGATED? — AFFIRMATIVE

By CAPT. G. S. FRIDAY
Capt. of Police, Police Dept., Columbia, S. C.

I am happy to have the privilege of being on the affirmative side.

First, I would like to put a few questions in your mind.

1. Do we investigate all criminal complaints that come to our department?
2. Do we investigate all complaints about our police department?
3. Haven't we been taught that traffic is a major part of law enforcement?
4. Don't we teach our recruits the causes of traffic accidents?
5. Where did we get all this information for the clearing house?

Webster's *Vest Pocket Dictionary* says "Investigate means to search into" and this little book also says that an "Investigator is an examiner." So, by all use of words, when a police officer goes to the scene of a motor vehicle calamity, he is an "accident investigator." (School solution: definition, "A systematic and analytical enquiry and examination of all facts, physical feature conditions, observations and results in a motor vehicle collision.")

I will agree that each accident should be handled as an individual accident and the necessary steps should be taken to get all the information that you may need at a later date.

You assist a lot of people when you collect data on an accident:

1. You represent your department at the scene—what you do at the scene places a picture in the minds of the public of what your department really is, so it's good public relations to investigate all accidents.
2. You collect data to be used by attorneys—they are business men of your area.
3. You collect material for insurance companies—many of us would not have been able to get our training had it not been for insurance companies, and Lord knows we owe them a great gratitude for their assistance.
4. You collect "selective enforcement" information that should guide your department on the who, when, where, why and how. From this information, you assign your personnel to your needs.
5. It is impossible to get all facts but get as many as you can. Your accident prevention program is based on accident investigation.

When we investigate all accidents we learn the characteristics and habits of people. We technical people usually look at a situation in a biased way. Minor collisions cost less than major ones, true, but you usually have ten minor to one major. If you ignore

the minor and investigate the major, you are not getting a true picture of the causes of accidents at a particular location. To clear up a problem area, you need time and statistics—and the only way to get statistics is to investigate all, large and small.

You are really doing the drivers a favor by investigating all accidents. An accident, minor or major, which has been investigated, with the proper charges made for the violations, should prove influential to the drivers in making them more accident conscious in the future, thereby strengthening our accident prevention program. If little emphasis is given minor accidents, little interest will be shown on the part of some drivers who may continue to take accidents "lightly" until they are involved in a serious one sometime.

Another thing, what does this investigating major and may be just recording minor acci-

dents do to the attitude of the public? If the public realizes, and they will, that you are only interested in them if they have a major accident, what will they think of your department? To the policeman, it may be a "minor," but if I ever have the chance to save up enough money to buy a new car and someone would crash a fender, by gosh that would be a "major" to me!

Our department policies are set up to give service to the public we work for and if it takes 30 minutes or all day to give this service to our people, I think we should do it. Nothing will make more friends for your department as much as helping someone in need, and a person upset from an accident is surely in need.

The one thing I would like you to remember is this: "Don't ever get so technical and efficient that you sacrifice your department's relations with the public."

SHOULD ALL MOTOR VEHICLE ACCIDENTS BE INVESTIGATED? — AFFIRMATIVE

By SHIRLEY CURTIS

Capt., Safety and Traffic Bureau, Michigan State Police, East Lansing, Mich.

In my opinion, all motor vehicle accidents should be investigated for several very important reasons—

1. Police are legally responsible for determining if a traffic law violation has been committed when an accident occurs and for taking proper enforcement action. Then, too, it is the sworn duty of police to protect life and property which is a primary consideration in any accident investigation.

2. Investigation of an accident permits the officer to observe the driver and report to the proper authorities any condition which appears to make him unfit for licensing as well as the fact that said driver was involved in an accident. The latter is a prerequisite for motor vehicle administrators in carrying out a driver improvement program.

3. Highway conditions which appear to need special attention based on the observations of the officer at the scene of the ac-

cident can be brought to the notice of proper authorities.

4. Investigation of accidents provides information on the number and causes of accidents which is a legal requirement in most jurisdictions. In this connection, facts reported by a trained police officer based on his investigation of an accident are unbiased and far more reliable than information on accidents reported by the drivers involved.

5. Complete and accurate information on the traffic accident situation is necessary to provide the basis for a sound accident prevention program—by police, educators, engineers, motor vehicle administrators, courts, public information media, and by the legislature. In addition, it provides the basis for training and research.

Before discussing in more detail the reasons why all motor vehicle accidents should be investigated, we need to know what we

mean when we say all accidents should be investigated. According to the Uniform Vehicle Code, accidents should be reported which result in death, injury, or property damage in the amount of \$25, \$50, or 100 dollars.

Although highly desirable to investigate the most minor accident, it certainly is not feasible to attempt to investigate those accidents which aren't even required to be reported by the Uniform Vehicle Code, namely,溜 car dents, fender scratches, or others resulting in minor property damage. Let's say for the purpose of this discussion that when we say all accidents should be investigated we mean all those resulting in death, injury, or property damage of 100 dollars or more.

Another term needs clarifying before we proceed and that is what do we mean by investigation. Webster defines investigate as meaning, "to follow up or make research by patient inquiry and observation and examination of the facts." According to the last report on traffic accident records, developed in 1960 by the President's Committee on Traffic Safety, accident *reporting* means the collection by police of readily available facts about accidents, while *investigation* is a far more thorough process calling for detailed inquiry into all available information pertaining to an accident.

These definitions of investigation are quite inclusive and few, if any, police departments have manpower or time to make the detailed inquiry necessary to obtain all available information pertaining to an accident. In fact, the Committee on Traffic Accident Statistics fully realized this when it prescribed certain minimum information which should be obtained on all accidents reported by the police.

It is my recommendation that investigation by police be sufficiently thorough and complete to obtain this information on all accidents resulting in death, injury, or property damage to the extent of 100 dollars or more. In addition, I believe it mandatory that information be obtained to identify any unusual driver, vehicle, highway, or operating control condition which there is good reason to believe may have contributed to an accident and any violation of traffic laws.

These are my minimum requirements for

the investigation of any accident. This statement, however, should not be interpreted to mean this information is sufficient for all accidents. Many times it may be necessary to go much further in the investigation on one or more particular phases of an accident.

The whole concept of accident prevention is based on the fact that nearly all so called accidents are caused occurrences and are not merely chance happenings.

Most accidents have a number of contributing factors, including driver failures, roadway deficiencies, vehicle defects, etc.

Furthermore, it is known that the same contributing factors which result in a minor accident one time may result in a crippling injury or death the next time under slightly different circumstances.

We also know accident patterns remain quite constant when traffic volumes and other influencing factors remain about the same and that future experience can be predicted within limits when past experience is known.

Sampling techniques may provide the information to establish some trends. They cannot, however, provide the necessary facts to quickly identify drivers with multiple accident records or high accident locations, nor evidence necessary for enforcement action in individual cases. Neither can such information be obtained from the prejudiced and highly rationalized reports of drivers.

Unless reliable and complete information can be obtained, accident prevention programs must be based on guesswork and opinion. And, past experience indicates such programs all too frequently are misguided, inefficient and costly.

What is needed is careful investigation of all accidents which occur by carefully trained, impartial and competent official investigators. Our own department considers this not only a legal requirement, but so necessary that it is our policy to investigate accidents at the scene whenever they are brought to attention regardless of the extent of damage involved. However, before closing our case, we would like to elaborate further, as time permits, to support our contention and ask our opponents a few questions as to how they would prosecute violations and carry out other recommended

accident prevention activity without investigating all accidents.

The apprehension and conviction of traffic law violators is considered one of the most effective accident deterrents and one or more violations are reported as contributing factors in most accidents. We would like to ask how enforcement action can be taken against violating drivers in accident cases unless accidents are investigated.

We believe if an officer is to take enforcement action when the driver commits a violation, but no accident occurs, it is even more important for such action to be taken when the same violation results in someone being injured or property damaged.

The importance of enforcement action in accident cases also is fully recognized by the Traffic Committee of the I.A.C.P., which recommends a minimum satisfactory accident arrest rate of 55 per 100 investigated accidents. Our own department exceeds this minimum arrest rate in accidents which are investigated and the number investigated exceeds recommended reporting ratios of 20 injury and 35 property damage accidents for each fatal accident in rural areas.

As previously stated, we also believe it is a primary responsibility of the police to assist in securing medical aid and transportation of injured persons and do everything reasonably possible to protect the scene from further accidents until injured persons and damaged vehicles can be removed.

Another question we would like to ask is, how is it possible to detect those drivers involved in accidents who appear to be physically or mentally impaired to the extent they should not be licensed to operate a motor vehicle unless all accidents are investigated. Our state of Michigan official traffic accident report provides a place for the officer to check when he thinks a driver should be re-examined for license competency and when this is done he explains his reasons for his recommendation for the benefit of licensing authorities.

We would like to raise another question, how it is proposed to bring to the attention of the proper officials inadequate traffic controls or roadway conditions which appear to require attention to minimize the likelihood of future accidents, unless all acci-

dents are investigated? Our official report form provides space for the officer to check when he believes the scene of the accident should be inspected to determine the need for engineering attention and, when this is done, he also explains his reasons for his recommendation. A copy of the officer's accident investigation report, in turn, is referred to the proper engineering officials for their consideration and as a result special corrective treatment is applied to many locations each year.

Still another question for our opponents is, how can they obtain necessary reliable information on the number, location and characteristics of accidents to serve as a sound basis for accident prevention programs by the various officials and agencies charged with responsibilities for accident prevention, unless all accidents are investigated?

Some of the kinds of information needed by the different officials include—

1. Engineers want to know the exact location of accidents, the effectiveness of their operating controls and accident frequency in relation to varying highway design and roadside characteristics.
2. Police want to know who was involved, what happened, if a violation was committed, where and when the accident occurred, as well as the condition of the driver, vehicle and highway.
3. Educators need to know who is involved and as much as possible about contributing factors, as well as the general characteristics of accidents.
4. Driver license administrators want to know who is involved in accidents, whether a violation was committed, the physical condition of the drivers involved, and any other information available which might have a bearing on the drivers' fitness to have a license.
5. Traffic safety groups and public information media need to know the extent of the problem, accident trends, contributing factors, etc.
6. Legislators need to be kept informed on the extent, trend and characteristics of the problem upon which to base the need for new or corrective legislation.
7. Those interested in basic research to

find out new and better ways to cope with specific aspects of the problem need to know what has already been learned from accident investigation to serve as a basis for further exploration.

Our opponents will probably say it is not necessary to investigate all accidents to obtain such information and even if it were

there is not enough manpower or money to carry out such a program.

The question before us is, should all accidents be investigated? not, is there enough manpower or money to do the job?

We firmly believe all accidents should be investigated and we believe we have cited adequate reasons to support our contention.

SHOULD ALL MOTOR VEHICLE ACCIDENTS BE INVESTIGATED? — NEGATIVE

By MAJOR MARTIN M. PUNCKE

Chief, Training & Personnel Div., Maryland State Police, Pikesville, Md.

The effort put forth.

Cost of the effort.

Results of the effort.

These are basic criteria used in any project or business operation involving saving of lives or financial gain. The police are no exception and our work must be evaluated by these criteria, if we are to enjoy the reputation of an efficient organization.

The subject under debate is certainly not a new one. I would like to quote from a report made to the National Conference of Uniform Traffic Accident Statistics, and the Traffic Committee, International Association of Chiefs of Police in 1955, by J. Stannard Baker, Director of Research and Development, and Roy E. B. Fisher, Research Assistant, for the Traffic Institute-Northwestern University.

Accident reporting forms and procedures generally represent a compromise between those reports simple enough to encourage complete reporting and reports complex enough to get complete information on each accident; that is, a compromise between quantity and quality.

As a result, neither quantity nor quality has been achieved. It would be better to try to get less information on the majority of accidents—only that necessary for administrative purposes—and more detailed information—for technical purposes—on some, if only a few accidents. It follows that an important distinction between reporting accidents for quantity and investigating them for quality must be made.

A workshop attended by representatives of interested national organizations, was held at the National Safety Council in 1952. Here it was agreed that the report of the accident should be simplified to meet only the administrative needs and thereby reduce police

work and encourage more complete reporting on the part of drivers.

This conclusion was subscribed to by the Committee on Accident Records of the National Safety Council, and by the Traffic Committee of International Association of Chiefs of Police.

The subcommittee on forms and statistical practices of the National Conference on Uniform Traffic Accident Statistics also considered the problem of getting better information about causes on a sample of relatively well-investigated accidents.

This is one of the main points involved when discussing the negative point of view on the subject of "should all motor vehicle accidents be investigated?"

We feel that if a proper sample is taken and evaluated, a valid result can be predicted. We already agree that the origins of sampling lie in probability theory. In most instances, the detailed examination of a valid sample is more accurate than the result compiled from large masses of material.

The man hours consumed by either a metropolitan or state department in accident investigation during the period of a year is certainly a large percentage of the overall man hours used by the enforcement agency. We must include, not only the time consumed by the investigating officer at the scene, but the time involved in making the report, sketches, processing by departmental personnel, punching of I.B.M. cards if this equipment is available, and the publishing of analytical reports. We feel that this time could be materially cut if the sampling procedure was used.

The man hours used for this purpose could be more effectively used in normal enforcement procedures.

In discussing this problem, we invariably ask ourselves, "What is the responsibility of a police organization in accident investigation?"

We are certainly charged with saving of lives and property. We have the responsibility of determining whether or not a violation has been committed, and to develop and preserve sufficient evidence to substantiate the charge in court.

We are responsible for making available sufficient statistical information obtained during our normal operation to other organizations having an interest in the accident problem.

I feel that the additional investigation time spent in determining the background causes of accidents, a development of factors which would tend to determine the civil liabilities involved, and any other detailed fact-gathering data requirement on all accidents, is not the primary responsibility of the police department.

Special studies on specific problems should be accepted by various organizations, and this information pooled for the use of all. A very good example is the study made by Cornell University on the crash injury problem.

Check your summary reports for the past few years and see how many factors have changed. In a specific area, has there been a sufficient change in hours of the day, day of week, or road condition to change your enforcement policies? I think not.

The gathering of accident investigation data with our present form, and the compiling of this information is a procedure which has grown with the advancement of police activity. Are we taking the approach, "This is the way we did it for the past 30 years; why change?" It is our opinion that this entire procedure now must be re-evaluated to determine exactly why we continue to follow the old procedures.

May I refer to the present controversy on the responsibility of police while on freeway patrol?

The police were expected to patrol the highway, investigate accidents, check abandoned cars, report defects in road conditions which, in my opinion, are all police functions.

We are then expected to assume the responsibility of miscellaneous duties of assisting people who are out of gas, changing flat tires, making minor repairs on motor vehicles, and many other non-police miscellaneous items.

We must ask ourselves, "Have we permitted the accident investigation problem to get out of hand in the same manner? Do we need and use all of the statistical data obtained? Are we obtaining it in the most efficient manner?"

The proper evaluation of a well-defined, complete, sample would be of more value than the processing of a volume of material.

Deputy Chief Sullivan, will show there is no relation between accidents versus accidents, but there is a relation between violations and accidents.

Manpower properly used on a great percentage of this activity may be used more efficiently in the direct enforcement effort. Violations do cause accidents, and the possibility of being involved in an accident is in direct proportion to the number of violations committed. Police must have the manpower to make an initial arrest.

The remarks of Mr. Huber are pertinent, that up to 50 per cent of suspended drivers continue to drive; and of Capt. Gardner, that we must have manpower to properly enforce the laws.

Enforcement is our primary responsibility; therefore, I sincerely recommend that we take a very close look and evaluate our motor vehicle accident investigation procedures.

ENGINEERING TRAFFIC SAFETY IN THE SMALLER CITY. WHERE DO WE GO FOR HELP?

By MYRON K. LINGLE

Traffic Eng., Illinois Div. of Highways, Springfield, Ill.

Traffic engineering assistance from the state is available to smaller incorporated communities in varying degrees.

First. On streets and highways under state jurisdiction, all traffic engineering service will be furnished by the state.

Second. On streets and highways under local jurisdiction, no preliminary traffic engineering service will be furnished by the state; but for local projects financed with motor fuel tax funds, the preliminary traffic surveys, plans and specifications must be submitted to the state for approval. The state will make final inspection for conformity to state specifications and policies.

Third. On streets and highways under local jurisdiction, where motor fuel tax funds are not involved, no detailed traffic engineering service will be furnished by the state. Engineers in highway districts and bureaus will respond to inquiries of local authorities with limited advice and recommendations.

In Illinois, it is unlawful for any local authority to place or maintain any traffic control device upon any highway or street which is under the jurisdiction of the Department of Public Works and Buildings without having obtained approval of the department. Without exception, the department will determine the need for traffic signs, and will erect and maintain them.

State traffic engineers devote a major portion of their time in defending the uniform system of traffic control, in refusing to employ unorthodox methods, and in educating the public. That traffic engineering is an art and a science is a truth not commonly known to most officials and citizens of smaller communities. And civic leaders are eager for traffic engineering by means of emotional appeal, by petitions, by political pressure, and by repetitious coercion. Sincere and enthusiastic workers for traffic safety cannot understand that a sign or signal installed in conflict with the traffic engineer's judgment is no cause for civic

reviling. A sign, a flasher, or a stop-and-go signal that violates a principle of traffic engineering is harmful; other control devices lose a share of their effectiveness, and motorists develop an increasing contempt for all signs and signals.

Speed zoning is the least appreciated art of traffic engineering. Routine complaint letters offer this hackneyed contention, "At least half the drivers are violating the 40 m.p.h. sign—the speed limit should be reduced to 30 m.p.h." The layman fails to see that a lowering of the number on the speed sign would merely increase the number of violators. Of course, the reason for these appeals for unrealistic speed limits is the popular, but erroneous, belief that motorists who travel 50 m.p.h. past a 40 m.p.h. sign would travel 40 m.p.h. in a 30 m.p.h. zone. When the traffic engineer explains that data from a speed survey are plotted and the plots joined with a speed-accumulation curve, and that the speed limit is based primarily on the 85 percentile speed of all vehicles, understandably the layman considers this a ridiculous method, and says so. He wants to control the speed of the motorists, not let them drive as they please.

Professor C. C. Wiley of the University of Illinois reported in 1949 that the changing of numerical values on speed signs, and the removal of speed signs altogether, did not affect the speed pattern of vehicles appreciably. This conclusion has been verified many times and places. When speed limits on Illinois highways through small communities were raised to realistic values, in accordance with the absolute speed law enacted in 1937, before-and-after studies demonstrated that actual speeds of vehicles were not faster, but slightly slower.

Civic leaders need to be convinced that realistic speed limits cannot be based upon opinion. Moreover, this is the law. A motorist, arrested for violating a speed zone which has been fixed without the benefit of a traffic investigation, can offer this lack of data as a valid defense.

Traffic signals installed within a municipality, on or off a State or federal route, must be financed by local authority. The need for the signals is generated by local traffic, and is not aggravated materially by through traffic. Local authorities may choose to use motor fuel tax funds for this purpose and usually do. Application for the use of M.F.T. funds for an intersection must be accompanied with vehicular and pedestrian counts and motor vehicle accident data. Minimum volume or accident history warrants must be satisfied to justify the installation of signals.

There is a popular notion that stop-and-go signals are the remedy of all traffic problems at busy intersections. But drivers who are halted on the thoroughfare for only occasional vehicles on the cross street will become impatient with these frustrating signals. Such signals are harmful because this disrespect for an encroaching number of unrealistic control devices grows into a general disregard for all of them.

Traffic signals must not be placed on the basis of opinion, nor because of a spectacular or publicized accident. When justification is based on accident history, a collision diagram must be prepared and only those accidents considered which can be prevented by traffic signals. For example, while signals may reduce right-angle collisions, they may actually contribute to rear-end crashes.

Traffic engineering in smaller communities too often is based on public and individual opinion. Promiscuous placing of stop signs and posting of unlawful speed limits are expedient attempts to solve local complaints and satisfy petitions. And yet these communities are confronted with an ever-growing traffic problem: school and pedestrian protection, parking, pavement marking, intersection design, access control, one-way streets, street lighting. Where do they go for help? Consulting engineers are one answer; sharing a traffic engineer with other communities is another; the county superintendent of highways is another. And then there is the state highway department.

Only twelve communities in Illinois employ full-time traffic engineers. Consultants, city engineers, and police usually perform traffic control functions in the twelve hundred cities and towns with a population

of less than 25,000. In the eight hundred incorporated communities with a population under 1,000, little if any traffic engineering is practiced.

The State does not have sufficient trained personnel to offer a complete traffic engineering service to these thousand communities, more or less. Our engineers are available, upon request, for the interpretation of traffic and motor vehicle laws, for workable explanations of the state and federal manuals of uniform traffic control devices, and the application of department policies.

In Illinois, the statutes require that all traffic control devices conform to the state manual published by the department. The manual prescribes the minimum warrants justifying the use of various traffic control devices, describes the purpose of each device, and specifies the size and shape of signs, signals, and pavement markings. This manual, together with the federal manual, is a workable textbook on traffic engineering sufficient for the small communities. The standards and principles contained in these manuals can be of great service in finding solutions to traffic situations, and in weighing the merits of proposals advanced by various citizen groups. The state manual is available, free of charge, to every incorporated community and to every county in the state. The federal manual can be purchased for two dollars from the Government Printing Office.

It is a source of wonder to me that city and town clerks, and leaders of citizen groups, write to the Governor, the Secretary of State, and State Police, and the legislators, for solutions to traffic problems. One would expect them to know that the engineers who built the highways, who erected the signs and signals, who painted the center lines and edge lines, surely are supervising the safe operation of the highways through their communities and environs. Civic leaders concerned with traffic safety should become acquainted with the district engineer in whose district they reside. They should know the district traffic engineer and the district maintenance engineer, for these are the operation officials of their highways and route numbered streets.

The district traffic engineer can do much

to effect the proper understanding between the public and official agencies in many traffic situations. One of his principal objectives is to replace opinions with facts. Local citizens must be educated to accept

uniformity in traffic control devices and their application. The district traffic engineer is a good and understanding neighbor. He is the one to whom the smaller cities can go for help.

ENGINEERING TRAFFIC SAFETY IN THE SMALLER CITY — SOLUTIONS TO THE PROBLEM

By JERRY P. GILBERT
Traffic Engineer, City of Springfield, Ill.

The problems of inadequate street capacity in urban areas of medium and small size, and the importance of curb-side parking as it restricts a street's ability or capacity to handle traffic are important in small community traffic engineering.

It appears evident, that everyone is not in complete agreement on all facets of this topic. It is these areas of divergent opinion, which, I believe, merit and require further consideration.

A great deal of research has taken place in the past on the subject of capacity as a function of roadside conditions, the most noteworthy and comprehensive of which is the *Highway Capacity Manual* by the Bureau of Public Roads.

This manual is frequently referred to throughout the following discussion.

The fact that curb parking restrictions increase street capacity is seldom questioned and is general knowledge among motorists and the general public. How much street capacity is increased by parking removal under various conditions is not realized or appreciated, either by the general public, or by many officials directly or indirectly involved in the highway transportation picture.

It is the quantitative aspect of the problem of capacity which has been treated so extensively in the manual and which make it so valuable. The information contained in the report now permits the prediction and evaluation of highway performance either before or after improvements.

My experience in three medium-sized communities in two states has led me to the conclusion that about the most fre-

quent cause of complaints, and the most difficult problem to solve, is the removal, restriction, and control of curb parking. And the smaller the community, the more unacceptable are these measures as a means to increase capacity.

Furthermore, it is in the smaller communities that alternate means of increasing capacity (street widening, expressways, etc.) are less available because of costs. Cities the size of Springfield appear to be too small to support expressways but too big not to have them.

In this respect, it seems that the smaller communities are going to be faced with traffic problems which are more insurmountable than those facing larger communities, relatively speaking. Yet the fact remains that more than half of the population of the United States is concentrated in cities of 100,000 population or less.

This situation coupled with the fact that it is estimated that the number of vehicle miles of travel will increase roughly 75 per cent in the next 20 years poses problems of inadequate capacity which are going to have to be met with widespread curtailment of parking in conjunction with other methods.

How these increases in motor vehicle travel and registration are going to be provided for is the subject of much discussion and concern throughout the country, and is one of the major challenges of our time.

Throughout these discussions, there appears to me a rather obvious omission of any positive statements as to what is

- in the future, for vehicular travel, and not for parking.
2. That the total costs to a community for storage of vehicles on the street is enormous—taking into consideration the costs of accidents, costs of capacity restrictions and delays, and other costs mentioned above.
 3. That curb parking restricts capacity much more than most people realize.
 4. That curb side parking on our major streets must inevitably be eliminated in the future, in view of projected estimates of auto registrations and travel.
 5. And that if curb-side parking must

ultimately be removed, even on widened or improved facilities, should not our policy of waiting until volumes build to capacity, be changed perhaps to recognize or take into consideration the problems which will develop at some future date when parking is removed?

I believe that curb side parking creates a much larger problem than most of us find it convenient to admit, and that the solution to the problems created by the removal of this parking is going to require much more cooperation and coordination of effort in the future, than has been given in the past.

ENGINEERING TRAFFIC SAFETY PUBLIC ACCEPTANCE AND IMPLEMENTING THE SOLUTION

By BERT W. JOHNSON
City Manager, Evanston, Ill.

Some say it cannot be done. Traffic congestion must get worse before the public will permit the solution. Don't propose more traffic capacities. More traffic will result. Don't offend by the rerouting of heavy traffic. Keep it where it has been. If traffic gets bad enough maybe mass transit will have a chance. Save the trees at all cost. Divert through traffic away from our community.

These are typical of the public's reasoning when they violently resist proposed street widenings, traffic rerouting, creation of cul-de-sacs and other proposed traffic engineering and safety improvements. This resistance, if voiced by enough people of prominence, seems to indefinitely delay needed progress and to alter priority scheduling so that "what can be accomplished is accomplished."

Politics is supposedly the art of the possible. As such, our political leaders must be convinced that the traffic problems are real, that they will not evaporate if allowed to do so. We need to do a better job of defining the problem.

We need to convince citizens and their political leaders, that traffic is with us in relentless and in ever-increasing volumes. We need to confess that there will never be total solutions to all of our urban problems. There appears to be no prospect for making everyone happy. One citizen's solution is another citizen's problem. Some gain, others lose.

In solving traffic safety problems especially, there are conflicts, contradictions, incompatibilities, and differences—between citizens with respectable motives and citizens of known self-interests. These differences must be tempered, shaped and molded if traffic solutions are to be implemented. There ultimately must be a balance between proposal and performance. No planning study, no engineering research should be authorized unless there is a political commitment that some positive action on the ultimate solution is to be voted.

Paul Ylvisaker of the Ford Foundation keyed the Washington World Traffic Engineering Conference last August and made this observation: "Cities are caught now be-

tween the extremes of contemplation and performance. Judging from the enthusiasm with which research has lately been welcomed by planners and politicians alike, we're in the stage where a study is worth a thousand deeds. The fact is, a study may make a thousand deeds unnecessary and another thousand deeds possible—by correctly redefining a problem or preparing the community to accept action. But that's not always the intent of those who commissioned the study; and there comes a point where someone must take responsibility and act."

In proposing a 1959 Budget for the city government of Evanston, Illinois, we tried to focus attention on the many-faceted character of our citizenry. This approach was used in the belief that we tend to direct our reporting to all of our citizens in general without making a conscious effort to relate it to distinct citizen groups in particular.

Here are a few citizen groups with diverse needs and preferences:

1. *Our Tax-paying Citizen.* He wants more for his money and resists any increased tax demands, whether on property, on his car or on the gasoline it uses. He resists street improvements financed by special assessments.

2. *Our Resident Citizen.* He wants little or no traffic to go by his home. He wants the bus routed near him but not in front of his property. His concern is for the safety of his children. He sees increased traffic as a depressant on property values, especially if any trees are involved.

3. *Our Motorist Citizen.* He is annoyed by traffic delays. He suffers from accident and personal injury and death. Up to a third of them do not live in the city through which they must travel. He is told that "taxpayers pay for a convenient, safe traffic system whether they receive such a system or not." He goes home to become a member of another citizen group with diverse needs and wants.

4. *Our Pedestrian Citizen.* He is too often the victim of unresolved traffic engineering problems, through delay in travel and through hazard to life and limb. School and college officials are wisely concerned about student pedestrian safety; yet the large school is a large traffic generator and

is often located on or near major thoroughfares.

5. *Our Merchant and Parking Citizen.* He, like all of us, oversimplifies. Parking should be abundant, free of charges, tax in enforcement. He tends to overlook the high priority of external accessibility, of circulation convenience, of safety values. Condemnation of parking enforcement is made in face of the known fact that a well-located parking space is worth at least \$15,000 in sales annually and that there is proof that merchants and their employees tend to pre-empt these prime parking spaces.

6. *Our Visiting Citizen.* He may be a temporary guest on his way to the office, a weekend shopper for downtown, and as a result will add to the traffic problems as he contributes to the economy and helps establish the reputation of the community's traffic engineering and safety practices. We cannot build a wall around our cities unless we are willing to reap the dire consequences.

7. *Our Future Citizens.* He is the youngster who cannot vote. Yet he will be affected by the decisions made. He should be encouraged to locate in communities which face up to decisions. He should be made to understand and support community objectives. He should be assured that there will be a financial base to support community standards.

How do we resolve these diverse interests, concerns and wants? This presents a challenge. We must balance separate interests to the general objectives of the community. In Evanston, Ill., we have recognized the need for obtaining agreement on our objectives. In 1956 a 35-item statement was unanimously adopted by the city council. Relating to traffic are excerpts from objective concerning Evanston's "street system":

- a) (30) . . . This street system serves two main purposes: 1) access to property, and 2) routes for the moving of vehicles and pedestrians within and through the city . . .
- b) . . . In order to relate traffic movement to the proper development of land, certain streets should be designated as major thoroughfares. These streets would continue to provide access to abutting property, but would also serve as the principal routes for vehicular traffic within and through the city. To serve effectively as such an artery, a thoroughfare must have the capacity to carry the traffic volume seeking to use it. . . . It is hoped that the present street system, with minor adjustments, will adequately serve fu-

ture traffic volumes and that street right-of-way will not require widening. . . .
or (2) . . . It is recognized that on-street parking must be restricted where it interferes with the primary function of the street on traffic movement. . . .

One of Evanston's proudest achievements has been its nationally recognized traffic safety record. There's no acceptance of complacency. It is not popular to be a ticket collector. It is in this setting that the city council authorized a 20,000 dollar transportation survey which will be released soon.

Does this mean that public acceptance and implementation of recommendations will ensue? It does not. It means Evanston has a rich history and has agreed on objectives to help provide a hopeful prospect. I must reserve the right to alter this picture five years hence.

Our six-year capital improvement program will advance traffic engineering proposals for 1962 through 1967. We know there will be controversy. There will be changes.

There will be postponements as Evanston continues in its search for excellence.

All of these proposals represent a real challenge for leadership. It requires a sense of relevance which not only anticipates tomorrow but creates the tomorrow in which we shall live. Public officials, elected and appointive, are involved.

Civic goals and standards must be high and the rate of progress must be creditable. Citizens also should be challenged to desire community standards to match their own private standards for living. Together, officials and the citizens they serve, must be equal to our traffic safety problems. We must be open to the new as new problems emerge. We must be positive in our approach.

Citizens must be confronted with the alternative courses of action. We must further dramatize the penalties of inaction and delay. As public officials, we must continue to be worthy of the public trust that is ours.

ILLINOIS JUSTICE COURTS — THE NEW LOOK

By ROBERT MCCLORY
Illinois State Senator, Waukegan, Ill.

During the past two years Illinois justice of the peace courts have moved from the kitchen of the justice's home, or from back of the hardware store where the justice of the peace was carrying on his regular business, to the Court House, the City Hall, or other public or appropriate place to hold court with dignity and decorum.

That is not to say that the transition from the old system to the new has taken place in every instance, but it is to say that in large measure a great transformation and improvement in the local court system has been accomplished during the past two years.

The impetus for local court reform occurred when a new judicial article was proposed by the legislature and voted upon at the 1958 general election. The most violent critics of the old system emphasized the need for eliminating the then existing fee system of justice, and substituting a system whereby the local Justices would be paid a salary.

Some of those who defended the old

judicial article contended that the justice of the peace system could be revised by legislation.

At any rate, when approval of the judicial article failed by a narrow margin, the Illinois General Assembly with the support of the Judicial Advisory Council, and the American Bar Association Committee on Traffic Laws and Courts developed a comprehensive program which was enacted into law at the 1959 session.

The 1959 legislation accomplished these goals:

1. Reducing the total number of justices of the peace from more than 3,500 to approximately 400.
2. Abolishing the fee system under which a finding of guilty was generally necessary in traffic cases in order for the justice of the peace to collect his costs, and substituting a flexible salary schedule under which county boards could fix appropriate salaries for the fewer justices of the peace.

3. Requiring that each county should be divided into justice districts of not less than three, nor more than five, with one justice of the peace for not less than each 20,000 of population, nor more than 40,000, or major traction thereof, except in Cook County where each township was designated as a justice district.

4. In addition to the salary provision, each county board was authorized to provide expenses for the office and assistants required by the justices.

Certain other changes were made at a special session of the legislature held in 1960, and at the recent regular 1961 session further improvements were made in the new system. Again, the Judicial Advisory Council was the sponsoring agency of this legislation, after having received thoughtful cooperation from James P. Economos, director of the traffic court program of the American Bar Association.

These further improvements consisted of provisions authorizing assignment of justices of the peace from one district to another in order to equalize work loads. In Cook County the assignments are carried out by the county board with the approval of the court administrator. In the downstate counties, the transfers are made by the county board under the supervision of the county court.

The county board was granted authority to fix the office hours of justices of the peace in order to assure their availability to administer justice at the local level. In addition, the county board has been authorized to establish minimum courtroom standards to be prescribed by the court administrator. As a result of this legislation, Dean Albert Harbo, court administrator for the state of Illinois, through the cooperation of the Illinois State Bar Association Committee on Traffic Laws and Courts, as well as through the cooperation of the American Bar Association traffic court program—and especially the good offices of Mrs. Lillian Baraban, Mr. Economos's assistant, has set forth a schedule of minimum standards which every county should be able to adhere to.

Provision and establishment of a central depository for justice of the peace records, and authority for a simplified modern day permanent record to replace the laborious

handwritten "well bound book" of earlier days has been enacted into law.

Efforts to simplify the approval of bail for traffic violators were unsuccessful at the recent session. However, practical solutions have been found in most counties, whereby designated police officers and sheriffs deputies have been appointed to approve bail in almost all traffic cases. In addition, the jurisdiction of the justice of the peace has been enlarged so that they may hear the more serious cases of driving while intoxicated, reckless driving, and leaving the scene of an accident, where approval for the hearing of such cases is granted by the County Court on motion of the states attorney.

Justices of the peace have been elected and are operating in all except 17 downstate commission form counties. These commission counties will elect their justices of the peace in November, and thereafter the fee system of justice will be at an end, except in those few municipalities where Police Magistrates were elected in 1959 and whose terms will expire in 1963. Thereafter, all police magistrates elected will be required to serve on a salary basis.

Some opponents of the new system have made strenuous efforts to discredit, and even to undermine this new system of local justice. However, my information, which includes a detailed report from the chief of the state police, indicates that in almost every county of the state, the new system is receiving local support and is reported to be working well. Further improvements are certainly needed. From the reports being filed each month with the county boards, and with copies to the court administrator, an important record of local court statistics will be available soon. In addition, the Committee on Traffic Laws and Courts of the Illinois State Bar Association, again with the cooperation of many other agencies, are developing a manual of procedure which should bring greater order, uniformity, dignity and respect to the justice of the peace courts of Illinois.

It goes without saying that the impression gained by the traffic violator in the local traffic court is an important factor in promoting traffic safety. We are proud of the improvements that have been made in Illinois, and will strive for further Traffic Court improvements.

PROPOSED UNIFORM TRAFFIC COURT RULES IN OHIO

By PAUL R. DONALDSON
Asst. Dir. of Law, Shaker Heights, Ohio

In the 1959 session of the Ohio legislature, three new sections of the Ohio Revised Code were enacted to authorize the Supreme Court of Ohio to promulgate rules and forms for criminal and traffic cases in all Ohio courts inferior to the Court of Common Pleas. In January, 1960, at the request of the Supreme Court and acting under this new legislation, the president of the Ohio State Bar Association, Allan B. Diefenbach of Akron appointed a nine member committee to study this problem and formulate rules and a form of traffic ticket for use in Ohio.

This committee consisted of a municipal judge, now a common pleas judge from a small rural area, the chief justice of Ohio's largest municipal court, a county court judge, the president of the Ohio State Automobile Association, a common pleas judge who formerly served as county prosecutor, a former assistant prosecutor, now in private practice, a member of the American Bar Association's Standing Committee on Traffic Courts, and a municipal prosecutor, who was formerly a police officer.

With this wealth of background and knowledge, the committee began to review the overall problem and its many related facets. It found, for example, that in the Bedford municipal court, 14 municipalities plus the state Highway Patrol and the sheriff's office bring traffic citations before this court. In the Shaker Heights municipal court, five municipalities plus the state Highway Patrol and the sheriff's office bring cases before the court. The problem of filing space in the clerk's offices of the different sizes of all of these various tickets was mammoth and necessitated a separate filing cabinet for each separate jurisdiction.

The committee found that some tickets did not even state a cause of action, while others did not state an offense. Some were completely unreadable and the judges of these courts found a great deal of trouble in properly determining the seriousness of each violation.

The committee, meeting almost every two weeks and during voluminous work individually between meeting dates, presented its first report to the Supreme Court December 2, 1960. Although the committee had furnished information to the Ohio Association of Chiefs of Police and the Buckeye State Sheriffs Association, the Supreme Court was besieged by police officials who asked the court that they be allowed to be represented on the Bar Association Committee. The court concurred and added to the committee two chiefs of police and another municipal court judge. The Supreme Court also sent to the committee a list of seven specific comments for them to review.

The review was made by the larger committee in semi-monthly meetings and on May 25, 1961, the final report was submitted and forwarded to the Supreme Court. We are, at this time, awaiting action of the court. Almost every large newspaper in Ohio has commented editorially on the new ticket, endorsing the idea and, in the meantime, over 100 municipalities have adopted the ticket as approved by the Ohio State Bar Association and many others are only awaiting the action of the Supreme Court to adopt the new ticket, although it will not go into effect officially until January 1, 1963.

The basis of starting on the ticket and rules was a booklet entitled "Uniform Traffic Ticket and Complaint and Modern Rules Governing Procedure in Traffic Cases," prepared by the American Bar Association Court Program, copies of which are available from the American Bar Association in Chicago.

In drafting the rules and designing the ticket, the committee consulted with the Ohio Department of Highway Safety, the Ohio Municipal Judges Association, the Association of Ohio County Court Judges, the Ohio State Automobile Association, the Ohio Association of Chiefs of Police and the Buckeye State Sheriffs Association. In

each case, suggestion and comment were invited. The ABA ticket, which is used extensively in New Jersey, Michigan, Missouri and many individual communities, and the basis for study, has the following essential characteristics:

1. Quadruplicate form, so that upon a single writing, various sheets, serving the court, the licensing authority, the police agency and the accused, with identical information, with consequent lessened opportunity for "fixing" tickets.
2. A series of pre-printed boxes for checking, which are descriptive of common driving offenses.
3. A similar series of boxes describing a series of road and pavement conditions.
4. A place on the reverse side of the respective sheets to record court action in the case.

The ABA uniform traffic ticket is approximately four and one-half by eight and one-half inches in size. Ohio adopted a ticket four and one-quarter by eight and one-half inches in order to meet the problem of some agencies in filing. Unfortunately, for use in Ohio, the ABA ticket was designed around offenses in fixed speed limit states which adhere strictly to the uniform Vehicle Code. Ohio has a prima facie speed limit law. Further, many of the listed offenses on the ABA ticket do not exist in that form in Ohio. However, the general format of the ABA ticket has been retained, including identification as to defendant's race, sex, weight and height. These essentials appear necessary for proper police records.

In describing the offenses, some difficulties were encountered stating the "assured clear distance" charge, the "reckless operation" charge, and the non-overtaking "left of center" charge. In each case, care was taken to use sufficient statutory language to make the charges adequate and clear for both the courts and the public. Some measure of variation from a standard form has been permitted to local courts in the design of the defendant's copy of the ticket. Most metropolitan courts permit waivers for minor violations, while courts with a lesser case load do not. Alternate forms are, therefore, provided, depending on the presence or absence of the waiver or traffic violations bureau. Latitude has also been af-

forded police departments to design the back of their copy of the ticket to comply with local requirements.

As to the rules, the problem of preparing procedural rules varies considerably from that encountered in New Jersey and Missouri. In those states, the state court of last resort is entitled to promulgate the entire system of pleading. In Ohio, the rules must be supplemental to and consistent with a statutory system. In addition, the system of pleading as established by the legislature in 1959, containing many amendments, is so new that insufficient opportunity has been afforded to note "bugs" and inconsistencies in the various statutory sections. Where these inconsistencies were obvious, an attempt was made to reconcile or at least state them. The rules themselves were grouped into four basic classes, as follows:

1. Preliminary, definite and general.
2. Arraignment and motions.
3. Specialized traffic practices including the ticket.
4. Trial and appeal.

In the preliminary rules, the committee re-stated some obvious and inherent court powers. While this might seem superfluous, it must be remembered that many misdemeanors and traffic cases are decided by mayors and county judges who are not lawyers. Consequently, it was considered desirable to remind them that they are judges, bound by professional standards and subject to discipline.

As to arraignment, the concept of separation of traffic and non-traffic cases, which is an important principle of the ABA program, is dealt with in these rules. Strict separation of arraignment of traffic and non-traffic defendants is attempted. The model ABA traffic rules carry this separation even further by having separate trials on different days or in different places. No such solution is realistic for Ohio, when one considers the large number of judge's or mayor's courts and the space problems of many multi-judge courts. Therefore, none was attempted. An additional reason for deviating from the ABA model rules is that in other states, arraignment and trial seem to be the same thing, whereas, in Ohio the two are considered separate. The rule on motions

is designed to encourage the filing of all available motions at one time to prevent unnecessary delay in trial.

As to the traffic practice portion of the rules, the committee felt strongly that traffic courts must not be operated for revenue to municipalities and that unrestricted use of the "bail forfeiture" and of the "traffic waiver" where tickets are light, should be discouraged. The committee recommended a general statement disapproving forfeiture without attempt at apprehension but countenancing it in individual cases for good reasons. An adjunct to this rule is the attempt to validate the sending in of a record of forfeiture for "points" under Ohio's point system for the non-appearance of a defendant who has not posted bail.

In dealing with the "waiver" system, the committee proposed two basic rules for a traffic violations bureau:

1. A specific list of the more serious offenses which cannot be handled without court appearance under any circumstances.
2. Any violation accompanied by unusual circumstances requires personal appearance in court by the defendant.

As to trial and appeal, the committee had

three more proposals. First, the rule for covering jury trials in courts not of record, is intended to confuse by differing language of the statutes and at the same time spell out some of the machinery for transfer of the jury demand cases.

The second rule is intended to be educational. Some sections of the Revised Code contemplate a thirty day rule for the filing of bills of exception. Unfortunately, other provisions create a ten day rule. While the committee considered the thirty day rule preferable, it was obliged to admit that under ordinary rules of statutory construction, the ten day rule would probably prevail. This conclusion is spelled out in this rule.

The third rule spells out the procedure under the jeopardy plea.

The largest current improvement in traffic courts in the state of Ohio in recent years was the abolishing of justices of the peace courts. The adoption of uniform court rules and a uniform traffic ticket is the next big step. The abolishment of mayor's courts in favor of elected municipal and county court judges who are experienced lawyers, trained in dealing with traffic offenders, could be the next big step.

TEENAGE TRAFFIC COURT AND SCHOOL

By JOSEPH P. CASKEY

Dir., Teenage Traffic Education Dept.
Municipal Court of Baltimore City, Baltimore, Md.

Last November a referendum was voted on favorably by the people establishing a new municipal court system for Baltimore City. Under this bill, all existing lower criminal courts and traffic courts were abolished; and an entirely new court with permanent judges, taking jurisdiction in the lower criminal and traffic cases, was established. The Governor appointed 15 judges for terms ranging from 18 months to six years, at salaries of \$15,000 a year for 14 of the judges and \$16,000 for the chief judge. At the expiration of the terms, they must run for election to a new term.

However, I would like to talk primarily about a specialized court, taking jurisdiction

in all teenage traffic violations, involving young people between the ages of 16 and 21. This court convenes each Saturday morning at nine A.M. and is opened by the showing of a traffic safety film of about 10 minutes duration, usually depicting a serious accident and pointing out its cause and prevention, as well as other safety education data.

The bailiff announces the entry of the judge; and after everyone is seated, the judge gives an opening statement on the purpose and aims of the court, which is to help perhaps the first-time violator, but on the other hand to deal stringently with the persistent youthful violator who disregards

the safety of others on the road. The judge will also quote statistics and other safety hints.

In this court, the judge can render one of three decisions: dismiss the case, fine or jail and suspend the license, or probation before verdict.

The last finding has become the one in which the court can retain an association with the youngster for a six month period. This special teen court has brought out the fact that the teenager is basically honest—in 95 per cent of the teen cases, the defendant enters a plea of guilty; however in the adult court, the reverse is true.

Since many youths are accompanied by either their parents or friends, the film and talk by the judge have an effect on all—even the police officer. The hearings are conducted on an impartial basis. The judge will call the youth by his or her first name, and here too the parents will for the first time get both sides of the story, which may differ greatly from the one told by Junior as having been picked on.

This specialized court also provides a tremendous opportunity to impress our youth with the dignity and fairness of our judicial system, since most of these young people will never have any contact with any other tribunal, and the first impression is usually lasting. Probably the greatest advantage of such a court is the control. Since the court retains jurisdiction over all under 21 violators, the persistent violator appearing in this court will soon be dealt with in a severe manner.

At the outset of the establishment of this court, we were carrying more than 300 cases each Saturday morning, where now we are averaging about 160 cases each week, and you must remember this is in a city of over a million population!

Of course, in Baltimore City, when Junior is given a traffic ticket, he cannot give it to Dad to mail for him. Junior must appear in court and stand on his own two feet, since under 21 years of age violators cannot pay out in advance of trial except in parking cases.

When the judge gives a youth probation before verdict, he or she is screened as to background and prior record to ascertain if he or she will be accepted. If accepted, the teenagers are instructed to report personally

twice a month for a personal check-in, at which time we can question them as to the driving and overall behavior; and likewise they may seek any help or ask any questions with which we may help. This phase brings us into direct relationship with the teenagers. Once a month they will be notified to attend a traffic safety class, which is held in the court room.

After six classes have been completed, a written test is given; and if passed, the youth is graduated and the violation is not placed on the driving record.

Each class is opened by a member of the clergy with a prayer, since we embody into our program the moral aspect. At the outset they are apprised of the reason for bringing them to these classes, and the value placed on these classes is the saving of the very life.

They are also told that completion of the course will result in no mark on the driving record—this is a strong incentive. The teenagers themselves are the lecturers, and this is one of the most important parts of the entire program, since they will listen to those of their same age and in the same boat.

Slides of recent accident victims are displayed on the screen, and this also has proved to be a powerful part of the class. At times the clergyman will give a talk of about ten minutes showing the moral responsibility involved in the operation of a car. The class is concluded by the showing of a traffic safety film of about 25 minutes, involving a complete story of a serious or fatal accident.

We are presently carrying more than 1000 on our rolls, and since the inception of this program, we have graduated about 15,000 from our school and have had less than ten per cent come back with repeat violations. Since we retain jurisdiction in these cases until the probation has been fulfilled, a subsequent traffic ticket will mean violation of probation; and since he must stand trial in the same court, the judge will have the probation case and the new case, and he can impose fines in both cases and suspend the license. In situations where a boy reports for a while and then stops reporting, we can summons the youth and remand him back to court and the penalty imposed.

This entire system began when I was given the post in charge of the teenage program with 25 teenagers to handle. I experimented with these 25 one night in April of 1951. This proved to be the first traffic safety school within the traffic courts in the nation. In June of 1951, upon the advice of Jim Economos, we issued the pay-out cutoff for under 21 years of age violators. This clogged our courts with teen violators, and of course this led to the establishment of the teen court in October of 1951.

There is no question as to its value and

its possibilities. During these years, this system of court and school has had a direct effect on our youthful community and has served as a deterrent in numerous instances. This court gives us a ready-made pool from which to select those drivers who want to know how to drive properly and keep their licenses. In many cases the young people beg for probation, since they know it will mean education and a clean record. Probation in this court is considered a break of courtesy, since not all are given this privilege.

WHAT DIRECTION CHEMICAL TESTS?

(a) LEGISLATION

By ROBERT L. DONICAN

General Counsel, Traffic Institute, Northwestern University, Evanston, Ill.

In discussing the legal aspects of chemical tests to determine alcoholic influence, it is interesting to look back a few years and review a bit of history on this subject. It was almost 25 years ago, February 6, 1937, to be exact, when the accused in the first chemical test case to be taken up to a court of appeal in this country was arrested for driving while under the influence of intoxicating liquor as he drove his automobile up the driveway to his home. The Supreme Court of Arizona, in approving his conviction for this offense, charted a favorable course for the use of chemical tests by law enforcement agencies throughout the nation in combatting the danger of the tipsy driver upon our highways. This decision was followed not too long thereafter by similar favorable opinions by the appellate courts in California, Iowa, and Ohio.

Over the course of this quarter of a century, a firm foundation of case law has followed these initial cases, involving almost every question which could be raised by the legal profession relating to the admissibility in the courtroom of evidence concerning the use of chemical tests to determine alcoholic influence. Appellate courts in the federal jurisdictions and in 45 states—in all the states except Alaska, Hawaii, Louisiana, Mississippi, and Wyoming—have had occa-

sion to pass upon legal questions relating to this type of evidence. The number of these cases may surprise many—it is just short of the 400 mark to date. 363 reported cases to be precise.

In general, our appellate courts have overwhelmingly approved the use of chemical test evidence in both criminal and civil cases involving inebriated drivers—when the tests have been properly conducted by qualified personnel and the evidence has been properly prepared and presented in court. So far, no appellate court has ever reversed a case taken up from the trial courts on the ground that chemical tests to determine alcoholic influence are not valid.

In the late thirties, state legislatures began to take cognizance of this relatively new (at least in this country) weapon against the motorist who injudiciously mixes his alcohol with gasoline. At its 1939 session, the Indiana Legislature was the first state legislative body to enact a law providing for the admissibility of chemical test evidence and establishing the familiar statutory presumption that a driver found to have 0.15 per cent or more blood alcohol concentration is under the influence of intoxicants.

In the early forties, three other states followed suit by enacting similar legislation—Maine, New York and Oregon. This was

soon followed by action of the National Committee on Uniform Traffic Laws and Ordinances in including recommended legislation on the subject in the Uniform Vehicle Code. Since then, other states also have enacted chemical test legislation in this field. Their number now is 36, plus the District of Columbia. But not all states have followed the pattern recommended in the Uniform Vehicle Code.

It behooves us here to note that permissive legislation has never been necessary in any state to establish the admissibility of chemical test evidence in the courtroom. Such evidence always has been admissible in every state when properly prepared and presented, under the age-old rules of evidence applying to the admissibility of any type of scientific matter. Many persons interested in traffic safety upon our highways, however, have diligently promoted and worked for the enactment of such legislation in their respective states with the view of encouraging and fortifying the use of chemical tests in their communities and thus greatly increasing the application of this modern scientific tool.

In some of our states, there has been active opposition for these many years against the proposals of these well-meaning safety-minded persons, usually and predominantly attributed to legislators themselves. The several reasons for such opposition among a few of the old warrior assemblymen, who are nevertheless the duly elected representatives of our people, are as well known to most of you as they are to me. A study of some of the recent legislation on this subject in a few of the states indicates that these influential but die-hard legislative opponents, in finally giving in, have taken their toll by bargaining for deviations from the recommended legislation in the Uniform Vehicle Code and successfully imposing undue limitations and restrictions upon the admissibility of chemical test evidence, to the point that some states were much better off solely under the case law of their appellate courts and without legislation in this field, than they are with it. To those devoted proponents of chemical test legislation in the 14 states which yet do not have it, there is a piece of advice to be derived from these experiences—do not compromise for the mere sake of having some chemical test legislation upon the stat-

ute books of your state to the extent that departure from the national standards recommended in the Uniform Vehicle Code is so great you just create another "Munich."

Over the years as the public has become better educated on the subject of validity and value of chemical tests to determine alcoholic influence, as more and more states have enacted specific legislation on the subject, as appellate court after appellate court has approved the use of this type of evidence against the "DWI" driver, it is found that in an increasing number of jurisdictions the motorist who gives little thought to how dangerous the mixture of gasoline and alcohol is and can be, is becoming wary of these tests, not by refraining from driving while in this condition, but it is manifest in his refusing to submit to such tests when the law finally catches up with him. This, of course, is most pronounced in the repeater-violator—he who has the prior conviction based upon chemical test evidence. In Indiana, where probably, percentage-wise, there are more law enforcement agencies with chemical test programs than in any other state, and for a longer time, it is reported that in a number of areas refusals to submit to chemical tests by drivers accused of operating while under the influence of intoxicants is greater than 40 per cent. During the legislative session in Illinois, this year, it was reported that the number of such refusals in Chicago now constitutes about 46 per cent. In a recent publication of the National Safety Council, it was reported that the percentage of refusals on the part of those apprehended by Oregon State agencies amounts to 68.5.

This naturally has resulted in a demand by many persons highly conscious of the need for traffic safety for a "compulsory" chemical test law—a statute which would make it mandatory for a motorist arrested for driving while under the influence of intoxicants to submit to a chemical test of his blood, urine, or breath to determine the extent of his blood alcohol concentration, even to the point of physically forcing him to submit to such a test if necessary. To most of our American citizens, the idea of the latter, of course, is highly repugnant, no matter how high the need for safety may be. With our inherent tendency to zealously protect the rights of the individual in this country and our ever present fears of creat-

ing a police "state," probably no American legislature will ever permit such action by force.

The problem, however, has led to the birth of a new type of chemical test statute—not a "compulsory" law, but the "implied consent" type of law. It provides, in effect, that as a condition of the privilege of driving a motor vehicle on the highways of the state, a motorist impliedly consents to submit to a chemical test of his blood, breath, or urine if he is ever arrested for operating while under the influence of intoxicating liquor, but that if he fails to comply with this condition by refusing to submit to such a test when so arrested and there is probable cause to believe he is under the influence, his privilege to operate in that state shall be revoked and cannot be restored for a definite period of time, usually six months. It also provides that if there is a refusal, no chemical test shall be conducted.

Thus it is not, as so many persons have mistakenly called it, a "compulsory" law. The accused has a choice—of refusing and forfeiting his privilege of driving, or submitting and, at least for the time being, retaining his privilege of driving. It also will be noted that there is no provision for signing an agreement upon the application for a driver's license—which would not reach the unlicensed driver or the out-of-state driver. The implied consent type of law reaches all of these alike—any privilege of driving in that state is forfeited upon refusal to submit. And the revocation of the driving privilege becomes effective regardless of the outcome of the criminal charge against the accused for operating while under the influence of intoxicating liquor. Even though he may be acquitted eventually upon trial of the criminal charge, revocation of his driving privilege because of refusal to submit to a chemical test becomes an accomplished fact.

A model law on this subject was drafted and approved by the National Conference of Commissioners on Uniform State Laws in 1937 and was approved officially by the American Bar Association in that same year. It is now under consideration by the National Committee on Uniform Traffic Laws and Ordinances for inclusion in the Uniform Vehicle Code. Many national organizations interested in traffic safety, such as the Na-

tional Safety Council, the International Association of Chiefs of Police, the American Medical Association, and others, have recommended the adoption of this type of law by all states.

To date, nine states have enacted this type of legislation—Idaho, Kansas, Nebraska, New York, North Dakota, South Dakota, Utah, Vermont, and just this year, Minnesota. The court decisions relating to the existing statutes on this subject in those states have been most interesting. Whenever the constitutionality of the act has been attacked, the courts have sustained its validity. Of special interest are recent decisions approving the validity of this type of law by the Supreme Courts of Idaho, Kansas, and Nebraska. Other decisions have been instrumental in clarifying for the law enforcement agencies and particularly, the motor vehicle administrator, how such a law can and should be administered. Reports from those states in which it has been in effect for some time indicate that the law is working out well and that its objectives are gradually being attained—encouraging the use of chemical tests on the part of those agencies charged with the responsibility of enforcing the traffic laws, reducing the numbers of drivers who are chancing operation of their vehicles after drinking, reducing the numbers of those who refuse to submit to chemical tests after arrest for driving while under the influence, and taking off the roads for an appreciable length of time those who refuse to submit to such tests and thus making it difficult for them to have their driving privileges restored.

Here again, though, those traffic safety conscious persons who are so diligently working to have their legislatures enact the implied consent type of law must be warned against undue compromise with some of the hard-bitten opposition against them. An example to be heeded is the recent legislation in Minnesota, which many of us believe has strayed so far from the provisions of the "Uniform Chemical Test For Intoxicating Act," recommended for adoption by the American Bar Association and the National Conference of Commissioners on Uniform State Laws, that its eventual effectiveness is much in doubt. Time, and experience with its administration, soon will show us whether the law is worth having on the books of that state.

Another phase of legislation to be specially noted is the recommended reduction of the 0.15 per cent statutory presumption to the level of 0.10 per cent. Many of our scientists in this country for a long time have felt that the 0.15 per cent figure has been far too liberal. This has been based upon many additional experiments in the past several years conducted under rigidly controlled and recorded conditions, which have led the vast majority of scientists experienced in this field to come to the definite conclusion that practically all of us human beings are unfit to drive a motor vehicle upon the highway under modern conditions with as much as 0.10 per cent blood alcohol concentration, and that many of us are unfit at levels much below that.

Pursuant to this, some national organizations with this background of support are recommending that the presumptive statutory level of 0.15 per cent be reduced by state legislation to 0.10 per cent. The National Safety Council has already gone on record in recommending that the provision in the Uniform Vehicle Code be amended accordingly. North Dakota has been the first state to follow this recommendation. This year, the legislature of that state amended its chemical test law to provide that if a person charged with the offense of driving while under the influence of intoxicating liquor is found, after a chemical test, to have 0.10 per cent blood alcohol concentration, it shall be presumed he was under the influence of intoxicating liquor. This presumption is applicable also in all other criminal cases and civil proceedings against him arising out of his driving while under the influence in North Dakota.

Some persons may contend that New York was the first state to set a pilot course in this direction. What that state actually did two years ago was to create an offense of a lesser nature than the offense of driving while in an intoxicated condition to which the statutory presumption of 0.15 per cent still is applicable. The lesser offense is known as "driving while in an impaired condition" and is supposed to be applicable only to those accused motorists who submit to a chemical test after arrest and their blood alcohol concentrations are found to be at levels of 0.10 per cent or more but less than 0.15 per cent. The possible punishment and time of loss of driving privileges upon

conviction, of course, are considerably less than upon conviction for the greater offense. An accused to whom a chemical test was not available, or who refused to submit to one, may still be convicted of driving while in an intoxicated condition in New York, but in order to be found guilty, technically, of the lesser offense of driving while impaired, the result of a chemical test is essential evidence.

This kind of law has intensified the spotlight on the oft-repeated question: "Why not a law in our states making it an offense of graduated degrees of seriousness to drive while having certain quantities of alcohol in the blood?" In other words, say persons who ask this question, why don't we have the type of law reported to be in effect in some European countries, e.g., Norway and Sweden, in which it is a crime to drive a motor vehicle when one has as much as 0.05 per cent alcohol in his blood, but if a chemical test shows 0.15 per cent or more alcohol in the blood, the mandatory punishment is much greater than for lesser quantities? Attention is directed to the fact that the offense is not for driving while impaired, or while intoxicated or under the influence of intoxicating liquor, but for operating a motor vehicle when having certain quantities of alcohol in the blood.

Of course, to enforce this type of law the result of a chemical test of the breath or body fluids is essential for prosecution. This brings up that old-age problem again in this country: should the motorist be compelled to submit to such a test, does he have the right to refuse it, do his civil rights under our federal and state constitutions prohibit requiring him to submit, etc.? Most likely the European countries are not confronted with these legal questions and therefore are not bothered with this problem in enforcement.

But when the public generally in this country become better educated as to what alcohol is actually doing on our highways in the matter of taking life, e.g., recent surveys in some of the states which show that it plays a role in anywhere from 40 to 60 per cent of the fatal traffic accidents in the community, then it is quite possible that we will have such legislation. The courts of last resort in this country in many instances have already charted such a course by holding that the well-known and widely discussed

privilege against self-incrimination is only applicable to testimonial compulsion and not to the obtaining of physical evidence and that the use of our highways by a motorist is a privilege, and not an absolute right,

which may be regulated by reasonable action on the part of a legislature. Already there are individuals and organizations in this country earnestly striving to have such legislation recognized in the various states.

(b) ENFORCEMENT

By JAMES R. BARRETT

Dir., Div. of Driver Safety, New York State Dept. of Motor Vehicles, Albany, N. Y.

The course of police in chemical test work has been clearly and consistently forward for more than twenty-five years.

The handful of experimenters who pioneered in this field in the early thirties has been joined by literally hundreds of officers who now perform the tests on regularized basis.

An idea of the extent of present service can be drawn from the reports on chemical test use. The latest shows that tests were performed in at least half the larger American cities (those with a population of 10,000 or more) in 1960 and that the number of arrests and convictions for drinking driving was appreciably greater than in the previous year.

These were more or less predictable occurrences and represented a continuation of a trend of earlier years.

The reasons underlying the upsurge of interest in this area, however, are not quite as apparent and it might be well to give them more than passing consideration.

Need for an objective measure

Police for many years were almost wholly dependent on subjective sobriety tests. On arresting a drinking driver, they would make tests of muscular coordination and note, in detail, his reactions and outward appearance.

Neither the test rating nor the officer's diagnosis were ever regarded as completely satisfactory evidence of intoxication. The reports were challenged by attorneys, questioned by expert witnesses, and patently disregarded by jurors.

Such a situation made it difficult, at best, for police to deal meaningfully with the inebriated driver.

It was little wonder then, that chemical tests proved to be of such immediate interest. Police, from the very first, saw them as a dependable and reliable way of demonstrating that a person had been drinking and, if he had, the amount of alcohol that remained in his bodily fluids.

This to them, represented a long step forward and they were anxious to utilize the tests to the fullest possible extent.

Legislative sanctions

Test results were offered in evidence as early as the mid-thirties but the full benefit of the newer methods was not realized until they were given the sanction of law.

The enactment of chemical test laws started in the late thirties and continues to the present time.

Thirty-six states now have chemical test laws and others give indication that they may soon adopt similar regulations.

The basic law affords recognition of tests and specifies the blood alcohol concentrations that may be regarded as evidence of alcoholic influence.

This is important but police soon found that they were somewhat handicapped by the driver who refused to submit to a test.

They might suspect that he had a high blood alcoholic content but unless a specimen was forthcoming, no test could be performed.

The solution to this problem came from the legislative halls. The state of New York, in 1953, enacted the first of the implied consent laws. It directed license revocation by administrative action for anyone refusing to submit to a test. This, in part, eliminated a great many refusals. Eight other states have since followed New York's example

and now have implied consent laws of their own.

As tests found wider usage, judges and prosecutors gave closer attention to the test report. They have come, in some jurisdictions, in fact, to look upon the blood alcohol reading as the determinant of the action to be taken in a case and have even, in some instances, gone so far as to regard a blood alcohol concentration of less than 15 per cent as a bar to prosecution on a drinking driver charge.

While always somewhat debatable, this view became even less defensible after findings of recent date showed that drivers could be adversely affected by blood alcohol concentrations of considerably less than fifteen hundredths per cent.

Here again legislation afforded help. The driving while impaired law passed by New York legislature in 1960, specifically prohibits operation of a vehicle if the operator has a blood alcohol concentration of even ten hundredths per cent.

The effect of this statute has been to encourage action against a whole class of drivers who otherwise might have escaped detection and arrest.

Figures show that there has been a twenty per cent increase in combined judicial-administrative action under the new law in the twelve months ending October first.

Judicial acceptance

The courts in the early days were extremely cautious in their expressions about the tests. They permitted their use in evidence but were more than guarded in any statements about the weight that was to be attached to them.

Gradually, however, a body of decisions developed and the status of the tests was more clearly defined.

Word of the new views was circulated largely through the Regional Traffic Court Conferences and Traffic Institute's specialized reporting service.

Enforcement was encouraged and chemical test case prosecutions greatly facilitated.

Police interest in tests

Conscious as they were of the advantages of the tests, police were generally a little hesitant about embarking on this field.

They saw the tests as a technical activity and looked for training that might serve as a bridge to a sound and workable program.

The Traffic Institute shared this view; and late in the thirties, it began giving chemical test training both in Evanston and at regional training sessions.

Armed with this background, trainees returned to their home departments where they started routine testing.

The favorable experience of agencies using these methods has whetted the interest of others and encouraged expansion of chemical test work.

Technical, professional advances

The enlargement of interest was fortunately accompanied by improvement and simplification of chemical test procedures.

Devices and instruments perfected in the late thirties enabled police to perform tests that had previously been laboratory specialties. This offered the advantage of immediate results and prompt arraignment of violators in court.

Further and more recent refinements in equipment have made it possible for police to perform speedy on-the-scene tests.

Scientists and technical people have at the same time, been doing important research. They have made extensive studies of the relationships between accidents and blood alcohol levels. They have found that alcohol is an important accident causative factor and they have established that driving ability can be materially impaired by even very small alcoholic concentrations.

Their beliefs and findings are reflected in statements of recent date. The declaration by the scientists at the Indiana Symposium on Alcohol two years ago had marked effect on operating practice and led, in several jurisdictions, to the reduction in permissible test levels.

The publications, reports and the manuals of the scientific groups have helped spread general knowledge and understanding of the tests.

The endorsement by medical and bar associations and those of the Safety Council and leading scientific groups have continued to win respect and support for the tests.

The approval that goes with routine use

of tests in medical and post-mortem examinations has also had beneficial effect.

Enlargement of public understanding

Public interest has, of course, been a primary force in shaping the over-all test program.

The citizenry, speaking as jurors or as complainants in the motor vehicle cases has made known its views on chemical tests.

The doubts and uncertainty that once prevailed have been dispelled by the flood of material that found its way to journals, news bulletins and other types of publications.

Acquaintance with the tests has been extended by discussion and demonstration. Police have been free in exhibiting the apparatus and explaining how it works.

Safety and medical organizations have shown chemical test displays to thousands upon thousands of people.

The education has had perceptible effect. The public, in recent years, has begun to show genuine concern about the drinking driver.

Despite the progress, and it's been considerable over the years, the chemical test movement has never been without difficulty.

Obstacle upon obstacle has beset the path of those endeavoring to advance the cause. Each, however, has been successfully met and the work continues as before.

Police have assisted in the preparation of legislative bills; they have taken part in public hearings and they have tried through the services available to them, to follow the course of the judicial decisions.

This has proved to be a sound approach and the pattern has been followed in state after state with good success.

The enforcement people have been conscious, too, of the dangers of misuse of tests. They have shown active interest in training and have accepted and furthered the idea of having a core of key men

schooling in standard test methods.

This has more than overcome the tendency of ambitious and irresponsible individuals to make exaggerated claims about the tests and test findings.

It has also been necessary, on occasion, to defend the tests against groundless but sensational attack.

Reports have occasionally appeared in the press about individuals who supposedly have found a way to negate or circumvent the tests.

Police and members of the national committee have been quick to respond to these charges and to furnish a true statement of fact.

Probably the greatest problem of all has been to overcome the popular misbeliefs about alcohol and its effects. Only the repeated recounting of instances about drivers with low blood alcohol contents who were killed or injured has had any marked effect in changing the view that drinkers are seldom if ever hurt in motor vehicle accidents.

The thoroughly fallacious theory of improved coordination and complete relaxation on the part of the drinker still commands a surprisingly wide following.

The police, in citing research and personal findings, have been able to do a great deal of good in this area.

As in other dynamic situations there are opposing forces at work in the chemical test field.

Cynics, obstructionists and violators would like to see a relaxation of present controls.

Police, administrators and scientists would like to have them extended to the point where they completely limit and restrict the number of drinking drivers traveling the public roads.

At the moment, the constructive view prevails.

The amount of test usage is on the increase and has been for some time.

(c) TESTING DEVICES

By ROBERT J. BORKENSTEIN
Chairman, Department of Public Administration
Indiana University, Bloomington, Ind.

Chemical tests for intoxication—the analysis of body materials for alcohol level, based on the accepted theory that alcohol is distributed quite uniformly in the water of all parts of the body—have achieved a degree of precision, reliability, and specificity that when properly conducted warrant the confidence of police, courts, and the general public.

The search for an objective and dependable correlate of alcohol impairment began with the advent of the machine and motor age at the turn of the century. The search tended in the direction of analysis of body liquids such as blood and urine for the purpose of diagnosing alcoholic influence.

Literally dozens of laboratory methods have been devised to fulfill varying requirements such as analysis of blood or urine from cadavers, the analysis of urine, blood, or saliva in traffic arrests when immediate results are not required, or the study of alcoholic effect in research problems.

These laboratory analyses of body liquids, while excellent for the stated purposes, are hardly helpful to the police officer who wants to use the results as a factor in making his decision as to how to deal with a drinking driver under investigation.

As the symbol of the impaired driver changes from gross drunkenness to impairment of intellect and judgment, so changes the need for immediate answers as to whether alcohol is present in sufficient quantity to account for the police officer's suspicions.

The breath tests, based on the principle that there is a reliable relationship between the level of alcohol in the blood and in the breath, offer a solution to this problem. Whether the results are used only to tell the investigating officer if he is right in his suspicion or whether the results are used for prosecution purposes, they become an important investigative tool.

A quarter of a century ago the National Safety Council established the National

Safety Council Committee on Tests for Intoxication. This committee remains to this day (now called the Committee on Tests for Alcohol and Drugs) the clearing house for information in this field for the Nation. One of the first actions of the Committee was to formalize the use of both the tests for physical signs of impairment and the chemical tests for alcohol by designing a standard reporting form. Another act of the Committee was to set up standards interpreting the meaning of blood alcohol levels.

The Committee encouraged research in all areas of the problem. With this the search was on for methods.

Even predating the establishment of the Committee, Hesse conducted experiments on human beings, perfecting an analytical method for determining urine and blood alcohol levels.

The apparatus and reagents for this method soon appeared as a package laboratory called "LaMotte Outfit for Determining the Concentration of Alcohol in Blood and Urine." This method is used considerably to this day.

Harger, basing his work on the quantitative excretion of alcohol from the blood into the breath, devised a method of analysis for breath alcohol that met the needs of law enforcement agencies so well that by 1937 his apparatus and method, the Drunkometer, were in routine use by police in many parts of the United States and other countries.

Soon two additional breath methods were described. Greenberg announced the Alcometer, a push-button, photo-electric, automatic, sequence-locked apparatus, and Forester reported the Intoximeter, a portable, sample-collecting test packet that can be used at the scene of an arrest. A preliminary reading is available at the scene to help the police officer make his decision concerning possible arrest. The rest of the packet is designed to be sent to a laboratory for analysis.

Following World War II, the activity

of the Committee on Tests for Intoxication was spurred by a recommendation by the President's Highway Safety Conference. The use of chemical tests for intoxication mushroomed.

Along with these increases in need, acceptance, and usage was considerable technical advance.

New chemical tests for practical law enforcement appeared. Kitagawa of Japan, announced the Drunkotester. It is semi-quantitative, disposable, and not intended to provide evidence-quality results, but rather quick screening results for the police officer's information, as do Grosskopf's Alcotest tubes, made in Germany.

The Breathalyzer, a quantitative photoelectric instrument, was first shown in 1954, followed by Harger's variation of the Drunkometer method using rebreathed air, an analytical simplification.

About three years ago The Photoelectric Intoximeter was announced by Forrester. This instrument is another photoelectric device using two breath samples taken simultaneously, one for an immediate answer and the other for later confirmation.

These are the breath tests to date, and 1961 finds chemical tests for intoxication in use in every state in the Union, according to the reports of the National Safety Council.

The use of breath as a material for chemical analysis has become popular for two reasons. First, the sampling and analytical procedures are so simple that a trained police officer can make reliable analyses. Second, the results are available at the time the police officer needs them . . . shortly after arrest.

The future may hold the adapting of advanced techniques such as gas chromatography or infra-red absorption spectrophotometry to this field. However, the mandate of the breath tests, speed, simplicity, and adequate accuracy, must be maintained, otherwise complexity will neutralize their effectiveness.

The breath methods, each requiring its own kind of maintenance and calibration, will, if used by properly trained operators; backed by professional level expert testimony to satisfactorily explain technology and to interpret the results, yield results that are sufficiently precise, reliable, and specific to deserve the confidence of police officers, the courts, and the public alike.

The need today is for better public understanding of the meaning of the tests and more adequate training for users to increase public and courtroom confidence. This would result in headlines in newspapers and be positive contributions to highway safety.

CHEMICAL TESTS IN DRIVER RESEARCH

By WILLIAM HADDON, JR., M.D.
Dir., Epidemiology Residency Program
New York State Dept. of Health, Albany, N. Y.

It would be impossible in the space available here to discuss or even to list the many ways in which chemical tests for the presence of alcohol have been, are being, and will in the future be used for highway safety research. Such purposes relate to the entire gamut of questions which arise in connection with the uses and misuses of motor vehicles. This follows from the remarkable preponderance of the use of alcohol as a factor in motor vehicle accidents, both fatal and non-fatal.

As a result, the scientific evaluation of almost any other aspect of motor vehicle accident causation requires a determination of the extent of its relationship with the drinking-driving, drinking-accident problem. In view of this, it is noteworthy that in a number of recent, uncontrolled and controlled investigations seeking causes of accidents, this has not been done with even minimum adequacy.

Fundamentally considered, the chemical tests, as they are referred to here, are

merely a tool, a yardstick, available for the measurement of one characteristic of drivers, whether under experimental or non-experimental conditions. There is nothing magical, or unique, about these tests—they have many parallels in related fields, notably in forensic and clinical medicine—and their use requires, regardless of the purpose for which they are employed, the same competence, care and intelligence as do such other analytical procedures; requirements which must be observed for the work in question to be both scientifically acceptable and practically useful.

These tests for alcohol have a necessary role in research concerned with groups of drivers and their accidents for the very same reason that they have a necessary role in the investigation of the accidents of given individuals. This follows from the well-documented fact that except in clear-cut and extreme cases these tests, when properly performed, provide the only reliable yardstick of the presence of alcohol and of its concentrations in the pertinent tissues of the body.

It has been repeatedly demonstrated that competent professional observers will frequently miss even the very presence of alcohol when confronted with a drinking driver, and that their estimates of the blood alcohol concentrations and degree of impairment involved when its presence is recognized frequently under-estimate the actual state of affairs to such an extent as to make such subjective methods largely useless for research purposes.

This would not necessitate the routine application of such tests in field studies of drivers involved in accidents, and of those not so involved where controlled work is done, if it were not for the work of Heise,¹ Smith and Popham,² Lucas *et al.*,³ Barmack and Payne,⁴ Freimuth *et al.*,⁵ Haddon and Bradess,⁶ McCarroll and Haddon and others. These workers have all shown that wherever and whenever the matter has been investigated with objective methods, pertinently high blood alcohol concentrations have been found to be the common denominator of large percentages of drivers in both fatal and non-fatal accidents.

In view of this and, in particular, because of the documented, frequent and substantial unreliability of other methods, (*e.g.*)

it has now become mandatory in field research concerned with eliciting causes of accidents, whether on a case study or scientifically controlled basis, for such tests to be applied in a routine, uniform fashion to very high percentages of all of those studied, whether or not the investigators concerned happen to suspect the presence of alcohol or believe this variable to be of importance in that aspect of the motor vehicle accident problem with which they are concerned. Where this is not done, and the complete practicality of doing so in the case of both fatal and non-fatal accidents has been well established by the same workers referred to above, the biases discussed may be expected to lead to gross underestimations of the extent to which this factor is present in the groups in question. This in turn may be expected to lead to very substantial errors in the relative importance placed on other factors which may also have contributed to the accidents in question.

The scientific adequacy and practical value of any investigation concerned with the field study of the causes of either fatal or non-fatal motor accidents, in which this has not been done, must be, for the reasons cited, most strenuously questioned. This holds regardless of the source involved and regardless of the difficulties, whatever their nature, cited in excuse. Theoretical and practical difficulties are the rule rather than the exception in research, and the ability to overcome them is the measure of scientific adequacy.

The mere fact, however, that such tests are employed in connection with the study of a group of drivers whether accident involved or experimentally studied—for example, in connection with their performance on a driving range—does not in any way guarantee that the work in question deserves to be either described by the word "research" or regarded as worthwhile. In short, the use of this particular tool, or any other, does not in any way absolve those using it from the responsibility of meeting at least the same minimum standards of scientific method customary in other fields of scientific activity. This has long been overlooked, chiefly by non-professional workers, undoubtedly sincerely interested in highway safety, but who appear to labor under the misconception that any process in

which data are collected, particularly in great volume and heavy with anecdote and reasonable sounding detail, automatically thereby ranks as scientific research. This is not the case.

The few dozen workers in the world now engaged in scientifically acceptable research with respect to highway safety are acutely aware of this situation, whether it involves the use of chemical tests or other aspects of highway safety. They are daily deluged with volumes of material: releases, reports, anecdotes, official pronouncements and statistics, speculations and (perhaps) claims of program efficacy, aches and explanations, all of which must be waded through in the hope that an occasional item will prove an exception to the rule that virtually none are worth the paper on which they are printed.

This is not a harmless situation. Much of this volume of material is, probably, dribbled with the vague intent to inform, often by responsible groups which would certainly know better with the result that improvement in the quality of safety research is even further delayed. In addition, the public standing of the profession from which this material is derived, and by which it is endorsed, the confidence with which it is proclaimed, all merely hide the state of our ignorance and the academic poverty upon which these statements are so often based.

If this seems an overstatement of the nature of certain of the forces delaying understanding of the problems of accident causation and prevention, consider the statement of the secretary to a then prominent official of one state after several years of daily concern with this problem:

"The most important thing we found out (about highway safety)," he said, "was that the bulk of the information we were getting from those in the field was the product of the sheerest and most mediocre of speculation and guesswork. Until we found this out, we did not know that our highway safety program was substantially without acceptable scientific or factual foundation."

To a major extent the few years which have elapsed since that statement was made have not diminished the accuracy or pertinence—nationwide—of his comments. (This is particularly true, incidentally, in connection

with the many current proposals and programs to deny driver licenses on medical grounds, since there is now no acceptable evidence that any medical group now known has an accident rate in any way different from that of otherwise similar drivers, or that even if this were the case that such measures would either constitute fair and reasonable measures of social policy or contribute to highway safety to any significant or worthwhile extent.)

It would be too much to hope for improvement in this chronic problem now entering its seventh decade if it were not for the slow but increasing entry into this field of increased numbers of professional research workers well trained in the disciplines which its problems entail, and who are little impressed with the methods and pronouncements still dominant in it. Such workers, together with the small number of scientists long active in the field, have already thoroughly documented the falsity of a number of items in the long established folklore on highway safety. Three examples, two from the subject area of this panel, should suffice to illustrate this, and the hazard inherent in the type of guesswork, subjective opinion and "common sense" on which so much in highway safety is based.

It was long believed by many, for example, that it was advantageous to the occupants of a car involved in a crash to be, as it is customarily phrased, "thrown clear," a belief which has apparently persisted unquestioned, but widely endorsed, for more than a half century. We now know, as the result of the excellent work of the Cornell crash injury research program, that the chance of fatal or other grade of injury is very greatly increased if the car occupant is thrown out of the "package" in which he has been riding. If highway safety experts had only faced up to and pointed out their ignorance of the facts even of this one aspect of the picture when the issue first arose decades past, it is likely that the matter would have been studied and decided before as many thousands were killed in this fashion.

As a second example of the harmful effect of such subjective guesswork and "common sense" as the basis of highway safety policies and pronouncements, consider the seemingly simple problem of the determination of the fraction of fatal ac-

cidents in which alcohol has been used by one of the principals (i.e., drivers and adult pedestrians). At the time four years ago in the Westchester County study of the frequency with which drivers killed in single vehicle fatal accidents had been drinking, a number of the policies and official statements of the state involved were based on an official statistic that alcohol was present only in some two per cent of the state's fatal accidents, a figure totally unsupported by scientifically adequate methods of data collection. The inappropriateness of this figure and its use in policy determination became quickly apparent when at very little cost, and with simple but scientific methods, it was found that for at least eight years the actual percentage of such single vehicle accidents in the large and heavily populated area studied was in reality 70 per cent.

Very similar data have more been obtained on a controlled basis for fatal accidents of one and other types occurring in New York City. Again, another example of the need for having opinion and policy on scientifically derived fact rather than guesswork, and of the harm which can accrue if this is not done.

As a third example, consider the widely believed, but scientifically unsupported folklore, that the very intoxicated driver poses no problem. This belief is nicely indicated by the following from an authoritative text: "It is the slightly intoxicated driver who constitutes the real threat . . . who characteristically demonstrates impairment of judgment more than impairment of sensory functions or psychomotor responses."

The "locked driver" constitutes neither a pedestrian nor a driving problem. Most of these individuals are either too drunk to drive or walk and hence sleep it off . . . Unfortunately, whenever the blood alcohol concentrations of fatally injured drivers have been scientifically analyzed, a relatively simple procedure, a very different picture emerges.

For example, in Baltimore, among 156 drivers killed consecutively in accidents of all types in a five year period, 37 per cent had blood alcohol concentrations of at least 0.15 per cent. Similarly, in Westchester County in the eight years 1950-1957, 49 per cent of drivers killed in single vehicle accidents had blood alcohol concen-

trations meeting or exceeding the liberal *prima facie* definition of intoxication (0.15 per cent by weight) and some, as has been often observed elsewhere, had concentrations which exceeded twice that value.

Finally, in the recently completed comparison of the blood alcohol concentrations of drivers fatally injured in New York City with those of non-accident involved but similarly exposed drivers, 46 per cent of accident responsible drivers had concentrations of 0.25 per cent or higher in comparison with 0 per cent among those similarly exposed, but not involved. These results, although also of significance in many other respects, here emphasizing, again, the need for appropriate methods as opposed to those currently serving in their stead.

These remarks have deliberately been chosen to cover certain of the broader problems of the sources of facts used by those who are either given the serious public responsibility of designing and directing control measures or who as members of the public particularly share the common concern with our continuing tolls of crushed bodies and vehicles. The same general and specific principles apply to research and facts relative to the use of chemical tests, whenever, wherever, and for whatever purpose employed. In the absence of such a foundation there should be a moratorium on statements and conclusions with respect to the subject, public or private.

That this is indicated is shown by the fact that as far as can be determined, there is not now a single United States or foreign jurisdiction reporting adequately collected and analyzed data with respect to the frequency of given blood alcohol concentrations among all principals (i.e., drivers and adult pedestrians) fatally injured in motor vehicle accidents grouped by accident type and length of survival. Until accurate reporting is instituted, it is impossible to measure the impact, if any, of prevention programs. It is even impossible to state the exact magnitude of the problem or to discuss the reasonableness of given proposals for its control.

Since we do not now have such continuing baseline information, we do not now know whether or not we are through our extensive and expensive programs of education and enforcement in any way influencing the occurrence of drinking-driver accidents.

This is not to suggest the discontinuation of these programs nor to suggest that they are unreasonable or without effect. Rather it is to point out that until we begin to use what this symposium refers to as chemical tests in a routine, scientific manner, we will not have any yardstick with which to measure the impact of our programs and the ways in which they can be improved.

No industry with a budget a fraction of that of organized safety would protect year in and year out without a highly sophisticated and carefully designed program of quality control. With respect to the prevalence of the drinking driver and the drinking driver accident, there is at present no such system anywhere in the world today. The time is long overdue.

The minimum requirements for adequate baseline reporting have been spelled out elsewhere in detail.¹ The general requirements in the case of fatal accidents, the area which should be cleaned up first, however, are very straightforward. First of all, it is necessary that a qualified medical examiner system, or its equivalent, be in operation and that the postmortem, blood alcohol concentrations of all of the adult principles (drivers and pedestrians) killed in the given jurisdiction be determined routinely, without exception. This is done at present in very few areas.

Second, post-mortem results derived from those living more than a few hours after their accidents should not be combined with those dying more quickly, since the body's metabolic processes reduce the concentrations of alcohol in such cases the longer the post-accident antemortem survival. This is but rarely done in the handling of such data.

Third, it is essential, a point almost universally overlooked, that the results be reported not as a hodge-podge derived from accidents of all different types, but rather, in terms of clearly defined, discrete accident categories. For example, it makes little sense to include the alcohol concentration, if any, of a driver killed while stopped at a stoplight with that of one killed by hitting a bridge abutment.

It is a relatively simple matter to divide accidents into one group in which the driver or his vehicle was probably responsible and a second, in which he and his vehicle were

clearly not responsible or less obviously so. In the former group fall drivers killed in accidents in which only their own vehicles are in motion and drivers killed in hitting other drivers in situations which leave little doubt as to their responsibility. An example of the latter is the driver who completely crosses the median strip on a divided highway and is killed in hitting an innocent car head on.

In the second category, composed of questionably responsible and non-responsible drivers, fall those killed either through no fault of their own or under circumstances in which responsibility is unclear. When these measures in the collection and analysis of data are instituted, a very different picture as to the alcohol concentrations of accident responsible drivers may be expected to emerge than that frequently given by official statistics.

Reference has already been made to the recent New York City work, one of the very small number of investigations in which these requirements of adequate data collection and analysis have been observed. That investigation demonstrated, as had the earlier Westchester County work the complete practicality and usefulness of adopting such long overdue methods. The organized highway safety profession will not be able, again, to measure with any degree of adequacy the pertinence and efficacy of its programs in this area until similar methods of data collection and analysis are adopted nationwide.

When this is done, it will be discovered as has already been the case in some areas, that there is often something very wrong with the ways in which accident data are now being collected and employed in justification of safety measures. This should not in any way pose a threat to those sincerely interested in the alleviation of the burdens which now result from our annual tolls of highway fatalities and injuries. The agencies responsible for highway safety have thereby a responsibility to supply this information. The applied research involved is straight-forward and relatively simple, and these results are at present more needed than those of any other simple type of research which involves the use of chemical tests: the subject of this symposium.

There is no reason why the immediate

future should not see the substitution of fact for the present over-abundance of opinion and guesswork in this as in the entire arena of highway safety. To the extent to which this is not done, extensive and expensive programs said to be pertinent to the saving of thousands of lives and the prevention of the maiming of millions more will continue to lack a rational, factual and scientifically defensible foundation.

JOINT SESSION WITH HOME SAFETY TRAFFIC SAFETY AND DRIVING SIMULATION

By SLADE HULBERT

Asst. Research Psychologist, Institute of Transportation and Traffic Engineering
University of California, Los Angeles, Calif.

It would be worthwhile at the outset to say what is meant by driving simulation (which is accomplished by a driving simulator). It means that a driver is placed in an automobile in a laboratory. He is then surrounded with a potential driving environment and upon commencing to drive he sees pictures, hears sounds and feels physical forces all of which are as realistic as is necessary for the particular study.

Essentially what it amounts to is that this fellow is pretending to drive but he is actually standing still; his reactions can be observed in detail. It also enables duplication of the exact highway situation for many subjects; that is to say, the same series of traffic events can be presented to a hundred people thus getting a statistical measure of what a hundred drivers do when faced with one set of traffic circumstances.

In addition to the ability to repeat identical situations, it also is possible to present traffic conditions that would be too hazardous or too costly for field experimentation on the road. The simulator also enables isolation of a single variable by holding all conditions constant except the one to be studied.

A national conference on driving simulation was held last March in Los Angeles under the sponsorship of the Automotive Safety Foundation, the U. S. Bureau of Public Roads, and the U. S. Public Health Service. Participants included engineers, highway administrators, scientists, and educators. There were representatives of industry, government, universities, safety organizations and research institutes.

The conference report¹ included on page 16 the following: "Driving simulation has been defined. Its role in highway safety research has been suggested, its benefits and limitations put into perspective. The assessment makes clear that new and useful

techniques are available for experimental research which can contribute importantly to safer highway transportation.

"Ultimately, a step-by-step development of increasingly complex simulators offers promise of new and urgently needed information on the functioning of the vehicle-driver-road system. This could lead to a major break-through in the program to increase traffic safety."

Simulators range in cost and complexity from million dollar flight trainers for jet pilots on down to devices that can be purchased for less than a thousand dollars to train high school students to drive. For research uses, the cost is dictated by the behavior to be studied. Complex traffic situations will require complex simulators; however, the cost will be more than balanced by savings in lives, insurance, repair charges, and time, as we put research results into practice.

The need for creating driving simulation research facilities was pointed out in the Williamsburg Conference Report in 1959. In a recent publication of the Special Committee on Highway Research Priorities of the Highway Research Board of the National Research Council, the driving simulator was included among the "19 broad areas of highway research, each of which is adjudged to rate A-1 in importance and urgency."

We believe that important advances may result from laboratory and field research into problems arising in driver licensing, highway design, vehicle design, traffic engineering control, and law enforcement and education. Driver reactions and habits play a large roll in all of these fields and to that extent they can benefit from driving simulation laboratory research and evaluation studies. At this time, by way of example, I shall discuss only three promising types of investigation: fatigue, aging, and

experience. Each is representative of a different type of study.

*Fatigue*² can be generally defined as a mental and physical condition of decreasing efficiency from which full recovery is possible. Some characteristics of importance for research are:

1. The act of measuring can drastically alter the condition.
2. The condition is likely to be irregular over time and specific to sub-tasks.
3. The experimenter must control environments and direct behavior in order to produce the condition.
4. All drivers can be affected by the condition.

I suggest that these characteristics also describe the following conditions:

- A. Effects of some ingested chemicals, such as drugs, alcohol, food, etc., excluding irreversible effects, e.g., poisons.
- B. Emotional states, such as anger, despair, frustration, etc.

These conditions represent research interests that today are somewhat diverse, each with its devoted group of investigators. If there are the common characteristics suggested above, and because of this a consolidated research effort can be mounted using driving simulators as a general tool, it might herald a number of simultaneous breakthroughs in previously unrelated areas.

Even if the driving simulator laboratory approach only serves to bring these researchers together, it will be worth the expenditure in terms of the interdisciplinary mental cross-fertilization that can result. I have yet to talk with a researcher interested in human behavior who did not become enthusiastic over the possibilities of doing his research within a simulation laboratory.

*Driving*³ can be generally described as a gradual process of organic change eventually resulting in irreversible impairments to function.

Research characteristics are:

1. The act of measuring has little if any effect on the condition.
2. The behavioral effect is likely to be consistent and predictable and resistant to change.
3. The condition must be investigated as

it is found in various individuals and groups of drivers; it is not subject to experimental manipulation.

These research characteristics apply at least in part to the following:

- A. Physical disabilities, sensory and motor.
- B. Mental disabilities, such as emotionalism, rigidity, persecution feelings, etc.

Experience in this context refers to exposure to a series of critical driving situations which affect subsequent driving behavior. Learning through experience provides driving training for the bulk of our population.

Research characteristics are:

1. The act of experiencing greatly effects responses to subsequent exposures of identical events.
2. Past exposures are difficult to determine and evaluate.
3. Some experiences terminate the drive.
4. Experiences can be vicarious in nature.
5. Negative transfer must be evaluated.

Research into the learning process as it continually occurs on our highways can result in more effective programs of public education and implement a positive approach of guidance to replace the current practice of scolding and punishment.

All three types of human factors exemplified by fatigue, aging, and experience lend themselves to vigorous and fruitful investigation in driving simulation laboratories. If science can discover what exactly happens to the abilities of the temporarily incapacitated, and the disabled and just how it is that drivers are learning to survive, a wealth of remedial efforts can be launched to offset the traffic toll.

Progress to Date

The simulation techniques that have been used so far at the University of California at Los Angeles are built around the showing of movies that were taken from cars moving on the highway. This work, on a limited scale, was initiated in 1948 by J. H. Mathewson and has resulted in a series of Institute studies of the human factors in highway transportation. Some simple task simulation techniques were developed and

cific areas of standardization. The subcommittee titles included general medicine, cardio-vascular diseases, neurological disorders, visual standards, auditory standards, orthopedic standards, mental health and drug and chemical aspects. These titles were similar to those used by a Symposium on Medical Aspects of Motor Vehicle Accident Prevention held in December, 1956, by the New York University—Bellevue Medical Center and the Center for Safety Education of New York University.

Using all available studies they could obtain, these committees reported a year later to the Board of Trustees of the medical society, which then accepted the report. The report was forwarded to the Secretary of Health and to the Governor's Traffic Safety Council. The Secretary of Health served as a liaison person between the medical society and the Secretary of Revenue. The Pennsylvania Optometric Association had submitted a somewhat different set of standards for visual testing, but one meeting between the committee of that association and the medical committee on visual standards quickly resolved the differences in favor of the standards set by the committee of ophthalmologists. The standards were then approved in principle by the Governor's Traffic Safety Council. They were later accepted by the Governor and the Secretary of Revenue, and after a tooling up period, put into effect a little over a year ago.

Last there be any thought that these standards might be considered final or unequivocal, there is hereby quoted from the introduction of the prepared driver standards the following: "Because of the sparsity and unreliability of statistical data, the standards which follow are based on an armchair analysis. Since automobile transportation is such an important economic factor, the emphasis is on restricting rather than revoking licenses. A functional approach has been attempted wherever possible. The diagnostic entity is important in predicting progression and recurrence of signs and symptoms."

It was further pointed out that because the periodicity of the examination of drivers is an important factor which must be considered from an ideal and practical standpoint, the report recommended that the examination be given all drivers on initial

application and re-examinations given at ages 30, 40, 50, 60, 65 and every five years thereafter. Periodic examination is still our aim, but it will take several years to get the initial examination of the five and a half million licensed drivers in Pennsylvania and to definitely establish the periodicity of examinations. In fact, we estimate that at the rate of 15,000 examinations per week, it will take seven and a half years to cover all of Pennsylvania's drivers.

Considering the importance of the human factors in driving safely and how lethal the modern vehicle is, today's driver unquestionably should be in a physical and mental condition which is not a severe hazard to himself and to his fellowmen. For many years, the Pennsylvania law concerned with driver licenses has had a general clause requiring the licensee to be free of any disorder which might prevent him from properly driving an automobile. Licenses have been removed, suspended or given on a restricted basis upon decision of the Bureau of Traffic Safety of the Department of Revenue that the individual was incapable of properly handling an automobile. The Bureau, however, had no well-defined medical standards for making its decision until the present ones were established.

A number of case histories of severe accidents clearly indicated the dangers to life and limb caused by drivers suffering from severe physical and mental disorders. In one instance, an individual was on the blind pension payroll and was operating a light truck, with his steering being directed by a child sitting between his legs. He was, not surprisingly, involved in a fatal crash.

In another instance, a truck driver hauling gasoline on a tractor-trailer truck was involved in seven or eight accidents before it was discovered that these accidents were caused by convulsive seizures. Not long ago, a mentally disturbed young man who had some psychiatric treatment drove east in the west bound lane on one of the high speed highways of the state for about 40 miles. Although it was night, he turned off his lights and drove at speeds of 90 to 100 miles per hour. He was killed when his car crashed into a roadblock the police had thrown across the highway. In

other instances, before the required examination for drivers went into effect, individuals were sporadically prohibited from driving because of reports sent in by practicing physicians.

The standards approved by the medical society and others concerned were condensed into categories or disqualifying groups which are listed on an IBM punch card for the purposes of simplicity, identity and ease of mailing, filing and tabulating. As listed on the card, disqualifying factors include the loss of use of both hands; 20/70 vision or less in the better eye with correction; neurological disorders, such as to prevent responsible control of a motor vehicle; any cardio-vascular disorder, including hypertension, such as to prevent control of a motor vehicle; neuropsychiatric disorders such as to prevent control of a motor vehicle; conditions causing lapses of consciousness, e.g., epilepsy, narcolepsy, hysteria, etc. (may be considered for licensure if episode free for two years with or without medication); alcoholism, addiction to narcotics; and uncontrolled diabetes.

Inasmuch as the Pennsylvania State Police has for many years been charged with the responsibility for visual acuity tests and were equipped with instruments and testing areas, it was decided that the visual testing and the testing for the loss of use of both hands would be done by the State Police. Thus, the individual who is to be tested first takes these two tests from a state policeman and then takes his testing card to a physician of his choice. He is encouraged to use his family physician for this purpose, since in some conditions, the medical history is a pertinent factor, but the individual makes the final choice as to his examining physician. The physician then mails the completed form directly to the Bureau of Traffic Safety of the Department of Revenue.

Prior to the initiation of the physical examination program for drivers, each physician in Pennsylvania was furnished by the State Health Department with a copy of the American Medical Association pamphlet "Medical Guide for Physicians in Determining Fitness to Drive a Motor Vehicle" as well as a short guide specifically concerned with completing the examination form.

Results of First Year of Operation

As of the first of June of 1961, this program had been in operation for a year. Like other large, new programs, this one started slowly and had a few difficulties at its inception, but is gaining momentum. The State Police have a limited number of persons and facilities for the examinations. It was therefore decided that for the first six months, only those newly applying for drivers licenses would be examined. It had been hoped that the next to be examined would be drivers licensed before 1924, a time when no examination whatsoever was required for obtaining a license; but, unfortunately, a flood in 1936 in Harrisburg destroyed or ruined a number of record files, so that this was not possible. Consequently, since the beginning of 1961, driver names have been selected at random for examination. In addition, all persons driving automobiles on state business have been required to be examined.

The physicians of Pennsylvania have cooperated extensively in promoting this program. At first, there was some fear on the part of a number of physicians about their legal liability in case an individual who had been examined had an injury-causing accident. However, the Attorney General of the Commonwealth has quieted these fears by an opinion which stated that the physician's responsibility as to the condition of the individual applied only to the individual's condition at the time of the examination and to those elements included in the examination. Furthermore, the legal department of the American Medical Association has stated that for the physician to be held liable, it is necessary to show:

(1) he was guilty of negligence in conducting the examination or in reporting his findings to the state; (2) that the negligent act was the primary cause of injury or accident; and (3) that damages resulting from the negligence were foreseeable, since an injury which cannot be foreseen, or reasonably anticipated as the result of negligence is not actionable. The decision is to whether an individual receives a renewal of his driving permit, receives a limited permit, or has his permit suspended or revoked rests with the Secretary of Revenue, so that the legal decision is made not by the physician doing the examination.

program activities as shown in the annual traffic inventory. Of the eight major states in the group in which Pennsylvania falls, Pennsylvania was the only state to receive such an award. The fact that Pennsylvania has the lowest rate here is, of course, not necessarily tied in with the driver examination program nor even necessarily the result of the thirteen-point improved traffic safety program inaugurated in February of 1960.

Of these thirteen points, the only one other than the medical examination program which might be considered in the health field is an educational program to encourage the use of chemical testing for intoxication. It is interesting to note in this respect that a survey by the State Police to determine the attitude of judges and district attorneys in the 67 counties of the Commonwealth on this matter indicated that in 55 counties there was favorable reaction toward chemical testing, but in the remaining 12 counties the authorities involved were either indifferent or against chemical testing. The 1961 session of the Pennsylvania Legislature passed a state-wide chemical testing law. As passed, it is a much weakened version of the original bill, using 0.15 per cent by weight in the blood as presumptive of intoxication instead of the recommended 0.10 per cent, and requiring specific consent of the driver for the testing rather than the recommended implied consent.

Pennsylvania is pioneering in an attempt to remove from behind the steering wheels of its automobiles, drivers with handicaps so severe as to make them, in the best of medical judgment, hazardous to themselves and in other individuals. The comparatively low percentage of rejections encountered among the 422,000 persons examined during the first year indicates that not many individuals are losing their driving privileges because of this examination requirement. We feel that the driving license is a privilege. In some respects it may be considered a right of an individual, but one individual's rights end where the other one's begin and therefore because of society's right to determine various types of licensure, the term privilege might be the best one to use.

Case histories, not only in Pennsylvania but elsewhere, have shown individuals with

the types of disorders used for rejections in Pennsylvania to be dangerous drivers in many instances. While we cannot, without more specific research data, such as some obtained by studies by McFarland in Boston, Goldberg in Sweden, Popham in Toronto and McCerroll and Haddon in New York City, adequately predict the number of severe or fatal accidents which will be prevented by removing such hazardous drivers from our highways, the "functional approach" as it is called by the medical society's committee, seems to be justified and reasonable.

It might be pointed out that this type of reasoning is behind many traffic accident preventive measures and many public health measures. The number of lives or disabilities saved by a traffic light at a given corner, by an unbroken white line in the middle of the road on a given hill, by the installation of a sewage treatment plant or by an air pollution abatement program cannot be well documented, but from the case history approach and in some cases from years of experience, (but experience which would not have been attained had ultimate, definitive cause and effect research been allowed to delay application) we continue to vigorously encourage and support these preventive measures.

It is to be hoped that the findings of the medical examination program in Pennsylvania will provide useful data to other parts of the nation in their evaluation of this aspect of working with human behavior factors of traffic accidents, the most important causative factor involved. It is believed that as the general public becomes more aware of the gravity of the problem, persons in ever-increasing numbers will turn to their physicians for advice and assistance in this field. Although the role of the physician in making decisions in this regard is not always an easy one, it is hoped that more and more physicians will accept this responsibility as a part of their role and duty and will realize how vital to the saving of lives and the prevention of injuries is an honest, critical evaluation of the driver.

Much more detailed consideration needs to be given to the age component for the major chronic disabilities of our people increase considerably as they get into the older age brackets. Pennsylvania has not yet completely decided on the periodicity of its ex-

aminations, but as has been pointed out by the medical society study, this component must be seriously faced and a decision made before long.

An important auxiliary benefit of the examination program is the uncovering of a number of cases of heart diseases and other disabilities of a chronic nature, often unknown to the individuals involved. Such conditions are being discovered on a rather large scale, and individuals with these conditions are receiving earlier treatment and subsequently have a better chance of preventing death or disability from them than would have been the case without early discovery due to the examination program.

The Governor's Traffic Safety Council, the Commissioner of Traffic Safety and the Department of Health feel that a further constructive step in driver safety would be a requirement that taxicab, bus, truck and other commercial vehicle drivers have a more frequent and a more rigid physical examination than the one currently in use for all drivers. Bills have been introduced into the state legislature along this line but none has, as yet, been enacted.

Summary

1. Since the behavior of human beings seems to be the most important factor involved in causation of traffic accidents, physicians and health departments should play a major role in helping to reduce traffic mortality and morbidity by focusing their time and efforts towards solving the problems of the physical and mental behavioral components that lead to accidents.

2. In the Commonwealth of Pennsylvania one point of a thirteen-point traffic safety program inaugurated by the Governor at the beginning of 1960 has been a medical examination for all individuals obtaining new driver licenses or renewing driver licenses. The compilation of this program took three years before it was actually put into effect. During this period of compilation, the Pennsylvania Medical Society, the Pennsylvania Department of Health and the Governor's Traffic Safety Council worked

together to devise a program of driver examination which would remove drivers who, by reason of severe handicaps, could be considered to be especially dangerous drivers.

3. The results of the first year of application of the physical examination of drivers program are reported. Of 421,837 learners and re-examined drivers, 0.14 per cent were rejected as being unfit to drive in accordance with the established criteria. By age, percentage of failures ran from 0.05 per cent in the 21 to 30 age group to 0.79 per cent in the 61 and over age group. Of this group of failures, there were 133 individuals who voluntarily surrendered their licenses because they felt they would be unable to pass the examination and so notified the Bureau of Highway Safety. In addition, a house-to-house survey of 978 applicants who failed to take the physical re-examination after notification found 130 to have failed to take the examination because they felt they could not pass it. This latter group had not officially notified the Bureau of Highway Safety.

4. Heart diseases and other disabilities of a chronic nature are being discovered due to the mass examination of drivers and potential drivers. Individuals with these conditions are thus enabled to receive earlier treatment than would have been the case without such screening examinations.

5. It is felt that in consideration of the marked increase in severe chronic disabilities in the older age groups, the examinations will need to be given on a periodic basis, although this periodicity has not yet been determined. The medical society's study recommends that examinations be repeated at ten-year intervals to age 60 and at five-year intervals thereafter.

6. It would seem to be desirable for drivers who spend much of their time on the road as commercial drivers of such vehicles as taxicabs, buses and trucks to have a more frequent and a more rigid physical examination than the one now required for all drivers.

The performance of the 167 rescuers was as follows: of the untrained rescuers, 90 per cent were able to produce tidal respiratory volumes above 300 cc's within one minute by the first variation of the mouth-to-mouth technique, and 89 per cent were successful in the same task with the second variation. By the mouth-to-airway technique, 100 per cent were successful, 50 per cent were successful with the mouth-to-nose technique, all within 60 seconds.

Of the trained rescuers using the back-pressure, arm-lift method (Holger Nielsen) under the same conditions, only 14 per cent were able to produce tidal volumes above 300 cc's within 60 seconds with that method and with the addition of an artificial oropharyngeal airway, 39 per cent were successful. Using a chest-pressure, arm-lift method (Sylvester) alone, 31 per cent were successful, and with the same method and an artificial oropharyngeal airway, 50 per cent were successful.

Thus, it can be seen that under these conditions, the mouth-to-mouth technique in the hands of untrained rescuers with minimum instruction was much more frequently successful than the back- and chest-pressure and arm-lift methods in the hands of trained rescuers.

What is the reason for the success of the mouth-to-mouth technique in this comparative study? I think that the essential difference is in the position of the head and neck, and jaw, of the victim in the mouth-to-mouth technique, in extension, by which the air passageway to the lungs is kept open; whereas with the back- and chest-pressure and arm-lift methods, this position of the head and jaw in extension cannot be maintained by the rescuer, who must devote his full attention to applying the pressure. The tendency of the tongue and jaw muscles in the relaxed, paralyzed position of the victim is to collapse, thus blocking the airway unless the head and jaw are extended, even with the insertion of an artificial oropharyngeal device.

The preceding points are illustrated by the following study on 80 anesthetized women, also done by Safar and his colleagues. These women were breathing normally and spontaneously, but their jaw and neck muscles were relaxed by the influence of the anesthetic. In other words,

they were asleep as during an operation (light, general anesthesia, stage 3, plane 1-2).

The airway of these patients was recorded as being open when the anesthesia-machine breathing bag was moving freely and there was no noise in breathing. The airway was recorded as being partially obstructed when the bag was moving but there was noisy breathing. The airway was recorded as being obstructed when the breathing bag was not moving and no air exchange could be heard despite respiratory motion of the patient's chest and abdomen.

In the supine position (lying on back) with the head flexed and the chin down, 100 per cent had an obstructed airway, and even with an artificial oropharyngeal airway, 98 per cent were still obstructed and 2 per cent partially obstructed. With the head in mid-position between flexion and extension, 36 per cent were obstructed in natural breathing and 54 per cent partially obstructed, and only 10 per cent had an open airway. With an artificial oropharyngeal airway inserted, 29 per cent were still obstructed, 51 per cent partially obstructed, and 20 per cent had an open airway.

In the extended position of the head, with the chin up, 5 per cent had an obstructed airway, 46 per cent had a partially obstructed airway, and 49 per cent had an open airway. With an artificial oropharyngeal airway, none were obstructed, 12 per cent partially obstructed, and 88 per cent had an open airway. With extension plus support of the jaw in a forward position, with natural breathing, 1 per cent were obstructed, 21 per cent partially obstructed, and 78 per cent open.

With an artificial oropharyngeal airway, none were obstructed, 2 per cent partially obstructed, and 98 per cent had an open airway. A similar incidence of airway obstruction was found with the patients in the prone position (lying on the stomach), both with the face directly downward, and with the face to the side, as in the usual back-pressure, arm-lift method.

I think that the preceding study corrects a number of popular misconceptions. To quote Safar, "It is a common belief that airway obstruction due to 'swallowing of the tongue' is prevented by the patient in the prone position. Our data and roentgen-

grams (x-rays) indicate that in the prone position the tongue does not simply 'fall forward' but rather that the site, mechanism, incidence, and degree of pharyngeal obstruction is similar in the prone as in the supine position.

"The thought that foreign matter such as vomitus or water would drain from the mouth by gravity provided another basis for the recommendation of the prone position in the past. In actual resuscitation, we often found semisolid vomitus and other foreign matter which did not 'drain'. Water and mucus formed foam could only be removed by wiping out or by the use of a suction machine. Drainage of foreign matter from the lungs in the prone position is as unlikely as in the supine position since the trachea is horizontal in both."

The performance of artificial resuscitation on the unconscious infant has long been a matter of considerable difficulty. The reasons are in part anatomical. Not only are the infant's ribs and chest softer, but the ribs are in a different position than in the adult, extending more directly forward from the spinal column. For this reason, the infant's breathing is more completely due to diaphragm motion than the adult's breathing.

The chest- and back-pressure and arm-lift methods of artificial respiration are intended to produce movement of the chest wall, but such movement as is produced is often negated by the contrary motion of the relaxed, flaccid diaphragm which moves back and forth instead of air moving in and out of the lungs.

This is, of course, not true in the normal conscious person, in whom the diaphragm is contracted and tends to move with, rather than against, the respiratory motion produced by chestwall expansion and contraction. Suffice it to say, in infants, methods to overcome the special problems they present, such as the rocking method (Eve), have been shown to be relatively unsuccessful; and the only method which

can be relied on to successfully produce sufficient air movement in and out of the infant is the mouth-to-mouth technique.

Detailed studies of the oxygenated hemoglobin and carbon dioxide levels in simulated victims' blood have shown that these are maintained within or close to normal limits, and that they are rapidly attained when the mouth-to-mouth technique is started. Additional advantages of the technique are the fact that additional pressure can be exerted, by forced expiration on the part of the rescuer to overcome partial obstruction of the airway that may exist despite the most skillful effort, due to the anatomy, the presence of excessive obesity, or other peculiar conditions existing in the victim which would preclude success by any other method of artificial respiration.

Large differences in the size of the rescuer and the victim are easily offset, and boys and small women have been successful at resuscitating victims twice their size. Mouth-to-mouth breathing can be done for over an hour by the untrained rescuer without excessive fatigue; this has been demonstrated a number of times.

Due to the advantages of the mouth-to-mouth technique of artificial respiration which have been detailed above, the National Academy of Sciences—National Research Council's Ad Hoc Panel on Manual Methods of Artificial Respiration—unanimously recommended this technique. Subsequently, the American National Red Cross, the several departments of the Armed Forces, the Public Health Service, and numerous other organizations adopted the mouth-to-mouth technique as the method of choice.

Case histories of many successful resuscitations performed by laymen with this method demonstrated that it is readily acceptable, easily learned, and has been, on a number of occasions, successfully applied without previous practice in the method by the rescuer.

OFFICERS OF THE

TRAFFIC CONFERENCE

NATIONAL SAFETY COUNCIL 1961-62

Vice President for Traffic—REX M. WHITTON, Federal Highway Administrator, Bureau of Public Roads, Washington, D. C.

Chairman—RICHARD O. BENNETT, Secretary-Treasurer, Insurance Institute for Highway Safety, Washington, D. C.

Vice Chairman—GORDON H. SHEEHAN, Professor, Michigan State University, East Lansing, Mich.

Executive Secretary—HARRY PORTER, JR., Manager, Traffic Department, National Safety Council, Chicago, Ill.

Executive Committee—RALPH R. BARTELSMEYER, Chief Highway Engineer, Illinois Division of Highways, Springfield, Ill.; J. W. BETHA, Executive Secretary, President's Committee for Traffic Safety, Washington, D. C.; RUSSELL I. BROWN, President, Insurance Institute for Highway Safety, Washington, D. C.; BERNARD R. CALDWELL, Director, The Traffic Institute, Northwestern University, Evanston, Ill.; J. J. CAVANAGH, President, Chicago Motor Club, Chicago, Ill.; BRYAN CRIMFIELD, Executive Director, The Council of State Governments, Chicago, Ill.; M. R. DARLINGTON, JR., Managing Director, Auto Industries Highway Safety Committee, Washington, D. C.; GEORGE M. DEMPSEY, Assistant Superintendent of Safety, Chicago, Milwaukee, St. Paul and Pacific Railroad, Chicago, Ill.; A. H. EASTON, Professor, Civil and Mechanical Engineering, University of Wisconsin, Madison, Wis.; JAMES P. ECONOMOS, Director, Traffic Court Program, American Bar Association, Chicago, Ill.; FRANK FLICK, President, Flick-Reedy Corp., Bensenville, Ill.; ROBERT B. FORNEY, Associate Professor of Toxicology, Indiana University School of Medicine, Indianapolis, Ind.; E. H. HOLMES, Director of Planning, Bureau of Public Roads, U. S. Department of Commerce, Washington, D. C.; DWIGHT M. McCracken, Vice President, General Manager Loss Prevention, Liberty Mutual Insurance Co., Boston, Mass.; BURTOS W. MARSH, Director, Traffic Engineering and Safety Department, American Automobile Association, Washington, D. C.; ELEAN E. OLNSTEAD, Traffic Engineer, Chicago Transit Authority, Chicago, Ill.; KARL M. RICHARDS, Manager, Field Services Department, Automobile Manufacturers Association, Detroit, Mich.; MATTHEW C. SZELSKI, Director, Safety and Traffic Engineering Department, Chicago Motor Club, Chicago, Ill.; JOHN E. SMILEY, Traffic Consultant, Insurance Institute for Highway Safety, Washington, D. C.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

YOU CAN'T TRAIN SUPERVISORS

By LOUIS B. HOELSCHER
Safety Director, Weyerhaeuser Co., Tacoma, Wash.

We don't train our supervisors; we don't believe that we can train our supervisors. We do believe that if we provide the climate, if we provide the tools, and if we provide the information, a supervisor can develop himself.

To put each of us on the same level of understanding, we ought to clarify what we mean by the word "training." Most people think of training in terms of teaching or using an imaginary funnel to pour knowledge into a supervisor's head. We view it in a different perspective.

Training, as we apply it, can be defined as the clarification and development of thinking and putting that thinking to use.

Even though I say that we cannot train supervisors, I will use the word "training" for lack of another word that communicates this process to other people.

I would like to review with you one phase of our supervisory training as it applies to safety; this one phase is the basis for most of the things we do or should do in supervisory safety training. We call this phase a Duties and Responsibilities Program. The program is based on the assumption that most supervisors do not know specifically what is expected of them. They are told that they are responsible for safety, but they do not know what this entails or what it means. They do not know how far their authority and responsibility in safety reaches.

How does the program work? We call in a homogeneous group of supervisors, sit down with them on a discussion basis and develop and clarify their duties and responsibilities. First we use a master list of major areas of possible duties and responsibilities and get agreement from this group of supervisors that these, part of these, and/or other areas are the areas in safety where they have or should have responsibility. (Attachment "A.")

When we have reached agreement upon the areas of responsibilities, we break down each area into specific duties and responsibilities; for example, one area in which the group feels they have duties and responsibilities may be accident investigation. We then develop and clarify with each group of supervisors the specific duties and responsibilities they have in this area of investigation. Through discussion, the group develops a list similar in content to Attachment "B," but much longer in length.

This list is then checked by their boss, who either agrees or disagrees with the individual points. If he disagrees with any of the points on the list, the group is called back into a meeting and the boss interprets to them why he feels this is not a duty and responsibility of theirs. Once the group knows the "why," they generally will accept the boss's decision. The group also has the opportunity to express the reasons why they feel it should be their duty and responsibility and through this process, have changed the boss's thinking. The same process is followed if the boss feels the group has omitted a duty and responsibility.

I know one of the questions raised in your minds is, "Why do all that? Our foremen know their duties and responsibilities; they know what management expects of them."

Some of our management people felt the same way, but let me give you an example of what actually happened in one operation. With one group of supervisors we developed 67 duties and responsibilities in safety. Without giving their boss an opportunity to review their list, we asked him to develop what he thought the duties and responsibilities of the supervisors in the group should be. He came up with a list of 31. The surprising thing, to us, was that only 14 items were on both lists.

Another question you might have is, "Why can't the boss sit down and write out the responsibilities for his subordinates?" First,

in our organization, we found that none of our bosses had a halo around their head—they didn't have all the answers. They just didn't know what should be all of the specific duties and responsibilities of their subordinates, and the example I just quoted bears this out.

Secondly, the big advantage to having the group of supervisors develop their own duties and responsibilities is that, through discussion, each member of the group has a chance to gain a better understanding of why this particular duty and responsibility is theirs and why they should carry it out.

For example, a specific duty and responsibility in the area of accident investigation might be to determine the real cause of the accident. The group leader's job is to get the group to clarify through discussion the question, "Why is it important to determine the real cause of the accident?"

During the discussion the inexperienced man in the group listens to the old hands and gains experience from them. The old hand has to listen to the ideas of his fellow supervisors and gains from their experiences. The inexperienced man many times injects new ideas which help add to the know-how of the old hands. The results we seek from these discussions can be stated in one sentence:

"People will always support that which they helped to create."

You may also ask the question, "Why do all this when we have job descriptions?"

This is my answer. Our company has one of the best programs of job descriptions in industry, but job descriptions have one drawback. A job description does not give a comprehensive outline of supervisory responsibilities for specific areas such as is outlined in Attachment "B"; nor does it provide a vehicle for carrying out other phases of the program, one of which I will review next.

We do know that developing the lists of duties and responsibilities is effective and fruitful. We also know that there is as much or more value in using the list for other purposes.

The list can be used to spot the "weak points" of an individual or the "weak spots" of an organization.

For example, we can take the list and evaluate each man's performance against each specific duty and responsibility.

For example, under the area of Logging Side (Attachment "B"), the supervisor can ask himself these specific questions of his subordinates: "Does the foreman pick out safe landings?" "Does he see that the jammer is properly and safely set up?" With each point he can ask similar questions and check whether the man is O.K. or needs help.

If the foreman needs help, the boss can call him in and review with him the lists of duties and responsibilities. The boss can then point out his weak points and talk to him in terms of how to do a better job; talk to him in terms of what problems he is having which prevent him from doing a better job in this area; talk to him in terms of what the boss, the safety supervisor, or the training supervisor can do to help him do a better job. Through this process we provide a climate by and through which the supervisor, in effect, sets up his own training program to help develop himself.

As a result of the individual evaluations, it might become apparent that a majority of the management people are weak in one specific area. For example, by evaluating each individual, the results may show that the group as a whole is weak in the area of accident investigation. With this information, the boss may want to set up group sessions on how to do a better job in accident investigation.

We base these sessions once again upon group discussions and supplement the supervisor's present knowledge with technical background and information with which they are not familiar and which will help them to do a better job of investigation. There are other phases of the program which the lack of time does not permit me to review with you.

Our method is based upon a principle that other levels of management, including staff, will fulfill their role best by insuring that the supervisor is provided with the climate, the tools and assistance, and the information necessary to inspire the wholehearted and constant interest and support of the crew. In our enthusiasm to promote a specific safety program it is very easy to detour around front line management. For example, is it better to publish a beautifully done brochure for safety induction purposes, or is it better to train the foreman to do the job? The first is the easiest and the trap many of us fall into. The supervisor must be helped

Wood Products Section

to do the job in safety rather than the safety man doing it for him.

Although we believe you can't train supervisors, we do believe we must provide the climate, the tools, and the information that will help him to develop himself.

ATTACHMENT "A" Woods — Safety

16. Log Transportation
17. Road Maintenance
18. Road Construction
19. Use and Handling of Powders
20. Machinery and Equipment
21. Log Dump and Rafting

ATTACHMENT "B" Duties and Responsibilities of Side Rod in Safety

LOGGING SITE

1. Pick out as safe a landing as possible
2. See that jammer is properly and safely set up.
3. Establish ground rules and instruct men in commands of landing.
4. Have dangerous trees and snags felled around landing.
5. Place men properly (put the right man in the right job insofar as possible.)
7. See that there is a safe disposition of the crew in the woods.

8. Decide when weather is too hazardous to work in when camp foreman is not present to make the decision.
9. Maintain as safe working conditions as possible.
10. See that visitors are standing in safe place.

IN CASE OF INJURY

1. Know first aid and be able to use it.
2. Decide whether an injured man is capable of continuing work or should receive medical attention and arrange immediate transportation in the latter case.
3. Properly equip injured person for transportation and send attendant with him.
4. Get rest of crew back to their own work and out of the way as soon as possible.
5. Replace first aid materials and stretcher used as soon as possible.
6. Following procedure to be used in case of any injury requiring medical care:
 - a. Notify timekeeper immediately by phone or radio of seriousness of accident and if ambulance and/or doctor is needed.
 - b. Tell briefly what happened and type of injury.
 - c. Give man's name (be sure it is correct).
7. If fatal accident, crew should quit for the rest of the day.

LOG LOADING

1. Instruct all men on landing in safety rules
2. See that horn signals are given before any movement of trucks on landing using the following signals: 1 blast of horn for alert, 2 blasts for go ahead, 3 blasts for back up.
3. See that truck comes to a complete stop before allowing men to climb on and off truck while hooking trailer.
4. Have safe disposition of men on landing.
5. See that all loading equipment is mechanically safe (hooks, machines, ropes, etc.)
6. Exercise authority and control over truck drivers and shovel loaders at shovel landing.
7. See that the correct number of binder chains are used and that they are used in the right place.
8. See that loads are built safely (both truck and rail).
9. Maintain as safe working conditions as possible.

NEW HORIZONS IN SUPERVISORY TRAINING IN ACCIDENT PREVENTION ACTIVITIES

By D. W. C. MAC BEAN
Accident Prevention Coordinator, MacMillan, Bloedel and Powell River, Ltd.
Vancouver, B. C., Canada

The following remarks made by E. G. Shorter, executive vice-president, MacMillan, Bloedel and Powell River Limited, at our logging operations' safety award meeting in Nanaimo, B. C., on January 20, 1961, spell out in clear terms the key to a successful safety program:

"The key to accident prevention is the quality and know-how of management and supervision, who must accept the responsibility and who are accountable to:—

- (a) Train and direct the working forces in production and safety.
- (b) See that our plants and equipment are safe, well maintained, and efficient.

"Our company considers safety one of the main functions of management—we cannot

accept poor safety records."

Safety is a subject of vital concern to everyone. When you compare conditions today with those of half a century ago, it is clear that the safety effort has succeeded remarkably well. When you compare the safety activities of supervisors today with those ten years ago, you will note a remarkable improvement in the safety performance of supervisors.

But in spite of the progress that has been made, there is still a long way to go in improving the safety performance of many supervisors.

Experience with past programs has revealed six major weaknesses in the accident prevention activities of some of our supervisors. Six corrective actions have been taken to overcome these weaknesses:

WEAKNESSES

1. Inadequate analysis of job hazards.
2. Inadequate analysis of accident causes. (Failure to honestly fix responsibilities.)
3. Inability of some supervisors to accept responsibility for employees' safety. (Lack of acceptance.)
4. Some supervisors do not understand how to communicate effectively.
5. Failure to measure performance of participating supervision.
6. Failure of employees to accept personal responsibility.

CORRECTIVE ACTION

Prepare new, and improve existing written job safety analyses.
Investigate all accidents promptly, thoroughly, and determine underlying causes.
Safety training of supervision.

Training in communications for supervisors.

Establish and maintain adequate gauges.

Motivation and education of employees.

Five of these weaknesses reflected directly on supervision, the sixth indirectly on supervision.

MAJOR PROBLEMS IN ACCIDENT PREVENTION WORK

Some of our supervisors have told us that their accident prevention problems are:—

1. Communication (Inadequate)
 - a) Lack of skill in communicating effectively.
 - b) Foremen not trained to effectively communicate.
2. Lack of time in which to carry out their safety responsibilities.

Caused by:—

 - a) Inability to delegate.

- b) Inability to plan.
- c) Work overload.
- 7. Lack of knowledge on how to utilize time to maximum advantage.
- 4. a) Lack of knowledge of their own duties and responsibilities.
- b) Lack of knowledge on how to delegate some duties and responsibilities to other people.
- 5. Clarification of areas of responsibility.
 - a) Areas overlapped by different foremen.
- 6. Inability to use safety aids and material to best advantage in group meetings and with individual employees.
- 7. Inability to recognize accident prevention problems within their department.
- 8. Lack of recognition, by management, of excellent past performance.
- 9. Inexperienced crews.
- 10. Incorrect crew attitudes.
 - Caused by:—
 - a) Limited knowledge of safety program.
 - b) Human difference.
 - c) Indifference.
- 11. Limited cost budget.
- 12. Lack of inter-departmental co-operation throughout division.
- 13. Failure to —
 - a) Recognize the importance of their safety duties and responsibilities.
 - b) Recognize the extent of their authority in safety work.

Our company decided to develop an accident prevention training program for supervisors based on the workshop principle. These workshops for supervisors would only be carried out at the request of divisional managers. They analyze the performance of their supervisors. They decide if their supervisors haven't the know-how to carry out their safety activities correctly and then they request us to help them through the medium of accident prevention workshops.

What should be accomplished by an accident prevention workshop? The persons re-

sponsible for the overall direction of the workshop must decide on the objectives to be reached and must formulate a comprehensive program to attain the objectives. Unless this is done the participants will derive very little benefit from the workshop. These programs, of course, are aimed at eliminating supervisory safety weaknesses as defined by divisional managers.

Our objectives are:—

- 1. To get the supervisors to define their accident prevention problems.
- 2. To enable the supervisors to gain a full understanding of their duties and responsibilities in accident prevention work.
- 3. To develop a practical plan of action for implementation throughout their operation, and based on various facets of accident prevention being considered by the group.
- 4. To get the supervisors to organize, plan, and develop their own accident prevention programs.
- 5. To coach supervisors in how to develop accident prevention programs.
- 6. To help supervisors develop themselves as workshop leaders.
- 7. To help supervisors learn involvement techniques. These techniques will enable supervisors to secure full participation from all workers in their accident prevention program.
- 8. To enable the supervisors to understand the importance of frequent talks about safety with their people.
- 9. To help supervisors gain the necessary knowledge and skill to communicate regularly with their people about safety.

Material Used in Workshops Include:

- 1. Supervisors Safety Training Manual—National Safety Council.
- 2. Quiz program based on the manual—National Safety Council.
- 3. Pattern for handling a quiz.
- 4. Question pattern for use of workshop leader when summarizing notes of actions resulting from discussions.
- 5. The "Communications For Safety" film series for foreman—National Safety Council.
- 6. Quiz program based on the films.
- 7. "Psychology of Safety In Supervision"

by Dr. J. L. Rosenstein—National Safety Council.

- 8. Twelve Target Program—B.C.L.M.A.
- 9. Pattern For Progress Program—State of Ohio.
- 10. Single Objective — Safety — United States Steel.
- 11. We Fix Responsibilities — Monongahela West Penn Public Service Co.
- 12. "Men and Motives In Safety Supervision"—National Safety Council.
- 13. Supervisory Responsibilities For Training.
- 14. Safety Quizzes—How To Use.
- 15. Problem Solving Procedures.
- 16. What Is Your Responsibility For Safety.
- 17. Guide For Discussion—Group Chairman.

Our Company conducts these workshops in the following manner:—

- 1. Number of sessions—(5) Five.
- 2. Number of supervisors in workshop—minimum of six to a maximum of ten.
- 3. Time of each session—Six hours.

FIRST SESSION

At the beginning of the first session the manager outlines:—

- a) Objectives of the company in accident prevention work.
- b) Divisional problems in accident prevention work.
- c) The results which he expects the supervisors to secure from the workshop.

The Workshop Leader, points out to the participants that the sessions will be on a participating basis. In other words, everyone will be involved in carrying out assignments throughout the sessions. The first session will be under the exclusive direction of the leader. The subsequent sessions are chaired by the participants themselves with the leader acting as a coach.

Items Dealt With In First Session include:

- 1. The group analyzes the manager's speech and decides on actions which they should take regarding the key points outlined in his speech.

2. The group (as individuals) outline problems they have in carrying out their safety duties and responsibilities.

3. Problem solving techniques are used on some of these problems, (using problem solving sheet).

4. The group analyzes the material and problems in Chapter 1 of the Supervisors Safety Manual utilizing (a) Quiz and (b) Pattern For Handling a Quiz.

5. Actions regarding Chapter 1 which should be considered by supervisors in setting up and organizing their own department safety programs are decided on by the participants, utilizing the question pattern sheet.

Similar procedures, as outlined above, are followed in dealing with the "Communications For Safety" film program of the National Safety Council, i.e.:

- a) Problems in films analyzed and corrective actions decided on.
- b) Key points in films analyzed.
- c) Actions, re key points shown in the film, which should be considered by supervisors in setting up and organizing their own department safety programs are decided on by the participants, utilizing the question pattern sheet.

The group progresses through the material to be covered during the subsequent sessions. Each member of the group carries out specific assignments related to the material being covered in the discussions. The workshop leader now confines himself to coaching all the participants.

The workshop group decide at the final session on an overall plan of action which they can incorporate into their department safety programs and into the overall divisional program.

Let me give you an example of a solution to a problem dealt with by a workshop group.

The problem—

Inability, and failure of supervisors to honestly fix responsibilities for accidents.

The procedure—

The workshop leader:—

- 1. Outlined a significant case to the group.
- 2. Outlined questions asked of the super-

visors concerned and the answers received from them.

3. Workshop group analyzed the case, the questions and answers related to the case, under the following headings:—

The "X" Division Case

Objectives:

- (i) to identify supervisory problems in the case.
- (ii) to determine correct actions for supervisors to utilize to offset identified problems.

This workshop group decided that their own analyses were:—

- (a) inadequate.

- (b) that a control should be set up to review their analyses.

As a result of the conclusion, a Superintendent's Foremen Investigation Board was established. This group reviews all investigations made by supervisors and pin-points responsibilities. The solution arrived at by this workshop group has brought an acceptance of supervisory responsibilities, previously lacking, for safety.

It is my belief that these workshops as used in our company have been successful in improving the safety know-how of line supervisors and in strengthening the accident prevention program throughout the company.

LOGGING SAFETY — INTRODUCTION

By FRED C. SIMMONS

Technologist, Northeastern Forest Experiment Station, Upper Darby, Pa.

Last year we considered the hazards involved in falling and bucking in our logging operations in the various forest regions around the country, and the safety programs designed to minimize them. This year we are going on to the other phase of our logging jobs—skidding, loading and hauling.

These also are high hazard operations, like falling and bucking. There is an important difference, however. In falling and bucking, the hazards are confined almost entirely to the workers themselves. There is a slim chance, of course, of dropping a tree on an unwary hunter or a walking bus, or a National Forest inspection officer. But with the almost universal use of the noisy power chain saw this has become very slim indeed.

But when you load a truck with logs and start it down a traffic-cluttered highway, it may be like shooting a 25-ton projectile down that highway. If the tires, brakes and steering apparatus are not in perfect condition, if the load isn't properly balanced and bound down, or if the driver isn't competent and alert, the results may be as disastrous as firing a projectile.

Like other industries, our lumbermen have

been caught in a cost-price squeeze in recent years. The price they could get for their products has been held down by that at which competitive products, many of them from foreign countries, were available. Their costs of labor, stumpage, supplies and equipment have been going up.

In an effort to overcome this squeeze, productivity of skidding, loading and hauling has been increased. These operations have involved heavier and heavier loads, and higher and higher speeds.

A few years ago I was stuck with the job of conducting a Yugoslavian economic planner around our region. He was a confirmed Communist, and very highly critical of almost everything he saw, and obviously didn't believe half of what I told him. He wouldn't believe the personal cars he saw parked around the entry road to a logging show in the Adirondacks belonged to the woodcutters. He wouldn't believe the vacationers he saw around Lake George were mechanics and stenographers. To him "profit" was a dirty word. But he was always bragging that there was no unemployment in Communist countries.

Then, near the tail end of the trip, we visited the Meadow River Lumber Co. log-

ging job near Rainelle, W. Va. We told him that up until 1945 this company was employing a crew of 200 men in the woods to supply 100 thousand board feet of logs a day to the mill by hand and horse methods. Now, with modern equipment this 100 thousand a day is supplied by a total crew of 60 men, in the form of tree lengths, and along with it comes enough material to make 200 tons a day of chips. His reaction was, "We couldn't do anything like this. What would we do with the other 140 men?"

The point is that on this job each man is forwarding more than three times the volume and weight of wood he was back in 1945. This means heavier loads and higher speeds—and increased safety hazards. Of

course, we have developed better and safer methods and equipment now than we had back in 1945; that has helped tremendously in diminishing these hazards. Much credit is due our equipment manufacturers for their excellent cooperation in improving the built-in safety features of the machines provided for our logging operations.

There are still plenty of things to be done in our safety record in skidding, loading and hauling. Every new machine or change in method brings new hazards that must be recognized and overcome. In addition, we are now commonly operating the year around, instead of just during the good weather periods. This creates additional problems for the safety officers.

LOGGING SAFETY — SKIDDING, LOADING AND TRUCKING

By J. L. TURGEON

Manager, Quebec Lumber Industries Safety Assn., Quebec, P. Q., Canada

Before entering the main subject of logging safety, I would like to give you a bird's eye view of what I consider to be the Northeast. I realize that the area is well known to most of you, however a few might not be too familiar with our part of North America.

In Canada, forests cover the greater part of the four maritime provinces; that is, Newfoundland, P.E.I., Nova Scotia and New Brunswick, and also of the provinces of Quebec and Ontario. In New England, the states of Maine, New Hampshire, Vermont and New York also have an important share of merchantable trees.

We find all kinds of topography: flat ground, hilly ground and mountains; we have well drained, sandy soil as well as clay and muskeg. Temperature varies a great deal, according to the region and season. While it sometimes reaches the nineties in July in New England and the southern part of eastern Canada, during the winter months, it is often 60° below zero, sometimes lower, in northern Ontario and Quebec.

If topography and soil formation does not

have too much bearing on felling and bucking, which were last year's theme, it is quite a different story when it comes to skidding and trucking. Good, solid ground will permit mechanical skidding, providing the slope is not too great. Nowadays, logging operations are getting more and more mechanized thereby reducing the number of men employed in the woods. I am convinced, however, that machinery will never replace or eliminate the horse in the North-eastern logging operations.

A few years back, skidding was responsible for only 4 per cent of our logging injuries; we cannot, therefore, consider skidding a very dangerous part of the logging operations. With mechanization, I believe that the frequency of injuries should go down and the severity up. As long as the machine operator knows his machine well and its capacity, this job is safe enough.

The helper or chockerman should never turn his back to the tractor and once his job is done, he should stay well away from the logs or trees being skidded and also the wires. What we do not like to see on skidding operations is the wheeled farm

tractor. It is not designed for the job and flips over too easily.

More attention is necessary when skidding with horses. Unlike a machine, you cannot stop his motor and put the brakes on. He is liable to move or kick at any unexpected moment. The horse should often be checked for injuries. A well treated and well taken care of horse is a gentle animal that may become quite vicious, if abused.

When approaching a horse, a person should always speak so as not to startle him. Several skidders direct their horses by voice and seldom use the reins. The man should never shout his commands; it will confuse the horse and make him nervous. When attaching the skidding chain, the man should stand beside the log, and not between the log and the horse.

When no reins are being used, the skidder should walk behind the logs and not too close. If reins are used, the trail should be wider so that the workman can stay well away from the logs; he should also walk on the inside of curves. The skid trail should be as straight as possible, free of stumps, roots, rocks and other obstacles. Steep slopes should also be avoided.

Skidway sites should be as level as possible and free of obstructions. There should be at least three or four feet of clear area on each side of the skidway so that the workmen can do their work without tripping. When the logs are small, a man usually works alone, using what is called a skid jack. If the logs are of medium size, they usually work in pairs. In either case, they must use their leg muscles to lift and not their backs.

Large logs are handled by horses with the use of a chain and block. In this case, the workman should never place himself between the skidway and the horse; he must stay in the clear and also at a safe distance from the horses.

When tractors or other mechanical equipment is being used for skidding, the dozer blade is often used to roll the logs on to the skidways. Loaders such as the Drott are also being used. If hauling immediately follows the skidding, they don't bother making any skidway at all.

Next step is trucking, which includes the loading of trucks, the trucking itself and

the unloading operations. I must say that we are more concerned about the trucking operations than we are about skidding. In 1959, 340 accidents, including two fatalities occurred on trucking operations; this represents 10.21 per cent of all logging and sawmill injuries for that year. The direct cost to the industry for these accidents represented 21.61 per cent of all costs; their severity is therefore higher than the average. In 1960, nine out of eighteen fatal accidents happened on the hauling operations and we are very much concerned about it.

Log loading of trucks is a dangerous operation and should be carried out with extra precautions. If a jammer is used, the cables and chains should be inspected daily to detect any weakness. The hooks or pig's feet should be kept sharp and in the proper shape. The bull ropes being used to direct the logs and release the pigs feet must be long enough so that the workers can stay away from the logs and the trucks.

If a side or Bouffard loader is used, the operator must always be on the watch, particularly when topping his load. Top logs will frequently roll over the pickets on either side of the truck and are liable to fall on anybody standing close or going by. When bringing down the arms, the operator must make certain that men rolling the logs are out of the danger area.

Drott and other specially designed loaders are now being used, and nobody has to handle the logs until they are on the truck, thus reducing the hazard. The operator, however, when moving his machine, must make sure that the helper or other persons are not in the way. A workman is usually required on the truck to rearrange the logs. He must be on the look out at all times and must get out of the way when the machine is bringing in a load. If he stands on the roof of the truck cab, he must have something to hang on to as it is often slippery and falls from this position are too frequent and cause serious injuries. Cranes equipped with log grapples are also being used in a less extensive way.

We have noticed on too many occasions that the pickets holding the loads are too short; sometimes more than 1/3 of the load extends over the pickets, and I am not exaggerating in stating that; at

other times, the pickets are too weak and could break if the load is shifted. Most of our truckers have a tendency to overload; this is a very dangerous practice, more so if the hauling is entirely or partly done on public roads. If the centre of gravity is too high, there is an additional danger of the top logs skidding forward or backward when going up or downhill and the excessive weight lessens the control of the operator over his truck.

Whatever the size of the load, at least, two good wrapping chains should be used.

Trucks must be in first class condition; the steering, brakes, lights and tires should be checked daily. Each truck should carry a first aid kit, fire extinguisher, emergency light or flashlight, and fares or warning flags.

Bush roads should be wide and kept in good condition, curves should be as long as possible and the inside cleared of trees or saplings to provide the best possible visibility. Steep grades should be avoided and when possible it is better to go around than over.

FOREST FIRE FIGHTING SAFETY

By MERLE S. LOWDEN
Director, Division of Fire Control, Forest Service
U. S. Dept. of Agriculture, Washington, D. C.

Fighting forest fires is dirty, hard, mean and dangerous work. We are constantly trying to make it safer. In spite of all that has been done, however, we have been unable to eliminate entirely many hazards of the job. This year 18 men died fighting fires for the U. S. Forest Service. In the last five years 59 men were killed in this work. In addition, there were many serious accidents resulting in broken legs, lost eyesight, brain concussions, and back strains, as well as hundreds of minor injuries. I don't need to tell this group of the pain, misery and hardship these caused. These accidents are sobering and a real challenge to forest fire control men everywhere.

Before I tell you what we are doing to meet this challenge, it might be well to explain something about the nature of forest fire fighting, its accident potential, and why it results in more fatalities than all other jobs of the Forest Service.

First, there are many dangers encountered in getting to forest fires. Our aim is to reach fires as quickly as possible after they start and to stop them while they are small. We have no opportunity to select the place where they start. Many fires start far from roads in rough, steep, timbered areas that are difficult to reach. Men must travel to these by foot, often without trails, or go by air. If by air it means parachuting, as in the case

of smokejumpers, or by helicopter. If by helicopter, they go to a place where the aircraft can set down, or the men jump while the copter hovers above the brush. Then the balance of the trip is by foot.

While all of these have their dangers we have had a good safety record with the smoke jumpers and helicopter crews. There have been no fatalities from jumping in 22 years and lost-time accidents have not been frequent. Airplane crashes associated with dropping chemicals, however, have been alarmingly frequent with four fatalities this year.

Even travel to fires by car or truck over rough and often poor mountain roads is dangerous, as I'm sure you realize. We have many serious truck accidents each year. This year we lost two men in a truck accident going to a fire in Montana and two on a motorcycle that ran into the back of a pickup on the way to a fire.

Our accident potential is further increased by the location or surroundings in which men work on fires. Often fires burn in very steep country. Men work on steep hillsides and sometimes literally on the sides of cliffs. In a few instances we have lowered men over cliffs by ropes to put out a spot fire which had the potential to spread fire with the wind and cause additional trouble. There are often rolling rocks or rock slides which

must be gone over or around. Getting through brush or timber can be particularly aggravating. Brush is often almost impossible to get through and can trap men in front of an advancing fire. There may be tall timber or snags which obstruct the view of the men. Tops and limbs may fall on them without warning.

The situation in which men work on fires is also a hazard. In spite of careful planning and organizing there is excitement, anxiety and hurry in a fire. Tensions are built up and men work under stress. It is hard work and men get very tired. All this is bound to contribute to more accidents, especially when duty on a hot fire usually means working around the clock. Night work is often especially hazardous.

Most tools are a hazard. Axes, hoes, saws, and similar tools are sharp and a slight glance or deflection can badly cut a leg, arm or head. Powered equipment such as tractors, trenchers, plows and pumps have their own special hazards. Something can go slightly wrong with machines and cause a serious accident.

We use as many trained and experienced laborers and supervisors as possible in fire fighting. However, regular crews are not sufficient to handle the large number of fires at one time that we have had in the last two years. There were 25,000 men on the fireline at one time last year and about the same during our worst period this year. There were 10 large fires burning uncontrolled in Idaho and Montana at one time in August of this year.

This large buildup of manpower forced the use of less experienced men in many places. We try to get mill and logging crews, agricultural workers and organized Indian crews as far as possible. These all work out well.

However, it is sometimes necessary to hire workers who have little knowledge of fire fighting, even though the employment service is very cooperative and helps us as much as possible to eliminate the unfit. The men are required to have suitable clothing and shoes. We try to have a doctor available to make an examination. A fireline is no place for a person with a weak heart and we have some heart cases each year. This all adds up to use of men inexperienced in the work and more prone to accidents.

I know you don't want me to dwell too much on our problems. Instead, I should tell you something about what we try to do to overcome them. A strong part of our program is analyzing the hazards and our own experiences to learn what we can do to improve our safety performance. Each lost-time accident is carefully investigated, analyzed and reported. We try to be penetrating in these studies and find out not only what happened but why it happened, and what we could have done to prevent it from happening. We go into the background and training of the man and his supervisor. We try to find out what part of our program reached each of them, or didn't reach them, and where it failed.

In 1960 we employed a psychologist for the summer fire season to visit our field stations and "go in" fires. He interviewed both laborers and bosses. He tried to find out how men reacted under stress on fires. One of the critical items this man pinpointed was the highly important job of the crewboss, the man in charge of 15-25 men. We knew he was important but this study brought the facts into stronger focus.

We have followed this with a special crewboss study this summer in which one of our experienced fire men studied the work of the crewboss on many fires in western states. From these studies we have valuable suggestions and recommendations for improving our efforts. We are already busy producing a special training movie on the crewboss job and otherwise changing preparations and giving more emphasis to this position.

Each year we have several workshops on special phases of our work where safety problems receive major attention. Workshops are held on such activities as smokejumping, air operations and equipment use. Recommendations of these sessions are reflected in work programs, handbooks, instructional material, and current plans.

Major emphasis in our entire fire program in recent years has been on improving work through training. Transfers of personnel and changes in duties are common in our organization. We also add many new men each year. A large per cent of our supervisory men have other regular duties in addition to fire control. Many work on fires only when called upon in an emergency. This gives us great strength in being able to make

maximum use of our own people for supervisors even though we have to shift some long distances. This year in August we brought in nearly 600 supervisory personnel to help on fires in Idaho and Montana. To have all these men competent to do one or more specific fire jobs is a large training order. We integrate safety into all instruction on the premise that a job well done is a job safely done.

In firefighting it is important that bosses know fire behavior—a highly technical subject. Our behavior training starts with national courses for top fire men who carry the training to regional and local schools. We have a basic requirement that every man in the Forest Service receive at least four hours of instruction in knowledge of fires and what to do in blowup fire conditions. Even though men have no regular fire duties they may be caught in the woods in a fire situation. They must be able to act with knowledge and decision to save those with them as well as themselves.

It is a constant challenge in our work, as I know it must be in yours, to do a better training job. We are having more men to train and, it seems, less time to do it. Last year a special development project was set up in our fire division to find out what others are doing and to find new and better ways of training. Training machines are getting widespread attention and we plan to give these a thorough trial. We are working with consultants on a fire simulation proposal which looks particularly promising. In simulation training we expect to place men under stress and on their own to learn by doing complicated fire problems.

We have had practice fires for a long time but we hope to have more sophisticated problems. We have a long-term program for developing training films, slides, and other visual aids. We have a training film for air attack on fires—a movie which recently won a national award.

A strong part of our fire safety program is to place responsibility with line supervisors. The boss man at every stage or level of the operation must have the responsibility for safety of all men under him. We use a lot of ways to get this. One device is to insist on strong discipline in our fire work. By this I mean discipline in the broad sense where we make men feel full responsibility

for the job they do, and for the men they supervise. We try hard to have men know we will not countenance mediocre work.

Strong policies and specific safety rules are further foundations in our program. Following a very serious fire incident in which 13 men were burned to death in 1956, we had a task force study the entire subject of fire fatalities and especially men being caught in fast-spreading fires. One recommendation of this task force was that we adopt a set of fire-fighting rules. The purpose of these rules—called our Ten Standard Orders—was to have men know them so well they would automatically react to what was required.

I might cite several to give you an appreciation of what they are like.

No. 2, "Know what your fire is doing at all times, observe personally and use scouts."

No. 3, "Base all actions on current and expected behavior of your fire."

No. 4, "Have escape routes for everyone and make them known."

No. 5, "Pos. a lookout."

No. 8, "Give clear instructions, be sure they are understood."

No. 9, "Maintain control of your men."

And then this admonition by the chief of the Forest Service, "Every Forest Service employee who will have firefighting duties will learn these orders and follow each order when it applies to his assignment." These Standard Orders are aimed chiefly at the crewboss or the leaders but they have application to the individual fire fighter too.

We have many rules on air operations. Rules are made for such things as use of parachutes and the height aircraft fly above the ground. For example, air tankers are strictly forbidden to fly closer than 75 feet from ground obstructions. Even that, you will agree, is low and is somewhat an arbitrary compromise. We are trying to increase this height and still hit the target. We have a limit to the hours pilots can work each day.

These rules have grown from the experiences of our men over many years and a multitude of jobs. Two years ago we had a young man rush to the cab when a helicopter landed. He was hit with a rotor blade on his head. Even though he was wearing a hard hat, he was killed. Now we strictly

insist that a watchman keep men clear when a helicopter lands. The pilot is busy landing the ship and cannot watch the people already on the ground.

Safety is directly built into our fire organization. On large fires the safety officer has many duties, including looking after the welfare of the men, being certain a fire behavior forecast is available to line supervisors, and many other things. He is not charged primarily with first aid, or welfare, or making out accident reports, although of course he is interested, and may help on these. His main job is to be certain safety practices are followed and that necessary preventive work is done before accidents happen.

We stress physical fitness for the firefighters. I mentioned previously men are required to take a physical examination. We try to have doctors at hiring centers. Our main organized crews, such as the Southwest Indians, are required to have a physical examination before they become members of a regular organized crew, and they have cards to certify this. We had some difficulties in getting the Indians to take these examinations. However, they like the work as it is a good income for them. When we made this an absolute requirement we had no further trouble.

I was in a national forest in California recently which had signed up more than 500 local Spanish-American laborers. These men work in fruit and other crops, but have many off times. They are organized into fire crews and more than 500 have cards certifying they had had their physical examination.

We limit the age of firefighters. Only in exceptional cases do we hire anyone less than 18 years of age. We check on older men who might not be physically able to stand the exertion required in fire fighting.

Another keystone in our safety program is research and development. There are many possibilities in equipment development to add to the safety of fire work. We have projects to develop better parachutes for both smokejumpsers and pilots. This work is centered at Missoula, Montana.

Many advancements in the type of chutes and other equipment which smokejumpsers use have been made. This includes protective clothing, which is important. It protects

their face and other vital parts of the body. One particularly perplexing problem has been shoes. Shoes for all firefighters, but particularly smokejumpsers and helijumpsers. We made special studies on shoes. The Army Quartermaster group has been particularly helpful in this and other development work.

During the last few years much attention has centered on flame-proof shelter or clothing for men. We have been helped in this by the quartermaster corps. We found that many men badly burned or who died from burns suffered greatly when their shirts and other clothing burned on them before they could get them off. We have developed specifications for materials that are flame resistant. These are being given comprehensive trial this year by several crews. If the material proves as suitable as is indicated, we expect to use it for most firefighters.

We have developed an "escape" fire shelter which weighs about two pounds. It is aluminized fabric packed in a bag to be worn on a man's belt. Through many tests we found men could stay in these shelters and have fires go around them. They are an emergency measure. We would not expect them to be used except where men were caught. If these shelters had been available previously the lives of many men would have been saved in fire accidents. These are not available to all firefighters this year because we could not get sufficient quantities in time, but we are getting widespread tests. They will probably be required for all firefighters in the future.

Many changes in methods of attack in recent years aid safety. We are trying to drop chemicals effectively from greater heights by varying amounts of materials, using different chemicals, and by getting chemicals to stick together better for effective drops. We hope in the future to be able to raise the effective height of air drops as I mentioned before. Then men need not take chances in flying so close to the ground.

Missile development work is now receiving attention. We are negotiating for a contract for a glide bomb, or device which will drop retardant or suppressant material on a fire to put it out or hold the spread until men can arrive.

There are many problems in the way of success, including a suitable container, what

to do with the container in order not to injure men on the ground at the fire, and how to warn men on the ground. One requirement of such a device would be to have it equipped with a built-in warning system to be heard for a considerable distance both in front and to the sides of the flight route. You can realize how much safer it might be to send a manless carrier than to fly a plane at low levels.

While we have a large and varied safety program we still have many accidents. We

know there are many opportunities for improvement. We must continue to analyze our changing job. We must better our training, our rules, our instructions, in fact our entire program. We hope some of the developments and research on equipment and techniques now under way or new ideas we haven't yet started to work on, will make fire fighting safer. We want our program to be keyed at all times to Fire Rule No 10: "Fight fire aggressively, but provide for safety first."

JOINT SESSION WITH PULP & PAPER SECTION

SAFETY IN PULPWOOD LOGGING

By CHARLES T. WRIGHT

Safety Eng., American Mutual Liability Insurance Co., Raleigh, N. C.

Last February, I had the pleasure of meeting with the Safety Section of the American Pulpwood Association in New York at their annual convention; an informative meeting.

Many constructive ideas and plans were developed. However, on several different occasions, I heard the supposition mentioned that a rather wide difference in educational levels exists between worker groups in the woods in different geographical areas of the United States. Somehow, this so-called "educational level" was getting the blame for differences in work methods, types of tools, etc., between different geographical areas. The impression was left that this somehow created an insurmountable problem safety-wise. Nothing tangible, mind you, just an impression.

For instance, one man gave an opinion that this "educational difference" is the reason the bow-type chain saw is used down South while the blade-type saw is used farther North. I leave it to you to judge whether or not this is significant in the measure of accidents.

I mention all of this only in making the point that we sometimes use pointless and often unrelated excuses for not having effective accident control in our operations. Is it not a fact that when we have a problem to cope with we must take *whatever* approach and action is necessary to an effective solution? You might say that "Teddy" Roosevelt's policy of "walk lightly but carry a big stick" meant that when he had a tough problem he managed to get just a little bit tougher and solve it for a desirable solution.

About two years ago the North Carolina Forestry Association decided something had to be done in the logging and lumbering industry in North Carolina, as a whole. Putting their decision into action, as a first step they organized an insurance committee and began doing research analysis to determine just what the reasons were behind the high cost of insurance in logging operations.

The committee, after much study, found out what insurance companies and the various state labor and compensation departments had known for some time. They found that while a number of factors were actually involved, just one major item was visibly responsible. What was this? Just this: The logging industry was having a high frequency of accidents which were, for the most part, of a rather severe nature. That is, they were costing a lot of money in hospital bills, doctor bills, and in many other tangible, directly related ways. All of this cost was in addition to the very high cost of inefficient operations which resulted from the same basic causes as the accidents.

What are these basic causes? The most important, at least the most basic and most in need of immediate attention, were:

- (a) Lack of adequate top management safety policy.
- (b) Poor to no enforcement of any existing policies.
- (c) Poor liaison or supervision between management and field.

The basic lack of top management policy had resulted in a disparity in equipment, tools, etc., used in the woods. A nearly complete lack of adherence to any safety standards existed. In a nut-shell, everything was wrong. Something had to be done about it.

On receiving the committee's report, the North Carolina Forestry Association and the North Carolina Department of Labor, who had worked so effectively in development of accident prevention in other industries in the state for so many years, called on some of the insurance companies' safety engineering departments to work jointly toward the attainment of the safety objective dictated by the high accident frequency referred to earlier. American Mutual hap-

pened to be one of those available and willing to do everything within reason to help.

The over-all record in both the pulpwood and saw log experience indicates that a lot of people have either forgotten some of the things they do know, or else they just aren't taking time to plan ahead and be guided by the things they have learned.

The main points we are trying to make here are:

First, people who are concerned with pulpwood in its various phases of production and use, go to great length to assure full growth and high production of pulpwood timber, but give *considerably less* attention to safety, in either the use of proper tools and equipment or in training workmen in safe work methods and practices.

Secondly, I would like to show that these same people are capable of accomplishing the latter by showing evidence of certain types of effective planning which they are doing, in a contrast comparison to some of the weak points where planned attention is missing.

Workmen's Compensation insurance carriers and other organizations, as well as individuals interested in safety, found many years ago that high accident frequency and severity go hand-in-hand with low operating efficiency, and therefore, result in high operating costs. The same sound engineering principles that can and do control accidents will normally produce highly efficient operations as well.

Safety in pulpwood logging can also mean efficiency in pulpwood logging.

The forest in North Carolina is third-ranking in product value in the state. It produces approximately \$750,000,000 in product value annually. The forest is second only to textiles as a source of industrial employment, furnishing 78,000 jobs. The total annual payroll amounts to approximately \$243,000,000.

These figures give us a basis by which we may estimate the value of safety as an efficiency factor. They also provide a measure of exposure to accidents and suffering in the industry as a whole. A relatively high percentage of this exposure, and certainly the majority of severity is to be found in the log woods.

The forest, in most any area, is a beautiful

Joint Session with Pulp and Paper Section

place, that does not readily reveal the vast number of hazards that lie there waiting to trap the poorly equipped, the poorly trained, or the careless pulpwood worker.

The great progress that has been made in controlling and improving the growth of forest timber is phenomenal, to say the least. Read the story in growth rings. Is there any doubt that the same brainpower that has developed such control could also develop controls that would prevent accidents and suffering to workmen? No, I'm sure there isn't.

There are examples of the results of very poor or no attention to *planned* forestry. Misshapen and damaged sections of trees which you often see are proof that many men in the pulpwoods are operating or have operated unsafely and without planned control of accidents.

An outstanding example of control of timber growth is found when a tight intersection of growth rings indicate the forest was being choked off by too thick growth for the first 15 or 16 years, but after thinning, the width of the growth rings increased immediately. Such a tree grew as much in the last six years after thinning, as in the 15 years prior to thinning.

When you see planning in action, the forester marks the butt of a tree, using a yellow dye and a manually operated pressure can. The tree is marked also at a higher point. When this tree is harvested, it will be cut because it is marked, and the stump, left in the ground, will show the mark. Trees that are not marked will not be cut. This is planned thinning.

The forester checks height of trees, and measures diameter. Often he takes a boring sample as a means of checking width of growth rings to determine rate or speed of growth. Seedling trees are used in speeding clear cut land.

Certain tools should be available and used by pulpwooders in the woods. Fire control items are a must for a well rounded control plan. Unfortunately, on many woods operations, we do not find these items.

Woods workers must learn basic safety precautions. Often you may find a man filling a chain saw gasoline tank by using an unsafe type can, perhaps with a spout too short and too large to enter the opening in the tank. Gasoline is often spilled on

saws with this type of unsafe equipment. This creates a rather serious burns hazard to the operator, to say nothing of the potential for setting fire to the entire woods area. Explosion is also a major accident producing potential.

Another unsafe operation is often found in starting the saw. On a very still day, the fumes that have risen from the gasoline filling operation are still hovering in the area. When the saw is started, the fumes may be ignited. If the unsafe gasoline can is too close, this can, and probably will, start a fire. It isn't necessary to explain the many heartaches that could result from this unsafe practice.

When felling a tree, the men should be properly equipped with safety helmets. When a tree is over 10 inches in diameter, it should be notched before cutting, in order to be sure of controlling direction of fall. Many other things must be taken into consideration but this is a primary need in directional control.

The men should be warned about felling a tree without first properly clearing or "swamping" on the back side of the cut, although the opposite area is clear enough to allow a proper escape route.

When you see a man pushing the tree with his hand, to control direction of fall, this puts him in a rather awkward position. Obviously it is necessary that he push the tree, because he has not notched it. It is all right to push the tree, but this should be done by another man with a pole long enough to reach well above the man using the saw.

When the tree falls through brush that was not properly cleared before the cut was started, the brush could whip back and strike the eye of the sawyer. A man experienced in this type of occurrence usually will turn his head well away from the potential whipping brush. However, this does not constitute proper protection. Certainly the man should have spent just a few seconds clearing out the area before cutting, thus minimizing the exposure.

When a felled tree has lodged on the heavy limbs on the underside, the sawyer may limb the tree by cutting underneath the log to remove the supporting limb. This means a high probability of the tree falling

and causing injury to the man. He should have properly blocked the tree to prevent its falling. Better yet, proper study of the tree would probably have dictated felling the tree in another direction where there would have been no blocking limbs.

When a sawyer is cutting tree into pulpwood lengths without proper support underneath, his saw will probably hang, creating additional hazards in trying to loosen the saw. It is conceivable that damage could be done to the saw during interruption of work. Need for proper shoring here is obvious.

Woodmen must be always on the lookout for the "widow maker" (broken limb hanging above men who are preparing to cut a tree below). Any disturbance of this broken limb could drop it on a man's head or shoulders.

At times you may find a sawyer breaking just about all the rules of safety in felling a tree. You can see that he does not have on a safety helmet. He is pushing the tree with his right hand while holding the saw with his left, throwing himself into a rather awkward position. Then you'll observe the vulnerability of his head to any loose or dead limbs that may be overhead and become dislodged. The brush is so thick that the saw could hang and cause it to jump into the man's leg. Worse, the brush will probably obstruct his escape route. In addition to creating unnecessary hazards, this is a case in point of complete inefficiency in the woods.

After the cut the tree may hang suspended in the air and the men are going to have to cut other trees before they can drop the intended one. This means they will expose themselves to serious "falling objects" hazards.

Proper pre-planning for direction of fall and good clearing would have allowed a clean fall to ground. This further demonstrates what we mean when we say safety and efficiency are one and the same.

When a small tree is bent over by the tree that hung, the man cutting it with a hand axe may be setting up a dangerous situation by cutting from the top side of the tree rather than underneath. With his first cut, a long sliver splits off and springs outward. This frequently causes injury to either the axeman or other personnel. This is a completely unnecessary operation that

could be eliminated or avoided if proper planning is utilized in the first place.

Fortunately, there are occasions in the woods when you see a little more planning for safety. The men are all wearing safety helmets, and are properly dressed otherwise. The sawyer who will be wading out in the swampy areas is wearing snake bite leggings in addition to the safety helmet and good protective clothing. Men with yellow helmets are supervisors. You may see the producer who stays with and supervises this particular pulpwooding crew.

You will see one of the sawyers approaching the tree, with his foreman looking on. The sawyer will be sizing up the top, determining best direction of fall, etc. He will take into consideration shape of top, location of other trees, direction of wind, velocity of wind, most advantageous point on ground for limbing, etc.

Prior to cutting the tree, the sawyer will use an axe to swamp out around the tree or clear the area for freedom of movement and safety. This is being done to prevent saw from hanging and jumping into his legs and also to give him a clear path to get out of the way of the tree when it begins to fall.

When the sawyer is making a cut, in the properly cleared area, he will be using both hands on the saw. This demonstrates what we referred to earlier. That is, the sawyer can hold onto his saw with both hands while another man uses a stick with a sharp point that will reach up some 10 feet on the tree for the purpose of pushing so it falls in the proper direction. And the supervisor will be looking on.

The limbing operation with chain saw presents the hazard of the saw hanging in brush and jumping into the legs. Severed limbs should be moved out of way as they are cut, as a means of improving controls over this potential accident producer.

A limbing operation with an axe should be done on the opposite side of the log from which the axeman is standing. Loose limbs also present a very serious hazard here in that they may be deflecting the axe into the person.

In some operations, logs are snaked out of the woods into a clear area for additional cutting and loading. There will be a protective cover over the tractor cab. This

protection is a must for safety of operators. The hard hat will protect against relatively light limbs, etc. and will give a measure of protection against larger trees. However, the sturdy cab protector is necessary for full protection of the operator.

One of the most hazardous situations in logging is found where a man is operating a farm type tractor which shouldn't be in the woods in the first place. In addition to the fact that it does not have any protection overhead this machine is not designed to snake logs. The tow chain is positioned above line of axle.

The center of gravity, that is the line of force, is located well above the axle and if the log bangs, the tractor can turn backwards onto the driver. This frequently happens.

In a specific accident resulting from one of the farm type tractors turning backwards on to the operator occurred recently down near Beaufort, North Carolina. Investigation revealed that the operator was 15 years old (violation of the North Carolina Labor Law) and had been placed on the tractor without any previous experience, although he had told the pulpwood producer that he had driven a tractor some place before.

At any rate, the log being towed by the tractor hung against the stump and the youth's foot slipped off the clutch and the automatic drive caused the tractor to turn backwards and crush the young fellow. The details of the investigation of this accident are too numerous to mention here but they did reveal many areas where planning was lacking and apparently absolutely no attention was given to safety of workmen.

Another major producer of accidents is lifting and handling of heavy materials. This produces serious strains. The safe handling of material requires a thorough knowledge of the correct way to lift; requires putting this knowledge into practice at all times, not just part of the time. It is estimated that manual loading of logs is practiced in approximately 90 per cent of the cases.

If anyone doubts that loading a truck of pulpwood logs is a big job, just multiply the weight of the log (about 80 to 90 pounds) times the distance it is handled, times the number of logs on the truck and you get a pretty good idea of the foot pounds of energy expended during a loading operation.

The man on top doesn't have an easy job either. He faces a number of very serious accident producing potentials. For instance, we could list the strain hazard from the lifting and handling of the log; the falling objects hazard in case he drops the log; the hazard of falling off the truck. Spikes should be worn on the shoes of the top loader. Just imagine what would happen if he makes a misstep backwards, or if a foot slips on loose or slick bark.

You may often find the wood being loaded by a man much too old to be straining and lifting in the log woods. Better selectivity and job placement would control this needless exposure.

An example of poor planning found recently was in the elevation plates welded on a truck bed to keep the logs off the tires. They were too small. The man has to cut short timbers to lay lengthwise on the bed to keep the logs up off the rear set of wheels. This lack of effective planning is symptomatic; may be a major cause of woods accidents.

Badly worn tires are hazardous. A blow-out on the road means, at the very minimum, a spilled load and a reloading operation, (again we have inefficiency). It could mean many more things, such as a severe wreck, death, collision with some other vehicle, and death or permanent disability to several people rather than one.

We have found there is some effort underway to reduce the exposures to accidents and to increase the efficiency of pulpwooding operations. Machines have been designed and built by people who have had many years of experience in pulpwooding. Such a machine can go into the woods and pick up a load of pulpwood, one stick at a time, load it onto a cradle, hook on and drive out to a more convenient pick up point for transport trucks, in an extremely short time. All of this is done with just one man at the controls. This man controls the pickup arm and does all the driving of the tractor. All of his pick up, handling, loading, etc. is done long after the sawyers have dropped the tree and sawed it into pulpwood lengths. This eliminates exposure to others being near by.

Obviously, this machine can take a lot of work off the individual and it is not nearly so subject to strains, injuries from falling

objects, etc., as a man is. Unfortunately, all pulpwooding operations cannot afford such a machine. What they have to do instead, is to properly equip their men with the best available, properly select the men to do the job, outfit them with safe clothing, and teach them the correct way to do the work. Sufficient supervisory follow-up is absolutely necessary to see that this is done.

It is reassuring to find a logging outfit that has taken the trouble, and felt it economically worth while, to construct a good useable road for access into the logging area. We'll find the foreman of the wood crew equipped with safety boots and safety helmet.

He will have the safety devices necessary for topping out trees on the stump, or for setting up derrick rigs for skidder operation where high water is a factor. The man's spikes are sharp and workable. Those rubber boots he is wearing have safety toe-caps.

Another safety type shoe shows the proper method of wearing trousers tucked into boots to prevent hanging on snags, etc. when trying to get away from a falling limb or tree.

We photographed a work truck with a lot of unsafe features:

1. Gasoline cans were carried on the same truck with workmen. (Unsafe type at that.)
2. The safety sides or cover over the truck only extended part way back, certainly not enough to fully protect a truck load of men.
3. There was no tailgate to protect men from falling out at the rear.
4. The truck was not equipped with a rear bumper and we doubt seriously if the lighting arrangements on the truck met highway standards.
5. Preventive maintenance was obviously lacking.

Another better rig for hauling men, not considered completely safe, did not have proper type seating. The truck did have a tailgate, was equipped with a complete cover and carried fire extinguishers and first aid kits.

Additional hazards inherent in log woods operations include the black widow spider, timber rattler, copperhead and cotton-mouth moccasin.

Yes, the log woods are beautiful, but such a small thing as an axe with blade up can

be compared to the copperhead—just waiting to strike. A small thing, but it's the small things that accumulate and result in big losses. Many times it's the small things we do and fail to consider important that create our most serious accident occurrences.

Most any way you go in the log woods you find beauty. You also find many hazards, many places where men can be badly injured or killed. Careless workmen can

injure themselves and others, they can start fires that will damage millions of feet of timber, and destroy wildlife that furnishes sport in hunting and trapping, for people who like the outdoors.

Proper planning, proper outfitting, careful selection of employees, training of employees, and sufficient supervision to see that this training program is carried out on a continuing basis, can prevent such happenings.

THE FUTURE OF TWO-WAY RADIO IN LOGGING SAFETY

By DONALD R. JONES

Mgr. of Marketing, Mobile & Portable Communications Products
Motorola Corp., Chicago

Your presence here today marks each of you as an expert in safety. As representatives for your company or governmental agency, your principal objective is to further improve safety programs and to seek out new tools which will aid you to reach your objective. My purpose is to provide you with information about two-way radio—a working tool which can assist you in your efforts for greater safety.

How can radio help you? Many ways! There are many examples of companies who have successfully employed two-way radio to improve their safety record. The problems of safety programs are not simple to solve. Each of you has specific problems. Effective use of radio in one particular application to provide improved safety for one of you—will not necessarily be what is required or needed by the man next to you. Nonetheless, the results achieved in some applications can provide insight to possible other applications.

I will have accomplished something worthwhile if one of you takes away the germ of an idea, which when further developed, will increase the safety in your organization. I shall spend my time exposing some sample applications of radio equipment to safety programs. I hope that the examples will stimulate your thinking and result in solutions to your particular problems.

First, radio can provide you a means of

communication which no other medium can provide in your particular working environment. Practically all operations today require a high degree of mobility. Without the application of radio, the person on the move, whether on foot or in a vehicle, is out of contact—unable to be reached until he checks in at various times during his tour. Lack of communications due to the requirement of mobility can make management substantially more difficult and operations far less efficient. For you, it may make an effective safety program impossible.

A good example of the use of radio in a safety program occurs in the trucking industry, which has had a substantially bad safety record. Two-way radio has become a common operating device for truck fleets in various industries. Expanding its use from the usual status as a means to increase efficiency to a place in the company's safety program has proven to be rather profitable in several large fleet operations.

In one trucking company, for instance, radio is installed in the vehicles used by the firm's five very active safety coordinators. The radio keeps the inspectors always available so that they can be directed to any place their presence is required—at the scene of an accident, for instance. More important, the radio communication allows the supervisors to prevent accidents because they can continually check the drivers.

TEXTILE SECTION

SAFETY IN COTTON GINS

By W. KEMPER BRUTON

Exec. Vice Pres., Arkansas-Missouri Cotton Ginners Assn., Blytheville, Ark.

Any program of promotion—safety or otherwise—can be just as successful as the attitude of management of the business that the promotion is built around. Our problem with management in the ginning committee is the two-fold type because we must first "sell" the association who in turn must reach the management of the 6000 gins operating from coast to coast.

As background information, there are 17 major states which produce and gin cotton, but only eight of them are represented in ginning by associations with full time executive officers. California and Arizona can be included in the group with organized leadership in safety because three large commercial ginning operations maintain their own safety engineers. They do not, of course, reach all gins in those states with an accident prevention message.

Knowing that to reach management effectively you must put the "dollar sign" on your approach, the members of the committee have been delving into the ramifications of costs in terms of lost time, medical aid, insurance, etc. As the ginning season shortens and volumes of bales per hour increases the item of lost time or down time resulting from an accident becomes increasingly serious.

The preliminary surveys made by the Ark-Mo Ginners Assn. on the costs of insurance per bale (as high as 70 cents) definitely set out the need for concerted action to reduce one of the ginner's highest costs in his operation. No one needs to be reminded of the skyward trend of medical care and its demands on the pocketbook of every individual today.

In trying to find "handles" to put on these various aspects of our problem, and to first of all ascertain some facts about our ac-

cident experience, we've found our industry is lost in a maze of rather unrelated statistics. We believe ginning accidents should be recorded as such and that we should not carry the burden of accidents happening in outside influences but charged to the gin because the employee's payroll record was in the name of the gin. Our committee has set forth to secure an IBM reporting system through the State Workman's Compensation Commissions with this goal in mind. We believe the insurance companies can be of great help in this matter.

Progress is being made. We have designed a "package" safety program for all state associations. It will include the new data sheet now in the hands of the NSC staff, news releases, posters, safety tips, leaflets, and, in the future, a manual.

No lost-time accident awards are being made by the Texas and Ark-Mo associations. Texas has issued a manual—very comprehensive and practical. Other associations are using NSC posters and allied material. A file of pictures of gin hazards is being compiled by Extension Service at much cost of time and effort. Slide presentations on safety practices have been made in several states. USDA is testing anti-slip materials to prevent falls in gins. A school for gin safety engineers is being prepared to be held next April.

Somewhere—someway—your committee feels it will be successful in developing a live-wire accident prevention program which will reach into every gin in the United States. The machinery manufacturers are with us—educational agencies are with us—we know the NSC is with us. All we need now is the owner of the gin—and through him—his employees.

FLAME RESISTANT TEXTILES

By THOMAS D. MILES

Supervisory Chemist, Laboratory Branch, Textile Functional Finishes
U. S. Army Quartermaster Research Center, Natick, Mass.

The constant presence and contact with textiles in daily living, from personal clothing to household furnishings, make their safety properties of general interest. How readily textiles ignite and spread flame is one of these properties.

Why do textiles burn? Follow a typical cotton fabric from the time a flame is brought near it and it bursts into flame. The flame spreads across the fabric until only an ash is left.

Take each step. The flame brought near the fabric heats it up. The heat decomposes the cotton into gases. The cotton is heated on a thermo-balance up to 500°C. The weight is continuously recorded. At lower temperatures, the weight of the cotton is unchanged. But as the temperature of the fabric rises, as it would in contact with a flame, the cotton decomposes into gases. The black line of ash is the weight of the solid remaining. Note that as the temperature rises most of the cotton is converted into gases. The remaining solid is a black char.

The first step, then, in the burning of a textile is the production of flammable gases by heating the fabric. As these gases move out from the fabric, they mix with air. At the point where the upper limits of flammability of this mixture of decomposition products and air is reached, ignition takes place.

The next step is that the flame spreads. Heat from the ignited gases (radiation from the flame and convection by hot gases) is sufficient to decompose more of the cellulose into flammable gases and the process continues until all of the textile has been decomposed. An ash is left which cannot be decomposed into additional flammable fuel.

Thus the textile burns because the flame source decomposes it into flammable gases which ignite and produce sufficient heat to decompose more of the fabric, to continue the process and spread the flame.

What can be done to change the burning properties of the textile? We have seen that flame spread needs two conditions. One is fuel, supplied by the decomposing cellulose. The other is heat to decompose more of the cellulose and allow the flame to spread. If heat or fuel could be removed, then flame spread would cease. The action of flame retardants has been explained either on the basis of removing the heat or removing the fuel.

There has been little direct evidence to support those theories based on removing the heat, since the measurements are difficult to make. However, it has been proposed that diluting the decomposition gases with inert gases moves the flame away from the fabric by changing the upper limits of flammability of the mixture. When the flame is moved away, sufficient heat cannot return to the fabric to further decompose it and spread flame. Bromine and chlorine containing compounds have been proposed to have the effect of diluting the decomposition gases. Another way of removing the heat is the use of chemicals that would undergo endothermic or heat absorbing reactions.

Most of the evidence that is available from studies on flame resistance is concerned with removing the fuel by changing the decomposition pattern of the cellulose. Evidence to support this theory is easier to obtain, since a variety of measurements can be made, such as the quantity of gas produced, the rate of decomposition of the cellulose, weight losses and the identification of the chemicals produced during pyrolysis. There is considerable evidence available that effective flame retardants alter the thermal decomposition of cotton.

This can be seen from the previous example. You will recall that this is heating cotton on a thermobalance. All flame retardants would initiate the decomposition of cotton at a temperature lower than the untreated fabric and all of them would con-

vert more of the cotton into a non-flaming char and thus less gaseous products than occurs with untreated cotton.

Effective flame retardants for cotton have been shown to be non-volatile acids or compounds which decompose into acids at flaming temperatures. They act as catalysts to change the decomposition of cellulose, both the rate of decomposition and the products of decomposition, to deprive the flame of further fuel. Listed next are some of the typical flame retardants used.

Ammonium sulphamate, mixed with diammonium phosphate, is typical of the non-durable flame retardants. About 5 to 7 per cent of weight is added to the fabric by the treatment which is applied by dipping the fabric or garment into a water solution of the retardant and drying it. There is no loss in strength of the treated fabric. The color and hand of the treated fabric are similar to those of the untreated. In addition, the non-durable treatments have the advantage of low cost, provided that the use does not require frequent retreatment. The main disadvantage is that they lose flame resistance on contact with water and thus have limited uses.

In looking for ways to make flame retardants durable to laundering, research was influenced by the early durable resin finishes for textiles. These were urea formaldehyde, melamine formaldehyde and vinyl chloride resins. Urea phosphate, THPC melamine formaldehyde and vinyl chloride-antimony oxide are examples of durable types. The weight added to the fabric is about three times that of the non-durables. This additional weight represents the reactive groups or binder that imparts laundry resistance.

With the exception of the aminophosphates (urea phosphate or other nitrogenous compound), which have durability to only a few washes and can lose their flame resistance through ion exchange, the durables can be subjected to repeated launderings and the flame resistance is designed to last the life of the garment. With all of the durables there is a reduction in strength of the fabric. To some extent this is characteristic of the chemicals used; for example, the APO types have less effect on strength than the others.

The amount of strength loss is also influenced by finishing conditions such as

cure time and temperature. This coupled with the fact that all of the durables require a cure with its need for special equipment, curing ovens, means that the durables are a specialty finish applied for the most part by a few finishers.

TABLE 1
COMMON FLAME RETARDANTS

	% Add-on	% Loss in Tensile Strength
Non-durables		
Borax-boric acid	5-8	None
Ammonium Sulphamate	15	None
Diammonium Phosphate	10	None
Ammonium Sulphamate-Diammonium Phosphate (2:1 ratio)	10	None
Durables		
Amino-phosphates	20	50
THPC	15-20	50
Vinyl chloride	25-30	35
Antimony Oxide	18	25
APO Types	18	25

What about the future of flame retardants? Have they reached the point where little or no improvement is to be expected? The non-durables have just about reached this point for the limited area where they are useful. There will probably be no major improvement in the properties of the non-durables in the future.

However, there is considerable room for improvement for the durables. Strength retention and cost are two areas for improvement. We have seen that the chemical types used for durables parallel the resin finishes and share some of their problems. Strength reduction is one of the problems associated with resin finishes. The future will probably see greater emphasis in the area of "non-resin" durable flame retardants.

Within the past few years there has been an enormous amount of research in many countries on inorganic polymers. This research is aimed at supplying, for rocket and missile uses, materials that will withstand extremely high temperatures. This is a property which most organic polymers do not possess. One of the by-products of this extensive research may be compounds that will find uses as durable flame retardants—an inorganic polymer that will have the low add-on and strength retention of the non-durables with the added feature of being resistant to laundering.

Less attention has been paid to flame resistant finishes for synthetic fibers. In contact with a flame the majority of synthetic

fibers melt. If this melt is free to drop away, the flaming does not spread along the synthetic. However, the melt is flammable and if it is held, for example by the presence of a resin finish, then flame will spread. Thus some of the flame retardants for melt fibers are designed to produce the melting and dripping that occurs with the untreated material.

An example is nylon netting with a resin to stiffen the net. Thiourea formaldehyde has been used in such combinations to make the finished netting melt and drip in contact with a flame. Its effect is due to the fact that the melting point of thiourea formaldehyde resin is near that of nylon.

The acrylics and modacrylics are examples of synthetic fibers which do not melt in contact with a flame. The modacrylics are flame resistant and include within the structure of the fiber, compounds such as vinyl chloride. The acrylics burn readily. It is known that diammonium phosphate is an effective flame retardant for the acrylics.

Although no studies have been made on the mechanisms for flame retardants for the acrylics, it might be interesting to speculate on what such mechanisms could be. It is known that under controlled combustion, the acrylics can be converted into a black char which retains fiber properties. This black fiber is nonflaming. Although the fiber has the appearance of carbon, studies have shown that it is a stable ring compound of carbon and nitrogen that has formed.

It may be then that effective flame retardants for the acrylics would be compounds that catalyze the thermal decomposition of the acrylic into this charred fiber form that results under controlled combustion.

What methods are used to measure the flame resistance of textiles? There are two general types of flame resistant test methods. One is the standardized method, an almost quality control test method, where emphasis is on the reproducibility of the test results. These are the methods that appear in procurement specifications of fabrics and in various regulations covering the use of flame resistant fabrics. These tests are widely accepted, and usually have been in use for a long time. Another characteristic is that an exact definition of all of the test conditions is listed.

An outstanding example of such a test is the vertical burning test. A sample of the textile about a foot long and several inches wide is held in a vertical position in contact with a flame for twelve seconds. The length of time the sample flames after removal of the flame source is recorded as well as a source of the amount of char that is present. This is estimated by the length of a tear made in the sample. The force applied in tearing the charred area is much less than that required to tear the uncharred portion. The standards throughout the world for tests of this type are shown in Table 2.

TABLE 2
INTERNATIONAL FLAME TEST REQUIREMENTS

Nation	Designation	Flame Source	Contact Time (sec.)	Measurements
U.S.	CCC-T-191 3903	Bunsen	12	afterflame char length
U.S.	CCC-T-191 3904	Candle	12	afterflame char length
U.S.	ASTM D526-61T	Bunsen	12	afterflame char length
Great Britain	BS 3119 1959	Bunsen	12	afterflame char length
France	94 03	alcohol (2cc)	10	afterflame char length
Australia Std	310-1959	alcohol (0.1cc)	10	afterflame char length
Germany DIN	53 906	Bunsen	6-14	afterflame char length

It is evident that a 12 second exposure to a bunsen flame is a test method that has been standardized throughout the world. In some of the test methods you will note that a candle is used as the flame source. This is for field testing since the candle has the advantage of being portable. Some of the cities in this country use this type of flame source in their test requirements covering tents for public assembly, and the test is run at the site where the tent is pitched.

The other general type of flame resistant test is the special purpose test. For various types of protective clothing, the flame source that will be the hazard in burning the textile is known. For example it may be molten steel, it may be an explosive powder. A test method is designed which uses the molten steel or explosive powder as the flame source.

A test method used in steel mills for protective clothing simulates the splash of molten steel on the fabric. It is also designed to tell whether the fabric system provides insulation enough to the molten steel to prevent serious burns. The fabric sample held at an angle is placed over a polyethylene film. The molten steel is poured on the sample and any flaming of the fabric or melting of the polyethylene film is noted.

In a test of protective clothing for handlers of powder, a weighed charge of the powder is ignited and it is noted whether or not the garments stuffed with flame resistant rags will ignite. In such a test it is of interest to know whether or not the conditions at the site of the sample garment are severe enough to burn untreated cotton.

The next example shows an attempt to include such a control in the test. Bits of untreated cotton are suspended on a wire fence in the same plane as the test garment. After the test is over each bit of cotton is examined and listed as not affected, scorched, or burned. Such bits show the areas where the conditions were severe enough to burn untreated cotton and those where only scorching occurred.

Another type of special purpose test is for areas where it has been found that the vertical bunsen test or some other standardized test cannot be used as a criterion of flame resistance. One example is the air-supported shelter. The escaping air from the tent is sufficient to put out any flaming.

Another example is a fabric that will pass

the vertical bunsen test but fail a field burning test. A weighed amount of paper is placed along one side of the tent and ignited. This fabric passed the vertical bunsen test but it burns readily in the field burning test. In trying to find an explanation for the behavior of this fabric, it became obvious that the plasticizer was the cause of the burning.

In the vertical bunsen test, the short contact time with the sample was not sufficiently long to distill the plasticizer from the fabric. However, in the field burning test the conditions were right for the distillation and ignition of the plasticizer. By making a cone of the fabric and heating it with a bunsen burner, the plasticizer could be ignited with a burning splinter. No ignition occurred when the plasticizer was removed with a carbon tetrachloride extraction. It was found that contact of the flame source through holes in the cone could replace the burning splinter as a means of igniting the plasticizer.

A brief word about uses of flame resistant textiles: in addition to the established uses of flame resistant textiles, such as military tentage, protective clothing for industrial workers, draperies and furnishings for places of public assembly, there has recently been added one use that is new in this country. This is hospital textiles. The Veterans' Administration has initiated a program to provide flame resistant textiles in certain hospital uses; for example, cubicle curtains that are used as room dividers, and clothing for the handicapped.

A STATE LABOR DEPARTMENT SELLS SAFETY

By W. C. CREEL

Safety Dir., North Carolina Department of Labor, Raleigh, N. C.

Safety must be sold and sold and sold. This has been said so many times that it is almost trite to a group of safety people. Everyone agrees, but sometimes the safety director fails to sell the supervisor, who, in turn, neglects to sell the worker. The same situation exists with state agencies. Too often, the state agency fails to see

the necessity for selling safety. In some instances, the power of legal enforcement overshadows the basic concept that safety must be sold on all levels by those who have the responsibility for promoting industrial accident prevention.

The state representative cannot carry a briefcase in one hand and a big stick in

the other and sell safety. He must be allowed to sell, he must be trained to sell, and he must believe in what he is selling. If the best results are obtained by a state agency, safety must be sold to industry just as it is sold by industry.

We at the North Carolina Department of Labor know that ours is a service agency. We also know that one of the services most needed by industry is in the field of accident prevention.

The need for accident prevention assistance by a State Labor Department is especially great for the small plant, and over ninety per cent of all the establishments in North Carolina have less than 100 employees.

Safety services can be sold because there is a great need by management as well as by the workers. There are those who say that a state labor department should direct its activities to the worker. We, at the North Carolina Department of Labor, do not feel this way. We feel that our services should be for the worker but should be directed through top management. Top management, especially in the small plant that does not belong to the National Safety Council, does not have a safety engineer and receives little assistance from his insurance carrier, needs assistance to curtail on-the-job injuries. Even more important, the most and best benefits for the production worker can be achieved by working through management.

There are many good ways for a state labor department to sell safety, and I like to think that we use most of them. However, I want to tell you about just one method which works well for us. I want to tell you about our special industry safety program.

Special industry safety programs are based on the need for special concentration in industries with high frequency rates or special problems. Programs have been conducted in six North Carolina industries with the following reductions in disabling injury frequency rates:

Industry	Per cent
Brick and Tile	36
Wood Furniture	43
Flywood and Veneer	15
Cotton Grey Goods	29
Fertilizer	40
Cotton Yarn	27

At the present time, we are conducting programs in our toundry and lumber industries.

The special program which I want to tell you about is in the textile industry, and this is our state's largest industry. The average employment is over 221,000 with an annual payroll in excess of 668 million dollars. We have concluded two programs in this industry, one in cotton grey goods and one in cotton yarn. I will discuss the cotton yarn program.

The elements of a special industry program include the following:

1. Review of industrial accident experience.
2. On-the-job study of operations and hazards.
3. Training school for industrial safety inspectors.
4. Special materials.
5. Consultations and visits.
6. Analysis and recommendations for perpetuating progress.

After the entree into an industry which we try to reach through the trade associations, the success or failure of a program largely depends upon our industrial safety inspectors whose job it is to carry the program to the individual plant. Our department is fortunate in having a fairly large staff of well-trained industrial safety inspectors. These men have received 150 hours of basic safety training and nine ten-hour special courses or training through the Bureau of Labor Standards of the U. S. Department of Labor. This includes ten hours of on-the-job training in a representative plant just prior to the beginning of a program.

Five visits are made to each plant with emphasis on plant inspection, accident analysis, and consultative service in organizing a plant safety program to fit the needs of the individual plant. The inspector has the training, he has the information and materials, and he has the desire to sell top management on the special industry safety program.

Participation in a special industry safety program is purely voluntary. It is a special safety service without charge and there are no strings attached. Special safety recommendations, including those as a result

of plant inspections, are made by the inspector at each plant participating in the special program. Again, compliance with these recommendations is voluntary. Even so, compliance has been secured for over 95 per cent of the recommendations.

Special materials are prepared to meet the immediate needs of an industry. These include process flow charts, how to inspect charts, and a series of safety bulletins which are sent from the Commissioner of Labor's office with an appropriate letter each month.

In addition, the best of the appropriate materials produced by the National Safety Council, the insurance companies, and other state and national agencies, are used. A special industry program usually lasts for two years, but long after the program is concluded, the results as measured by frequency rates and workmen's compensation insurance rates continue. From time to time, as the occasion may arise, special follow-up materials are prepared and distributed.

As the industrial safety inspector makes his five visits to each plant participating in the industry program, he collects detailed descriptions of every disabling injury which has occurred during the program period. As a result of this accurate and current information, worthwhile analysis of the industry injuries can be made.

On analysis of a three year period of the parts of the body effected by 5,746 disabling injuries in over 400 cotton yarn plants showed the following:

Part injured	No. injuries	Per cent
Hand or finger	1,903	33
Back	1,089	19
Trunk	783	14
Foot or Toe	745	13

A study of the same 5,746 disabling injuries showed the source of work injuries as follows:

Source	Per cent
Handling Objects	27
Machine	25
Falls of Persons	17
Falling Objects	9

A breakdown of the machine injuries shows the following: looms, 17 per cent;

spinning frames, 14 per cent; cards, 12 per cent.

One very tangible benefit of a special industry safety program is the preparation of a special operational safety checklist. The cotton yarn list includes specific checks for the following operations: combing, drawing and roving frames, spinning frames, cards, and lappers. These check lists are widely used through this industry.

While the North Carolina Department of Labor makes no direct claim for being responsible for industry safety achievements, other than bringing the problem to the attention of the industry leaders and carrying the message and materials to the individual plant management, we are proud of the continued safety progress in industries where special programs have been conducted. The results have been good and have been lasting. In North Carolina's vast cotton yarn industry, the state disabling injury frequency rate at the beginning of the program in 1951, was 10.9. The rate for 1960 is 6.3. This 42 per cent reduction is highly indicative of the success of safety work in this industry.

Along with the reductions in frequency rates comes reductions in workmen's compensation insurance rates. Despite several increases in workers benefits and many, many increases in medical and hospital benefits, the rise in workmen's compensation insurance rates has been very small. In fact, the increase has been far less than in other direct costs of labor, materials, or transportation. The cotton yarn workmen's compensation insurance rate for a North Carolina plant is now 65 cents per 100 dollar payroll. This rate compares favorably with the rates in other states, and surely is a direct result of fine and continuing accident prevention work in the industry.

A state labor department can, and should, sell safety. There is a real need and the special industry safety program offers a real opportunity.

We, at the North Carolina Department of Labor, are delighted with the opportunity to work with industry and will continue to do so at every opportunity.

LET'S LOOK INSIDE!

By D. V. HILL
Safety Director, Kingsport Div.
The Mead Corp., Kingsport, Tenn.

I know very little about the textile industry, or problems with reference to the prevention of accidents. In fact, I doubt if I would know the difference between a "spindle" and a "loom."

But I am sure you do have problems, and your people get hurt! And you wish to learn how to solve these problems. I want to help!

Definitely, your management is interested in accident prevention. You must be interested, or you would not have dedicated your life's work to the cause of suffering humanity.

And the people in your plant are interested, because their lives, and the welfare of their families depend upon how efficiently the accident prevention program is carried out in your plant or industry.

The things I will say to you today are not new! Those of you who have been in the field of accident prevention for a long time have probably heard everything that I will say.

But, perhaps there is someone who is new to the field and I can help him, or her, just a little bit. If I can, this paper will have been worthwhile.

So, let's look inside this business of organized accident prevention. Let's see how effective it has been. Then we will look inside our own plant programs and see how they can be made more effective.

Last year in our country, the National Safety Council tells us, 93,000 of our neighbors and friends were killed by accidents, and 9,400,000 were hurt. Of this number, 13,800 were killed and 1,950,000 were hurt in industry, while 38,200 were killed by automobiles and 1,450,000 were hurt.

In our homes, 27,500 were killed and 4,100,000 were hurt. These included such cases as the small child scalded to death by the overturned pan of boiling water on the kitchen range, the man who dropped his electric razor into the sink filled with water and the mother and baby who were

electrocuted when a small radio toppled into the bathtub from a shelf.

While we are primarily talking about industrial accidents, we must not forget that a worker killed off the job is just as dead as he can be!

You may be saying to yourself, "Surely our accident prevention program must not be very good if we let almost 100,000 people die needlessly by accident, and 9,400,000 people are hurt—and property losses in amount of \$13,600,000 were incurred in 1960!"

But let me remind you that if the accident rate that prevailed in 1914, when the National Safety Council came into existence prevailed today, the figures I quoted would be many times greater than they are.

We have made progress, and we must continue to go forward. So let's see what we, as individuals responsible for accident prevention in our industry, are doing and can do.

I have often heard it said that there are two causes of accidents: men and women.

But I am being facetious. The principal causes of accidents are (1) unsafe acts or (2) unsafe conditions, and, in many cases, combinations of the two.

First, let us define the word accident:

The word accident is used universally to infer a "happening." Usually there is couplet with its meaning a sense of "suddenness." Existing definitions for accident range from short expressions containing only a few words to lengthy compositions. There seems to be a tendency to color the definition because of certain aspects that are predominant in the mind of the writer defining the word.

A pointed definition is that accidental injury must be sudden but not necessarily instantaneous.

Accident has been called an unlooked-for mishap or an untoward event that is not expected or designed. A learned judge says that if a third party deliberately and will-

remember when a logger, or a paper mill worker, or a textile worker, or any man, needlessly dies, be it in Oregon, Maine, or South Carolina, or anywhere on this globe of ours, his death diminishes you and me, because we are "involved in mankind."

And just as "No man is an island, entire of itself," so no single industrial organization is an isolated island of self-benefit. Every store or factory, every individual enterprise is "a part of the main." So whatever you are doing to prevent acci-

dents in benefiting, not just yourself, not just your industry, not just your community, it is benefiting mankind.

The men who have devoted their lives to accident prevention know full well "for whom the bell tolls," and their great and eternal objective is to silence its tragic knell, by stamping out needless suffering, hardship, and death in our society.

Let us look inside our hearts to see if we have that most important weapon with which to fight our battle! Thank you.

EVERYONE—EVERYWHERE—ALL THE TIME

By PAUL F. HILL

Asst. General Mgr., National Safety Council, Chicago

You will search the pages of history unsuccessfully for a single example of a social problem in which acceptance or rejection did not finally follow the dictates of public opinion. Regardless of the speed at which this opinion was formed or regardless of how long it took for public opinion to be translated into public demand, the entire basis of action was predicated on the public's knowledge and understanding of the problem.

We also know that developments from experience have become dictates to the systematic and orderly approach to the solution of any major problem.

Let me ask the question—how much physical punishment, torture, sorrow, unhappiness and economic waste will it take, beyond the point of public opinion, to cause us Americans to refuse to tolerate needless accidents?

If we were to turn to a half-dozen of our best known dictionaries for a definition of this thing called an accident, we would, of course, find a half-dozen good and acceptable definitions. In going one step farther and summarizing all these definitions, we would find that "an accident is an occurrence in a sequence of events which usually produces unintended injury, death, or property damage."

We who have spent some time in this particular field of accident prevention all

too often recognize that the word "accident" is used as a cover up for law breaking, clumsiness, risk taking, fatigue, temper, illness, infection and plain lack of intelligence. We know that each and every underlying cause of every accident, regardless of whether it is in our home, in recreation, on the highway, or on our job, could be minimized if we were determined that steps be taken to provide adequate knowledge, skill, and proper attitude in the minds of members of our society relative to their everyday activities.

Everyone—everywhere—all the time—clearly defines the need to work at the accident problem 24 hours a day, every day of the week.

Is there a great difference in the area of personal responsibility when it's related to how one becomes injured or loses his life? What is it that causes us to callously disregard certain types of accidents which take so many lives and cause so many injuries? All too often those of us involved in accidents hurriedly and frantically drum up excuses or alibis to justify our being involved in an accident.

In our home, it's frequently the condition of floor surfaces, or some member of the family that has left some obstacle out of place, that provided that basis for a mishap. In traffic, it's the other driver, or the highway engineer, or a breakdown of

equipment. At play, it's something else; and at work, it can either be an act of a fellow worker or something management has or hasn't done right.

To this point it's doubtful that I have given any one of you a new idea or told you anything which you haven't long ago learned for yourself. Each of you in your respective company or staff positions has adopted systems of record keeping, or analyzing these records, and of promoting accident prevention techniques based on these data. Your companies have invested funds in giving you the tools and equipment necessary to carry out your assigned responsibilities. Many of you are reporting outstanding records of accident reduction in your plants, but have you checked the number of man-days lost on the job resulting from accidents happening away from work?

Some of you have maintained, and some of your companies are maintaining, good records on off-the-job accidents. Many companies tell us that there are many more man-days away from work resulting from home accidents, traffic accidents and recreational accidents than are recorded on highly hazardous-type jobs in the plant.

Now what can we do in our "fraternity of safety men" to further bring down this accident curve, both on and off the job, among members of our family, our fellow workers, associates, and friends?

First, we must emphasize individual responsibility and it must be exercised at all times and in all activities. The feeling of safety must permeate from the top to the bottom every family, in every plant, in every community and throughout the nation. Cooperation, mutual recognition of necessity, mutual respect, and mutual confidence are the basic components essential to a successful safety effort. Yes, they are the basics to any successful program or effort.

It is interesting to note that French officials in the 18th century recognized this fact and enacted into law a requirement that workers and management in government explosive works have their homes and rear their families in the immediate premises of the plant.

A well-planned action program to reduce all accidents may be thought of as "a system" to derive maximum benefits from

existing resources. The question of leadership, program direction and united cooperative effort can then be effectively focused on the problem.

We must clearly answer the following questions, which are uppermost in the minds of people:

1. Why should I become interested and more active in the accident prevention program?

2. What proof is there that a reduction in accidents will benefit me or my family?

3. What evidence is there to prove that, as an individual, I can do anything worth while?

4. What steps should be taken to effectively organize a coordinated approach to the problem?

5. Where may I obtain selective source materials and information on the subject?

6. To whom may I turn for help in activating a sound program?

The merging of individuals into group effort, and groups into organization effort is essential if our impact is to be productive. Prevention of accidents will be the measure of our success.

We must not fail to develop in the minds of every individual with whom we have contact a feeling of deep and sincere responsibility for his fellow man. We must go up stream, against a flood of public apathy and assume the responsibility for leading others in the same direction. The job of packaging "safe living" so as to make it attractive and acceptable is not an easy one. It can be done however, and we can do it.

In the words of Winston Churchill, it will take "blood, toil, sweat and tears." A great transformation in the public's understanding of the humanitarian and economic aspects involved in the accident problem is the first priority.

If we would consider ourselves as members of a select, special team assigned to work on the "new frontier" of accident prevention, return to our respective communities determined to take the lead, others would soon join in the effort.

In conclusion, we must bear in mind that cooperation, consideration, confidence and conduct go hand in hand in the leadership role to prevent accidents to everyone—everywhere—all the time.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

**WHEN: October 29 through November 2, 1962
WHERE: Conrad Hilton Hotel, Chicago**

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

**See the Latest in Safety Equipment
At the Greatly Expanded Congress Exhibit Hall**

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

OFFICERS OF THE WOOD PRODUCTS SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—WILLIAM HUIE, The Crossett Company, Crossett, Ark.
First Vice Chairman—*W. M. ALLISON, Sr., Safety Dir., B. C. Lumber Manufacturers Association, Vancouver, B. C., Canada
Second Vice Chairman and Program Chairman—T. E. NORTH, Safety Dir., Rayonier Canada Limited, Vancouver, B. C., Canada
Newsletter Editor—C. R. RUSTEMEYER, Canadian Forest Products Ltd., Vancouver, B. C., Canada
Secretary and Membership Chairman—E. A. ROLDS, Safety Eng., Weyerhaeuser Company, Longview, Wash.
Regional Representatives: *Great Lakes*—ROY E. JOHNSON, Kroehler Manufacturing Co., Kankakee, Ill.; *East*—SEYM JACKSON, Safety Officer, U. S. Forest Service, Washington, D. C.; *South*—*J. T. DUNLAP, Dierks Forests, DeQueen, Ark.; *West*—PAT RATTEN, Simpson Logging Co., Shelton, Wash.; *Canada-West*—*W. M. ALLISON, Senior Safety Dir., B. C. Lumber Manufacturers Association, Vancouver, B. C., Canada; *Canada-East*—*E. H. REEVES, Gen. Mgr., Lumbermen's Safety Association, Toronto, Ont., Canada
Engineering Coordinator—ARNDT SKONNING, Western Electric Co., Chicago, Ill.
Sawmilling Committee—R. E. BELL (Chairman), Safety Dir., The Crossett, Ark.; ROY F. POWELL, Poodatch Forests, Inc., Warren, Ark.; HOWARD A. CURTIS, Simpson Logging Co., Shelton, Wash.; JAMES MORRIS, Ozon Lumber Co., Prescott, Ark.; S. L. GREGORY, Pope & Talbot, Inc., Portland, Ore.; **Advisor to Committee**—*W. M. ALLISON, B. C. Lumber Manufacturers Assn., Vancouver, B. C., Canada
Logging Committee—JAMES GRADY (Chairman), Western Pine Assn., Portland, Ore.; JOHN TURGEON, Quebec Lumber Industries Safety Assn., Quebec City, P. Q., Canada; K. L. GIPSON, Georgia-Pacific Corp., Portland, Ore.; FRED C. SIMMONS, U. S. Forest Service, Upper Darby, Pa.; G. R. POTTS, Lumbermen's Safety Assn., Toronto, Ont., Canada; **Advisor to Committee**—*JOE T. DUNLAP, Dierks Forests Inc., DeQueen, Ark.
Paper and Plywood Committee—J. S. BOWMAN (Chairman), Mgr., Safety and Loss Prevention, United States Plywood Corp., New York, N. Y.; DON MACLEAN, MacMillan, Bloedel and Powell River, Ltd., Vancouver, B. C., Canada; GORDON MERRICK, Algoma Plywood & Veneer Co., Algoma, Wisc.; H. CHANDLER DREW, Medford Corp., Medford, Ore.; J. J. PLASKY, Safety Engineer, Georgia Pacific Corp., Hillsboro, N. C.; H. C. BEHNKDT, Personnel Director, Wood Products Div., Weyerhaeuser Co., Marshfield, Wis.; NEIL K. LEACHMAN, Employers Mutuals of Wausau, Portland, Ore.; *ROBERT M. GILMORE, Rayonier Inc., Hoquiam, Wash.
Furniture and Millwork Committee—THOMAS L. RASMUSSEN (Chairman), The Connor Lumber & Land Co., Laona, Wis.; GEORGE SCHNEIDER, Andersen Corp., Bayport, Minn.; V. K. ANDERSON, Kroehler Manufacturing Co., Binghamton, N. Y.; ROBERT J. DUNNAGAN, North Carolina Department of Labor, Winston-Salem, N. C.; ROBERT E. HOLLADAY, Thomasville Chair Co., Thomasville, N. C.
Cooperage Committee—I. W. SHUTT (Chairman), Safety Engineer, Jos. E. Seagram & Sons, Inc., New York, N. Y.; W. E. LYNN, Hiram Walker & Sons, Inc., Cooperage

Div., Peoria, Ill.; R. K. FORRESTAL, London & Petrolia Barrell Co., London, Ont., Canada; J. RANDALL THOMAS, Edwin Bell Cooperage Co., Pittsburgh, Pa.; *Advisor to Committee*—*R. C. CHILDRESS, Cooperage Div., National Distillers Products Co., Memphis, Tenn.

Trade Association Committee—ROBERT P. MILLER (*Chairman*), International Paper Co., Long Bell Div., Longview, Wash.; FRED WADE, Northern Interior Lumbermen's Assn., Prince George, B. C., Canada; V. V. COTMREN, Forester, Southern Pine Assn., New Orleans, La.; *Advisor to Committee*—*E. H. REEVES, Lumbermen's Safety Assn., Toronto, Ont., Canada

Off-the-Job Safety Committee—GEORGE NORRIS (*Chairman*), B. C. Lumber Manufacturers Assn., Vancouver, B. C., Canada; L. W. HAGERUP, Lumbermen's Mutual Casualty Co., Chicago, Ill.; LOUIS POSEY, Diamond National Co., Spokane, Wash.; *Advisor to Committee*—*CHARLES ZESKEV, JR., T. M. Mastin & Co., Kansas City, Mo.

Contest and Statistics Committee—LOUIS B. HOELSCHER (*Chairman*), Safety Dir., Weyerhaeuser Co., Tacoma, Wash.; CHARLES H. JONES, Michigan Mutual Liability Co., Chicago, Ill.; W. D. WILLIAMS, Personnel Mgr., Kroehler Manufacturing Co. of Kentucky, Louisville, Ky.; *Advisor to the Committee*—*LOUIS GLAZER, Dierks Forest, Inc., Kansas City, Mo.

Nominating Committee—A. F. REINWART (*Chairman*), T. H. Mastin and Co., St. Louis, Mo.; E. H. REEVES, Lumbermen's Safety Assn., Toronto, Ont., Canada; HERBERT A. LADWIG, Employers Mutuals of Wausau, Wausau, Wis.

Staff Representative—ROBERT CURRIE, National Safety Council, Chicago, Ill.

*Past General Chairman

OFFICERS OF THE TEXTILE SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—W. M. KLEINMANN, Safety Dir., Johnson & Johnson, Chicago, Ill.

Vice Chairman—MRS. IDA C. AYERS, Personnel Asst., Collins & Aikman Corp., Norwood, N. C.

Secretary—JOHN B. SKINNER, Chief, Ind. Hygiene Section, American Mutual Liability Insurance Co., Wakefield, Mass.

Newsletter Committee—B. S. STRENGTH (*Chairman*), Chemstrand Corp., Greenwood, S. C.; E. B. MANNING, Supervising Engr., Liberty Mutual Insurance Co., Charlotte, N. C.

Engineering Committee—I. M. DAVIDSON (*Chairman*), Southern Div., Eng. Mgr., American Mutual Liability Insurance Co., Atlanta, Ga.; JOHN G. SAYERS, Supervising Engr., Loss Prevention, Employers Mutual of Wausau, Charlotte, N. C.; FRANK W. MARCACCIA, Chief of Ind. Inspection, Rhode Island Department of Labor, Providence, R. I.; R. W. LANE, JR., Plant Mgr., Union Asbestos & Rubber Co., Marshville, N. C.; *CHARLES L. TROMMER, Safety Dir., Mohasco Industries, Inc., Amsterdam, N. Y.

Education and Training Committee—GUY BOOKER (*Chairman*), Safety Supvr., Chemstrand Corp., Pensacola, Fla.; T. M. GOWYS, Dir. of Safety & Training, Chatham Mfg. Co., Elkin, N. C.; WILLIAM A. HAWN, Safety Dir., Graniteville Co., Graniteville, S. C.; H. E. WILLIAMS, Safety Dir., Fieldcrest Mills, Inc., Spray, N. C.; RALPH F. JOHNSON, Safety Supvr., Firestone Textiles, Inc., Gastonia, N. C.

Special Fiber Committee Chairman—*CHARLES L. TROMMER, Safety Dir., Mohasco Industries, Inc., Amsterdam, N. Y.; ROBERT I. BARR, Safety Supvr., Industrial Rayon Corp., Painesville, Ohio; *GLENN G. FLEMING, Corp. Safety Dir., Celanese Corp. of America, Charlotte, N. C.

Off-the-Job Committee—C. L. HENKEL (*Chairman*), Safety Supvr., E. I. du Pont de Nemours & Co., Kinston, N. C.; JOHN McALPINE, Safety Supvr., Celanese Corp. of America, Inc., Rock Hill, S. C.; *H. S. BAUCOM, Safety Dir., North Carolina Ind. Commission, Raleigh, N. C.

Cotton Ginning Committee—W. KEMPER BRUTON (*Chairman*), Executive Vice Pres., Arkansas-Missouri Cotton Ginners Assn., W. Memphis, Ark.; CHARLES MIERKEI, Continental Gin Co., Birmingham, Ala.; ALFRED M. PENDLETON, Extension Agricultural Engr., Dallas, Tex.; T. V. McLAUGHLIN, Personnel Mgr., Producers Cotton Oil Co., Fresno, Calif.; ED BUSH, Executive Vice Pres., Texas Cotton Ginners Assn., Dallas, Tex.; KIRSCHKE McRAE, Dir., National Cotton Council, Memphis, Tenn.; TOM MURRAY, Dir., National Cotton Ginners Assn., Decatur, Ga.; VERNON P. MOORE, U. S. Ginning Laboratory, Stoneville, Miss.

Membership Committee—E. B. MANNING (*Chairman*), Supervising Engr., Liberty Mutual Insurance Co., Charlotte, N. C.; W. C. CREEK, Safety Dir., North Carolina Dept. of Labor, Charlotte, N. C.

Program Committee—MRS. IDA C. AYERS (*Chairman*), Personnel Asst., Collins and Aikman Corp., Norwood, N. C.; J. D. BROWN, Safety Dir., American Enka Corp., Enka, N. C.

Nominating Committee—*A. E. CONNELLY (*Chairman*), Safety Supvr., E. I. du Pont de Nemours & Co., Inc., Martinsville, Va.; *FORREST N. PETTY, Dir., Safety and Bene-

fts, Dan River Mills, Inc., Danville, Va.; *E. L. PERMENTER, Supervising Engr., Loss Prevention Dept., Liberty Mutual Ins. Co., Spartansburg, S. C.

Advisory Committee—*FRANCIS BETHUNE, R.N., Employers Mutuals of Wausau, Atlanta, Ga.; *JOHN J. BURGER, W. J. Dickey & Sons, Inc., Oella, Md.; *J. A. WINKLER, Dist. Engr. Mgr., American Mutual Liability Insurance Co., Atlanta, Ga.

Staff Representative—R. G. BELKNAP, National Safety Council, Chicago, Ill.

*Past General Chairman

BILL GOVE

*President—The Bill Gove Organization
Coral Gables, Fla.*

Bill Gove delivered the Early Morning Class lectures at the 49th National Safety Congress, October 17-20, 1961, attracting overflow crowds to the grand ballroom of the Conrad Hilton Hotel, Chicago. Mr. Gove has addressed the members of more than 100 trade associations, 372 service clubs and hundreds of sales and advertising clubs, and has lectured at several universities. He has conducted sales clinics for many leading companies.

TIME MANAGEMENT

(Early Morning Sessions of the 49th National Safety Congress)

By BILL GOVE

Pres., The Bill Gove Organization, Coral Gables, Fla.

SESSION 1 — TIME — ITS NEW DIMENSIONS

I was with Minnesota Mining for 15 years and pretty close to safety. They talk about it and think about it. It is a pretty dedicated place. You say, "How do people get this way?" And then someone says in a lot of cases it is compulsory, and you have got to get this way. Someone else will just say it is common sense.

You know you have to keep people healthy. It increases man-hours, output, production. It is simple to explain, and then someone like Ned Selman says, "This is not the real reason these guys have a gleam in their eyes. You will find it out. This is people at their best. This is one guy who in a lot of different ways is trying to help another guy."

"It sounds kind of corny, but you are going to be here with these people all week, and you will find this is the way it is—one guy trying to help another guy, and this is people at their best."

It is good to be back to the land of the living. I've been doing a communications conference with some college professors out on the Coast.

I figure they are saying something that we could use in the manager-man relationship. They are saying something that will make all of us do better and be better and take a bigger bite of life, but I will be darned if I can figure it out.

There are about 15 anthropologists that work with people in huts, and also with octopuses. I had lunch with a guy named Gregory Bateson. I know he is saying something I want to hear.

I said, "Dr. Bateson, bring your material down to me. I would like to build myself up to what you are saying, but I figure you are talking to other anthropologists."

"For instance, they talk about multiphasic

tests. They bring their people in and try to put a square peg in a round hole." We found a guy who could do it.

In reference to what I am going to talk about before we are through, I think he said something we could all use in all relationships, not only manager-man, but maybe parent-child, and husband-wife, and friend-friend, and citizen-community, and certainly man-safety. We like to do it this way this morning.

I would like to talk about the idea that has been near and dear to my heart, an idea of not how to do the job, but how to find time to do the job, and maybe find extra time.

Tomorrow I would like to talk about what we talk about when we get together, building stronger, more grown-up relationships.

The third day I would like to talk about some of the areas of persuasion which again we talk about when we get together, but here is something I asked Roy Benson about this morning.

I thought it might be a good idea. I am going to be riding around the corridors all week, and I thought if you had a question in communications or about boss-subordinate relationships, that you might stop me and say: "Here is one I would like to have you cover." Now if I don't have the answer, and there may be a pretty good chance I don't, I know people around the greater Chicago area that do have the answer. I will call Phil Prince over at Sears Roebuck, or I will call someone at St. Paul. I'll get the answer or close to the answer for you, if you want it. I'll be the vehicle for reporting back to you. I thought this might be fun.

You know, generally the speaker-audience relationship is strictly one way. You know,

I'm talking. There isn't much you can do about it. I would like to change that. We are going to be together for four mornings. Here is your chance to participate.

Do you know what that means to me? That means there is a tremendous amount of power in this room. If you have a problem, there is a pretty good chance that you can solve it if you have the opportunity of meeting with everyone here.

Just a word about business around the country as it affects all of us. When you zoom in on cities, towns and villages all over the country, and you see the new plant expansion and the new churches and the hospitals and schools, and shopping districts, it is hard to be anything but optimistic.

You know, my subject this morning has to do with the dimensions of time, and it all started as a result of a most unsophisticated study. I kid you not. It was an unsophisticated study.

For instance, when I find someone who is really doing it, I guess because I'm such a wheel spinner myself, I am intrigued by this guy.

I know people who write a couple of books a year. They write 20 trade journal articles on safety. They serve in the vestry.

This guy serves in the vestry in his church. He is just doing it. He has got an animal farm, and all the chinchillas are in heat. He is just swinging it.

So I go to this guy and I say, "How do you find the time?" And you know, here is a funny thing. Generally, they can't tell you. They can't articulate. The real doers can't articulate this.

I know what the books would say. They would say this man has a profound respect for time. I don't think he has. In fact, if anything, I think he might very well have a profound disrespect for time as we know it.

You ask this guy any time during the day, "What time is it?" He can't come within an hour and a half of telling you. I guess this is the reason, because when we think of time, we think of it in terms of seconds, minutes, hours and days.

I think he has a different concept of time. Oh, I guess he uses external techniques. Most of us when we are overwhelmed with detail write things down,

don't we? Psychologists say that we relinquish some of the responsibility when we put it down. Take it out of here, put it down, so we can see it. It loses a lot of its bigness, and I think people use spare time to get a lot of things done.

I was on the plane from Chicago to San Francisco with Mr. Herbert Hoover. He said, "Mr. Gove, you talk about the time thing. Last year I wrote a book in my spare time. Did you know that 15 minutes a day equals 11 full days a year? Did you know that 30 minutes a day means 22 full days a year? All I do is use the time waiting for dinner, waiting in the airports. Just waiting. I wrote a book."

I'm sure they all do this, but I am more convinced that when most of us think of time, we think of a clock, of a calendar, and we play games called: "Beat the Clock." We figure we get up a little earlier, stay up later, and we have got it beat. There is no way in the world you can beat this. It goes relentlessly on and on. I am convinced, and this is the idea I want to share with you this morning, one of four ideas—I am convinced when the real doers think of time, they think of it as having more than one dimension. They think of time as having many dimensions.

Here is the key. They know they can't do anything about the clock. It will beat them to death, but they can do something about the dimensions of time.

Here is "habit" as the first one. Look, when I relegate to habit those irritating, nonproductive details that bug me, that take so much of my time—when I delegate or relegate them to habit, then I free myself for conscious, creative effort, and when I do this, habit you see, becomes a dimension of time.

Here is the key. You can't do a thing about the clock. You can control habit.

I think it was Albert E. Gray of Prudential who said: "People who get things done have formed the habit of doing the things other people don't like to do."

This almost sounds oversimplified to the point of saying good baseball players get more base hits, catch more balls, score more runs, bat more runs than do bad baseball players.

There is more to it than this. Mr. Gray followed it up by saying: "And generally

the people who get all these things done, don't like to do these things any more than anyone else at first, but they do them, and here is the key. They do them because they found the results they get more than make up for the effort they put forth."

Now if you check this out with the psychiatrist, he would probably put it this way. He would probably say when we start to do anything—attend a safety meeting, take a cake, join Alcoholics Anonymous, take piano lessons, improve our golf game, any human activity, when we start to do anything we are either motivated by pleasing methods or pleasing results.

Now if we're motivated by pleasing methods, we do the parts of the job that are fun, pleasant, easy, the things we like to do—which probably accounts for the fact that 85 per cent of the people who take piano lessons learn to play one song, "Peg O' My Heart." The people on the other hand, who are motivated by pleasing results, do the parts of the job that are fun, pleasant, easy, and then they form the habit of doing some of the things they don't like to do because they know this is the answer.

When I first heard this, I thought it was the most exciting thing that I, as a salesman and as a father and as a husband, had ever heard, because I have always been a little worried about myself.

I don't go for this confessional-on-the-platform-introspection bit, but in the first place I hate to get up in the morning. I'm the world's worst. I put a call in. I have a wrist alarm. I give the maid on the floor at the hotel permission to break the door down if I don't get up in the morning. I could sleep in a bowling alley, you know.

Well, this has always worried me, and I hate detail work, and this has worried me. Actually, I'd rather call on someone I know than I would to establish a new relationship. Well, you know, I figured I might have a thyroid deficiency, or I might be a slob, you know.

Then all of a sudden someone like Dr. Gray, that I can trust, comes along and says, "Man, you are perfectly normal. Nobody likes to get up in the morning. In fact, if you jump out of bed with a smile and you say, Boy, what a day! Oh, I can't

want to get on that job! Those wonderful people! you are nuts."

You know the problem, not me; but it was most encouraging after all these years of reading all the books on motivation and taking all the management development courses. Boy, what a relief to find out that people who get things done don't seem to have any more education or inspiration or drive or ambition or adrenalin in their glands than anyone else. They just form the habit of doing the things other people don't like to do.

I have a neighbor who hates his boss. He said, "My boss is the kind of a guy who would vote a town dry and then move."

I said, "You're making a liar out of me. I tell people one of the prime requisites for happiness is liking one's job. You hate your job, but you are real big."

"Oh," he said, "This doesn't have much to do with . . . You see, I don't intend to spend the rest of my life working for this guy. But while I'm working for him, I can't afford to develop any lousy habits, because when I take my record to some guy I want to work for, I want to show him my record, and I want to be able to say, 'Look, this is what I did. This is my record. This is the kind of a job I did for a guy I didn't even like, and now think what I can do for you, Dad, if I started to like you just a little bit.'"

You know, at Braniff, we used to tell the hostess: "The reason you want to do a good job, Mary, is because you are about the only contact we have with the customer. If you are nice to them, they will come back, but if you are inconsiderate and impatient and surly, there is a pretty good chance they won't, because we get a high percentage of first riders. It is important we keep them. If you do a good job," it was implied, "we will prosper."

So we approach it differently altogether in this area. We say: "Look, Mary, don't do a good job for what doing a good job will do for Braniff. Do a good job for what a good job will do for you later. You're only going to be with us a year and a half. We know what the figures are. That is about as long as you gals stay. While you are with us, some of the habits you develop you will carry over with you into the more important job of being a

mother and a wife and a citizen. So don't be polite, patient and considerate of our passengers, just because we'll do better. We will do better, but be patient and considerate for what doing it his way with another person does for you."

I get a feeling there is a lot of this in safety. You don't do it because it makes it better for General Motors. You do it because this is the way one guy should react to another guy. You don't have to read the books to know this.

I think it is this way with safety. You don't do it because the books say it. You do it, and we do a lot of things in manager-man relationships that the book doesn't say ought to be done.

People don't write a thesis about this. You can't dig it. It is being pool-room smart. It is acting this way toward him because that is the way you are supposed to act. Habit, and the habit of.

I must tell you about this friend of mine out on the Coast. I wish he were here to tell this story. You would all walk out sideways so you wouldn't fly.

His name is Carl Bock. He is a Jewish refugee. One leg is shorter than the other. He has a thick lip and a heavy accent.

He has had a tragic background of a brother and a sister made into soap in the concentration camp. He came to this country as a butcher by trade. He worked one year house to house for the Fuller Brush Co. He led the West Coast despite the fact he only knew fourteen words of English. What a guy!

He had been here a year, and a life insurance man—I think there is a story here for all of us as parents, as managers and as men—wrote him a \$20,000 endowment policy.

After the salesman had the sale worked up, Carl said, "How much did you make selling me this?"

The salesman told him. Carl said, "Take me to your boss."

That was 11 years ago. Carl Bock wrote ten and a half million dollars worth of paid-for life insurance, and I want to tell you when we get together as salesmen, this is as good as you can get.

You could take all the 3 million dollar writers in Chicago and put them in that

phone booth out there and still get in yourself.

In our business this is the 4-minute mile. This is not only climbing Mt. Everest, it is taking the family up there for a picnic. This is drinking goat's milk. This is 63 home runs a year.

How did he do it? We figured if we could find out what makes him tick, we'd have a story to tell teachers and parents and managers.

So they brought him in. The Ph.D's gave him a battery of tests. They put wires on his arms and gave him the shock treatment. What did they find out? Did they find out he was smarter than we are? He has a 92 I.Q.

He works harder than we do? No, he doesn't. He spends more time in front of people who can buy than we do. He has a wonderful technique. He talks with prospects. He pats them on the cheek. He says, "Buddy, if you look as good on the inside as you look on the outside, I think I can get you a little more life insurance."

He says, "I wouldn't guarantee it, but if we'll work together, we will see what we can do, Buddy."

You say he must have a dynamic sales personality. Here is a man who must be supersensitive to people's needs and wants. Actually, he irritates as many people as he sells. He wouldn't recommend you to sell this way.

How does he do it? His boss says this is not oversimplified. He says the average life insurance man gets up in the morning. He dresses. He says, "I should call some people. I should check with my bird dogs. I should send out some longhand direct mail letters, but it's hot. I'm not in the mood. This is not my up-cycle today."

Carl Bock gets up in the morning, dresses, shaves, calls five people, checks five bird dogs, sends out five direct mail letters.

Carl Bock has formed the habit, so with Carl Bock habit is his executive assistant. Habit takes care of the things that we should do as regularly and as automatically. You shouldn't have to think about safety. You should feel about this the way you feel about brushing your teeth in the morning. You shouldn't go to work without this

any more than you go to work without your pants on.

Carl Bock has formed the habit, so habit becomes a dimension of time. You can't do anything about the clock. You can control habit.

Here is another one—energy. You talk about this all the time in the plant. Work simplification. Time and motion, waste energy, waste money. We never talk about it as people.

Mertness. Just staying awake. Oh, what a story there is for you. Just staying alive, staying awake, keeping tuned in, keeping your antenna. It is more than an attitude problem. It is a dimension of time.

I live in Coral Gables. We have a suburban high school. We compete in all sports with Miami senior high tough kinds: Miami-Jackson, Miami-Edison. We have been state champions three out of the last five years. We have got a tough little guy coaching who brings out the best in the kids. Those who quit, they hate him.

Those who stay call him when they come home at Christmastime before they call their mother. He asked for the best. He brought out the best. It is tremendous.

We're talking about this time thing. Maybe you will get a kick out of this story.

He said, "You know, the school board only allows us 20 days in the spring. Everyone gets it. There are 20 days in the spring for spring practice. So I get my kids together," and I say, "How would you like 40 days?" They say, "Oh, you are kidding, coach."

"No, no. I will show you how we can get 40 days. Here is how, if you listen, if you stay awake, if you try to get it the first time, if we don't have to repeat. When that whistle blows, stop the play. If you are in midair, stop."

"If you listen, I will promise you to

double your effectiveness; that is just like having 40 days."

Staying awake, being alert. Here is the idea this morning.

Too many of us, when we think of time, think of seconds, minutes, hours.

You probably imagine this thing I'm holding is a 3-minute egg timer for timing eggs. It is to you and me, but to a good friend of mine this means more than a 3-minute egg timer.

He calls on doctors for the Lincoln Pharmaceutical Co. He details doctors. He has to compete with Eli Lilly, Upjohn, and those fellows for time.

He walks in to the doctor. He says, "We're very good. We have drugs that we don't even have a disease for yet. Next year we're coming out with a new wonder drug. You have to be in perfect health to take it."

"I call on doctors, and they are busy. They go on house calls and then to the office. I only get in there for a few minutes a day. I say: 'This is a 3-minute egg timer. I took all the things I want to tell you about, broke them down into a 3-minute sales talk, and when the sand gets to the bottom, I will quit talking and like the Arab, steal quietly away.'"

"The doctors say, 'For heaven's sake, Charlie, you can't give your talk in three minutes.'"

"I can, providing I do all the talking."

"If the doctor interrupts, I turn it right back again. If the phone rings, I turn it back. He ain't going to be treating his patients on my time."

We are going to be talking about the dimensions of time, and I can almost hear someone say, "Why doesn't he say safety? This should be number one." It is.

I didn't think it was until I got here, but what a dimension of time this is.

This was the springboard. In fact, one of the boys said, "If a good looking gal comes to the door and says, 'Why, young man, come right in, don't go in.'"

So I think over the years I have made a lot of mistakes, as is apparent, but I think that working with my boy, Billy, working with Nancy and Harry, I have tried to be careful. If there was a cause for criticism, I tried to make sure that I criticized the thing they did and not them.

And this is first page, I know, in every human relations manual, but we get so preoccupied with the job to be done it is very easy to criticize the guy. There is a big difference between refusal and rejection.

I say to my Billy, "There is nothing in the world that you could do, Billy, that would make mummy and me love you less. You could get in a marijuana raid and you are only eleven years old, and it would be front page in every paper in America, and we wouldn't love you less. You would still be our boy, but boy, we are going to call you on things we don't like."

We're being bombarded on all sides by books, magazine articles, lectures on how to be better. Isn't there a danger of taking this thing too seriously?

I think so. The most unattractive managers I ever had were the guys that were growth-oriented, but real pompous and officious. They don't get through to the men.

We used to talk in Minnesota Mining about personnel, and growth in this area was more a matter of subtraction than addition. When we cut out, when we eliminate greed, avarice, jealousy, hate, we are closer to the whole person.

Bob Tosky is a pro at our country club in South Miami, and he talks about the golf swing as more a matter of subtraction.

He said, "Too many times we go to the teacher and he has us putting our hands under and holding the club like you do a bird. I want to be able to take that club away from you when you start back, start back with the hips and when you come down, come down here in one piece. You know what they do, they forget to tell you to hit it."

Tosky says, "Take the club back and if you move yourself into position, the rest will take care of itself."

I think there is a lesson here. He said we don't make a bad shot because we lift up our heads, he says, "We lift up our heads because we make a bad shot."

Subtraction. We cut out. We talk about our organization cutting out.

We said yesterday that too many of us—and I'm included and talking to myself—too many of us, when we think of time, think of minutes, seconds, hours, days, this is the time and so forth. We play games about beat the clock. I suggested that maybe we think instead of the clock, which goes relentlessly on, we think of time as a habit.

We will negate that habit and free ourselves.

I've been talking about energy. We have been talking about energy in the plant for years, wasted energy, wasted time, a real correlation between the two. Yes, how I feel when I go on the job pretty well determines how I feel about doing the job and ultimately how I do the job and in my particular case as a salesman, how long it takes me to get through to someone.

And when I say it is no longer a problem of personality or function, it is a time problem, for it calls for a time concept.

I said alertness to stay awake, a dimension of time. Stay awake. Fewer accidents, more output, the meaning of time.

Here is the fourth one. I said I would save this for today—attitude. I don't have to tell you about this. All around the corridors yesterday and today we have talked about these safety attitudes. Some people have it and some people don't.

They talk about some of the old timers. "You are just a kid. I've been on this job for 35 years."

They say the younger people coming up into the organization are generally easier to get to be safety oriented, to have safety attitudes. I could only talk about the attitude in my business. I hope the adapting will be up to you.

What kind of an attitude are we talking about that gets through to people? What is the grown-up attitude that we talk about every time we get together?

Well, J. F. Croft of Minnesota Mining used to sum it up this way. We would have a three-day seminar and they would fill us up with training, motivation and con-

trol. And you walked out figuring you were a salesman. You didn't do anything, you were going out with stuff loaded up to here and you would think, where in the world were you going to use all this stuff.

But we hope it stays filled up to there so that it will come through for you in the clunch. That is why we give so much.

I used to say, you know, we can forget everything we know about selling, we can forget everything we know about supervision, we can forget everything about being a good parent and father, if we will always remember to go into every relationship with the attitude, "How can I help this other person solve a problem?"

How can I help this other person grow, if he wants to grow?

At the communication conference, we talked about this for a week and I think there's something here for us in all our relationships. They said, "We goof up in communications. We fail to get through to people. We have communications breakdowns, because too many times, we get so concerned with the answer; too concerned with the answer and not concerned with the problem itself."

In fact, on the table they had a big card that said, "To hell with the answer; what is the problem?"

We talked about this.

Now in the seller-buyer relationship, we say it this way: "I am a salesman, I am trying to get through to him." Now in a persuasive situation like this, you are a supervisor and try to get through to the man.

In the situation like this, there are two problems involved: Mine—how to get the order. His—how to get a product, a service that will do the job for him. His is the key, I think.

My success in solving my problem is in direct proportion to the number of his problems I help him solve.

Here is what we say to our salesmen. When I, as a salesman emphasize my problem, I am acting like a peddler, and they are a dime a dozen. But when I emphasize his problem, mine takes care of itself. I am acting more like a pro.

We had a guy who went to a meeting in the morning before breakfast and this guy worked over his men. They called him the Colonel. He was the president of his company. You wouldn't believe it. He was answer-oriented.

He worked these poor guys over at 8 o'clock in the morning. They called him the Colonel. I asked one of the fellows, "What is he? Was he in World War I?"

He said, "He started it."

So the Colonel said, "We are going to have a new contest. Those that get their quota will get to stay on the payroll."

You know, murder! And then he wound up and he held up a product and said, "I have got 105,000 of these in the warehouse. What will I do with them?"

I just wonder how they can survive with this kind of leadership? How can they get by with this primitive leadership pushing people around?

Then at 11 o'clock they had another meeting on top of this meeting and the general sales manager, who knew what the score was said, "We have to get an increase. You heard the boss. But let's talk about how we are going to get it. Let's forget the answer and talk about maybe taking a look at the quality of our calls. Eighty per cent of our business is coming from about twenty-five per cent of our accounts. So let's do some forecasting."

"Let's really look this over."

I have a friend of mine who is really shy. When we were toastmasters together, he used to say he couldn't lead a group together in silent prayer. He said he didn't play football because every time he saw the guys in a huddle, he thought they were talking about him.

I think there is a story here.

He came to me and said, "I have a real problem." He is an auditor and he was going through this orthodontist business and having a new baby in the house and he said, "I understand some guys pick up some extra dough on the outside. Any ideas?"

I said, "What do you think of mutual funds?"

"To sell them or to buy them?"

"No, what do you think of them?"

"Oh, I think it is a good idea. An insurance program. It is good to gamble."

I said, "Well, Aetna is looking for some qualified people. Call 'em over the weekend."

He said, "Oh, Bill, I couldn't sell."

I said, "Let's forget the word sell. Could you solve problems? You're an auditor. Could you go to people and sit down and talk with them and show them how to balance their finances? If they need insurance could you tell them they need it? And if they could take a little off the top for themselves, could you tell them? Could you help them solve problems? Never mind selling."

Now of course, the perfect ending to a sales story is that this man is now making \$2,000 a month and his wife has a new mink coat. But, I don't believe it is true. However, it looks like he's going to have to quit his job and go at it full-time.

He has a wonderful story. He says, "All I want to do is help you solve your problems. If you have got one, you will want to know it and by the same token, if you don't have one, you will want to know the problem-solver."

It is a different idea from going into a selling situation as we salesmen know it, and boy, we have been brutal in this area, manipulating, technique stuff, charged personality. The idea of his going into a selling situation as a salesman was totally unsuitable, but this approach worked for him.

Teachers know this. They get so jazzed up with PTA and other problems. The only job is to help my Billy be a better boy.

Doctors forget it. I go on a trip, three days without sleep. Sometimes my eyes are bugging out. I think I have a rare oriental disease. I call a house doctor in a motel and I go right down and I am lucky, the waiting room is empty.

Does he follow me in and say, "Mr. Gove, I am going to help you solve a problem?" Does he say, "See those diplomas on the wall? They got me ready for you." Does he imply this?

No, I have to sit down with the nurse and she has a questionnaire. I am dying, but she has got to ask questions. "What

income bracket are you in? Any insanity in your family?"

All I want him to say is, "I am going to help you solve a problem." This is how we get through to people. You can forget everything else you know.

We had people in our plant at Minnesota Mining, and you wouldn't believe it, some of the snuff-chewing Swedes are rough. So, we have the University of Chicago Survey. We wanted to find out how come this guy is so rough? None of his employees ever had any grievances.

You would go to somebody and say, "Do you work for Paulson?"

"Do I work for him? Am I working for that son-of-a—?"

"How long have you been working for him?"

"Sixteen years. If you want to know anything about him, just ask me."

"Sixteen years? Why don't you ask for a transfer if you don't like him?"

I talked to a lot of guys and asked a lot of questions, and finally I find out that this guy is real tough, he eats his young, but he tells the truth. He is impartial and he works like hell himself.

It doesn't say this in management books. This ought to be page one, because this is what we talk about when we talk about our bosses, when we get together over a cup of coffee. We don't say, "He is not a very good scientific manager. He doesn't delegate authority."

We say, "He lies. He is a liar and you can't trust him." That is what we say.

So we say to this guy, "You don't want to move?"

He says, "Well, no, at least you know where you stand here."

But here is something you don't tell him. Paulson has had more foremen come out of his department than any other guy in the plant and the people who work there know it. They know this is the way this guy gets his big kick out of life. He won't make a big thing out of it because he has absolutely never been known to smile. They say he doesn't take a vacation like anybody else, he goes to Camp Lejeune in North Carolina for his vacations and teaches the Marines how to fight dirty.

But something is happening here. He is a problem-solver. He gives them a fight, but don't talk about any of his people. Don't talk about them to him or you are in real trouble.

Is there a management story here? I think so.

I came into Cincinnati the other morning about 4 o'clock in the morning and the airlines had lost my luggage. I guess when you travel as much as I, this is the worst thing that can happen to you. I went up to the senior night agent's desk and I buzzed the buzzer and this guy came out. He looked like he was in charge of Oven No. 3 at Buchenwald.

I said, "Did anybody find a piece of luggage with the initials BG on it?"

He said, "What's the matter, did you lose it?"

I said, "Not really, but you know, this is the way I open every conversation at this time of the morning."

"Where's your check?"

I said, "I have got a problem. The guy in Louisville who pulled my ticket, pulled the check for my luggage."

I thought: he was going to say, "Oh, you lost your check when you lost your luggage." Instead of that he said, (cross my heart and hope to die!), "What was the number on the check?"

I said, "I usually have it tattooed on my nose."

We tell our people that when this happens, never mind the vital statistics. Those can wait. Tell them you are going to help them. Tell them you are not even going to have your coffee until you help them get the luggage. Then write it down. Never mind who is to blame. Find the damn luggage first.

I think one of the squawks I had, working for a bag company, is in this problem-solving. I always knew what their problem was. This was the first company I worked for. I always knew their problems. Did you ever feel this way? I always knew what their goals and what their dreams and what their objectives were. They made no secret of this. We used to get it in a bulletin once a week and at the annual sales meeting it would be strung across the room.

"Let's get eighty-two in '41," and all that jazz and all the slogans.

Then the president would get up and tell us just exactly what was expected of us. We had to know what they were looking for. But you know, I always had the feeling that I knew what their problem was but they weren't taking the time to find out what mine was. I felt like going to them and saying, "Look, I will swap you. I will do this and you do this, and man, together we will make music. I will go where you want me to go when you want me to go."

All I want to say to them is, "I will break my neck to get you a bigger share of the market. I will go as far as I can go. I will tell you the truth when you ask me something. I will knock myself out because I know what your goals and your dreams are. But here is what I want you to do. I want you to tell me the truth when I ask you. I don't want to have to go to one of my suppliers and have them tell me about a new price increase or a policy change. You tell me. I can be trusted."

As I say, we have made a lot of mistakes as parents. We have two teen-age daughters and we think swapping is the only thing that has worked in our house. We used to say to Nancy, "Honey, this is the first time you have ever been a teen-ager, but don't forget, this is the first time we have ever been parents of one. We can have a lot of fun for a time or it will be murder. What happened to the neighbor's kid? Fifteen years old and love went out the window. The parents and kid are bickering all the time. Money, we have a lot of love and fun and laughs. We will swap. Here is a list of things we will do. We will be flexible. Here is a list of things we want you to do. We will tell you. And if we goof up, you tell us."

I remember one thing Minnesota Mining did in all their training. We used to say, "We have 600 salesmen and we have 600 training courses. Every training course has a man's own initials on it." We try to give the guy what he needs. Could you imagine a blanket training course now?

Here is a real wonderful extrovert. He loves people and he gets the same manual everybody else gets and opens it up to page one and it says, "Be friendly."

He says, "If I were any more friendly, they'd have me on a morals charge." So the whole program becomes suspect.

I had a chance to check this concept out with Bishop Sheen. I was on a program in New York the same day that he was doing a Catholic Charities meeting in another part of the hotel. I raced from my meeting to hear the last 20 minutes of his talk, and, gentlemen, if you think he is great on TV, you ought to see him in person. This love and compassion and warmth just project like nobody's business.

And after the meeting we stood in line and I shook hands with him and I asked for a couple minutes of his time. He was very tired but he said, "Sit down and we will talk for a minute."

I told him right off the bat I was an Episcopalian and he didn't try to convert me, and I thought I would be fair with him and I wouldn't try to convert him either. I told him for the first time in my life, as a salesman and as a salesmanager with personnel responsibilities, being a little responsible to help people grow, if they want to, and I said, "For the first time in my life in this business I am holding my head a little higher and walking a little straighter because I am no longer being the seller of our relationship as a personnel-oriented popularity contest where you get people to do things for you, or to buy things from you just because they like you."

"I see people going into problem-solving relationships, each with a responsibility and each one aware of the responsibility that he has to make the relationship grow to make the relationship stay fluid."

"I feel better about the problem-solving attitude than I have felt about my concept since I have been in this thing, working with other people. Does it have the intellectual and the psychological and the

spiritual base that any idea needs to survive?"

He said, "Well, I am not much of a salesman."

I started to say, "No, just one of the best three or four in the world, that is all."

He said, "But I guess what happens in the relationship when we go in as a problem-solver, if you are going to be a problem-solver, you have to give, and we are all at our best when we give."

"So what happens? When you give, you feel better. When you feel better, your attitude improves and when your attitude improves, you get through to people. And when you get through to people, they do some of the things you ask them to do, and when you do these things back to the first party, you feel better."

Our minister had a fund-raising drive and it went over the top. At the opening vestry meeting, a very substantial gift was reported by a very generous parishioner. When the gift was voted on, someone in the vestry fund said, "No wonder this guy gives; he has got it."

And our minister said, "I wonder if he gives because he has got it, or if he has got it because he gives?"

What have we said so far? Time, habit—we can do something about the dimensions. Habit, energy, alertness, attitude. Attitude, going into a relationship, read all the books you want, I am convinced going into a relationship should be with the idea, whom can I help? How can I help this man grow if he wants to grow? That is the only foolproof managerial supervisory technique.

I want to talk about some of the things we talk about as salesmen tomorrow. But specific ideas. You will have some fun with it, I think. What we think about any relationships where we must persuade.

SESSION 3 — THE 'SWAT' CONCEPT

I want to say to Bill McLean of U. S. Steel, they gave me a question for you to answer that is a beaut. But I want to make sure I have got it in this frame of reference.

"Dear Bill, I think a good supervisor ought to get tough once in a while, pound the table, give his people the reason why it is better to do what he asks them to do now. I know guys that can do this and get away with it. Me, I raise my voice and the guy wants to try a judo hold on me."

We used to talk a lot about this. How is it some guys really move in there when the shoes must get out of the factory and things must be done, and get it done; and other guys, I don't know, there is something about them, they move in and they compound the felony when they ought to be tough.

I used to work around the country with salesmen and I think there is a partial answer to it, three of them. I would go into a town and I would work with a guy and I would try to pick his brains and find out how he was doing it. I would actually make calls with him, then take the things I found out from him back to St. Paul and build a story for all the people. There were no secrets. This is how some of the research and development out in the field started. It was good stuff. I would actually field work with the salesmen and listen to what they said.

Then one day my boss said, "I want you to go to New Orleans and work with Van Allen."

We had heard about this guy. He was a real character. They used to call him "Stuttering Van." He never sent in any reports. The back of his car was a mess. He didn't use his point of sales material. He was a slob.

I said, "Why don't you fire him?"

He said, "Hell, he's our best man. Let's soften him up a little bit, give him a \$50 a month raise."

I went to New Orleans and he picked me up at the airport and sure enough, he gave me the silent treatment. He didn't want any part of old Bill.

I took it as long as I could and I finally said, "I'm here to pick your brains, to see how you do it, and maybe pass along a few ideas that will help you. And incidentally, you don't have to act like this, because Chuck gave me permission to give you another fifty dollar raise. Don't say anything to the rest of the fellows."

He said, "Don't worry, I'm just as ashamed of it as you are."

And then we made a call. In those days we were selling Scotch Tape against string for packaging, you know. Even though most of you aren't in selling, you will understand the problem. Scotch Tape costs about a buck and a quarter and all the string you could carry away was about two bits. So we had to sell speed, convenience, and versatility.

So I walked in with Van and he made the pitch and as likely as not, the retailer would say, "Well, that looks pretty good, but I think I will stick with string."

And Van would say, "What's the matter? You stupid?"

He said, "When your wife washes her clothes, does she take them down to the river and beat the hell out of 'em? Maybe you had better get on the stick before it is too late."

I would edge to the door, you know. You won't believe this, this interview and others like it actually reached the negotiation stage before any blood was spilled. And then the retailer would make a fatal mistake. He would say, "You seem to be pretty sold on this and I guess I could swing for a trial order. How much do you think I need?"

Van would always look at him and say, "Don't you worry about this, Paul. This is the order form right here. You sign it and I will fill in the top." Then he said, "I want you to press hard because there are four copies."

Here is my reason for telling the story. I didn't know it then, but I do know it now, and I wouldn't go within 1,000 miles of New Orleans without visiting Van. He is one of my favorite people.

Van was the kind of a guy who would walk on his hands and knees over broken

glass at 3 o'clock in the morning to replace one of the little 15-cent cover plates on the dispensers. He had service built-in like patch pockets on a suit of clothes. It always seemed to me he was going one step further. "I will service that for you, Ruddy Boy, but I want you to serve old Van."

Over the years, here was a guy who, if the retailers were busy, he would probably go clean the window in the store. Here was a guy who, if they didn't wait on him when he first went in, if they were busy, he would start waiting on customers. Over the years he developed almost the license to get tough.

So, I know guys who do this and get away with it. I raise my voice, and—I don't know—this is such a delicate area. I think the most unattractive supervisors and bosses I ever knew in my life were guys you couldn't figure out; you know. They would be going along real sweet and gentle and nice with you. Then they would get hell from the home office and all of a sudden it would be murder.

There would be times I'd rather have the first boss I ever had, Harry Spore. When I go back to Boston, after I call my mother, I call him. He was tough, but he was tough all the time. We knew exactly where we stood. We knew if we lied to him he would throw us out the window. Everybody knew it.

Sure, we used to talk about him over coffee, like I said the other day. If you are going to be tough, be tough all the time; if you are going to be nice—I don't know. That is a delicate area.

A guy like Van would say it like this, "If you are going to pound a table, make sure you have got a solid table. If you are going to raise hell with your kids, make sure that, up to then, you have done your part."

Another note:

"Dear Bill, I have been a supervisor for three years. I get along. But how can one tell whether he is a good leader or not?"

We used to talk about this a lot in leadership. I know you have gone through this. It is kind of fun. How can you tell whether you are a good leader or not?

Our management used to talk about three

kinds of leadership. There are probably 303, but this should be a linear rather than a line consideration.

Kinds of leaders, autocratic and democratic and free rein. As I said, it should be linear in the sense that there are so many degrees. One guy is a little bit autocratic and he is a little democratic and he has probably got free rein. We used to say nobody is all autocratic, nobody is all democratic, nobody is all free rein, and it is a good thing, because the key word here, I think, is dependency.

You supervise according to a person's needs. Obviously, when you tell a man to put the helmet on and keep the gloves on, this is autocratic. He doesn't have to meet with the other guys and say, "Now the question is whether we should wear the goggles or not." You wear them because it not only protects you, it protects others as well. This is autocratic.

When we bring our new people in and give them a product to sell, this is autocratic. When we give them our price sheet, we say, "This we want you to know." Like MacFarland said, "We want you to be creative, but not with the multiplication table. Nine times two is eighteen, let it be. If you are going to fool around, not with the figures." When you figure discounts, this is autocratic. Dependency.

With new people just coming into the organization, we of necessity are autocratic. I mean, that the word comes from us, and this is it, no argument, no discussion.

Democratic, on the other hand, is supposed to give—that we make a premise, that we discuss it and, of course, Kennedy must make the final decision after we discuss it. So there is a little autocracy in democracy, isn't there?

Free rein—you don't look over the shoulders of your pure scientist. You don't dwell on research and these people we think don't need supervision.

So the answer to the question on leadership is, I think the key here is dependency. How much leadership do they need? When a first starts in an organization of course he needs it. So of necessity it is autocratic. And then we find as a man grows on the job, his dependency decreases and the need for supervision decreases.

As I say, what kind of a leader am I? I hope I am a little bit of all three of them. I sure as hell don't want to be autocratic, but at times I hope I have got the guts to say, "This is the way it has got to be, Charlie, and it has got to be that way right now." I hope I am not completely democratic. I hope I am not completely free rein. Again, that is the question, I think, the levels or degrees of leadership that we talk about.

I would like to say you could talk about this all day. There are even cute little tests we can pass around if we had the time, where you answer certain questions and it tells you what kind of a leader you are.

Just a fast review. We talked about habit, energy, alertness.

And I said attitude. When we are in any kind of a relationship there are two problems involved. There is my problem and that relates to selling. My problem as a salesman is how to get the order. His problem as a buyer is how to get something done for him. Now it seems to me that my success, the answer to my problem, is in direct relation to the answer to his problem, and when I emphasize mine I am a peddler. When I emphasize his, I am a pro. We talk about this, I guess, in all relationships.

Now I think we can have some fun. And then there is consideration, time consideration.

Communication! I have to tell you, if I get through to a guy, communication must be mentioned with time. We could talk for days on creating a favorable climate, for getting the things done in communication. We could talk about being a good listener. Dr. Nichols at Minnesota has a 3-day clinic on developing the facilities for listening. The good Lord gave us two ears but only one mouth. Maybe we shouldn't try to outsmart nature.

We could talk about cutting out details, getting to the core of the problem, identifying it, clarifying it, using alternatives, or compromise—bit things. But you know, these are abstracts. Getting at it personally, the reason why it is better to do something now than to delay it, why it is better for everyone.

So we have five little sentences that we

remember to use in all relationships where it took persuasion. I know it is bad teaching to put them all down, but I think you may have some fun and I think you may remember them.

"I have an idea."

"What do you think?"

Now you are selling a guy on safety.

"Don't worry, I will take care of the details."

"Others did this. And here is what they told us"—and

"I suggest—"

In good advertising, particularly industrial advertising copy, you will see those five ideas running through them. I don't mean we used these words, we can think of other words easier than these.

You know, they say there is a difference between an idea and a gimmick. Bruce Barton said the difference is that a gimmick attracts attention, but an idea always promises somebody something.

We use these five little sentences in all persuasion in every relationship. They keep us alert to it and they help us remember. It is a kind of a birdie on the shoulder thing, you know. Notice one thing about them, each one of them commits us to do something.

In selling if I go to a guy and say, "I have an idea," I had better have one. It commits me to have ideas.

What commits us to listen? You know you can talk all night about people listening, but if I get in the habit of saying, "What do you think? How do you feel about this?" I would like to know your thinking on this, then I am committed to listen.

Over-simplified? Maybe. We use it, we like it.

"Don't worry, I will take care of the details." Aren't these wonderful words? You go on a vacation and the babysitter is there and you think of the 10 or 15 things that have to be done and she says, "Stop worrying. Have a wonderful time. Forget it, we are going to forget you, and we will take care of everything."

You leave for the Safety Congress. You have 150 details and your secretary says, "Mr. Smith, will you forget it? I will handle everything for you."

We must use all problem solving analogies and case histories: "Here is what happened in Fort Wayne, Indiana, at the International Harvester Plant. They did this, and out of this safety experiment, here is what they told us, and then based on what they told us, I would like to suggest that we do this." Five sentences. Let's go through them.

"I have an idea." Like I say with my company, I have some ideas I would like to share with you. This commits us.

My daughter married an ex-football player, weighs about 230 pounds, has to clench his fist to keep from walking on his fingers.

A lovely boy, I have got a new granddaughter, a little baby about a year old.

My son-in-law went into the printing business and he had no selling experience and down in Miami printers were awfully tough. He didn't know how to sell. He would go into a customer and the customer would say, "How much is it?"

He would say, "Don't louse me up. Do you want to buy this printing?"

So finally we built him a little sales talk. Now he said, "My name is Jim Winslow. I know you are buying from someone else and I know you are happy because I have seen the work they do. But from time to time I would like to come in and give you some ideas. Ideas I pick up outside from trade journals or from competitors and other salesmen. I want you to try these ideas. If they work, you will sell more of everything and if you sell more of everything and if you use more printing, all I would like is a crack at the printing. Right now I don't deserve any of your business. Give me a chance to earn some of it."

And in safety, here are some ideas we have tried out. Here is what they do. This persuasion.

"I would like to have your opinion." A GE dealer in Phoenix sells refrigerators and appliances. People come in and shop him. They take the model numbers off the top of his stove and then go to a discount house and try to get the clergyman's discount.

Before they leave his store he says to them, "Thanks for coming in here. I know you are going to shop around, but before

you make your final buy, come back and see me again. Here is why. You can buy this refrigerator any place in town, but if you buy it some place else, you don't get me with it. But go ahead and shop around. And to show you my appreciation for your coming in here first, I have a little gift for you." And he goes in the back room to a freezer and gets a half a gallon of ice cream and says, "I want you to have this." Now how much shopping around are you going to do with a half a gallon of ice cream? What do you think?

You know, some people would have you believe that if you give a guy a big smile and come on big with the personality bit, you have it made. Nothing could be further from the truth. About the highest compliment that we can pay another person is to listen with understanding, to ask for his opinion and then listen. Probably that is the highest compliment.

We used to use this if someone said, "I will think it over." We would always say, "All right, if you want to think it over, but the thought occurred to me while you are thinking it over, you might have some questions come up and I won't be here. So, do you have any objection if we think it over together now while I am here?"

We have been talking about time and I am not going to go into that any further.

"What do you think?" Another thing, the toughest job I ever had to do was the thing they called delayed reaction, you know, because I am a blabbermouth. I am a compulsive talker, as you can well see.

So the boss always used to say, "Bill, don't feel that compulsion to talk when somebody says something. Wait a little while." Here is a good tip. He said, "Ask another question. That will give you time to get your poise, give you a chance to answer the first one."

When someone says to you, if you are trying to sell a gross of something, "Can I buy it in half a gross?" Don't say, "Yes, you sure can." Then he can still say, "I will think it over." Ask another question. You are trying to sell a gross. You are asked, "Can I buy it in half a gross?"

Say, "Do you want it in half a gross?"

He says, "Yes."

"Well, you've got it in half a gross."

Communication . . . What wonderful words, "Don't worry, I will take care of the details," are. You know life insurance people do that, and they are the real pros.

They said, "Mr. Gove, if you get hit by a truck, Mama gets this. If you get hit by a buffalo, she gets this. If there is a buffalo driving the car at the time you are hit, double indemnity. Now if you outsmart us and live to be 65, you have got this, and all you have to do is deposit this amount each month. There is nothing to it. We take care of all the details."

Direct mail people do this. They say, "Tear off the top of your neighborhood grocer and send the bum in now. Don't delay, the contest closes at midnight. There is a bonus for your prompt decision. All you have got to do is put a little X in the square where it says 'bill me.' Send no postage. Send no money. We take care of all the details. Don't worry."

Wonderful words of communication.

Now I don't know what the psychological significance of this quote, "Don't worry, I will take care of the details," is, but I know how effective the use of these words with the right spirit is.

Now in the time we have, let's see why it has been suggested this way. "Others did it, they told us—" Testimonials, cases, cases of problem-solving, as old as problem-solving. Here is the reason why this happened over here.

You do this all the time. You build from past experiences, you build safety records from past experience, past history. A doctor doesn't say, "We treated this guy for three and a half years for jaundice before we found out he was a Chinaman."

I will admit Aetna Life Insurance had a cute bit. They had a little book you can carry in a pocket and it has all the answers to life insurance in it. Somebody says, "I don't need life insurance." And you can look in this little book. One of them said, "You can't get to first base with me," and they had these answers categorized and the salesman said, "It isn't a question of whether I can get to first base with you. It is a

question of, when you are dead, can your wife get to first base with the butcher, the baker and the candlestickmaker?"

I suggest these are wonderful words. Now you see, we are communicating. These are some of the high points of communications broken down. "I suggest"—many times that is about all it takes in persuasion, all it takes based on the history of, "We found this out about it."

"I would like to suggest," then suggest something specific so he has to make his mind up on a specific consideration.

Will Foster of the Borden Company said one of the best milk salesmen they ever had in New York sold more milk by mistake than the others did on purpose. He had no teeth. He would go up to the housewife and say, "You had better buy Borden's milk. You wouldn't want your kids to look like this, would you?"

Van Allen, with all his stuttering, would pass them the pencil. Someone said, "Don't light pressure me with this pencil thing."

He said to them, "To hell with you, use your own pencil."

"I have an idea—what do you think—don't worry, I will take care of the details—others did it—here is what they found out—they told us." There again, communications as a dimension of time.

You can't do anything about the clock. You can control your verbal, your communication habits.

Habit, I am going to repeat, relegate to habit the irritating details so they won't take so much of your time. Free yourself for conscientious effort. Energy, waste one, waste the other. Alertness, staying alive; attitude, going into the relationship with the attitude how can I help this other person solve a problem if he needs me?

Communication—

I have a gimmick for you.

What do you think?

Don't worry, I will take care of the details.

Other, did this.

I suggest.

SESSION 4 — YOU ARE BETTER THAN YOU THINK YOU ARE

We were talking about something while we were up here and I am going to chat with you a minute. I had about 51 people come up and give me notes during the week and you know, over 40 of them carried this theme, "Well, you see, I try all these things, but with some people nothing works." Or, "What do you say to a guy when you want to sell him on the idea of safety but he says 'I have been doing this for 20 years, Charlie, don't come up here and bug me with this. If I want to wear the hard hat and goggles, I wear them.'"

Then it seems to me, Bob Butler said that this then becomes a supervisory problem. This is not a safety problem at all. What do you do when this guy is a half hour late every morning? What do you do when he starts making a pass at your secretary? You know, these things happen. This is a supervisory problem.

First, I would guess, it would seem to me, that if you are a safety man, you go to the guy's immediate boss. You don't go to him, do you? You go to his boss and say, "There are some of the things he has been doing. Let's watch it."

In school we say if the kids aren't doing the job, the teacher has got to share part of the blame. We have a teacher who says, "I never give A's." I told my wife we had better check her out. Maybe she is not getting an A for teaching either. So this is bothering her. I don't know what the answer is.

Here are some of the problems. Oh yes, one guy was kind of cute, he said, "Let me show you how this works for me. When I say I have an idea, the guy says, 'What do you want me to do now?'" When I say, "What do you think?" he says, "I think it is going to take a hell of a lot of time, or, 'I don't like it.' When I say 'Don't worry, I will take care of the details,' he says, 'Are you kidding? You damn well know you can't take care of the details. You won't even be here. We will have to take care of the details.'"

So this whole theme was, "I am doing all these things that I am supposed to be doing, but I am not getting the people very safety

conscious in my plant." I have to say this, somebody is getting somebody safety conscious, otherwise how come 10,000 people are getting together here?

People are always squawking to me about the airlines. Look, somebody got me a quarter of a million miles in the last year with a minimum of problems and I spend half my life in airplanes. Somebody got me from here to here. Of course, once in a while you fly when the pigeons won't even take a chance. You put a quarter in the insurance machine and you get a Hershey bar.

Do you suppose there is nothing here? Do you suppose when we say, "I tried these things and they don't work," do you think psychologically maybe this lets us off the hook? Do you think so, John? Maybe, but I don't. But if you are not getting through to your people on safety, maybe that is something for you to think about.

I have to mention here, too, remember about 25 years ago when the truckers were really fighting it out with the railroads, you know, the railroads were doing every thing they could to give the truck people a bad image. They were fighting them. For every mile of highway they were able to get they had to fight for it, right down the line. The railroad had an axe to grind and they were fighting every inch of the way, squawking.

And remember, all of a sudden you started to change your mind about the truckman. First of all, he was a big goon, a bad actor, and he drank and he fell asleep on the job and all that stuff. All of a sudden he is the guy that dims the light so you can get ahead on the hill, he gets the reputation of being the best driver in the world. He helps you if you are out on a lonely road and have a flat tire.

They have a movie called, "Knights of the Road," and do you think this happened by accident? No, no, no—design. Here is how they did it.

Every time a good report would come in on a truck driver about his driving or helping someone on the highway, up it went on the bulletin board. The American Trucking Association would feed this material out.

What happened? They told these guys they were good for so long that they got good. Today a truck driver knows he is the best driver, knows he has the best safety record because people so long have been telling him he is good.

Maybe we ought to think about this. They talked in this conference about changing roles. They said the reason marriages break up is that the guy identifies himself as a husband and he goes into the relationship and he isn't about to change.

In our business we talk about changing roles with the purchasing agent. We call our purchasing agent—if we could just change places with him once in awhile. We know for instance, when he buys he has to submerge his taste and buy for someone else. He likes red trucks, he buys green, if the company specifies green. He has a lot of pressure on him. If he buys too much the comptroller gives him hell. If he buys too little, the sales force give him hell. He is right in the middle. He wants a seat at management's table. He thinks buying is important; he is in constant conflict.

How nice it is when we as salesmen walk in and say, "Charlie, I know the problems you have and my job is not only to sell you stuff, but to help you solve some of your problems."

Changing roles. "I know you have been on this job for 20 years, you have done a good job. I know how you feel about wearing your helmet and hard shoes. What the hell, I'd feel the same way if I were you."

Oh yes, there is one more here, I think, somewhere. It says, "Setting personal goals seems to me the most important thing we as salesmen can do. Yet you seem to play down the importance of this. How do we know it when we get there if we don't know where there is?"

I don't to play down the idea of setting personal goals. I just mean a lot of times we let our goals get in the way of the job at hand. That is a problem that at times we have in selling.

My boss, Al Drew, with Beechnut years ago, had a point system and when we reached 300 points we got a bonus for the month and it was a very, very important part of our income. So the thirty-first of

the month Al would call and say, "How did you do, Bill?"

I said, "What do you mean, how did I do? I got them."

He would say, "How many?"

I would say, "Three hundred seven."

He would say, "Congratulations, that's a boy. This is eight months in a row, isn't it?"

I would say, "Don't make a big thing out of it. I always get them."

That was the thirty-first. The next morning he called right around breakfast and said, "Hi, Bill."

"Hi, Al."

"How many points have you got?"

And you would just start to say 307 and all of a sudden it would occur to you this is the next day and you ain't got none. The next one you get will be one.

Now there is a tendency to shoot for that 300 and say, "Boy, look at it," and you get to the middle of the month and you only have 75 and you panic and push and it shows in your relationship to people. So every month he would say, "You do all the things that you did, put up the display, point-of-sale material, tell your story, make the number of calls, quality calls, and then your goal will take care of itself."

The only point I make is, too many times we let our goals get in the way of our job at hand. If we do all the things every day in this safety program, every day the things we know that we should be doing, the rest takes care of itself.

Again, back to what do you say when they don't ring for your safety ideas? I think most of the time most of these people need a little reassurance. Look, I like this example. You buy an automobile. You move away from the dealer. You have a brand new car. You should be on Cloud 9. But are you?

Maybe you are saying to yourself, "Maybe I should not have swung for those extras. Maybe I should have hung on a little longer and gotten a better deal." Maybe you say, "Gee, that 1933 Essex I turned in, that wasn't a bad car, burnt orange, had nice lines."

All you need is a little reassurance. All you need is for someone to come up to you

and say, "I see you have a new car. Where did you get it?" And you tell him. And he says, "No wonder, that is the best place in town to buy automobiles."

But this doesn't happen. You walk into a guy by the name of Cecil. Now there are Cecils in the safety program too, aren't there? You know, Cecil comes along and sees the car and he kicks the tires and says, "Where did you get it?"

"I bought it from Jim Moore, the dealer."

He says, "What's the matter? You crazy? You know what Jim stands for."

You say, "I guess it is short for James."

He says, "Exactly, Jesse James. This guy is a direct descendant. I could have got this car for you for \$400 less than you paid for it. The guy I do business with loses money on every deal."

You say, "How does he stay in business?"

He says, "He juggles the books."

Reassurance! Do it this way because this is the way it is being done now. People don't want to be different.

What do you say to them when they say, "I have been doing it this way for 20 years and I don't want to change"? That is your problem.

What do you say when the teacher says, "I can't get these kids to go along with me"? That is her problem.

Don't ever forget this. If everybody were as safety conscious as you are here, all 10,000 of you, they wouldn't need you. If everybody did this regularly and automatically like they brush their teeth, like they put their pants on in the morning, we wouldn't need you. They don't, so they need you. And that is why you are here.

Back with Minnesota Mining, we used Scotch Tape for packaging in industrial applications and once in a while we would come out with something new. I was in on the promotion of a new thing called butcher tape. It was an acetate fiber tape that was used to seal hard to wrap Kalama-zoo vegetable parchment paper in a butcher shop.

What happened? We had a real problem because when the butchers wrapped the package, most of them left their greasy finger print and it wouldn't stick. Well, it was murder. Because I was in on the

promotion, the company always said, "Bill, we want you to go out and take care of these people." Hundreds of people with problems all over the country. Now we had a choice. We could have gone back and when the guy said, "This damn stuff doesn't stick," we could have said, like Van, "What's the matter? You stupid? Why the hell don't you wash your hands?" Or, if you had the weight, you could wrestle with the guy.

But I think there is a story here. Instead, we would go into him and say, "I am no. a bit surprised you have this problem, getting this darned stuff to stick. Every butcher we know had the same problem. But you know, we found out that if the butcher would take the tape and hold it in the middle and leave the two adhesive flap ends open and then seal it, they had no more problems."

In other words, it wasn't, do this because I say so. Here is what happened in a similar situation.

Remember, I told you the opening morning I went to this communications conference. This is the idea. You can forget everything we have talked about here, but stay with me for the next 10 or 12 minutes.

As I said, I knew this guy was saying something I could pass on to you, something that would be meaningful, something I hadn't heard before.

I had a chance to have lunch with him, and I said, "Boy, this is rough. I generally work with people who get together in conferences and conventions and they want to do better and be better and take a bigger bite out of life and you have given me nothing I can tell them."

He said, "Well, you ought to talk about change. When people get together to pick each other's brains, make no mistake about it, they are talking about change."

And I thought, this morning, sure we are. We are talking about getting through to the guy who doesn't have a good safety attitude, aren't we? Isn't this the reason we are here, to get people to feel the same way about safety as we feel? This is change. This means he feels this way and now he has got to start feeling another way. Change. A very delicate thing.

But Batson, the Englishman, said, "If we are going to talk about change, we

must remember this. A person doesn't change because someone asks him to change. A person doesn't change because of pressure to change. A person doesn't change because he has a tremendous desire to change. You people in America have been working that desire thing to death. A person doesn't change because he has a positive attitude toward change. Persons change because they experience change. Somehow they are disciplined or forced into a situation of change and they change then, and only then."

I think a neighbor of mine jumps up in the morning with that attitude. He sings in the bathtub. He plays an inspirational record in the morning before breakfast. Then he looks in the mirror and says, "You can do it. Everything in the world that man can conceive, man can do. You can be chairman of the board of your company."

You know his problem? The bum never leaves the house.

Eddie Rickenbacker had all his people in Miami Beach for a convention, 161 of them, their luggage had been delayed. These are airline people. Their luggage was in Baltimore and in Albany and Charlotte and Boston. They had to scrounge around as we do and pick up toothpaste and toothbrushes and shaving stuff and have the one pair of pants they had on pressed.

At the opening meeting Rickenbacker looked over the rostrum and said, "See what I mean? I have been yelling at you, I have been sending you—every week on the week—a bulletin, saying 'don't lose their luggage. If you lose it, we lose them.' Apparently this didn't make any difference. Now, how the hell do you like it? How do you like it?"

He had deliberately delayed their luggage. Eddie Gilchrist in Miami told me, "Up to this time when somebody would lose a piece of luggage, they would walk up to me in the airport and say, 'I lost my luggage.' I felt like saying 'Well, don't bother me with this foolishness.'"

"Now when it happens, it is something different. Now it is under my skin. I know how it feels when it is under my skin. There is a real, real difference."

I told you about my son-in-law. He would tell a good story about printing.

but he had an intellectual quarrel with asking people to buy. He would stop. My boss used to have a word for this kind of salesman. He said, "He is very colorful; he is yellow."

I gave him 50 books on how to ask people to buy, stress urgency, give them reasons why it is better to buy now than it is to delay, and it meant nothing to Jim. He said, "If they want to buy, they will buy."

I said, "They won't. You have got to ask them."

Finally I went out and made some calls with him. I said, "After you tell your story, simply say to him, 'If it is all right with you, we will send this along.'"

The first guy he said it to, he said, "If it is all right, we will send this along."

And the guy said, "Go ahead."

I thought we were going to lose him. I thought he was going to say, "Don't be hasty, Charlie." Now he has got more nerve than an abscessed tooth. Now he has got it under his skin. Now it has happened to him.

We don't know how it will be until after it happens.

I used to work for Minnesota Mining. I had one customer in Portland, Maine, who supported me there, and boy, I had them locked up, you know. We played golf together on Saturdays, and my wife and his wife played bridge all week. You know, nobody was going to move in on me. One day I came into this jobber's place on Saturday morning and as far as the eye could see, was competitive merchandise. I was out and this other guy was in.

There I was, I was dead. And in a thing like this, your worthwhileness, your life's blood is at stake. I have to report this to the home office and I am on a bonus basis and I am out of business. As far as I can see it is competitive merchandise. He has to sell this before he even gets back to mine. You can't even see my stuff.

Some guy came up from Boston and gave them the clergyman's discount and he swung for it. I went across the street and bought a cup of coffee to get my poise back. I was shook, you know. Finally, I

went over and said, "How could you do this to me? I work with your salesman, I am in here every day, I check and rotate your stock, I put on sales meetings. Some stranger comes and puts me out of business. Why?"

And do you know what he said?

He said, "I never thought this meant this much to you."

Do you know why he didn't? I never told him that this meant that much to me. I was so preoccupied with being a big shot, walking in Saturday morning, checking the stock, taking the order, playing golf with him, seeing that the wives got along pretty good, it never occurred to me to establish any kind of a grownup relationship in a business way with him.

After that, every week we sat down and I said, "We are swapping, Buddy. This is what I have been doing. This is what you have been doing. You haven't been doing this. I haven't been doing that. Let's get back on the stick, Charlie. Let's go."

But it took this experience to get me back.

Five or six notes said, "Don't kid yourself, Bill. Sure it is all right for you to come on with this inspirational jazz and say people get safety under their skin. Don't kid us, the reason we are so safety conscious is because it is just good business to be safety conscious. Why don't you forget all this jazz? It is all right to appeal to people's self-interest."

Well, I guess it is, but I get a little concerned about this. Most of the Madison Avenue stuff we read about appeals to the worst in people, self-interest, vanity, keeping up with the Joneses, what other people will think. This to me is the worst in man that they are appealing to.

But ask yourself this: The greatest movements of all times have succeeded because they have appealed to the best in people. Christianity, for instance. The good Lord didn't get His disciples together and say, "Here is what is in this for you, Buddy, if you go along with me."

He probably said, "Look, everyone will think you are crazy. They will stone you. They will think you are nuts. You will not in your lifetime see any positive effect of the work you do. But do it, because this whole philosophy shows how one man

should not toward another man. It has got to be good."

So what happens? Ten or twelve ignorant fishermen sold this great story, appealing to self-interest?

No, I don't think so. Appealing to the best in them. The truckers appeal to the best in men. You are good. You help people on the highway. You flash them by. You are a damn good driver. You appreciate the value of safety.

So after a while, what happens? The trucker said to himself, "I am a good driver. I have a good safety record. I help people. You are damn right I am good."

During World War II, of all the zillions of words we heard in speeches, what is the line you remember most? What Churchill said, "Blood, sweat and tears." That got to be the most significant line that came out of the war. Did this appeal to people's self-interest? It did like hell.

He said, "We will promise you nothing but blood, sweat and tears." He rallied the country, y' see. He didn't say, "I think if we do this we will beat the Germans. If we do this, our taxes will be lowered and then we will go there and move in on them and take their industries and then we will be able to cut that out."

He said, "There is nothing I can promise you. I give you nothing."

In this church fund-raising drive we went through, we promised them nothing. We didn't say, "We want you to give." We said, "We want you to give until it hurts, because if you are just giving off the top and it ain't going to hurt you, we don't need you. We have got to have the people that bleed a little bit if we are going to build this."

So we get in a medium middle class family and an average subscription is \$1,700. You think they didn't bleed?

The inaugural address, how many words? Seventy-two thousand words in Kennedy's inaugural address. I don't care how you feel about him, but there is the one line you remember: "Think not what the country can do for you; think instead what you can do for the country."

I don't know, I am not going to say

1961 National Safety Congress

how he meant that or anything, but I say, isn't it funny that was the headline after the address. All the other things he talked about—but that was the headline.

I am convinced that you are here, not for self-interest. I have got to believe this, otherwise I have wasted my time. I have

got to believe that you are here not for self-interest, but because safety really means something to you. This is the way one person should act toward another person.

If this is over-simplified, I have wasted four mornings. I hope I haven't.

PLAN NOW - -

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.
