National Safety Council

OFFICERS — 1961-62

Chairman, Board of Directors—WILLIAM H. LOWE, Treasurer, Inland Steel Company, Chicago, Illinois

President Emeritus—NED H. DEARBORN, President Emeritus, National Safety Council, Titusville, Pennsylvania

President—HOWARD PYLE, President, National Safety Council, Chicago, Illinois

Vice President for Farms—HARRY L. POWELL, Assistant to Vice President, The Goodyear Tire & Rubber Company, Akron, Ohio

Vice President for Finance—CURTIS BARNES, Senior Vice President, Finance and Property, United Air Lines, Chicago, Illinois

Vice President for Homes—GEORGE M. WHEATLEY, M.D., Third Vice President and Medical Director, Metropolitan Life Insurance Company, New York, New York

Vice President for Industry—R. P. HAMILTON, Superintendent of Safety, St. Louis-San Francisco Railway Company, St. Louis, Missouri

Vice President for Labor—LLOYD D. UTTER, Director, Industrial Health and Safety Division, United Automobile Workers, Detroit, Michigan

Vice President for State and Local Safety Organizations—H. G. MANGELSDORF, Standard Oil Company (N. J.), New York, New York

Vice President for Membership—JOHN L. GILLIS, Vice President, Monsanto Chemical Company, St. Louis, Missouri

Vice President for Motor Transport—MARK ROBESON, Vice President, Yellow Transit Freight Lines, Inc., Kansas City, Missouri

Vice President for Production—ROBERT R. BURTON, Senior Vice President, Kenyon & Eckhardt, Inc., New York, New York

National Safety Council

(Officers, continued)

Vice President for Public Information—CHARLES W. FERGUSON, Senior Editor, The Reader's Digest, Pleasantville, New York

Vice President for Research and Education—DR. WILLIAM P. YANT, Research Consultant to the President, Mine Safety Appliances Company, John T. Ryan, President, Memorial Laboratory, Pittsburgh, Pennsylvania

Vice President for Schools and Colleges—DR. LOWELL B. FISHER, Chairman, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Illinois

Vice President for Traffic—REX M. WHITTON, Federal Highway Administrator, U. S. Department of Commerce, Washington, D. C.

Vice President for Women—MRS. RAYMOND SAYRE, Ackworth, Iowa

Executive Vice President—G. C. STEWART, Executive Vice President, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

General Manager—W. G. JOHNSON, General Manager, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

Secretary and Treasurer—R. L. FORNEY, Secretary and Treasurer, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

Assistant Treasurer—J. D. FULFORD, Director, Treasury Bureau, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

National Safety Council

TRUSTEES — 1961-62

Chairman of the Trustees—HOWARD PYLE, President, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

Vice Chairman of the Trustees—WM. WHITE, President, The Delaware & Hudson Railroad Corporation, New York, New York

Members

MELVIN H. BAKER, Chairman, National Gypsum Company, Buffalo, New York

JAMES B. BLACK, Chairman, Pacific Gas and Electric Company, San Francisco, California

S. BRUCE BLACK, Chairman, Liberty Mutual Insurance Company, Boston, Massachusetts

ELMER H. BOST, Chairman, Warner-Lambert Pharmaceutical Company, Morris Plains, New Jersey

H. S. M. BURNS, Former President, Shell Oil Company, New York, New York

HOWARD H. CALLAWAY, President, The Garden Industries, Incorporated, Hamilton, Georgia

WALTER F. CARKY, President, Automobile Carriers Inc., Flint, Michigan

WILLIAM G. CHAMBLER, President, Scripps-Howard Supply Company, New York, New York

LUCIUS CLAY, Chairman, Continental Can Company, Inc., New York, New York

MORGAN J. DAVIS, Chairman, Humble Oil & Refining Company, Houston, Texas

HARRY A. DEBOUTTS, President, Southern Railway Company, Washington, D. C.

J. DOYLE DEWITT, President, The Travelers, Hartford, Connecticut

MORSE G. DIAL, Chairman, Union Carbide Corporation, New York, New York

E. F. DU PONT, Director, Employee Relations Department, E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware

FREDERICK W. ECKERT, Chairman, Metropolitan Life Insurance Company, New York, New York

National Safety Council

1961-62
Board of Trustees (continued)

CALVIN FENTRESS, JR., Chairman, Allstate Insurance Company, Skokie, Illinois

JOHN F. GORDON, President, General Motors Corporation, Detroit, Michigan

BOWMAN GRAY, Chairman, R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina

JAKE L. HAMON, Dallas, Texas

E. ROLAND HARRIMAN, Brown Brothers Harriman and Company, New York, New York

J. V. HERD, Chairman, The Continental Insurance Company, New York, New York

WILLIAM A. HEWITT, President, Deere & Company, Moline, Illinois

FREDERICK R. KAPPEL, Chairman, American Telephone and Telegraph Company, New York, New York

JOSEPH L. LANIER, President, West Point Manufacturing Company, West Point, Georgia

SAM LAUD, Chairman, Executive Committee, General American Transportation Corporation, Chicago, Illinois

GEORGE E. LEIGHTY, Chairman, Railway Labor Executives' Association, Washington, D. C.

WILLIAM H. LOWE, Treasurer, Inland Steel Company, Chicago, Illinois (Ex-Officio)

NEIL McELROY, Chairman, The Procter & Gamble Company, Cincinnati, Ohio

ROBERT G. PAGE, President, Phelps Dodge Corporation, New York, New York

G. T. POWWALL, Secretary, United States Rubber Company, New York, New York

SHERBURNE PRESCOTT, Belle Haven, Greenwich, Connecticut

GWILYM A. PRICE, Chairman, Westinghouse Electric Corporation, Pittsburgh, Pennsylvania

HOWARD PYLE, President, National Safety Council, 425 North Michigan Avenue, Chicago 11, Illinois

WALTER P. REUTHER, Vice President, American Federation of Labor and Congress of Industrial Organizations, Detroit, Michigan

W. S. S. RODGERS, Former Chairman, Texaco, Inc., New York, New York

National Safety Council

(Trustees, continued)

EDWARD L. SHEA, Former Chairman, Ethyl Corporation, New York, New York
 ARTHUR E. STODDARD, President, Union Pacific Railroad Company, Omaha, Nebraska
 DR. JOHN F. THOMPSON, Chairman of the Executive Committee, The International Nickel Company, Inc., New York, New York
 JUAN T. TRIPPE, President, Pan American World Airways System, New York, New York
 WM. WHITE, President, The Delaware & Hudson Railroad Corporation, New York, New York
 ROBERT W. WOODRUFF, Chairman, Finance Committee, The Coca-Cola Company, Atlanta, Georgia
 LESLIE B. WORTHINGTON, President, United States Steel Corporation, New York, New York

National Safety Council

BOARD OF DIRECTORS — 1961-62

Chairman of the Board of Directors—WILLIAM H. LOWE, Treasurer, Inland Steel Company, Chicago, Illinois
 Vice Chairman of the Board of Directors—DR. LOWELL B. FISHER, Chairman, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Illinois

Members

EDWARD S. ADAMS, Director of Safety, Iowa Farm Bureau, Des Moines, Iowa
 FRANK R. AHLGREN, Editor, The Commercial Appeal, Memphis, Tennessee
 CYRIL AINSWORTH, Deputy Managing Director, American Standards Association, New York, New York
 ROBERT H. ALMISSE, Safety Manager, Merck Chemical Division, Merck & Co., Inc., Rahway, New Jersey
 FINLAY C. ALLAN, Assistant to the President, United Brotherhood of Carpenters and Joiners of America, Washington, D. C.
 HOMER ALLEN, Associate Professor, Physical Education, Purdue University, Lafayette, Indiana
 W. M. ALLISON, Senior Safety Director, British Columbia Lumber Manufacturers Association, Vancouver, B. C., Canada
 LOUIS H. ANTOINE, Resident Vice President, The American Insurance Company, St. Louis, Missouri
 MRS. ALMER ARMSTRONG, Indiana Farm Bureau Cooperative Association, Indianapolis, Indiana
 DR. DEWEY F. BARICH, President, Detroit Institute of Technology, Detroit, Michigan
 CURTIS BARKES, Senior Vice President, Finance and Property, United Air Lines, Chicago, Illinois
 F. R. BARNACKO, Manager of Compensation and Safety, Bethlehem Steel Company, Bethlehem, Pennsylvania
 R. R. BARTELSMEYER, Chief Highway Engineer, Illinois Division of Highways, Springfield, Illinois
 RICHARD O. BENNETT, Secretary-Treasurer, The Insurance Institute for Highway Safety, Washington, D. C.
 MRS. P. D. BEYIL, Sacramento, California
 M. F. BLANCHARD, Manager, Safety Services, Allis-Chalmers Manufacturing Company, Milwaukee, Wisconsin

National Safety Council

(Board of Directors, continued)

WILLIAM E. BILLINGS, Executive Vice President and Secretary, Greater Cleveland Safety Council, Cleveland, Ohio
J. T. BLALOCK, Vice President, Pacific Indemnity Company, Los Angeles, California
HARRY H. BRAINERD, Executive Manager, Western Pennsylvania Safety Council, Inc., Pittsburgh, Pennsylvania
CLARK D. BRIDGES, Managing Director, Industrial Medical Association, Chicago, Illinois
GEORGE T. BROWN, Deputy Director, Bureau of Labor Standards, U. S. Department of Labor, Washington, D. C.
ROBERT U. BROWN, Editor, Editor & Publisher, New York, New York
RUSSELL I. BROWN, President, Insurance Institute for Highway Safety, Washington, D. C.
E. J. BURMEER, Chairman of the Board, The Silver Fleet Motor Express, Inc., Louisville, Kentucky
ROBERT R. BURTON, Senior Vice President, Kenyon & Eckhardt Inc., New York, New York
BERNARD R. CALDWELL, Director, The Traffic Institute, Northwestern University, Evanston, Illinois
EARL N. CANNON, Consultant, The Greyhound Corporation, Chicago, Illinois
ALFRED W. CANTWELL, National Director Safety Services, The American National Red Cross, Washington, D. C.
WALTER F. CAKEY, President, Automobile Carriers Inc., Flint, Michigan
J. J. CAVANAGH, President, Chicago Motor Club, Chicago, Illinois
DR. A. L. CHAPMAN, Assistant Surgeon General, Chief, Division of Accident Prevention, U. S. Public Health Service, Washington, D. C.
ALLEN L. COBB, Director of Industrial Safety, Kodak Park Works, Eastman Kodak Company, Rochester, New York
JOHN M. CONVERY, Industrial Relations Consultant, National Association of Manufacturers, New York, New York
OWEN COOPER, Executive Vice President, Mississippi Chemical Company, Yazoo City, Mississippi
SANFORD B. COUSINS, Vice President, American Telephone and Telegraph Company, New York, New York
ERNEST G. COX, Chief, Section of Motor Carrier Safety, Bureau of Motor Carriers, Interstate Commerce Commission, Washington, D. C.

National Safety Council

(Board of Directors, continued)

BREYARD CRIFFIELD, Executive Director, The Council of State Governments, Chicago, Illinois
NELL J. CUNRY, President, California Cartage Company, Inc., Los Angeles, California
E. M. CUSHING, Director of Industrial Relations, United States Rubber Company, New York, New York
M. R. DARLINGTON, JR., Managing Director, Auto Industries Highway Safety Committee, Inc., Washington, D. C.
NED H. DEARBORN, Drake Manor, Titusville, Pennsylvania
JOHN DENSON, Editor, The New York Herald Tribune, New York, New York
CECIL B. DODD, Manager, Industrial Relations, Weirton Steel Company, Weirton, West Virginia
MISS DOROTHY DOWNS, Assistant to Director of Engineering, Firemen's Mutual Insurance Company, Providence, Rhode Island
T. A. DRESCHER, Milk Industry Foundation, c/o Borden's Farm Products, Division of The Borden Company, New York, New York
E. F. DU PONT, Director, Employee Relations Department, E. I. du Pont de Nemours & Company, Inc., Wilmington, Delaware
DR. J. DUKE ELKOW, Professor, Department of Health and Physical Education, Brooklyn College, Brooklyn, New York
HOWARD EXNES, Director, Bureau of Health Education, The Equitable Life Assurance Society of the United States, New York, New York
HENRY W. FALES, Vice President—Manufacturing, St. Croix Paper Company, Woodland, Maine
CHARLES FERGUSON, Director, Safety Division, United Mine Workers of America, Washington, D. C.
CHARLES W. FERGUSON, Senior Editor, The Reader's Digest, Pleasantville, New York
R. H. FERGUSON, Assistant Director of Industrial Relations, Republic Steel Corporation, Cleveland, Ohio
A. C. FIELD, JR., Manager, Public Affairs, WGN Inc., Chicago, Illinois
DR. LOWELL B. FISHER, Chairman, North Central Association of Colleges and Secondary Schools, University of Illinois, Urbana, Illinois
FRANK FLICK, President, Flick-Reedy Corporation, Bensenville, Illinois
PARKER C. FOLKE, Safety Advisor, Socony Mobil Oil Company, New York, New York

National Safety Council

(Board of Directors, continued)

BENSON FORD, Vice President, Ford Motor Company, The American Road, Dearborn, Michigan
 ROBERT B. FORNEY, Associate Professor of Toxicology, Indiana University Medical School, Indianapolis, Indiana
 EDWARD G. FOX, President, Bituminous Coal Operators' Association, Washington, D. C.
 ROBERT G. FRAZIER, M.D., Secretary, American Academy of Pediatrics, Evanston, Illinois
 MRS. GERTRUDE H. FRIESE, General Personnel Supervisor, New York Telephone Company, Brooklyn, New York
 A. H. GALLOWAY, President, R. J. Reynolds Tobacco Company, Winston-Salem, North Carolina

DR. J. C. WRIGHT, Secretary, Committee for Advancement of School Administration, American Association of School Administrators, Washington, D. C.

DR. WILLIAM P. YANT, Research Consultant to the President, Mine Safety Appliances Company, John T. Ryan Memorial Laboratory, Pittsburgh, Pennsylvania

DR. D. WILLARD ZAHN, Dean, School of Education, Temple University, Philadelphia, Pennsylvania

CARLTON L. ZINK, Product Research Department, Deere & Company, Moline, Illinois

ANNUAL MEETING OF MEMBERS

INVOCATION

By THE REV. CHARLES M. CROWE, D.D.
Pastor—Wilmette Parish Methodist Church
President—Church Federation of Greater Chicago

ETERNAL GOD, Thou who are the creator of the race of men and in Whose care and keeping reside the destinies of nations, we acknowledge Thy lordship over life and the sovereignty of Thy divine laws in all human affairs. Grant, we pray Thee, the leadership of Thy wisdom in the deliberations of this important assembly. May the concerns here expressed for the safety and well-being of the people meet with Thy favor. And may they lead to a greater protection and preservation of the manpower of the nation. Renew among us a deep respect for the sacredness of personality and a genuine consideration for our fellow men. We would make common cause with all who seek to elevate and dignify and make secure the society of free men. Guide the leaders of the nation and the efforts of all responsible people to make peace with honor possible in our time. May all that is said and done during these days of conference be in the service of humankind and to Thy honor and glory.

MINUTES OF THE ANNUAL COUNCIL MEETING

The 1961 Annual Council Meeting of the National Safety Council was held in the Grand Ballroom of the Conrad Hilton Hotel, Chicago, on October 16, with Howard Pyle, President, presiding.

Following the singing of the national anthem, the Invocation was offered by the Rev. Charles M. Crowe, President of the Church Federation of Greater Chicago. Dr. Crowe's prayer is printed on a following page.

In welcoming the delegates, Mr. Pyle extended special greetings to those present from foreign countries, and to the large number of young people in attendance, who were participating in the youth sessions of

the Congress. He then proceeded with the business of the meeting by announcing a quorum present, in person or by proxy.

It was voted to dispense with the calling of the roll; also to dispense with the reading of the minutes of the previous annual meeting, as the minutes had been printed and circulated to the membership.

Mr. Pyle called for the report of the Nominating Committee, which consisted of the following members: Edward C. Myers, Chairman; Walter F. Carey, George A. Jacoby, Robert T. Ross, Walter K. Koch, Franklin M. Kreml, Herman J. Spoerer.

Mr. Spoerer reported in behalf of the Nominating Committee, pointing out that

the Constitution authorizes the Committee to name candidates for election to the Board of Directors and to all elective offices, and to place in nomination at the Annual Council Meeting said candidates, as well as the candidates for election to the Trustees named by the Trustees. The selections of the Committee, Mr. Spoerer stated, were reported to the Secretary of the Council more than 75 days before this meeting, and a printed Nominating Committee Report, announcing all nominees, was mailed to all members of the Council on August 29, 1961.

By reference to the printed Nominating Committee Report, a copy of which had been supplied to each person in the audience, Mr. Spoerer presented nominations for Trustees, Directors, and Officers.

There were no nominations except those presented by Mr. Spoerer. Mr. Pyle announced that there were 27,424 votes favoring the slate presented by the Nominating Committee, and no votes opposed. Those attending the meeting voted without dissent in favor of the nominations, and Mr. Pyle declared the nominees elected. (Secretary's Note: Complete lists of the Trustees and Directors for 1961-1962, including those nominated and elected at this meeting, as well as those continuing in office from previous elections, are given on preceding pages of this volume. A list of the Officers for 1961-1962 is also printed on preceding pages of this volume.)

Mr. Spoerer expressed the Council's special appreciation to two Vice Presidents who are relinquishing their posts this year—John H. Schwartz, Jr., who is leaving the Finance Vice Presidency, and Walter E. Montgomery, who is leaving the Industrial Vice Presidency.

Mr. Pyle brought to the audience a greeting from Ned H. Dearborn, President Emeritus of the Council, who was unable to attend the Congress this year, and introduced various Officers of the Council who were seated on the speakers platform. He also announced that the 1962 National Safety Congress would be held in Chicago, October 29-November 2.

Mr. Pyle reminded the members that a special grant of funds from the Metropolitan Life Insurance Company has made it possible for the Council to recognize outstanding research work in safety by means of an annual award. He then introduced Dr. George M. Wheatley, a Vice President of Metropolitan and the Council's Vice President for Homes, who announced that the 1961 award had been made to J. Stannard Baker, Director of Research and Development of the Traffic Institute, Northwestern University.

The award to Mr. Baker, Dr. Wheatley stated, was based on case studies of traffic accidents which he described as being a "significant, pioneering effort to study traffic accidents in depth." In accepting the award, signified by a plaque and a \$1,000 check, Mr. Baker expressed his appreciation and also gave credit to several associates who had worked with him on the project. The award, he said, should be an incentive to many others to enter the challenging field of safety research.

A report by G. C. Stewart, Executive Vice President, and the President's address given by Mr. Pyle, are also included as a part of these Transactions, on following pages.

R. L. Forney
Secretary

REPORT OF COUNCIL OPERATIONS

By GEORGE C. STEWART
Executive Vice President, National Safety Council

This is the one opportunity of the year when I can tell you something of the operations of your Council.

In the time available, it is impossible to even list, to say nothing of discussing, the hundreds of activities in which the Council is engaged. All I can do is try to give you some highlights.

First, however, let's take a look at the product of all of these activities—the prevention of accidents.

During the period 1950-1960, accidental deaths per hundred thousand population decreased 14 per cent. Not only did the population rate decrease, but there was a decrease in each category of accidents—work, traffic, home and public.

So far this year, three categories are lower and one the same as for the same period last year.

Now for some of your Council's activities—

Training in safety is being, and will continue to be, emphasized. Our purpose is to train more people who, in turn, will become trainers.

We are having a good response to our correspondence training course. Since it was started, there have been 1,000 enrollments. Some 500 of these have completed the course.

We have produced training films, promoted driver training in high schools and encouraged traffic courts to conduct retraining courses.

The true nature of your Council, and its methods of operation are much better understood today than when I spoke to you on this subject a year ago.

The quality, both in appearance and content, of the Council's publications has improved.

We have had a gratifying increase in the circulation of our Family Safety magazine. In the past 18 months, it has risen from 3,000 to 100,000.

The state and local councils have made

substantial progress in strengthening their programs.

The business affairs of your Council are sound. We expect to finish the year with a small surplus of income over expenses.

The Council's relations with other organizations are cordial and cooperative.

I want to say a word about the Council's traffic safety activity. The basis for all of these activities is the Action Program of the President's Committee for Traffic Safety.

The Council endorses, supports, promotes and makes an accounting of the Action Program.

All Conferences contribute to the Council's efforts to achieve the objectives of the Action Program. These objectives are—

Sound and uniform traffic laws.
Adequate accident reports and their use to guide programs.

Good instruction for youth and children.
Firm enforcement of traffic laws and intelligent supervision of traffic.

Strict requirements for obtaining and retaining a driver's license.

Increased safety on existing roads and streets through engineering.

Construction of additional streets and highways designed to carry traffic safely.

Motor vehicles designed and constructed to make them progressively easier to operate safely and minimize the injury potential in the event of an accident.

Vehicles maintained in safe operating condition.

Citizens who are informed as to the need for and nature of safety measures, and who, being informed, support traffic safety programs.

Voluntary coordination of programs and activities among all working for traffic safety.

That, very briefly, is the Action Program. Everything the Council does in the field of

traffic safety is deliberately, thoughtfully and carefully designed to support one of these objectives.

Our basic instrument for carrying this out is the Annual Inventory of Traffic Safety Activities. The Inventory is the public accounting system of the Action Program. It is a report of progress or failure by cities and by states and, in some cases, by counties. It is the only instrument of its kind in existence. It gathers, on a purely voluntary basis, statistics from over 1,200 cities, 49 states, 2 counties and Puerto Rico.

Every year statistics on each of the objectives on the Action Program are assembled. They are analyzed and the performance of each state and city is compared with those of cities and states in the same population groups. These analyses, together with recommendations, are then returned to the people who provided the information. This program is administered by the National Safety Council.

The Inventory is monitored by several national organizations such as the American Bar Association, the International Association of Chiefs of Police, the Traffic Engineering Institute and others. Every year we make an effort to have these groups come in and improve the questionnaires and the methods of comparison and analysis. Every year we try to do a better job.

This is a valuable service. It is the only service of its kind in the world. It goes to the states and cities without charge. Some 30,000 people are involved in filling out these questionnaires and in using the returned analyses.

The Inventory is the basis on which we conduct your traffic safety program. You may think I have stressed the Inventory unduly, but I have a purpose in doing so. There is nothing in this world that is being done that can't be done better. Anybody who turns away from constructive criticism is sick. Any organization that won't critically examine its own operations is dying. But you cannot let action die because of criticism. And any organization that stops trying to do something it knows to be sound and needed, because it is criticized, is unworthy of respect.

Now we get literally hundreds of letters praising the service provided by the Inventory. We also get a few, but rather vocal, criticisms and some belittlements of this activity. Because of these, I think that it appropriate to make this statement—

The National Safety Council works every day of the year with all the resources it has, using all the talent and experience of its members and staff to prevent accidents. And, it is going to keep on working. It is trying to prevent accidents and it is never going to stop trying.

ANNUAL ADDRESS OF THE PRESIDENT

By HOWARD PYLE
President, National Safety Council

Since my address follows that of General Stewart on our program, I should like to express the appreciation I am sure we all feel for the excellent analysis he has given us of the Council's program, its great strengths, its imposing potential and its tremendous responsibility.

At this point in these annual proceedings it is customary for the President of the Council to offer such personal observations and comments as may seem desirable or appropriate, as the full work of the Congress gets under way.

I wish all of you could see this audience from where I stand here this morning. It is tremendous. There is something about it that I think might be illustrated by a good story. I think we might indulge in one bit of laughter at this juncture in spite of the seriousness of the things with which we are dealing.

This story is told of Mark Twain who was inclined to be quite profane. When something happened that he didn't like particularly, he could swear like a section hand, and did, regardless of who happened to be around. On a particular morning he was shaving and by the most unfortunate circumstance he cut himself rather badly and immediately he let go.

It was really blasphemous.

Now his wife, who for many years had been doing her best to try to break him of this bad habit, had learned every single, solitary phrase he knew so well. So, as he tapered off and the air cleared a little, she stepped into the bathroom door and standing there in an attitude of great seriousness she repeated all the things that he had said so he could hear how it all sounded.

He stood there with a dripping razor, the cut bleeding profusely. With a half smile on his face he listened to her go through the whole unpleasant routine.

When she had finished, he said "Honey, you are wonderful. You have the words, but you don't have the music."

The thing about this crowd is that you have both the words and the music. As I meet you in the field, or elsewhere, I am continuously impressed with your zeal and fervor as professionals and as citizens dedicated to the work that occupies us all.

Now on the inside of the front cover of our annual report, and I trust each of you will take a good look at it as you have the time, there is another acknowledgement to which I would like to refer. It says, "In recognition of the thousands of dedicated volunteers and the many official and private agencies and organizations that make up the safety movement in America."

In exactly 25 words this statement of appreciation identifies the main strength of accident prevention as we know it and work with it year after year in all the areas of our several responsibilities.

Let it be said here and now, as it has already been implied by General Stewart, we have only praise and the most fervent gratitude for any and every force, personal or otherwise, that is usefully engaged in this great humanitarian work. If there were twice or three times as many of us working full time in this field of activity, there would still be all kinds of important duties for every force present. This means, my friends, that there is precious little time for any thing that might slow down the work or result in a single death or injury that might have been averted had all of us been hard at it as we should be.

It's a real tribute to the members of the accident prevention community that there has been so much productive cooperation among all concerned. It is one of the many things that has impressed me most about this work in the altogether too brief time I have been associated with it. Should anyone be in doubt about this point, I would suggest a review of the action program and a bit of reflection on the extent of the meeting of minds that was required to produce this answer to our need for immediate action all along the traffic control front.

Now time and further research must and will improve on our plans for the future. In the meantime, however, if a single death or injury occurs while we are hesitating for the want of a more perfect answer, it would seem to me that we would deserve the most critical judgments of every citizen in the land.

We will never know all the answers to anything as complex as the challenges with which we are faced in accident prevention, but we certainly will deserve the stigma of failure and neglect if we are ever slow about acting with the full strength of what is already known.

Of the gravest importance to our mission is this added truth that I am afraid maybe we may overlook once in a while. While we are the custodians of the national safety through accident prevention, we are also obligated to help protect a way of doing things in this country that is as American as Independence Day.

For me there is a very special and heart-warming significance in the fact that accident prevention is essentially a citizen effort. People organized and otherwise doing their utmost for their country, something that needs to be done where the people live, where they work and where they play.

In my personal judgment, from the experience I have had, in doing things many different ways, there is no substitute for the effectiveness of this kind of citizen responsibility.

Now to ignore it or to make less than the most of its potential by failing to inspire it and lead it with every resource at our immediate command, is to risk the loss of a way of doing things that is indispensable to our way of life.

As often as private initiative and local responsibility fails or for any reason is bypassed or pre-empted, something extremely vital, without which a free society simply cannot live, dies. Perhaps I can illustrate what I mean, show you why I have such a deep concern about this sort of thing.

While on duty in the White House, I was once brought into a discussion that proposed the appropriation of several millions of dollars to be distributed among the states under circumstances with which I was convinced the states would not agree. To be

sure of my position I personally called the governors of each of the states by telephone and asked them this question: "If your legislature were now in session and you took this issue to them for approval, would it be endorsed? What would the reaction be? Fundamentally, would they endorse it?"

After all, the state legislatures are generally regarded as the closest possible elected officials to the people by way of the districts in which they live.

Without exception the answer from every governor in the United States was, "No, my state legislature would not approve it," although some of the governors personally were in favor of the idea.

Believe it or not, I lost the argument in spite of the evidence I produced. The political pressures from certain sources were simply too great and the program went ahead. As God is my judge, ladies and gentlemen, this is a true story and if time permitted I could tell you others like it.

I simply cannot believe this is the way we want things done in this country. In fact, I doubt that there is ever any justifiable reason for taking the view—well, the folks at home haven't done anything about it, or enough, so we will do something about it with their money.

Now we cannot speak and we cannot act for others who serve the public, but we can and must speak and act for the thousands of dedicated volunteers and the many official and private agencies and organizations that make up the safety movement in America. The challenge for us is how closely can we and will we work with the people?

How constantly and faithfully can we and will we join with them in advancing the work of accident prevention, while at the same time we protect the people's way of doing things that need to be done for and by the people?

To the extent that we succeed, and believe me, ladies and gentlemen, we cannot fail in this responsibility, we will not only stop accidents, but we will be able to stand with the citizenship of this country as living, incontestable proof to the world that a free people is most of all a responsible people.

In my personal judgment there is no more

urgent business than this at hand today and I would hardly except even the international problems that must inevitably be the responsibility of governments. The peoples of the world need inspired leadership from us just as badly as their diplomats do. Since our constant prayer is that our leaders may deserve to prevail, what then can we, should we and must we do as a people?

Our answer must be to lead them and to help them with such responsibilities as accident prevention, as we have never led them and never helped them before in our entire history. I contend if they are willing to spend billions of dollars every year as a possible deterrent against atomic oblivion, they are willing to help avoid the end of the world every year for more than 90,000 men, women and children who die because of accidents we know could be avoided.

Now this may not seem quite as urgent as Berlin, or the tensions of the United Nations, or the control of outer space, or intercontinental missiles, or whatever your particular attention is in that regard. On the other hand before we draw this kind of conclusion about anything as important and elemental to the structure of the world's well-being and to our well-being as a people,

let's recite together, these very significant bits of literary revelation:

For the want of a nail a shoe was lost
For the want of a shoe a horse was lost
For the want of a horse a rider was lost
For the want of a rider a battle was lost

For the want of a battle a kingdom was lost
And all for the want of a horseshoe nail.

Ours is as urgent a business as I know. We have only begun to handle it as well as we can and as well as we must.

May this 49th National Safety Congress and Exposition multiply our usefulness many times in the name of safety everywhere all the time.

Ladies and gentlemen, may I suggest that you now try to see all the exhibits, and engage in as many of the program activities as possible. This is your Exposition. We are only here to serve you.

In behalf of the officers and the members of the Board, may I express our appreciation for your attendance at this annual meeting and for the interest you have shown.

ANNUAL BANQUET

INVOCATION

By THE REV. EVAGORAS CONSTANTINIDES
Priest, St. Demetrios Greek Orthodox Church, Chicago, Ill.

IN THE name of the Father and of the Son and of the Holy Spirit,
Amen.

Almighty God, in all wisdom hast Thou created the universe and in all love hast Thou made man in Thine image and likeness.

Thou hast established this universe as man's dwelling place, his throne of glory. Thou hast equipped this abode of man with all the blessings for his sustenance and regulated it with all the laws for his safety and well being.

Man has gone a long way in discovering the marvels which encompass him and, pleased with what he discovered, wants to be further inspired by adventures into the cosmos with which Thou hast surrounded him.

With new highways, waterways, airways and spaceways constantly being carved on, in and about the earth, we pray to Thee, Almighty God, that Thou enlighten all men to use these avenues to progress with prudence, love and consideration toward one another, so that they may become factors in man's growth in Thy direction instead of pathways to his extinction.

Grant that man may use his reason in all his movements, regard his safety and the safety of others as an obligation, and thus consider the preservation and safekeeping of his body, the vessel in which Thy Spirit dwells, as a commandment from Thee and allow his life, the most treasured possession which Thou hast given him, to grow in dignity, blossom in safety and culminate its earthly existence by Thy hand, not his.

This we ask in the name of Your Son and our Lord and Redeemer, Jesus Christ. Amen.

NATIONAL SAFETY CONGRESS BANQUET

Congress Banquet

The banquet of the 1961 National Safety Congress was held in the Grand Ballroom of the Conrad Hilton Hotel, Chicago, on October 17, with William H. Lowe, Chairman of the Board of Directors, presiding.

The Invocation was given by the Reverend Evagoras Constantinides, Priest of St. Demetrios Greek Orthodox Church, Chicago. The reverend Mr. Constantinides' prayer is printed on a following page.

During the dinner, banquet guests were entertained by an orchestra under the direction of Bud Dinwiddie, and featuring vocal soloist Larry Gray.

Seated at the speakers table, and at special tables on the ballroom floor, were the Council's officers and members of the Board of Directors. These were appropriately introduced to the banquet guests by the Chairman.

The Chairman read telegrams of greeting from the Honorable John F. Kennedy, President of the United States, and the Honorable Richard J. Daley, Mayor of Chicago.

President Howard Pyle presented the Trustees Award of the National Safety Council to the Honorable John Dempsey, Governor of Connecticut, and to the Honorable Fay Wheelon, Mayor of Sioux Falls, South Dakota, Connecticut and Sioux Falls won the awards for their accident prevention performance in 1960.

The Trustees Award is presented annually

to the state and city which, during the year, did most to protect their citizens from accidents of all kinds. The Award is based not only on actual accident records, but on accident prevention activities by industry, media, churches, civic and youth groups, public officials, and safety organizations.

For earning this recognition Governor Dempsey and Mayor Wheelon received from President Pyle the *Flame of Life* Award. The Award is an abstract crystal sculpture in the form of a flame, which curls in an upward sweep from a narrow base to a pointed top. It is fashioned to symbolize the flame of life which accident prevention seeks to sustain.

In accepting their awards, Governor Dempsey and Mayor Wheelon paid tribute to safety leaders in Connecticut and in Sioux Falls whose efforts played a significant part in securing the recognition. Special guests from Connecticut and Sioux Falls were asked to stand and be recognized.

The banquet address was given by John F. Gordon, President of General Motors Corporation. In introducing Mr. Gordon, the Chairman outlined his distinguished career with General Motors, beginning in 1921, progressing through a succession of responsibilities in various divisions of the Corporation, and culminating in the elevation to his present position in 1958.

Mr. Gordon's address, "Safeguarding Safety Progress," is included as a part of these transactions, on following pages.

SAFEGUARDING SAFETY PROGRESS

By JOHN F. GORDON
President, General Motors Corporation

When I began to think about what I should say tonight, I assumed that the one subject I should not discuss was "safety." For one thing, I am not a safety expert. For another, the subject is being quite thoroughly covered this week, I understand, in scores of expert presentations on just about every conceivable aspect of safety.

However, I soon found out that in seeking another topic I was violating a sound rule: "Never take anything for granted." Governor Pyle and General Stewart assured me quite strongly that I should talk about safety.

So, with the indulgence of you professionals, that will be my theme.

My own interest in safety stems from more than personal considerations. A constructive interest in safety is part of my job. We insist that it be part of the job of all the people in General Motors.

Safe working conditions and safe conduct on the job are essential to the well-being of the men and women of our company—and to their efficient performance.

Safe products are essential to the success of our business—and to the manifestation of our sense of responsibility.

And helping in the promotion of safety throughout the community is a vital part of our role as a "corporate citizen."

The tangible benefits of our occupational safety program in General Motors leave no doubt that a demonstrated interest in safety is worth the effort. Our record is a matter of considerable pride and gratification to us.

By "us" I do not mean just top management. I mean all the people of General Motors, for all share both the credit and the benefits.

Safety promotion in industry is a team effort. Every individual must participate, just as all must help achieve such industrial goals as high productivity and high quality.

This universal obligation for safety adds emphasis to the responsibilities of management.

Down-the-line individual cooperation is a result of sound leadership. Management must provide a safe working environment. It must develop safe procedures. It must train employees. It must assure adequate supervision. It must stimulate safety consciousness through continuing education.

Above all, management must keep everlastingly at the job. Accidents are a continuing threat. Their prevention must be a continuing effort.

In 1960, GM people set a new record of industrial safety for themselves. Out of every thousand GM employees in the United States and Canada, 998 went through the entire year without a lost-time accident or occupational disease. Stated another way, we had less than one lost-time injury per million man-hours worked.

This year, for the fifteenth time, the National Safety Council presented its "Award of Honor" to General Motors.

If you think this sounds like boasting, you are quite right. It is boasting. I admit it without embarrassment because I believe we all should take more conspicuous pride in safety awards. We should be proud not only of the commendation itself but—more important—of the achievement on which it is based.

To give the safety movement the greater momentum it needs, we must build its prestige. We should "blow our own horn" over a safety record as enthusiastically as we do over a production or sales record.

I realize, of course, that an essential tool of the safety professional is the "view with alarm" technique. At the same time, it seems to me that "pointing with pride" should not be neglected.

It will help keep safety in the limelight. It will also help ward off fearful or fatalistic public reactions that can be evoked by an excessive diet of dire warnings.

The latest edition of "Accident Facts" contains, along with sober reminders of the challenges still confronting you, many evidences of heartening progress. For the sake

of your own morale, if nothing else, you ought to look at these from time to time.

Taking the quarter century since 1935, we find that the population death rate for all accidents has dropped almost one-third. Moreover, the total number of accidental deaths per year has declined. And this has occurred despite our great population increase and the greater exposure to hazards in today's more complex society.

In the occupational safety field, we find the death rate down almost one-half and the injury rate down more than half. We note individual company records of up to 31 million man-hours of work without a disabling injury.

On the highway, the fatality rate per 100 million vehicle miles has dropped from 15.9 in 1935 to 5.3 last year—a decline of two-thirds. This gain has been achieved despite the fact that we have almost three times as many motor vehicles traveling more than three times as many miles.

Obviously, there is no basis for complacency in these figures. The record can and must be greatly improved. But there is a basis for confidence—confidence that sustained, intelligent application of recommended measures will achieve continuing progress.

Adherence to this conviction is a necessary defense against certain forces which threaten to impede the safety movement. These forces are many and varied, but they have one thing in common. They are all founded on the false premise that the situation is hopelessly out of control and that a drastically different approach is needed.

From this common starting point, various groups go in different directions. One takes the worn and crowded road to Washington to seek the supposed magic of federal intervention. Another sets forth like medicine men to peddle a new gadget or gimmick. Another, moving backward, urges drastic, "police-state" measures. Still others just roam about looking for scapegoats.

You who have professional competence and responsibility to promote safety must oppose these diversionary forces in two ways. First, you must continue to resist the siren call of alleged panaceas. Secondly, you must demonstrate as effectively as possible the worth of established safety measures.

The organized safety movement in this country is now about a half-century old. At this age, I am sure it is capable of demonstrating considerable maturity in meeting its challenges. Insofar as it does, you will not have to worry about the retarding influence of self-appointed experts.

At the same time, maturity must not dull intellectual curiosity and initiative. You know well that your basic programs, sound as they are, can be further refined and supplemented. While rejecting the obviously impractical, you must continue to adhere to the idea that innovations are both possible and desirable.

There are at least two compelling reasons for doing an even better safety job.

One is the fact, of which I am sure you are aware, that each added measure of safety tends to be more difficult to achieve than the previous one. The law of diminishing returns goes to work unless efforts are constantly improved and intensified.

The other goal to continuing improvement of safety efforts is the fact that technological progress often brings new problems as well as benefits. There are those who deplore progress because of this. Actually, solving newly created problems is simply an inherent part of making progress through innovation.

There are also those who welcome change but who rashly undertake new activities without adequate preparation.

The competent safety worker plays a key role in technological progress by educating both the fearful and the foolhardy. He makes new machines and methods serve us better by showing us how to live with them.

Since I am not a professional, I shall not presume to offer any technical suggestions for keeping safety abreast of progress. However, I should like to urge intensified action in one particular area—off-the-job safety programs.

This is a highly promising and largely unexploited field. The greater our progress in reducing work accidents, the greater the off-the-job accident problem looms in proportion as a threat to individual security, to industrial efficiency and to the general welfare.

In most cases today, the worker is safer

on the job than off the job. More than two-thirds of the accidental deaths and more than half of the injuries to workers occur off the job. In companies with good work safety programs, the ratio of off-the-job injuries averages about 7 to 1.

Certainly, management's most important responsibility in the employee safety area is to help the worker avoid job-related accidents. However, helping him stay safe at home, on the road and elsewhere is a most desirable and quite feasible extension of a company's safety program.

The many companies which are already active in this area of safety promotion endorse it highly on the basis of their own experience. And I am sure that public safety authorities welcome this further support from their colleagues in industry.

Reference to off-the-job safety immediately brings to mind the biggest single part of the whole accident problem. That is highway traffic safety.

Because of its size and complexity, the traffic accident problem calls more urgently than any other phase of safety for intelligent thinking and aggressive action.

This need is further underscored by the fact that the traffic safety field has in recent years been particularly beset by self-styled experts with radical and ill-conceived proposals.

The current popularity of automotive safety engineering as a hobby for people in all walks of life has contributed little of importance, I'm afraid, to this highly technical field.

The general thesis of these amateur engineers is that cars could be made virtually foolproof and crash-proof, that this is the only practical route to greater safety and that federal regulation of vehicle design is needed.

This thesis is, of course, wholly unrealistic. It also is a serious threat to a balanced approach to traffic safety.

To begin with, it is completely unrealistic even to talk about a fool-proof and crash-proof car. This is true because an automobile must still be something that people will want to buy and use. Safety, in any environment from a bathtub to a bomb shelter, is a relative term, not an absolute. In the case of the automobile, we can only

design into it the greatest degree of safety that is consistent with other essential functional characteristics. Beyond that, we must depend on intelligent use.

The suggestion that we abandon hope of teaching drivers to avoid traffic accidents and concentrate on designing cars that will make collisions harmless is a perplexing combination of defeatism and wishful thinking. It is a little like suggesting that we neglect good health habits in favor of reliance on miracle drugs — and on some method of compelling people to take them. And it ignores the notable progress that so many states and cities have made in accident reduction through driver improvement.

Certainly, the design and performance characteristics of the automobile are a factor in the problem. Automobile manufacturers have long worked diligently and productively to make good driving easier and to provide increased crash injury protection. I hardly need detail for this audience the long list of improvements that have been developed and adopted.

I assure you that this progress will continue. New designs and devices will be adopted as rapidly as our research, development and test work assures us that they are practicable and desirable.

Progress will continue, that is, if we may continue to adhere to the approach that has produced the gains of the past. Every year's new model cars are safer as well as better in other respects, but these improvements are in response to forces at work in our free competitive economy — not in response to regulatory forces.

There is certainly a proper and productive role for government in safety promotion. However, the imposition of arbitrary controls as a substitute for strongly motivated voluntary action by competent engineers in industry might well inhibit progress.

There is little doubt that today everybody is for safety. This is true in the highway area as in other fields. I believe the vast majority of people want to drive well and are deeply concerned about traffic hazards.

In my opinion, you don't have to sell highway safety as such. You have pretty well overcome any public indifference to your basic objective. To this extent the public is already with you.

Your major task now is to spell out and sell the measures that will achieve greater highway safety. This can be done—if three conditions are met.

First, always be sure that the measures for which you ask support are fully worthy of support. The public is not apt to buy an inferior idea just because its objective is safety.

Secondly, always do a competent selling job. The mere fact that safety is important guarantees neither an audience nor an impact.

Thirdly, always be specific in seeking a public response. "Public support" is an abstraction that must be translated into concrete terms. Tell people exactly what they should or should not do to reduce the number and severity of accidents.

It has been my experience that long-term public information and education programs need frequent critical reappraisals.

It is wise to ask ourselves repeatedly: *Are we saying the right things? Are we saying them clearly and persuasively? Are we really reaching people?*

In sheer volume of publicity, traffic safety is probably second to no other good cause. And there is no question but that much of what is being done, both locally and nationally, is of excellent quality.

However, the persistent and proper emphasis of traffic safety workers on the need for greater public support suggests that the effort can and should be further improved.

The problem may lie in part in the fact that this is the one area of traffic safety for which responsibility is not clearly allocated. Perhaps the benefit of highly diverse participation in public information activities

is being diluted by lack of fully adequate coordination.

Or it may be that still higher performance standards in the field of safety communications must be defined and applied.

I do not pretend to have the answer, but I am convinced that this problem merits your continuing, earnest attention.

With public support for necessary action more fully mobilized, progress in highway safety will be greatly accelerated. People will no longer merely say, "Why don't they do something?" They will know what needs doing and they will help get it done—as good drivers, good parents and good citizens.

Moreover, the benefits will extend to other fields of safety. Today, the term "highway user" doesn't mean a special class. It means just about everyone. Thus, greater safety consciousness on the road will have a broad and potent carry-over to every other activity where safety is a critical factor.

I have full confidence in the ability of the men and women of the organized safety movement to make accelerating progress—both in technical areas and in mobilizing public support.

You have all the requisites to render distinguished public service: unselfish interest, professional competence, cooperative spirit and unflagging energy.

And you have this great organization, the National Safety Council, as an invaluable mechanism to help give direction and impetus to your efforts.

I am sure that I am joined by all thinking persons in commending you, wishing you well and pledging support in your great humanitarian work.

SAFETY EXPOSITION EXHIBITORS—1961

Acme Protection Equipment Co., South Haven, Mich.
Industrial gas masks, chemicals and accessories.

Advance Glove Mfg. Co., Detroit, Mich.
Work gloves.

Aetna Casualty & Surety Co., Hartford, Conn.
Safety educational and services including Aetna Drivetrainer

Akron Brass Mfg. Co., Inc., Wooster, Ohio
Fire Hose Nozzles and accessories.

Alan Wood Steel Co., Conschoocken, Pa.
Abrasive rolled steel floor plate.

American Allsafe Co., Inc., Buffalo, N. Y.
Sweat Bands and Greenline emergency release.

American Biltrite Rubber Co., Chelsea, Mass.
Rubber, composition and neoprene safety soles.

American Chain & Cable Co., Inc., Bridgeport, Conn.
Sling chains and sling chain assemblies, wire rope slings and assemble-your-own wire rope slings.

American Industrial Safety Equipment Co., Inc., Cleveland, Ohio
Face shields, goggles, gloves and mittens.

American LaFrance Corp., Elmira, N. Y.
Fire apparatus and fire fighting equipment.

American Optical Co., Southbridge, Mass.
Head, eye, respiratory protective devices; safety clothing, safety specialty products.

American Society of Safety Engineers, Chicago, Ill.
Society for the professional safety specialist.

Ampco Metal, Inc., Milwaukee, Wis.
Non-sparking, corrosion-resistant safety tools.

Ansul Chemical Co., Marinette, Wis.
Dry Chemical fire protective equipment.

Antrex Corp., Chicago, Ill.
Battery-powered public address megaphones, helmet radios, tape recorders.

Apex Safety Products, Detroit, Mich.
Safety hats, caps, face shields.

Atlas Safety Equipment Co., Inc., Brooklyn, N. Y.
Industrial Safety Belts, harnesses, and straps.

Auto-Crat Mfg. Co., Los Angeles, Calif.
Safety belts, interceptor harnesses, baby-guard belts.

Bachrach Industrial Instrument Co., Pittsburgh, Pa.
Instruments for gas analysis and air measurement.

Bashlin, W. M. Co., Grove City, Pa.
Linemen's and industrial safety equipment.

Bauer Mfg. Co., Wooster, Ohio
Wood and aluminum safety ladders.

Bausch & Lomb Optical Co., Rochester, N. Y.
Safety glasses, ortho-raters and "Titan" safety frame.

Beam's Mfg. Co., Reading, Pa.
Auto safety belts.

Best's Safety Publication, New York, N. Y.
Publishers of "Safety Maintenance" magazine, "Best's Safety-Maintenance Directory" and "Your Safety News."

Bethlehem Steel Co., Bethlehem, Pa.
Wire Rope slings, standard and braided slings.

Brossard, Lester L. Co., Chicago, Ill.
Traffic mirrors and traffic lane markers.

Browne, Stewart R. Mfg. Co., Inc., New York, N. Y.
Electrical safety equipment, explosion-proof and vapor-proof portable inspection lites, explosion-proof flashlites, grounding devices.

Buhrke, R. H. Co., Chicago, Ill.
Occupational safety equipment and products for construction and maintenance.

Bullard, E. D. Co., Sausalito, Calif.
Industrial safety equipment.

Bustin Steel Products, Inc., Dover, N. J.
Star tread material.

Campbell Chain Co., York, Pa.
Sling chains, welded and weldless chains.

Chance, A. B. Co., Centralia, Mo.
Hot line maintenance tools and line construction tools.

Charleston Rubber Co., Charleston, S. C.
Electrical worker's gloves. Bulldog wood safety clamps, red danger flags, plastic and fabric coated industrial aprons and sleeves.

Chemical Corp., The, Springfield, Mass.
Protective hand creams, cleaners and lotions.

Chicago Eye Shield Co., Chicago, Ill.
Head and eye protective equipment.

Chrysler Corp., Detroit, Mich.
Automobiles and trucks.

Clark, David Co., Inc., Worcester, Mass.
Safety Equipment, sound protector, space suits.

Clark, J. R. Co., Spring Park, Minn.
Industrial ladders.

Columbus-McKinnon Chain Corp., Tonawanda, N. Y.
Alloy steel sling chains.

Cornelius Co., Minneapolis, Minn.
Portable high pressure air compressors.

Davis Emergency Equipment Co., Inc., Newark, N. J.
Respiratory protection, combustible gas indicators, safety and first aid equipment.

Detex Watchclock Corp., Chicago, Ill.
Watchmen's clocks.

Diets, R. E. Co., Syracuse, N. Y.
Automotive lighting and safety equipment.

Dockson Corp., Detroit, Mich.
Welding helmets, face shields, cup and spectacle type goggles, respirators and eye savers.

Dow Corning Corp., Midland, Mich.
Sight saver cleaning stations, shoe saver, safety shoes.

Dräger Oxygen Apparatus Corp., New York, N. Y.
Safety equipment.

Eagle Mfg. Co., Wellsburg, W. Va.
Safety cans, oilers, oil and gasoline containers.

1961 National Safety Congress

Edmont Mfg. Co., Coshocton, Ohio
Coated fabric work gloves.

Electronic Specialties Co., Batavia, Ill.
Warning lights, barricades.

Elkhart Brass Mfg. Co., Inc., Elkhart, Ind.
Fire extinguishers, municipal and industrial brass goods.

Elliott Service Co., Inc., Mount Vernon, N. Y.
Accident prevention displays, safety conference programs, Supervisor's Weekly Bulletin, suggestion system, service.

Emerson, J. H. Co., Cambridge, Mass.
Resuscitators, inhalators and safety matting.

Encyclopedia Britannica, Inc., Chicago, Ill.
Technical reference service.

Falcon Alarm Co., Inc., Summit, N. J.
Automatic fire detectors and systems, audible safety signals.

Federal Sign & Signal Corp., Blue Island, Ill.
Sirens, warning lights, horns, bells and electronic sirens.

Fendall Co., Chicago, Ill.
Head and eye protection equipment.

Ferno Mfg. Co., Washington C. H., Ohio
Emergency folding stretchers and chairs.

Fibre-Metal Products Co., Chester, Pa.
Eye, Head, and face protection and welding accessories.

Fine Organics, Inc., Lodi, N. J.
High flash, low toxicity safety solvents.

Ford Motor Co., Dearborn, Mich.
Ford automobiles, featuring lifeguard steering wheels, sun visors, seat belts, instrument panel padding, and door latches.

Frommelt Industries, Dubuque, Iowa
Portable welding shields and protective heat cloth.

Fyrepel Products, Inc., Newark, Ohio
Aluminized glass cloth, heat protective clothing for industry and fire fighting.

Fyr-Fyter Div., Fyr-Fyter Co., Dayton, Ohio
Fire extinguishers, resuscitators and respirators.

36

Safety Exposition Exhibitors

General Fire Extinguisher Corp., Chicago, Ill.
Fire extinguishers and allied products.

Glendale Optical Co., Inc., Valley Stream, N. Y.
Chippers and welders goggles, face shields, safety spectacles.

The Globe Co., Products Division, Chicago, Ill.
Grip-Stru grating, stair tread materials.

Globe Safety Products, Inc., Dayton, Ohio
Resuscitation and breathing equipment.

Goodrich, B. F. Footwear & Flooring Co., Hood Rubber Co., Watertown, Mass.
Waterproof industrial footwear, hood waterproof industrial footwear, Hood industrial coated and unsupported gloves.

Granet Corp., The, Framingham, Mass.
Coated Fabric work gloves.

Grinnell Co., Inc., Providence, R. I.
Fixed pipe fire protection systems.

Gro-Cord Rubber Co., Lima, Ohio
Neoprene, rubber, composition soles and heels for safety footwear.

Halperin, A. E. Co., Inc., Boston, Mass.
First aid kits, safety equipment, burn-quel.

Haus of Krause Safety Shoes, Rockford, Mich.
Men's safety shoes for distributors serving industry.

Haws Drinking Faucet Co., Berkeley, Calif.
Emergency eyewash fountains, emergency showers and goggle wash fountains.

Hild Floor Machine Co., Inc., Chicago, Ill.
Explosion-proof vacuum cleaners and floor machines.

Hopfeld Industrial Mfg. Co., San Rafael, Calif.
Fiber glass ladders, structural members.

Horizon Industries, Minneapolis, Minn.
Pre-measured toilet bowl cleaner in tablet form.

Hygiene Research, Inc., New York, N. Y.
Protective ointments and mastproofing cloth for goggles, welding masks, windshield.

Hy-Test Safety Shoe Div., International Shoe Co., St. Louis, Mo.
Safety footwear; also conductive and special types of atomic usage.

37

1961 National Safety Congress

Industrial Acoustics Co., Inc., New York, N. Y.
Audiometric examination room, technical publications and industrial hearing conservation programs.

Industrial Gloves Co., Danville, Ill.
Leather, asbestos, duck, wool, Woven-Gard, Permaproof, and aluminized duck and asbestos finger guards.

Institute of Industrial Launderers, Washington, D. C.
Industrial Launderers and cleaners.

Insto-Gas Corp., Detroit, Mich.
Torches and furnaces.

International Film Bureau, Inc., Chicago, Ill.
Safety films and film library supplies.

Interstate Rubber Products Corp., Los Angeles, Calif.
Safety trafficones for traffic control.

Iron Age Safety Shoe Div., H. Childs & Co., Inc., Pittsburgh, Pa.
Linemen's and women's leather and rubber industrial safety footwear.

Jackson Products Air Reduction Sales Co., Div. of Air Reduction Co., Inc., Warren, Mich.
Insulated electrode holders, cable connectors, face shields and goggles.

Jamleson Laboratories, Inc., Van Nuys, Calif.
Air filtration device for use in industry.

D. Jay Products, Inc., Newark, N. J.
Safety marking rope.

Jomac, Inc., Philadelphia, Pa.
Industrial clothing.

Jones & Co., Providence, R. I.
Full vision visor goggles.

Junkin Safety Appliance Co., Inc., Louisville, Ky.
Power press guards, grinding wheel shields, stretcher equipment.

Justrite Mfg. Co., Chicago, Ill.
Safety cans, oily waste cans, safety electric lanterns, flashlights and fire extinguishers.

Karel First Aid Supply Co., Chicago, Ill.
Industrial hospital equipment and medical supplies.

Keystone View Co., Meadville, Pa.
Occupational and driver vision test, lantern slide projectors.

Safety Exposition Exhibitors

Kidde, Walter & Co., Inc., Belleville, N. J.
Fire detecting and extinguishing equipment, ultrasonic burglar alarm.

Kimball Safety Products Co., Cleveland, Ohio
Personal protective devices for industrial workers.

Klein, Mathias & Sons, Chicago, Ill.
Linemen's safety equipment and tools.

Knapp Brothers Shoe Mfg. Corp., Brockton, Mass.
Safety Shoes.

Kunz, J. Glove Co., Chicago, Ill.
Linemen's, bridgemen's and welder's quality gloves.

Lawter Chemicals, Inc., Chicago, Ill.
Fluorescent safety colors.

Legge, Walter G. Co., Inc., Chicago, Ill.
Safety floor maintenance materials, conductive coating, static eliminators.

Lehigh Safety Shoe Co., Emmaus, Pa.
Leather and rubber safety footwear.

Liberty Mutual Ins. Co. of Boston
New survival car II.

Logan Emergency Showers, Inc., Glendale, Cal.
Emergency showers and decontamination showers.

Lynrus Finishing Co., Inc., Poughkeepsie, N. Y.
Flame-retardant fabrics.

McAn, Thom Safety Shoe Div., New York, N. Y.
Safety Shoes.

McDermott, Julian A. Corp., Ridgewood, N. Y.
Warning and safety lighting for municipal, industrial, utility and aviation use.

McKay Co., Pittsburgh, Pa.
Industrial chain, tire chains, arc welding electrodes, stainless and alloy wire.

Malco Electronics, Inc., Minneapolis, Minn.
Audiometers for industrial hearing testing.

Marsh & McLennan, Inc., Chicago, Ill.
Insurance broker and agencies.

1961 National Safety Congress

Martindale Electric Co., Cleveland, Ohio
Protective dust masks, eye protectors, face shields, safety electric test instruments.

Medical Supply Co., Rockford, Ill.
Flexible unit aid, snake bite first aid, burn first aid.

Metropolitan Life Insurance Co., New York, N. Y.
Useful materials for use in community health and safety programs.

Meyer Machine, Inc., Red Wing, Minn.
Safety clamps.

Micro Switch, Div. of Minneapolis-Honeywell Regulator Co., Freeport, Ill.
Safety interlock switches and electric controls for power machines.

Milburn Co., Detroit 7, Mich.
Ply skin protective creams, ply garb safety and protective clothing, plygloves plastic coated work gloves, ply waterless hand cleaner.

Miller Equipment Co., Inc., Franklin, Pa.
Linemen's safety belts, strap accessories and industrial safety belts.

Mine Safety Appliances Co., Pittsburgh, Pa.
Safety equipment for every industry.

Minnesota Mining & Mfg. Co., St. Paul, Minn.
Heat reflective "Scotchshield" brand chemical fabric used in protective clothing for fire fighters and industries with heat problems.

Mobile Classroom Rental, Inc., Chicago, Ill.
Mobile classroom equipped with Drivo-trainers.

National Chemsearch Co., Chicago, Ill.
Safety solvents and other safety chemicals.

National Medical Supply Co., Chicago, Ill.
Industrial first aid supplies equipment and instruments.

Newco Mfg. Co., Inc., Kansas City, Mo.
Wire rope fittings, safety hooks, load protectors.

Notifier Corp., Lincoln, Neb.
Fire detection, sprinkler supervisory, watchman tour, municipal alarm systems.

Occupational Hazards, Cleveland, Ohio
Publishers.

Ohio Chemical & Surgical Equip. Co., Div. of Air Reduction Co., Inc., Madison, Wis.
Complete array of modified E & J life-saving resuscitative equipment.

Safety Exposition Exhibitors

Onox, Inc., San Francisco, Calif.
Onox, skin toughener and footmats for athlete's foot.

Osborn Mfg. Corp., Warsaw, Ind.
Safety pliers and tongs for feeding punch presses.

Oxygen Equipment & Service Co., Chicago, Ill.
Respiratory equipment.

Oxy-Gear, Inc., Chicago, Ill.
Portable emergency oxygen inhalator kits, controlled flow pure oxygen.

Pac-Kit Co., Greenwich, Conn.
Unit type first aid equipment.

Packwood, G. H. Mfg. Co., St. Louis, Mo.
Safety industrial skin cleaners and dispensers.

Patent Scaffolding Co., Inc., Chicago, Ill.
Wood, aluminum and magnesium safety ladders, suspended sectional steel tubular steel and aluminum scaffolding, sidewalk protection canopies, steel grandstands and fold-a-way scaffold.

Peck's Products Co., St. Louis, Mo.
Solvents, hand soaps.

Pioneer Rubber Co., Willard, Ohio
Gloves; all kinds, liquid proof.

Portable Light Co., Inc., New York, N. Y.
Vehicular and emergency searchlights, general alarm sirens.

Porto-Clinic Instruments, Inc., New York, N. Y.
Driver testing and training equipment and visual aids for driver and traffic safety.

Positive Safety Mfg. Co., Cleveland, Ohio
Power press guards.

Prairie State Products Co., Chicago, Ill.
Metal and electrical safety and directional signs.

Progress Industries, Inc., Warwick, R. I.
Safety goggles.

Protectosol Co., Chicago, Ill.
Fire prevention equipment for flammable solvents.

Pulmosan Safety Equipment Corp., Brooklyn, N. Y.
Respirators, eye protection, helmets, protective clothing, asbestos and leather gloves.

1961 National Safety Congress

Radne Glove Co., Inc., Rio, Wis.
Gloves, apparel, protective equipment—leather, asbestos, and steel reinforced.

Radiator Specialty Co., Charlotte, N. C.
Safe-T-Cone rubber traffic guides.

Rhett Woodworking Safety Guards, Wilmington, N. C.
Jointer and shaper guards.

Rockwood Sprinkler Co., Worcester, Mass.
Automatic fire protection systems; sprinklers, waterfog, fogfoam and foam.

Rose Mfg. Co., Denver 4, Colo.
Industrial safety equipment.

Safeguard Mfg. Co., Woodbury, Conn.
Modern press guards.

Safety Box Toe Co., Boston, Mass.
Safety steel toes.

Safety Clothing & Equipment Co., Cleveland, Ohio
Safety clothing and equipment for every type of industrial worker.

Safety First Products Co., Elmsford, N. Y.
Fire extinguishers.

Safety First Shoe Co., Inc., Holliston, Mass.
Safety steel toe shoes for men.

Safety Tower Ladder Div.; Air Space Device, Inc., Burbank, Calif.
Safety equipment for fixed ladders and scaffolds.

Salisbury, W. H. & Co., Chicago, Ill.
Linemen's rubber protective equipment.

Sarole, Inc., Linden, N. J.
Non-traumatic carrier.

Sawyer-Tower, Inc., Watertown, Mass.
All types of protective and safety clothing.

Scott Aviation Corp., Lancaster, N. Y.
Scott air-pak demand inhalator, demand respirator, hydro-pak.

Searjeant Metal Products, Inc., Mendon, N. J.
Punch press safety guards, controls and accessories.

Safety Exposition Exhibitors

Seiberling Latex Products, New Bremen, Ohio
Rubber and neoprene industrial gloves.

Sellstrom Mfg. Co., Palatine, Ill.
Face and eye protection equipment.

Servus Rubber Co., Rock Island, Ill.
Rubber footwear of all types.

Speakman Company, Wilmington, Del.
Industrial emergency showers, eye-wash fountains.

Standard Safety Equipment Co., Palatine, Ill.
Industrial safety equipment.

Standard Signs, Inc., Cleveland, Ohio
Signs for industrial accident prevention.

Stephenson Corp., Red Bank, N. J.
Automatic resuscitation equipment and chemical breath test for intoxication.

Stonehouse Signs, Inc., Denver, Colo.
Industrial accident prevention signs.

Step-Fire, Inc., Monmouth Junction, N. J.
Fire extinguishers.

Surety Rubber Co., Carrollton, Ohio
Personal protective equipment for industrial and electrical workers.

Switzer Brothers, Inc., Cleveland 3, Ohio
Fluorescent safety paint for high-visibility marking of hazards.

Swiveller Co., Inc., New York, N. Y.
Universally adjustable lighting equipment.

Taylor, S. G. Chain Co., Inc., Hammond, Ind.
Alloy steel sling chains and allied products including alloy steel drop forged hooks.

Tect, Inc., Northvale, N. J.
Vythene and other tectsolve safety solvents.

Titmus Optical Co., Inc., Petersburg, Va.
Safety eyewear, ophthalmic instruments, lenses, frames and sun wear.

1961 National Safety Congress

U-C-Lite Mfg. Co., Chicago, Ill.

Explosion-proof portable electric hand lamps and emergency lights.

Union Wire Rope Corp., Kansas City, Mo.

Wire rope slings, towlines.

United States Rubber Co., New York, N. Y.

Industrial safety clothing, safety footwear.

United States Safety Service Co., Kansas City, Mo.

Modern industrial eyewear, sold direct to user.

Wagner Sign Service, Inc., Chicago, Ill.

Wagner changeable copy displays.

Wamsutta/Pacific Industrial Fabrics, New York, N. Y.

"Safetex" flame retardant fabrics—durable to laundering—for safety clothing. Protective fabrics for industrial uses, made of various fibres.

Watchmoke Optical Co., Inc., Providence, R. I.

Plastic eye protection and safety signs.

Welsh Mfg. Co., Providence, R. I.

Safety goggles, lens, face shields and helmets.

West Side Iron Works, Inc., Grand Rapids, Mich.

Barricades, warning lights, safety vests.

Wheeler Protective Apparel, Inc., Chicago 10, Ill.

Industrial safety clothing for heat and abrasive hazards.

Williams Jewelry & Mfg. Co., Chicago, Ill.

Safety awards, badges and trophies.

Willson Products Div., Ray-O-Vac Co., Reading, Pa.

Industrial goggles, gas masks, helmets and respirators, and allied safety devices.

Wilson Rubber Co., Div. of Becton, Dickinson & Co., Canton, Ohio

Rubber and synthetic industrial gloves for every use.

Woolrich Woolen Mills, Woolrich, Pa.

Acid resistant industrial safety clothing.

Zenith Radio Corp., Hearing Aid Div., Chicago, Ill.

Diagnostic audiometers that also can be used for individual and group screening.

Safety Exposition Exhibitors

EDUCATIONAL EXHIBITORS

Chicago Police Dept., Education Section, Traffic Div.

Traffic safety display.

Inter-American Safety Council, Inc., New York, N. Y.

"The Safety Council serving Latin America."

National Society for the Prevention of Blindness, New York, N. Y.

Educational material on conservation of eyesight in industry.

Division of Accident Prevention, Public Health Service, Washington, D. C.

Accident prevention program & materials.

Recreation Shooting Safety Committee, National Safety Council, Chicago, Ill.

Recreational shooting safety program materials.

U. S. Forest Service, Washington, D. C.

Smookey Bear—Forest Fire Prevention, and Forest Service Safety Materials.

1961

INDEX TO ALL VOLUMES

(An author-subject index)

- A**
- Abbas, M. J.
Stopping methods in the Lake Ambrosia uranium mines. 18:23-24.
- Abercrombie, S. A.
The college-university highway traffic and safety project. 23:23-24.
- Abrams, Herbert K.
Occupational health hazards, medical aspects. 12:5-12.
- ACCIDENT CASES, see CASE HISTORIES AND ACCIDENT STUDIES**
- ACCIDENT CAUSES, see CAUSES OF ACCIDENTS**
- ACCIDENT PREVENTION FUNDAMENTALS**
The accident syndrome (Schulzinger), 6: 86-10.
- Annual address of the President of the National Safety Council (Fyfe), 1:23-25.
- Dynamic safety criteria, an engineering approach (McAdams), 12:19-20.
- Everyone, everywhere, all the time (HUI), 25:36-37.
- My brother's keeper (Broucker), 11:4-8.
- Safeguarding safety progress (Gordon), 1: 28-31.
- Things money won't buy (Harrison), 13: 10-13.
- What you don't know can hurt you (Schap-
leberg), 23:17-19.
- ACCIDENT PRONE**
A new concept of accidents which takes is-
sue with the accident prone idea (Rogge),
8:29-31; same, 18:10-12.
- A protractor for safety (use of ARIL survey
form) (Jenkins), 17:34-37.
- ACCIDENT STATISTICS**
Safety is our challenge (Harrison), 13:22-24.
- ACCIDENT STATISTICS—METHODS**
The ASA (American Standards Association)
injury frequency rate is a good measure
of safety performance (Wallace), 12:45-48.
- Data processing of accident records (a sym-
posium), 19:23.
- Data processing of accident records (Miles),
19:31-32.
- Do injury statistics have to be dull? (Wil-
son), 19:47-50.
- The importance and value of accident re-
porting (Schneider), 6:78-79.
- An M.D.'s use of electronic data processing
in health and safety (Brooks), 8:4-7.
- Report of statistics and contacts committee
of the Marine section: breakdown of the
marine transportation report into four
groups (Morrow), 14:90-94.
- Using serious injuries (Haier), 8:75-77.
- AERIAL BASKETS**
Aerial basket ups and downs (Lorenz), 20:
24-27.
- AERONAUTICS**
Human factors in light plane safety
(Brown), 9:77-81.
- Lessons learned from aviation crash injury
research (Rothe), 6:51-54.
- Safety before the flight, jet engine test (Ma-
honey), 2:18-23.
- Stores training: rigid purpose, flexible
method (Lone), 2:31-34.
- AEROSPACE INDUSTRIES**
Safety in the mach numbers or else (Wil-
kins), 2:9-11.
- AEROSPACE SECTION**
Joint session with Chemical Section, 2:12-18;
same, 8:46-52.
- Officers and committees, 2:35-36.
- Sessions, 2:5-28.
- AGE AND SEX**
The aging driver (Klamm), 24:49-51; (Sam-
ley), 24:51-53.
- Case studies of one-car accidents involving
young drivers (Bishop), 23:41-45.
- Teenage traffic court and school (Goskey),
24:73-74.
- Ahern, John J.
Safety engineering, a modern concept, 12:
18-19.
- AIR TRANSPORT SECTION**
Officers and committees, 2:37-38.
- Sessions, 2:29-34.
- Albiser, Robert H., see Morrison, Lewis H.
and others.
- ALCOHOL**
Chemical tests in driver research (Haddon),
24:53-57.
- What direction chemical tests? Legislation
(Domigan), 24:74-78; Enforcement (Bar-
rett), 24:78-80; Testing devices (Borken-
stein), 24:81-82.
- Alexander, C. E.
Management's role in accident prevention,
5:67-71.

Allen, Homer
Teacher competencies in safety. 28:121-124.
Altier, Harold J.
Press fortune with safety. 3:45-46.
Amberg, Edward J., Jr.
Radioactive isotope systems in the paper industry. 21:16-22.

AMMONIUM NITRATE
Low-cost blasting agents (Damon). 16:26-35.
Observations on underground blasting with ammonium nitrate-fuel oil explosives (Stott). 16:37-48, including appendix A: Major disasters; appendix B: Explosives accidents at mines using ammonium nitrate field-mixed blasting agents.
Safe practices in strip mining (Quenon). 7:20-31.

Anderson, Merrill H.
Water utility safety panelist. 20:14.

Armstrong, Ellis L.
The interstate highway system. 24:12-18.

Aspenlieder, Joseph V.
Safety in the west Delaware tunnels. 16:17-22.

ASSOCIATIONS, see SMALL BUSINESS AND ASSOCIATIONS

ATOMIC BOMBS
Civil defense and associated problems, with emphasis on schools (Sennett). 23:24-28.
Civil defense and disasters you hope will never come (Brandtlinger). 23:19-24.

ATOMIC RESEARCH LABORATORIES
Competence, confidence and cooperation: the safety director's challenge (Bonner). 2:5-7.

ATTITUDES
Attitudes essential to the safety movement (Gaffner). 6:80-91.
My brother's keeper (Brouwer). 11:4-8.
Pardon me, is your slip (attitude) showing? (Wise). 20:5-12.
A protractor for safety (use of job attitude test AR11) (Jenkins). 17:34-37.
The straight line of communication (trying to change other people's behavior) (Kumata). 17:50-51.
See also **PSYCHOLOGY**

AUTOMOTIVE AND MACHINE SHOP SECTION
Officers and committee. 1961-62. 3:47-48.
Resolutions. 3:1-22.

AWARDS AND CONTESTS
Incentive and yardstick, national college and university safety awards (Carter). 23:54-57.
The lost time injury (Jonassen). 14:45-48.
Tanker 66-11.
The 1961 Metropolitan award for traffic safety research, given to J. Stannard Baker (Formey). 1:30.
Of the job safety at World Beatos (Speers). 11:26-29.
Presentation of awards at annual business meeting of Marine Section (Gage). 14:72.

Presentation of labor safety awards (Utter). 13:25-28.
Report of committee on home and off the job safety (Bemilton). 23:6-7.
Report of the ship safety achievement award committee of the Marine Section (Devlin). 14:30.
Reports of awards committee of the Marine Section (Mackey). 14:50-51.
Ships earn the Jones F. Devlin awards presented by the American Merchant Marine Institute (Brenyard). 14:38.

A straight line on safe driver awards and incentives (Shingler). 17:51-54. Same. 23:139-141.
Thirty years of mine rescue training in Ontario (McPhail). 16:10-11.
Trustees Award of the NSC presented at the annual banquet. 1:27.

Ayers, Richard K.
Thumbs down on violators. 20:34-37.

BACK INJURIES

A more dynamic approach to the prevention of back injuries in an industrial environment (Marlin). 19:48-51.
Safety's role in preventing back injury (Boggs). 12:51-54.

Baker, Lee W.
Communications for safety, how can we make our safety messages more effective? 12:13-18.

Bare, Harold L.
Supervisory safety training programs for the mining industry. 16:51-54.

BARGE AND TOWING INDUSTRY

Safety, built-in (McNeal). 14:8-10.
Safety, built-in, on river towboats (Kehres). 14:10-12.

Safety, built-in, on towboats and barges (McCormick). 14:13-15.

Safety, built-in: the characteristics of the hydroconic tug (McAllister). 14:15-8.
Barnako, Frank R., see **Morrison, Lewis R.** and others.

Barrett, James R.
What direction chemical tests for intoxication? Enforcement. 24:75-80.

Barrocas, Robert P.
Mechanical accidents. 12:23-27.

BASKETS, see AERIAL BASKETS

Batter, M. M. "Smookey"
Increased on the job fire training, a must in the pulp and paper industry. 21:19-11.

Baugh, Woodward B.
Relationship of operating rules to safety rules. 22:10-13.

Baumgartner, Leone
The impact of home accidents on the family. 6:91-97.

Bayley, T. A.
Eliminating the risk of overhangs in fertilizer piles. 6:71-74.

BELTS AND LIFE LINES

Aerial basket use and down, "belting in" with a lanyard and belt (Lorenz). 20:23-24.

Falls during bulk materials loading operations (Carabe). 4:11-12.

See also **SEAT BELTS**

Bennett, Frank
Civil defense and associated problems, with emphasis on schools. 23:24-25.

Berg, Gene S.
From how until then. 23:125-126.

Berry, Richard W.
Report of general chairman of the Marine Section. 14:32.

Berneth, John A.
Electrical hazards in the glass industry. 11:4-12.

Breiden, William E.
How do we know public employee work is safe. 6:21-22.

BICYCLES
A model bicycle control program for college and university campuses (Neure). 25:36-101.

Bird, Frank E., Jr.
Damage control, a new horizon in accident prevention. 12:65-70.

Birmingham, Donald J.
Clinical observations on the cutaneous effects associated with curing epoxy resins. 16:13-17.

Bishop, Richard W.
Case studies of one-car accidents involving young drivers. 23:41-45.

Blackledge, Sydney
Report of passenger and cargo services. 14:34.

BLASTING
Low-cost blasting agents (Damon). 16:26-35.
Observations on underground blasting with ammonium nitrate-fuel oil explosives (Stott). 16:37-48.

Safe practices in strip mining (Quenon). 7:20-31.

BLASTING CAPS
Forming practices with high explosives (Doughless). 2:24-25.

BOATS AND BOATING
Electrical safety in ships (and small boats) (Gates). 14:70.

Engineering small boats for safety (Miller). 6:27-40.

The mobile boarding unit in law enforcement and boating safety (Hutson). 6:43-46.

Review of marine casualties (Rawley). 14:74.

Weather forecasting for boating safety (Kutchenko). 6:13-27.

Boget, Herbert T.
What do we need to make falls an effective area of emphasis for agricultural safety? 6:75-74.

Boggs, Charles W.
Safety's role in preventing back injury. 12:51-54.

Bond, Robert D.
Images of driver education in the '60's. 23:116-121.

Bonner, E. G.
Competence, confidence and cooperation, the safety director's challenge. 2:5-7.

Borkenstein, Robert J.
What direction chemical tests for intoxication? Testing devices. 24:81-82.

Bostell, Paul P.
Some observations on occupational dermatoses. 13:12-15.

Boisford, James H.
Noise abatement at mines and quarries. 16:55-61.

Bourne, G. Ernest
How the safety council manager and safety education supervisor can cooperate in their activities (panel). 23:28-30.

Bowen, James H.
Ear protection and audiometric examination. 16:81-84.

Brandtlinger, Fred H.
Civil defense and disasters you hope will never come. 23:19-24.

Brenyard, Frank
Report of public relations committee. 14:39.

Breese, Milton
Report of safety information and poster committee. 14:84.

Brodie, Leon
When men behave like buffoons. 15:7-9.

Brooks, Bert W.
An M.D. a use of electronic data processing in health and safety. 6:4-7.

Brouwer, Paul J.
My brother's keeper. 11:4-8.

Brown, Harold N.
Human factors in light plane safety. 6:47-51.

Brown, H. F. and Kutz, G. M.
The Kinis and Browne fire and static electricity demonstration. 12:53-56.

Browne, Howard C. and others
Design and testing of a new high pressure cell. 6:2-15.

Brownell, S. M.
Safety—for what? (The Gordon Graham memorial lecture). 23:7-14.

Brown, W. Kemper
Safety in cotton gins. 23:25.

Buchanan, David L.
Report of Great Lakes area. 14:87-88.

Buck, Donald S.
The human dimension in safety. 17:8-15.

Buckley, Robert W.
Water survival courses. 6:60-62.

Budzik, Paul M. and Kadic, George R.
Control or extinguishment of gob fires. 7:11-18.

COSTS OF ACCIDENTS

- Belt conveyor accident (Volts), 4:15-16.
Causes of claims and their effect on claim cost in vessel operation (Smith), 14:52-56.
Cost of injuries to man injured in knife switch explosion (Reynolds), 4:9.
Damage control, a new horizon in accident prevention (Bird), 12:68-70.
The economics of safety (some lists for evaluating the indirect costs of accidents) (Crosby), 12:4-6.
Engineering analysis of accidents (Lott), 21:51-56.
Increased on the job fire training (Bates), 21:6-11.
Programming safety in forestry work (Masterson), 2:27-31.
Stevedoring and safety before and after the opening of the St. Lawrence Seaway (Shuppert), 14:34-37.

COURTS

- Illinois justice courts, the new look (McClary), 24:55-58.
Mandatory personal appearances in traffic court (Racella), 24:40-41; (Frost), 24:41-44.
Proposed uniform traffic court rules in Ohio (Donaldson), 24:70-72.
Report on American Bar Association national symposium on correcting the violator, and the need for research (Powers), 24:44-45.
Teenage traffic court and school (Caskay), 24:72-74.

Cox, Harold

- Local safety councils (Panel), 23:30-31.

Craff, Charles A.

- Modern role of the safety specialist, 12:7-10.

CRASH INJURY RESEARCH

- The effectiveness and use of seat belts in the United States (Wolff), 24:25-36.
Lessons learned from aviation crash injury research (Rothe), 6:51-54.
Surgeons and safety, the joint action program (Vader), 6:13-14.

Crael, W. C.

- A state labor department sells safety, 25:30-32.

Crosby, Ralph J.

- The economics of safety, 12:4-6.

Crown, Charles M. (Rev.)

- Invocation at the annual meeting of members, 1:19.

CYTOGENIC FLUIDS

- Safe handling of cytogenic fluids (Neary), 6:16-21.

Cunningham, W. Roy

- Dust study program, Pennsylvania department of mines and mineral industries, 7:21-26.

Curtis, Shirley

- Should all motor vehicle accidents be investigated? (debate, affirmative), 24:56-58.

Cutter, Walter A.

- Airtrides essential to the safety movement, 6:50-51.

D

Dale, T. K.

- Safety aspects in the modernization of a coal mine, 7:3-4.

Damon, Glenn H.

- Low-cost blasting agents, 16:28-36.

Dawson, C. Fraser

- New developments in television and their implications for driver education. (A symposium), 23:105-107.

Dawson, C. Fraser

- Student projects in college safety education courses, 23:30-31.

Danforth, W. J.

- Safety councils and safety education supervisor (panel), 23:30.

Dauterich, R. D.

- Discussion of paper entitled "Management and safety" by Henry Z. Carter (14:24-25), 14:26.

Davis, Dwight M. and Morris, William C.

- Summary and evaluation of new methods of driver education as applied in large and small schools, 23:111-112.

DeGroot, Gaston R.

- Safety control—NS Savannah, 14:59-62.

Dempsey, O. M.

- Report of the railroad-highway traffic safety committee, 23:3-4.

Denomme, Raymond

- Safe building maintenance is cost improvement, 8:24-27.

DERMATITIS

- Clinical observations on the cutaneous effects associated with curing epoxy resins (Bremeskow), 12:15-17.

Dettis, Jones F., Jr.

- Some observations on occupational dermatoses (Roscell), 12:12-13.

DeJong, James F., Jr.

- Report of the ship safety achievement award committee, 14:90.

DISASTERS AND EMERGENCIES

- Appendix A, major disasters involving ammonium nitrate (Scott), 16:28, 43-44.

Dismore, J. W.

- Training drivers to meet emergencies (Moseley), 23:66-61.

Dismore, J. W.

- When industry has a serious emergency, what is the public's job? (Webb), 6:57-62.

Dismore, J. W.

- See also CASE HISTORIES: CIVIL DEFENSE: FIRST AID

DISCIPLINE

- The constructive use of discipline in safety violations (Riddle), 12:39-43.

Discipline in relation to a company's safety record and competitive costs (Volts), 4:16.

See also RULES

DISEASES

- Auto driving fitness and the physical equation (Mikew), 17:28-30.

Disease study program, Pennsylvania department of mines and mineral industries (Cunningham), 7:24-26.

Occupational health hazards, medical aspects (Abrams), 12:5-12.

See also DERMATITIS

Doherty, Terrence T.

- The effects of enforcement on the quantity and severity of traffic accidents, 24:24-26.

Donaldson, Paul R.

- Proposed uniform traffic court rules in Ohio, 24:70-72.

Donigan, Robert L.

- What direction chemical tests for intoxication? Legislation, 24:74-78.

Dott, Joseph E.

- A "P & I" underwriter's part in maritime safety, 14:52-56.

Douglass, John J.

- Forming practices with high explosives, 2:22-26.

Downs, Dorothy

- Presiding at session on civic leadership, 6:4-6.

Dretz, Eva M.

- Implications for elementary safety education, 23:108-109.

DRIVER EDUCATION—HIGH SCHOOLS

- The driver education teacher and teaching machines (Hartman), 23:52-54.

- An evaluation of some aspects of the driver training program in the Los Angeles City schools (Zahn), 23:109-111.

- Images of driver education in the '60's (Dow), 23:116-121.

- New developments in television and their implications for driver education (A symposium), a) Williamson, 23:101-107; b) Strick, 23:102-103; c) Damron, 23:103-107.

- Summary and evaluation of new methods of driver education as applied in large and small schools (Davis and Morris), 23:111-112.

- Training drivers to meet emergencies (Moseley), 23:66-61.

DRIVER LICENSING

- A hypothesis on licensing the school bus driver (Kole), 17:67-74; same, 23:133-139.

- Is driver license suspension fulfilling its role? Driver licensing viewpoint (Bohedi), 24:46-48; Citizen viewpoint (Huber), 24:48-49.

- Periodic physical examinations for drivers (Wilber), 6:127-131; same, 24:91-96.

DRIVERS AND DRIVING

- The aging driver (Klamm), 24:49-51; (Shipley), 24:51-55.

- Auto driving fitness and the physical equation (Mikew), 17:28-30.

- Better driving for the whole family (Sabota), 12:67-82.

- Case studies of one-car accidents involving young drivers (Bishop), 23:41-45.

- Driver performance, a true measure of motivation (Peroff), 17:37-42.

- The human dimension in safety (Buck), 17:61-62.

- Important factors in safety—centering traffic safety around drivers' motivations (Rusch), 11:12-21.

- Industry and off the job safety (Kerns), 6:112-115.

- Periodic physical examination for drivers (Wilber), 6:127-131; same, 24:91-96.

Report on American Bar Association national symposium on correcting the traffic violator, and the need for research (Powers), 24:44-45.

Slide rule to safety (Pine), 17:31.

Traffic safety and driving simulation (Hubert), 6:121-127; same, 24:134-91.

Training drivers to meet emergencies (Moseley), 23:66-61.

The wide angle view (driver improvement through proper visual habits) (Smith), 17:42-45.

DRIVERS AND DRIVING—COMMERCIAL

- Driver selection is important (Murray), 17:62-67; same, 23:137-132.

- Encompassing the contract school bus operators in the training program (Nelson), 17:90-92; same, 23:133-137.

- The Ohio Fuel Gas Company's driver improvement course includes material from the Smith system (Claus), 20:27-29.

- A predictor for safety (Jenkins), 17:34-37.

- Use of job attitude survey-form AR11 to discover accident repeaters.

- Slide rule to safety (test of six safe drivers selected from 2,000) (Pine), 17:30-33.

- What transit operators think about accidents (Franklin) (use of the interview technique), 17:52-57.

- See also TRAXXIST

Dunce, Donald

- Teen-age accidents, 6:51-54.

Dunlop, Norman

- The new power press safety code, an interpretation of section IV press construction and installation, 3:35-36; and of section VIII, inspection, 3:39-40.

DUSTS AND DUST CONTROL

- Dust study program, Pennsylvania department of mines and mineral industries (Cunningham), 7:21-26.

- Occupational health hazards (Abrams), 12:5-12.

E

Eadie, George R. and Budnik, Paul M.

- Control or extinguishment of gas fires, 7:11-18.

Eberhart, Kraus

- The consuming danger of assuming, 16:13-17.

EARLY MORNING SESSIONS

- Time management (Gove), 26:5-28.

EARS

- Ear protection and audiometric examination (Bower), 16:61-64.

ECONOMICS OF SAFETY, see COSTS OF ACCIDENTS; SOCIO-ECONOMIC AND CULTURAL ASPECTS

EDUCATION

- Safety—for what? (Brounell), (A comparison of education patterns as they relate to the ideas and ideals of the United States and Russia), 23:7-13.

ELECTRIC SHOCK

- Aerial basket ups and downs (Lorenz), 20:24-27.

Electrical hazards in the glass industry (Sersich), 1:13-15.
Electrical safety in ships (Estes), 14:53-71.
Ground faults in quarry electrical systems (Cassell), 4:5-7.
Low voltage shock hazards (McCreadie), 3:12-21.
Review of significant accident case histories, electrical accidents (Fitzgerald), 12:27-30.
Safety aspects of grounding portable tools (Matuszek), 4:3-4.
 See also articles listed in the other electrical headings.

ELECTRIC UTILITIES
Aerial basket ups and downs (Lorens), 20:21-27.
Electrical rubber gloves in the primary area (Sault), 20:15-20.
Fire fighting near live electrical apparatus (Fitzgerald), 20:13-17.
Ground-to-ground use of rubber gloves (Meyer), 20:20-22.
Working from lineman's platform (Hatfield), 20:23-24.
Your trip to "success" (Sammis), 20:30-31.

ELECTRICAL EQUIPMENT
Fire fighting near live electrical apparatus (Fitzgerald), 20:13-17.
Ground faults in quarry electrical systems (Cassell), 4:5-7.
Hazards caused by improper application of knife switches (Reynolds), 4:7-10.
Safe practices in strip mining (Quenon), 7:31.
Safety aspects of grounding portable tools (Matuszek), 4:3-4.
Safety in the use and maintenance of electrical storage batteries (Bogert), 9:10-11.

ELECTRICAL EQUIPMENT INDUSTRY
Safe practices in manufacturing process in the semiconductor industry (Baron), 9:16-17.
Safety in printed circuit manufacturing (Weaver), 9:8-9.
Safety in the manufacture and operation of electronic test equipment (Lightfoot), 9:4-6.

ELECTRICAL EQUIPMENT SECTION
Officers and committees 1961-62, 9:15-19.
Sessions, 9:4-17.

Find, from L.
School transportation (panel), 23:14-15.

ELEVATORS
Safety aspects on the use of mechanical raise climbers (Colvin), 16:22-23.

Moderated session "Public Liability from incident to final disposition", 10:17.

EMOTIONS, see PSYCHOLOGY

EMPLOYEE PUBLICATIONS

Important human factors in safety (Rusack), 11:14-21.

EMPLOYEES

Employee safety (school plant operation) (panel), 23:15-17.
Stimulating employees use of protective devices (Fukhrman), 20:13-34.
A "worker's creed" (Brodus), 18:2.
 See also **PUBLIC EMPLOYEES**.

EMPLOYMENT

Safety—for what? (Brownell), (Education patterns as they relate to American youth and the world of work) cites "An urban service corps," 23:12-13.

ENFORCEMENT

The effects of enforcement on the quantity and severity of traffic accidents (A symposium), (Kuester, Thomsen, Doherty, Eklund), 24:12-28.
Getting people to understand law enforcement (Kreml), 12:93-94.
The mobile boarding unit in law enforcement and boating safety (Hudson), 6:43-46.
What direction chemical tests for intoxication? Enforcement (Barrett), 24:78-80.
 See also **COURTS**.

ENGINEERING

Dynamic safety criteria, an engineering approach (McAdams), 12:18-22.
Engineering analysis of accidents (as seen by an insurance firm) (Lott), 21:51-56.
Engineering traffic safety in the smaller city: where do we go for help? (Langley), 24:61-62; solutions (Olibert), 24:63-68; public acceptance and implementing the solution (Johnson), 24:69-82.
Safety engineering: a modern concept (Abern), 12:15-19.

ENGINEERS

Design specifications for a safety engineer (Rockwell), 12:75-79.
Preparing the safety engineer and upgrading performance (Weaver), 12:79-80.
What do we expect of the safety engineers? (Harper), 12:73-75.

EPOXY RESINS

Clinical observations on the cutaneous effects associated with curing epoxy resins (Birmingham), 18:13-17.

Esler, O. T.

Electrical safety in ships, 14:53-71.

Exhibitors at National Safety Congress & Exposition, 1:32-43.

EXPLOSIVES

Forming practices with high explosives (Douglas), 2:23-28.
Low-cost blasting agents (Damon), 16:26-28.
Observations on underground blasting with ammonium nitrate-fuel oil explosives (Stoff), 18:27-48, (including appendices on major disasters and accidents).
Safe practices in strip mining (use of ammonium nitrate) (Quenon), 7:30-31.

Safety in storage, transportation and handling of guided missiles and rockets (Mycro), 2:14-16; same, 8:48-50.

EYE SAFETY

Eye safety in chemical processing (Guelich), 9:34-38.

F**FALLS OF MATERIALS**

The 1962 campaign to reduce injuries from falls of ground (Kohly), 18:26-27.

FALLS OF PERSONS

Do injury statistics have to be dull (Wilson), (Lake Superior district mines), 18:18-20.
Falls during bulk materials loading operations (Christie), 4:10-13.
Review of marine casualties (Hawley), 14:78.
What do we need to make falls an effective area of emphasis for agricultural safety? (Bogert), 6:72-74.

FARM SAFETY

National conference for farm safety, membership for 1961-62, 6:149.
Our stake in a healthy agriculture (Johnson), 6:52-56.
Reaping the harvest of your farm safety program (Burrows), (meeting ideas), 6:73-77.
Rural young people, safety program planning, 6:73.
Teen-age accidents (Duncan), 6:61-66.
What do we need to make falls an effective area of emphasis for agricultural safety? (Bogert), 6:72-74.
Why a summary of basic and applied research in the field of farm and home safety? (Knapp), 6:72.
Workmen's compensation in agriculture (Foss), 6:70-71.
Youth involvement in accident prevention programs—traffic safety, "signs of life," 6:81-82.

FATIGUE

Auto driving fitness and the physical equation (Muxen), 17:27, 29.

Faulkner, L. A.

The new power press safety code, discussion of section VII, designing, construction and setting of dies, 3:34-39.

Ferguson, Douglas M.
An old axiom, school bus accident summary, 1960, 17:82-84; same, 23:148-151.

FERTILIZER INDUSTRY

Eliminating the risk of overhangs in fertilizer bins (Baylev), 8:71-74.

FERTILIZER SE ION

Officers and committees, 5:81-82.

Sessions, 5:59-77.**Field, Paulsen J.**

Other practical approaches for working together in safety for the labor unions and management, 12:34-36.

Index**FILM BADGES**

A film badge station (Lavolette), 14:29.

FILMS AND SLIDES

Cites film, "Look and tag" (Volter), 4:14.
Gas company's driver improvement course begins with film "What's your driver eye-Q?" (Clout), 20:27.
Inland Waterways planning film on handling of flooding (Stechling), 14:53.
Preview of slide-script on underground haulage safety (Wooden), 18:12-17.
Safety, built-in on towboats and barges (McCormick), 14:13-19 (descriptions of slides shown at the meeting).
Some films used in safety education course (Gordally), 23:47-48.
Sound films at bargain basement prices (Thatcher), 2:29-31.
Training film on fire fighting on oil tankers completed by U. S. Coast Guard (Doty), 14:67.
Visual aids and their use in safety and maintenance train, construction industry (Symonds), 8:11-14.

Pine, Jerome L.

Slide rule to safety (in traffic safety), 17:20-22.

FIRE AND EXPLOSION

Building safety into oil tankers (Rogers), 14:31-32.
Control or extinguishment of gas fires (Budzik and Eadie), 7:11-18.
Electrical safety in ships (Estes), 14:70.
Experience in fighting mine fires with foam fire-fighting apparatus (Jamison), 7:32-33.
Explosion of a Baker-Perkins mixer in an Army Ordnance plant (Felix), 2:12-13; same, 6:46-47.
Fire fighting near live electrical apparatus (Fitzgerald), 20:13-17.
Flame resistant textiles (Miles), 23:27-30.
Forest fire fighting safety (Louden), 23:13-15.
Hazards caused by improper application of knife switches (Reynolds), 4:7-10.
Increased on the job fire training, a must in the pulp and paper industry (Baker), 23:8-11.
The Kins and Browne fire and static electricity demonstration, 12:83-86.

FIREARMS

Shooting safety in organized youth groups (Wymann), 6:19-21.
Shooting safety in outdoor education (Smith), 6:16-19.

FIREWORKS

The kaboom is now kept in Washington (McGee), 6:119.

FIRST AID

First aid at the accident, 8:27-34 (demonstrations by American Junior Red Cross).
Thirty years of mine rescue training in Ontario (McPhail), 18:6-11.
 See also **RESUSCITATION**.

Fitzgerald, G. W. N.
Fire fighting near live electrical apparatus, 20:13-17.

FLAMMABLE LIQUIDS

Developments in the use of fire resistant hydraulic fluids for underground coal mining equipment (Minnick), 7:13-14.
Health and fire hazards of flammable liquids used in plastic processing and fabrication plants (Tubich), 18:20-23.
Safe handling of cryogenic fluids (Neary), 8:19-21.
Without knowing it you may be killing yourself (Josselyn), 21:41-43.

FLEETS, see DRIVERS AND DRIVING—COMMERCIAL; TRANSPORTATION; TRAVEL**FOOD AND BEVERAGE SECTION**

Officers and committees, 1961-62, 10:18-19.

FOREIGN COUNTRIES

Appendix A, major disasters involving ammonium nitrate (Toth), 18:38, 43-44.
Control of extinguishment of gas fires (Buck and Eadie), 7:15-18.
Experience in fighting mine fires with foam fire-fighting apparatus (Jamison), 7:33.
Fire fighting near live electrical apparatus (Pittsford), 20:15-17.
Logging safety, skidding, loading and trucking (Korvev), 28:11-13 (Canada).
New horizons in supervisory training in accident prevention activities (MacBean), 28:17-19 (Canadian wood products firm).
Safety, built-in: the characteristics of the hydrocarbon tug (McAllister), 14:3-5.
Safety for what? (Brownell), 22:7-12. (A comparison of education patterns as they relate to the ideas and ideals of the United States and Russia).
Thirty years of mine rescue training in Ontario (McPhail), 18:8-11.
Voluntary agencies in Saskatchewan, Canada (Smith), 6:106-109.

FOREMEN AND SUPERVISORS

Competence, confidence, and cooperation, the safety director's challenge (Bonner), 2:5-7.
Gauging foreman effort (McCracken), 18:21-26.
Modern role of the safety specialist (Crafft), 12:7-10.
New dimensions in fleet safety (Robeson), 17:4-5.
Safety in the mach numbers or else (how the atomic age has upgraded the safety program) (Wilkins), 2:3-11.
A supervisor's safety creed (Wilson), 18:50.
Supervisory safety training programs for the mining industry (Barr), 18:31-34.
You can't train supervisors (Hoelscher), 28:4-6.

FORESTS

Forest fire fighting safety (Lowden), 23:13-17.
Programming safety in forestry work (Masterson), 8:21-31.

Forney, R. L.
Minutes of the annual council meeting, 1:13-21.

Foss, E. W.
Workmen's compensation in agriculture, 6:70-71.

FOUNDRIES

The foundry buffoon, an industrial menace (Weber), 18:5-7.

Franklin, Burns M.
What transit operators think about accidents, 17:33-37.

Frederik, Willem S.
Human engineering and material handling safety, 18:54-59.

FREEDOM

Safety—for what? (Brownell), (A comparison of education patterns as they relate to the ideas and ideals of the United States and Russia), 22:7-12.

Freeman, Walter (a summary of a talk).
Implications growing out of change, to safety, 23:107-108.

Friday, G. S.
Should all motor vehicle accidents be investigated? (debate, affirmative), 24:38-44.

Frost, Earle W.
Mandatory personal appearance in traffic court, 24:41-44.

FUELS, HIGH ENERGY

Occupational health hazards (Toth), 18:38.

Fuhrman, Warren S.
Stimulating employee use of protective devices, 20:32-34.

Gage, W. M.
Annual business meeting of the Marine Section, 14:77-78.

Galinas, Forrest
Safety councils and safety education supervisors (panel), 23:30-31.

Gallagher, Richard E.
Health departments and home safety, 6:119-121.

Gane, Roy A.
Report of Military Sea Transportation Service (MST), 14:79-79.

Gardner, H. V. and others
Round table discussion on glass industry, 11:23-25.

GAS INDUSTRY

Maintaining interest in safety (Mueller), 20:29-30.

The Ohio Fuel Gas Company's driver improvement course (Olser), 20:27-28.
Pardon me! Is your slip (attitude) showing? (Wise), 20:3-13.

Stimulating employee use of protective devices (Fuhrman), 20:32-34.

GASES

Fume production from AN-FO blasting agents (Toth), 18:38.

Occupational health hazards (Toth), 18:34.
See also METHANE.

Gatrell, J. H., see Gardner, H. V. and others.

Gilbert, Jerry P.
Engineering traffic safety in the smaller city; solutions, 24:55-56.

Gilbreth, Lillian M.
Safety and the physically handicapped homemaker, 6:144.

GIMMICKS, GADGETS

"I'm a bug" for safety program (Catonagh), 3:13-16.

Putting across your safety message, a touch of glamour (Burrows), 20:37-41.
Reaping the harvest of your farm safety program (Burrows), (use of advertising gimmicks at meetings) 6:73-77.

GLASS

Electrical hazards in the glass industry (Korvev), 11:23-25.

Roundtable discussion (Carter and others), 11:23-25.

Safety with glass (Ostrander), 11:21-22.

Sliding glass doors (Kearns), 6:118-119.

GLASS AND CERAMICS SECTION

Officers and committees, 11:23-26.

Sessions, 11:4-25.

GLOVES

Electrical rubber gloves in the primary area (Korvev), 20:18-20.

Ground-to-ground use of rubber gloves (Meyer), 20:20-22.

GOOGLES

Eye safety in chemical processing (Guelich), 8:31-38.

Stimulating employee use of protective devices (Fuhrman), 20:32-33.

Goodman, M. J.
Report of Maritime Administration safety activities, 14:79-80.

Gordon, Archer S.
The principles and practice of heart-lung resuscitation, 20:41-43.

Gordon, John P.
Safeguarding safety progress. (This was the annual banquet address), 1:28-31.

Gore, Bill
Time management (Early morning sessions), 23:5-28.

GRADE CROSSINGS

Report of the railroad-highway traffic safety committee (Dempsiey), 22:3-4.

Graham, Gordon—Memorial Lecture
Safety—for what? (Brownell), 22:7-12.

Gray, H. M.
A new challenge for safety, 21:4-6.

Griffin, Glenn F.
Influencing behavior for safety, 21:12-16.

Griffiths, Robert M.
Southern California supervisory safety training program, 14:41-45.

Guelich, Joseph
Eye safety in chemical processing, 8:34-38.

GYPSEUM INDUSTRY

Hazards caused by improper application of knife switches (Reynolds), 4:7-10.

H**HABITS**

Time management (Early morning sessions) (Gore), 23:4-6.

Haddon, William, Jr.
Chemical tests in driver research, 24:32-37.

Hair, O. C.
Using serious injuries, 8:73-77.

Halladay, Edward E.
The effects of enforcement on quantity and severity of traffic accidents, 24:38-39.

Hamilton, R. P.
Report of committee on home and off the job safety railroads submitted brochures to NSC, 22:4-7.

Why off the job safety? 22:3-6.

HANDLING MATERIAL

Falls during bulk materials loading operations (Christie), 4:10-13.

Human engineering and material handling safety (Frederik), 12:51-53.

Lethal weapons in materials handling (Smith), 14:37-40.

Mechanical accidents (Barrois), 12:25.

Hannaford, Earle S.
Motivation, the art of letting people have it your way, 17:17-23.

Hartman, H. D.
Water utility safety panelist, 20:44.

Harper, G. W.
What do we expect of the safety engineers? 12:73-75.

Harriman, Fred
A quote from a talk on fatalities to electric linemen (Hotfield), 20:23.

Harris, E. E.
Safe handling of low level radioisotopes, 12:59-62.

Harris, William C., and David, Dwight M.
Summary and evaluation of new methods of driver education as applied in large and small schools, 22:111-112.

Harrison, George M.
Safety is our challenge, 13:22-34.

Harrison, J. S.
Things money won't buy, 18:10-13.

Hartman, Charles H.
The driver education teacher and teaching machines, 22:15-21.

HATCHES

Escape hatches on river towboats new standard equipment (Kehres), 14:11.

Hotfield, H. E.
Working from linemen's platform, 20:23-24.

Hosley, John B.
Review of marine casualties, 14:72-77.

HEALTH AND MEDICAL ASPECTS

The accident syndrome (Schulzinger), 6:66-70.

The aging driver (Sapley), 24:51-53.

- Auto driving fitness and the physical equation (Mirken), 17:28-30.
 Ear protection and audiometric examination (Bowen), 16:61-64.
 The industrial nurse's role in the safety program (Knappe), 11:31-33.
 An M.D.'s use of electronic data processing in health and safety (Brooke), 8:4-7.
 The medical-industrial hygiene-safety team in industry (McGee), 10:10-13.
 Occupational health hazards, medical aspects (Abrams), what is being done for prevention, 12:5-12.
 The occupational nurse's role in the direction and referral of emotional problems (Kloiber), 8:25-27; same, 18:6-8.
 Psychological accidents, the industrial physician's viewpoint (Killex), 5:22-24; same, 18:3-5.
 The psychology of accidents (Maciver), 12:11-13.
 Surgeons and safety, the joint action program (Worfe), 6:13-15.
 When should the medical department blow the whistle? (Irwin), 17:57-59.
- HEALTH DEPARTMENTS**
 Health departments and home safety (Callagher), 6:119-123.
 The impact of home accidents:
 a) On the family (Baumgartner), 6:91-97.
 b) On community groups (Lowe), 8:97-103.
 c) On community planning (O'Harrow), 6:102-105.
 Voluntary agencies (Smith), 6:105-109.

Safety aspects of grounding portable tools. 4:3-4.

Mears, John A.
A model bicycle control program for college and university campuses. 23:98-101.

MEAT PACKING
Get all of the facts (Kirk). 10:7-10.

MEAT PACKING, TANNING AND LEATHER PRODUCTS SECTION
Officers and committees. 10:20.

Mechling, F. A.
Report of inland waterways committee. 14:85-86.

MEDICAL ASPECTS, see HEALTH AND MEDICAL ASPECTS

MEETINGS
Increasing the octane rating of your safety meeting (use of humor, magic, gimmicks) (Burrows). 17:53-57.
Operational safety meetings initiated by steering groups (Gardner). 14:44.
Putting across your safety message, a touch of glamour and magic (Burrows). 20:37-41.
Putting the right angle into school bus driver safety meetings (Check). 17:84-90; same, 23:151-155.

Mentzer, Frank
Camping and survival. 6:22-22.

METABOLISM
Human engineering and material handling safety (Frederick). 12:34-35.

METAL PRODUCTS INDUSTRY
Damage control, a new horizon in accident prevention (Bird). 12:66-70.
Fernando's hideaway (Podzius). 3:3-7.
Forming practices with high explosives (Douglas). 2:23-24.
The foundry buffoon, an industrial menace (Webster). 12:5-7.
Safe application of electric controls on machine tools (Peregoy). 12:43-44.

METALS
Non-destructive testing of metals (Falk). 18:3-4.
Occupational health hazards, environmental (Tolk). 13:3-4.

METALS SECTION
Officers and committees. 18:17-19.
Sessions. 18:13-16.

METHANE
Development in methane monitoring (Zelizer). 7:44-46.
Methods of using auxiliary fans for face ventilation with continuous mining systems (Lingo). 7:8-10.

Safety on the west Delaware tunnels (Aspenleiter). 16:30.

Meisger, Herbert J.
Review of significant accident case histories, electrical accidents. 12:27-30.

Meyer, L. C.
Ground-to-ground use of rubber gloves. 20:20-21.

Miles, E. W.
Data processing of accident records. 10:21-22.
Participant in data processing of accident records symposium. 10:23.

Miles, Thomas D.
Flame resistant textiles. 23:37-39.

Miller, Gordon H.
Engineering small boats for safety. 6:37-40.

Miller, H. Gene
Participant in data processing of accident records symposium. 10:23.

MINERAL INDUSTRIES
Low-cost blasting agents (Damon). 18:25-26.

MINING
The 1962 campaign to reduce injuries from falls of ground (Kohn). 16:26-27.
Noise abatement at mines and quarries (Zoteford). 18:30-31.
Observations on underground blasting with ammonium nitrate-fuel oil explosives (Scott). 14:37-46.
Supervisory safety training programs for the mining industry (Sare). 16:31-34.

MINING-COAL
Control of extinguishment of gob fires (Buckner and Bode). 7:11-18.
Developments in methane monitoring (Zelizer). 7:44-46.
Developments in the use of fire resistant hydraulic fluids for underground coal mining equipment (Mienick). 7:45-46.
Dust study program, Pennsylvania department of mines and mineral industries (Cunningham). 7:23-28.
Experience in fighting mine fires with foam fire-fighting apparatus (Johnson). 7:33-35.
Hazards encountered in mining thick, inclined coal beds (Green). 7:18-23.
Methods of using auxiliary fans for face ventilation with continuous mining systems (Lingo). 7:8-10.
Safe practices in strip mining (Quenon). 7:24-31.
Safety aspects in the modernization of a coal mine (Dole). 7:3-4.

MINING-METAL
Do injury statistics have to be dull? (Wilson). 16:47-50.
Low-cost blasting agents (Damon). 18:25-26.
Preview of slide-script on underground haulage safety (Wandel). 16:13-17.
Safety aspects on the use of mechanical raise climbers (Colvin). 16:22-23.
Stopping methods in the Lake Ambrosia uranium mines (Abbas). 16:23-24.

Safeguards for big crowds at amusement parks and fairs (Mullendore), 8:33-34.
Training drivers (and people in other categories) to meet emergencies (Moseley), 22:46-51.

PAPER INDUSTRY, see PULP AND PAPER

Parker, J. L.
Participant in data processing of accident records symposium, 19:32.

Parsons, John M.
The apex in school bus maintenance, 17:17-19; same, 28:162-163.
School transportation (panel), 23:11-15.

Patterson, Ronald
Mr. Patterson read an outline of the Detroit school disaster plan, 23:27.

Pergey, F. C.
Safe application of electric controls on machine tools, 12:43-44.

Perloff, Robert
Driver performance, a true measure of motivation, 17:37-42.

PERSONAL PROTECTIVE EQUIPMENT

Aerial basket ups and downs (Lorenz), 20:24-27.
Electrical rubber gloves in the primary area (Schultz), 20:18-20.
Ground-to-ground use of rubber gloves (Meyer), 20:20-22.
Life jackets and vests (McCormick), 14:14.
Stimulating employee use of protective devices (Furman), 20:32-34.
Working from linemen's platform (Hatfield), 20:22-24.
See also GOGGLES

Peter, Richard H.
Introduction to guided missile and rocket safety presentation, 2:13-15; same, 8:46-47.

PETROLEUM INDUSTRY

Building safety into oil tankers (Rogers), 14:43-52.
Data processing of accident records (Miles), 18:31-32.
Gauging foreman effort (McCracken), 19:24-26.
Safety built-in on our barges and towboats (McCall), 14:8-10.
This is a safe ship (Ellis), 14:54-58.
Using serious injuries to determine the effectiveness of safety programs (Haier), 6:75-77.

PETROLEUM SECTION

Officers and committees, 19:33-30.

Sessions, 19:3-28.

Phillips, Albert
Safety councils and safety education supervisors (Panel), 23:31.

Philo, Ken
Handling of prestressed concrete members, 8:18-20.

PHYSICAL EXAMINATIONS

Periodic physical examination for drivers (Wibbar), 6:127-134; same, 24:91-98.

Physical classification of individuals in the military service (Opash), 19:43-48.
When should the medical department blow the whistle? (Irwin), 17:57-58.

Pierson, Mrs. Henry S.
Civil leadership, representing the volunteer, 6:5-8.

PLASTICS

Clinical observations on the cutaneous effects associated with curing epoxy resins (Birmingham), 9:15-17.
Engineering control of plastic materials (Tubich), 18:17-22.
Occupational health hazards, environmental (Tolka), 13:4.

Podzius, Bruce
Fernando's hideaway, 3:3-7.

POISONS AND POISONING

Without knowing it you may be killing yourself (Jasser), 21:41-45.

See also CHEMICALS

POLICE

The effects of enforcement on the quantity and severity of traffic accidents, A symposium, 1:Kestinger, Thaxton, Doherty, Malinsay, 24:118-28.

Porter, R. L.
Sperling and unusual applications of pressure relief devices, 8:43-45.

POWER PRESS AND FORGING SECTION

Officers and committees, 19:61-62, 3:49.

Sessions, 3:23-46.

POWER PRESSES

How power press operators get hurt (Salter), 14:43-52.

The new power press safety code, interpretation and discussion of the nine sections, 2:23-44.

a) Purpose and scope, definitions, references to other codes (Kelly), 2:23-25.

b) Construction and installation (Dunlap), 2:25-38.

c) Safeguarding at the point of operation (Krohn), 2:38-39.

d) Auxiliary equipment (Stiles), 2:39-40.

e) Designing, constructing and setting of dies (Faulkner), 2:39-39.

f) Inspection (Dunlap), 2:39-40.

g) Operation (Kelly), 2:40.

h) Questions and answers, 2:40-44.

Press forging with safety (Allor), 2:45-46.

Powers, Thomas M.
Report on American Bar Association national symposium on correcting the violator, and the need for research, 24:14-15.

PRAYERS

Invocation at the annual banquet (Constance-Hildes), 1:26.

Invocation at the annual meeting (Crouse), 1:13.

A prayer on the courage to live a simple life (Ladner), 6:153.

A prayer to close the Safety Conference of Women's organizations, 6:7.

PRESSURES

Design and testing of a new high pressure cell (Broune and others), 5:3-15.

Fundamentals of pressure-relieving devices for unfired pressure vessels (Hodnick), 5:15-43.

Specific and unusual applications of pressure relief devices (Porter), 5:43-45.

PRINTING AND PUBLISHING SECTION

Officers and committees, 19:61-62, 21:59.

Sessions, 21:38-56.

PRINTING PLANTS

The craftsman's interest in safety (Imppe), 21:38-39.

Engineering analysis of accidents (as seen by an insurance firm) (Lott), 21:51-56.

Safety looks to management (Sperry), 21:39-41.

Safety motivation (Burkhart), 21:45-51.

Without knowing it you may be killing yourself (chemical hazards in the graphic arts) (Jasser), 21:41-45.

PROGRAMS, see ORGANIZATION

PSYCHOLOGY

The accident syndrome (Schulzinger), 8:56-70.

Driver performance, a true measure of motivation (Perloff), 17:37-42.

Motivation, the art of letting people have it your way (Hennsford), 17:17-25.

A new concept of accidents (Rog), 5:27-32; same, 18:8-14.

The occupational nurse's role in the direction and referral of emotional problems (Kloiber), 5:25-27; same, 18:6-8.

The personal factor in accident prevention (Klopper), 19:27-28.

Psychological accidents, the industrial physician's viewpoint (Ellis), 5:22-24; same, 18:3-5.

Psychological approach in job training (Neu-mann), 14:11-15.

The psychology of accidents (MacIver), 12:11-12.

Safety, built-in on river equipment (also attitudes and emotions of the crews) (McNeill), 14:8-10.

When men behave like buffoons (Brody), 18:7-9.

PUBLIC EMPLOYEE SECTION

Officers and committees, 19:61-62, 3:36-37.

Sessions, 3:21-31.

PUBLIC EMPLOYEES

How do we know public employee work is safe? (Braden), 2:21-22.

Let's talk about our common problems, 3:21.

Safe building maintenance is cost improvement (Gendarme), 8:23-27.

PUBLIC SAFETY

Camping and survival (Mentzer), 6:122-23.

Communications for safety, how can we make our safety messages more effective? (Haker), (Endorsement NSC's "Everywhere, all the time" program) 12:13.

Local cooperation for safe outdoor recreation (McGee), 6:10-12.

Public safety committee, NSC, 1961-62, 6:145-148.

Safeguards for big crowds at amusement parks and fairs (Mullendore), 8:33-34.

Surgeons and safety, the joint action program (Wade), 6:12-15.

When industry has a serious emergency, what is the public's job? (Webb), 6:27-32.

See also BOATS AND BOATING; SPORTS; WATER SAFETY

PUBLIC TRANSPORTATION, see TRANSIT

PUBLIC UTILITIES SECTION

Officers and committees, 20:45-46.

Sessions, 20:13-44.

PULP AND PAPER INDUSTRY

Increased on the job fire training, a must in the pulp and paper industry (Bater), 21:6-11.

A new challenge for safety (Gray), 21:4-6.

Radioactive isotope systems in the paper industry (Amberg), 21:16-22.

Safety is built into the Kamyr continuous digester (Lasker), 21:22-26.

Safety in pulpwood logging (Wright), 21:30-36; 28:118-22.

PULP AND PAPER SECTION

Joint session with Wood Products Section, 21:30-37; same, 28:18-23.

Officers and committees, 19:61-62, 21:57-58.

Sessions, 21:4-37.

Puncke, Martin M.
Should all motor vehicle accidents be investigated? (debate, negative), 24:58-60.

Pyle, Howard
Annual address of the President of National Safety Council, 1:23-53.

QUARRIES

Self conveyor hazards (Volts), 4:13-17.

Ground faults in quarry electrical systems (Cassell), 4:15-7.

Noise abatement at mines and quarries (Botsford), 18:55-61.

Quenker, J. E.
Why you should have an off-the-job safety program, 8:45-67.

Quinn, Eugene E.
Safe practices in strip mining, 7:28-31.

QUIZZES

Pardon me! Is your slip (attitude) showing? A listener's quiz (Wise), 20:12.

R

RADAR

Review of marine casualties (Hawley), 14:72-74.

Rader, Robert
Report of gulf area, 14:84-87.

RADIATION

Occupational health hazards (Abrams), 13:6.
Radioactive isotope systems in the paper industry (Amberg), 21:16-22.
Safe handling of low level radioisotopes (Harris), 12:53-62.
20-20 hindsight: a shipyard radiation safety program (Lavallette), 14:36-42; Discussion (Chappell), 14:32-34; (Holtzinger), 14:35-36.

RADIUM PLANTS

Quote from 1958 study on Illinois plants where "gross contamination and excessive levels of radiation typify nearly all radium processing installations" (Abrams), 13:8.

RADIO

The future of two-way radio in logging safety (Jones), 23:23-27; same, 23:23-25.

RAILROAD INDUSTRY

Relationship of operating rules to safety rules (Baugh), 22:10-13.
Report of committee on home and off the job safety (Hamilton), 22:4-7.
Report of the railroad-highway traffic safety committee (Dempsey), 22:3-4.
Safety is our challenge (Harrison), 13:34.
Why off the job safety? (Hamilton), 22:5-6.

RAILROAD SECTION

Officers and committees, 1961-62, 22:14-15.
Sessions, 22:3-13.

Ravella, James A.
Mandatory personal appearances in traffic court, 24:40-41.

RECREATION

Local cooperation for safe outdoor recreation (McGee), 6:10-12.

See also **SPORTS; WATER SAFETY**

REIDER, ROY

Safety in the Rover project, 6:53-56.

RELIGIOUS SAFETY ACTIVITIES

How churches and synagogues can help prevent accidents (Hollingsworth), 6:139-142; Brief panel discussion on same, 6:142.
National committee of religious leaders for safety, 1961-62, 6:152-153.

RESEARCH

Announcement of the 1961 award for traffic safety research, to J. Stanhard Baker; NSC annual council meeting (Forney), 1:20.
Chemical tests in driver research (Haddon), 24:162-67.
Control or extinguishment of gob fires (Budzak and Madala), 7:11-13.
Driver performance, a true measure of motivation (Forney), 17:37-42.
Dust study program, Pennsylvania department of mines and mineral industries (Cunningham), 7:24-26.
Experience in fighting mine fires with foam fire-fighting apparatus (Jamison), 7:32-43.
Flame resistant textiles (Miles), 23:27-30.
The impact of home accidents on community groups (Lowe), 6:37-103.

Important human factors in safety (Rusch), 11:14-21.

Low-cost blasting agents (Damon), 16:28-36.

Technique for research (Nofftinger), 23:113-115.

Training drivers to meet emergencies (Moseley), 22:64-81.

Why a summary of basic and applied research in the field of farm and home safety? (Knapp), 6:72.

RESPIRATORY EQUIPMENT

Stimulating employee use of protective devices (gas mask labor contract) (Furman), 20:33.

RESUSCITATION

The principles and practice of heart-lung resuscitation (Gordon), (Also same for mouth-to-mouth resuscitation), 20:41-45.
The rationale for mouth-to-mouth resuscitation (Monte), 6:131-137; same, 24:98-102.

Reynolds, C. J.
Hazards caused by improper application of basic switches, 4:7-16.

Rhodes, T. F.
School transportation (panel), 23:14-15.

Richards, Karl M.
What makes effective seat belt promotion? 24:33-40.

Riddle, Standish C.
The constructive use of discipline in safety violations, 12:39-43.

Robert, Robert P.
Report of the shipbuilding and ship repair committee, 14:93.

Roberts, Kenneth A.
Federal interest in highway safety, 24:3-12.

Roberts, Mark.
New dimensions in fleet safety, 17:1-5.

ROCKETS AND MISSILES

Integrating safety into a modern weapon system (Hickel), 2:8-9.

Introduction to guided missile and rocket safety presentation (Pfeifer), 2:12-13; same, 8:146-47.

Lyle gun replaced by rocket in ship construction (Doji), 14:67.

Safety in rocket propellant manufacture (Surock), 2:17-18; same, 8:181-82.

Safety in storage, transportation and handling of guided missiles and rockets (Myers), 2:11-16; same, 8:148-50.

Safety in the Rover project (Reider), 6:53-56.

Rockwell, T. M.
Design specifications for a safety engineer, 12:73-79.

Rogers, Royden H.
Building safety into oil tankers, 14:48-52.

Rogg, Sanford G.
A new concept of accidents, 6:27-33; same, 18:5-14.

Rokusek, H. James
Employee safety (panel), 23:16-17.

Romig, A. F.
A group dynamics approach to safety problems, 10:3-7.

ROOF CONTROL

Hazards encountered in mining thick, inclined coal beds, 7:18-22.

Roth, Victor E.
Lessons learned from aviation crash injury research, 4:31-54.

RUBBER SECTION

Officers and committees, 11:27-36.
Sessions, 11:36-23.

RULES

Achieving and maintaining respect for company rules (Van Name), 12:35-36.

Are there too many safety rules? (Nichols), 12:33-35.

The constructive use of discipline in safety violations (Riddle), 12:39-43.

Relationship of operating rules to safety rules (Baugh), 22:10-15.

Safety rule enforcement, a key to accident prevention (Wiley), 12:62-66.

RUTIME DISCS

Fundamentals of pressure-relieving devices for unfired pressure vessels (Hodnick), 5:23-42.

Specific and unusual applications of pressure relief devices (Porter), 5:43-45.

RUSCH, HUGH L.

Important human factors in safety, 11:14-21.

S

Sabota, William F.
Better driving for the whole family, 12:87-92.

SAFETY

Safety—for what? (Brownell), (A comparison of education patterns as they relate to the ideas and ideals of the United States and Russia), 23:5-13.

Some quotes from various sources pertaining to a safety philosophy, 23:34-35.

SAFETY BELTS, see BELTS; SEAT BELTS**SAFETY COUNCILS**

How the safety council manager and safety education supervisor can cooperate in their activities (a panel discussion), 23:1-23.

a) Bourne, G. Ernest, 23:23-30.
b) Cox, Harold, 23:30-31.
c) Little, Harold F., 23:31-32.

Representing civic organization viewpoint (Noelling), 6:3-7.

Safety organizations (McGee), 6:116-119.

Thumbs down on violators (Ayers), 20:34-37.

SAFETY DIRECTORS, see FOREMEN AND SUPERVISORS

SAFETY EDUCATION

College and university advanced courses in safety education (Silkew), 23:52-54.

How the safety council manager and safety education supervisor can cooperate in their activities (a panel discussion):

a) Bourne, G. Ernest, 23:23-30.
b) Cox, Harold, 23:30-31.
c) Little, Harold F., 23:31-32.

Implications for elementary safety education (Draiz), 23:105-109.

Is safety education academically respectable? (Silkew), 23:50-61.

The safety education program of the Philadelphia public schools (Krelovec), 23:34-41.

Safety—for what? (Brownell), (A comparison of education patterns as they relate to the ideas and ideals of the United States and Russia), 23:5-13.

State laws for safety education (Nihan), 23:23.

Student projects in college safety education courses (Dunron), 23:50-51.

A survey of general safety education courses (Corbally), 23:45-50.

Teacher competencies in safety (Allen), 23:121-124.

Validity, effectiveness of various safety education teaching techniques (a group study), 23:46.

SAFETY IDEA EXCHANGE

Fernando's hideaway (Podolous), (Unsafe practice observation plan tie-in with safety idea exchange), 3:2-7.

SAFETY LAMPS

Developments in methane monitoring (Zelker), 7:44-45.

SAFETY MOVEMENT, see ACCIDENT PREVENTION FUNDAMENTALS

SALLEE, S. D.

How power press operators get hurt, 3:22-32.

Sammie, J. Wren
Your trip to "success", 20:20-31.

SANITATION

Safe building maintenance is cost improvement (Dunroun), 6:23-27.

Schepelowsky, A. F.
What you don't know can hurt you, 23:17-19.

Schmidt, Edward
Is driver license suspension fulfilling its role: driver licensing viewpoint, 24:46-48.

Schneider, Rollin
The importance and value of accident reporting, 6:15-17.

SCHOOL AND COLLEGE CONFERENCE, NSC

School and college conference, sections, and committees, 1961-62, 22:162-169.

SCHOOL BUSES AND DRIVERS, see SCHOOL TRANSPORTATION

SCHOOL SAFETY PROGRAMS

Civil defense and disasters you hope will never come (Brantlinger), 23:19-24.

Employee safety (panel), 23:16-17.

From now until then (Scarp), 23:123-124.

Implications for elementary safety education (Drews), 23:108-109.
The little red car and where it went (Thayer), 23:42-43.
The safety education program of the Philadelphia public schools (Kruslovic), 23:34-41.
See also COLLEGES AND UNIVERSITIES

SCHOOL TRANSPORTATION

The apex to school bus maintenance (Parsons), 17:97-100; same, 23:162-163.
Around the school bus route (Voll), 17:73-82; same, 23:144-147.
Driver selection is important (Murray), 17:62-67; same, 23:127-132.
Encapsulating the contract school bus operators in the training program (Nelson), 17:90-92; same, 23:150-157.
A h-a-z-a-r-d problem, school bus selection (Lynch), 17:92-97; same, 23:157-162.
A hypothesis on licensing the school bus driver (Kale), Tables of injury and death statistics included, 17:67-74; same, 23:122-126.
New dimensions in school bus fleet safety (Lease), (Patrols; accidents), 17:77-78; same, 23:142-143.
An old axiom, school bus accident summary, 1960 (Ferguson), 17:133-34; same, 23:148-151.
Putting the right angle into driver safety meetings (Chick), 17:94-95; same, 23:153-156.
School transportation (panel), 23:14-15.
School transportation general sessions 17: 62-109

Schulz, Howard V.
What makes effective seat belt promotion? 24:17.

The accident syndrome, 6:64-70.

SEAT BELTS AND HARNESSSES

The effectiveness and use of seat belts in the United States (Wolf), 24:28-36.
What makes effective seat belt promotion? A symposium (Schulz, Monio, Richards), 24:37-49.

SELLING SAFETY

Putting across your safety message, a touch of glamour (Burrows), 20:37-41.
Time management (Early morning sessions) (Gore), 23:11-12.
Sentinels of safety, 6:94-99.

SEWER CONSTRUCTION

The sliding trench shield as a safety device (Otter), 6:14-18.

Shipley, O. D.
The aging driver, 24:51-55.

Shirack, Robert J.
Safety in rocket propellant manufacture, 2: 17-18; same, 5:81-82.

SHOES

Stimulating employee use of protective devices (Furman), 20:22.

Smith, E. A.
Electrical rubber gloves in the primary area, 20:18-20.

SIGNS AND SIGNALS

Standardization of optional internal ship emergency signals one of MSTs safety activities (Gow), 14:75-79.
Uniform markers for recreational waterways (Wilson), 6:46-48.
What you don't know can hurt you (Scheplovsky) (used for personal warning signals), 23:18.

SILICOSIS

Dust study program, Pennsylvania department of mines and mineral industries (Cunningham), 7:24-26.

Silverdale, Leslie R.
Is safety education academically respectable? 23:60-61.

Simmow, Fred C.
Losing safety, introduction, 23:10-12.

SIMULATORS

Traffic safety and driving simulation (Muller), 6:124-127; same, 24:88-91.

Singer, Grant L.
The pre-construction conference as a means of establishing safe working practices, 5: 8-11.

Slingerland, E. J.
A straight line on safe driver awards and incentives, 17:74-76; same, 23:139-141.

SMALL BUSINESS AND ASSOCIATIONS

Belt conveyor hazards (Voll), 4:13-17.
Engineering analysis of accidents (Lott), 23:51-54.
International City Manager's Association and public employee safety programs (Bernard), 6:21, 23.

Organizing for safe water skiing (Laurson), 6:33-36.

Safety, built-in: some policies of the Inland Waterways Safety and Health Association (McCurmick), 4:4-12.

Safety in cotton gins (Bruton), 25:26.
Small business and associations committee, NSC: officers and committees, 1951-62, 10: 21.

A state labor department sells safety (Creel), 23:39-42.

The why and how in initiating and developing an association accident prevention program (LeGore), 10:10-16.

Smith, Christian
Voluntary agencies in Saskatchewan, Canada, 6:106-109.

Smith, Earle
Causes of claims and their effect on claim cost in vessel operation, 14:53-56.

Smith, Fred R.
Lethal weapons in materials handling, 14: 37-40.

Smith, Harold L.
The wide angle view (driver improvement through proper visual habits), 17:43-49.

Smith, Julian W.
Shooting safety in outdoor education, 6:18-19.

Smith, Robert H.
Report of joint cargo and tanker safety discussion groups, 14:22.

SMITH SYSTEM

Smith system.
The Ohio Fuel Gas Company's driver improvement course (Clear), 20:27-28.
The wide angle view (driver improvement through proper visual habits) (Smith), 17: 43-49.

SOCIO-ECONOMIC AND CULTURAL ASPECTS

Driver performance, a true measure of motivation (Ferioff), 17:37-42.

How churches and synagogues can help prevent accidents (Hollingsworth), 6:138-142.

The impact of home accidents:
a) On the family (Baumgartner), 6:81-97.
b) On community groups (Loud), 6:97-102.
c) On community planning (O'Harrow), 6: 103-108.

Implications growing out of change to safety (Freeman, talk summary), 23:107-108.

Integrating accident prevention with production (Sullivan), 12:5-7.
Safety is our challenge (Harrison), 12:22-24.

SOLVENTS
Without knowing it you may be killing yourself (Jassett), 21:41-43.

Speers, J. R.
Off the job safety at World Bestos, 11:26-29.

Sperry, O. E.
Safety looks to management, 21:39-41.

NOTES

PLAN NOW - -

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

AEROSPACE SESSIONS

COMPETENCE, CONFIDENCE AND COOPERATION —THE SAFETY DIRECTOR'S CHALLENGE

By B. G. BONNER

Safety Engineer, General Dynamics Corporation, General Atomic Division
San Diego, Calif.

In this age of modern scientific technology, the problems of a safety engineer and the hazards to workers are as different from those encountered in the 1940's as the modern jet bomber is from the piston-driven bomber of World War II.

The nature of work being undertaken by modern industry is such that a good safety engineer cannot devote much of his time to routine matters of machinery guarding, wearing of personal protective clothing, and housekeeping problems.

General Atomic Division, General Dynamics Corporation, is an example of the type of industry which will become more prevalent in the '60's although there are few comparable industries in operation today. Its primary activities are research and development in the nuclear field. Here are some of its projects:

An advanced high-temperature gas-cooled graphite-moderated reactor for generation of electric power

Nuclear reactors for research, training, isotope production, and medical and industrial uses

Experimentation with atomic beams

Research in controlled thermonuclear reactions

A gas-cooled reactor and closed-cycle gas turbine plant for marine propulsion

Nuclear energy for space travel

Chemical and metallurgical research on metallic hydride characteristics

Thermoelectric research and other basic and applied research projects

Competence, confidence and cooperation are synonymous with an effective safety program. Competence and confidence must be developed by the safety engineer, and if properly developed, cooperation will take

care of itself. None of us is totally competent to cope with today's safety problems, for to do so would require each of us to be graduates or to have studied extensively in chemistry, physics, metallurgy, electronics, nuclear energy and associated fields. Most of us have prepared ourselves in one or perhaps two of these fields. It is our challenge to develop ourselves in those fields in which we are deficient.

The academic background of today's industrial workers is higher than ever. Approximately 1350 people are employed at General Atomic. More than 60 per cent are college graduates, including approximately 10 per cent who have Ph.D. degrees. A large number of those who do not have degrees have completed a part of their college education and continue to pursue their degrees in night school. Many of the senior scientists and engineers have been drawn from the professional staffs of leading universities in this country and abroad.

Once the safety engineer has proved reasonable competency, developing confidence is no real problem. Mutual confidence must exist between the safety engineer and other personnel whether he be a senior scientist, technician or maintenance man. It is easy to see that a chemist, physicist, or metallurgist will have much more knowledge of the hazards peculiar to his work than will the safety engineer. It is extremely advantageous for the safety engineer to avail himself of this knowledge, but in most cases, it is not available until the safety engineer has indicated reasonable competency and has gained the confidence of the scientist. It is, of course, necessary for the safety engineer to have confidence in the people with whom he is dealing. This normally comes only through experience. It doesn't take long to find out whether a person has

a sincere interest in safety or merely give it lip service.

Management at General Atomic has the philosophy that its members should pursue their scientific research with a maximum of freedom and a minimum of regimentation and rules. This is conducive to academic freedom which in turn stimulates creative research, but it does introduce some problems which brings us to the matter of co-operation. Our management requires safety department appraisal and approval of certain aspects of work such as pressure vessels, use of liquid hydrogen, high voltage and similar hazardous operations, but prefers not to exert regimentation in other areas of research. For this reason it is extremely unlikely that I would ask a senior research person to stop an operation because of the safety hazards, although this could be done if conditions were severe enough to warrant such action.

Through personal contact with supervisory personnel, a fairly successful program of selling safety has been developed. This has been done almost entirely through cooperation rather than through rigid rules and regulations. Bear in mind that good scientific personnel are not always easy to obtain, so every reasonable means is exerted to retain the good ones. Well educated people are not difficult to convince that there are other important aspects of a safety program besides the safety record and Workmen's Compensation insurance premiums. Having a minimum of safety rules requires a maximum of cooperation to obtain the desired results.

Perhaps you would be interested in hearing about some of the safety problems which have been encountered in certain types of work being undertaken at the Laboratory. Time will permit only a brief discussion of some of them.

One of our laboratories has been specially equipped to manufacture liquid hydrogen in small quantities which is used by some of our staff in research projects. Liquid hydrogen is used rather than liquid helium principally because it is less expensive. In one particular experiment, liquid hydrogen serves the purpose of slowing down the neutrons and reducing their temperature, in this instance, 20° Kelvin or -423° Fahrenheit.

The liquid hydrogen laboratory is approxi-

mately 14 by 20 feet and contains in addition to the usual laboratory apparatus, a cryostat for liquefying hydrogen. Within this laboratory is a storage room approximately 6 by 8 feet in which the hydrogen gas manifolds are installed and in which is located a storage dewar for the liquid hydrogen. Both areas are equipped with an alarm system set at 20 per cent LEL which is connected to our Gamewell system located in the main security guard station. Each room has a sensing element near the ceiling. A small diameter copper tube extends from each sensing element to the outside of the laboratory where a gas tester is kept in stand-by condition to determine, during an emergency, if hydrogen actually exists inside the laboratory without unnecessarily exposing personnel.

The ventilation system provides one air change every two minutes in the main laboratory and two and one-half changes per minute in the storage room. The storage room has smooth walls and high pitch plexiglas ceiling to prevent any accumulation of hydrogen, contains no electrical switches, fixtures or motors, has conductive flooring and is equipped with spark-proof tools. Operating personnel, which is limited to two well-trained people, wear protective clothing when entering the storage room during hydrogen liquefaction. Adequate warning signs and lights are displayed during liquefaction operations and special emergency procedures have been adopted. A safety check-off list is rigidly followed prior to start of liquefaction.

Moisture and oxygen entering a storage dewar could cause an ice formation which, when broken, could set off electrical sparks with disastrous results. We avoid the possibility of this by connecting a dual column oil bubbler to each storage dewar when it is outside the laboratory. Each storage dewar is equipped with a special adapter for venting and transfer. This adapter, when inserted into the neck of the dewar, provides a vent to carry off the vaporized gas and is designed so that the transfer tube may be inserted into the dewar through an opening at the top without removing the adapter. The adapter has a slight overpressure of helium or hydrogen gas when the transfer tube is being inserted which further minimizes the possibility of ice blockage in the neck of the dewar.

Dr. Earl Long, one of the nation's outstanding authorities on liquid hydrogen, is assistant director of the General Atomic Laboratory and has contributed invaluable assistance in helping resolve our liquid hydrogen safety problems. At the time the liquid hydrogen operation was being considered, Dr. Long was director of the institute for study of metal, low-temperature lab, University of Chicago and was a consultant for General Atomic.

One of our groups is conducting a classified study involving the use of controlled nuclear pulses for propulsion of space vehicles. This is a unique application of nuclear energy. Many safety hazards have been encountered for which safety precautions have been developed.

Another interesting study is research in controlled thermonuclear reactions called the Fusion Project, which is being co-sponsored by the Texas Atomic Energy Research Foundation, a group of 11 Texas utility companies, and General Atomic. As you know, fusion is concerned with the fusing or joining of atoms whereas fission is the splitting of atoms. In effect, the Fusion Project seeks to harness the power of the hydrogen bomb.

The basic equipment in this experiment is the torus, a doughnut-shaped device made of copper which employs a magnetic field around its circumference and a bank of condensers on the lower level of the building to supply power. These condensers are capable of generating for a microsecond, 75,000,000 kw, equal to about one half the total generating capacity of the United States. The torus contains heavy hydrogen, also known as deuterium gas, to which is applied approximately 90,000 v. of current for experiments.

Experimental work is focused on the basic problems of raising the temperature of the particles in ionized gas to temperatures ranging from one million to one billion degrees and keeping them suspended so they will not touch the walls of the material container. The ultimate goal of controlled fusion research is to develop a source of inexpensive power which uses a virtually inexhaustible source of fuel, heavy hydrogen

which exists in the sea in great quantities. It is estimated that the potential energy of one gallon sea water is equal to about 350 gallons of gasoline.

Many safety precautions have been taken for personnel protection. Interlocks have been installed on all doors, both outside and inside, to preclude unintentional firing, and a flashing light is in operation at the main entrance during firing. Personnel at the control panel are protected against possible flying objects from the torus by a laminated blast shield which is constructed of alternating layers of 1/4-inch steel and 1/2-inch plywood. Personnel wear ear muffs during high power experiments. All persons assigned to the project have been trained in basic first aid. A building coordinator keeps the keys for the control panel and all doors. Before any work can be done on the condensers, each one must be shorted manually using a shorting bar. At least two persons must be present at all times and they must be in sight of each other.

Many other safety problems, both industrial and radiological, are encountered around a facility such as General Atomic. Many specially designed pressure vessels are in use which have required particular attention. Some of these vessels operate in both the vertical or horizontal position so it is not practical to provide underground containment. We have constructed large above-ground, double-walled steel barriers which are used in conjunction with blasting mats to contain flying objects that may be propelled from the vessel. Nuclear materials, beryllia, highly toxic materials and pyrophoric metals are handled according to methods prescribed by the Atomic Energy Commission, federal, state, and local agencies.

So, it seems to me, that the challenges facing a safety engineer in this frontier of science are twofold—first, obtaining and obtaining the support of the individuals who are directing the research and development is absolutely basic and essential. The other challenge is to continually strive to learn some of the basics of highly refined scientific disciplines—and this isn't easy for a guy like me who only had college freshman physics.

INTEGRATING SAFETY INTO A MODERN WEAPON SYSTEM

By THEODORE R. MIKEL

Supervisor, Safety Engineering Group
Aerospace Div., Boeing Airplane Co., Seattle, Wash.

From man's early existence, he has been concerned with safety and has attempted to make himself safe, not only from a hostile environment and enemy attack, but also from the implements and devices that he has conceived to extend his capabilities. As man's implements have become more complex, so have their hazards. ICBM and IRBM Missiles are examples of modern nuclear-armed weapon systems that reach a new level both in complexity and in potential hazard to both operating personnel and the populace in general.

This complexity in modern weapons has forced the Armed Services to evolve the weapon system concept, and that concept in turn has placed the responsibility for system safety directly on a weapon system manager. Before describing some of the problems and factors of safety encountered during modern missile developments, we should consider an approach to weapon system safety.

For any military weapon system, it is the Armed Services that must have the ultimate responsibility for safety, but while the responsibility for safety as well as all other aspects of the weapon system must lie with the Services, that responsibility cannot be fulfilled without the enthusiastic and wholehearted support of the aircraft and missile industry.

It is to industry that the military must delegate the major responsibility for defining safety requirements, designing and developing a safe system, and establishing safe operating procedures. In accepting responsibility for weapon system management, industry also must accept the responsibility for providing a safe system.

In modern weapons it is not practical to save the consideration of safety until after the system has been built and put into operation, nor is it sufficient to leave safety to the individual designers. In manned systems, efforts directed to safety of the crew are well known. Fire warning sys-

tems, ejection seats, communication and emergency systems, all contribute to safety of man in a machine. In unmanned systems safety has taken on a much broader meaning and it has become increasingly apparent that system analysis is required to define clearly the safety problems prior to preliminary design, and a constant monitoring effort is required through detail design, production, and operational use.

It is very much the responsibility of the military service and industry to see that, for a given weapon system or project, a safety program is designed to encompass all safety aspects from system studies, preliminary design, integration of system, manufacturing, system test and demonstration through to operational use. All of these phases must include protection of both operations personnel and the general populace from equipment failure or human error.

It will always be a goal to achieve as near 100 per cent safety in a system as practical. This is a noble stand. However, no one will disagree that safety has its price, both in dollars and in degree of mission success. In the design of today's nuclear weapon system, capable of mass destruction, we cannot afford to leave the decision concerning the degree of safety to chance or that which is practical.

The decision as to the degree of acceptable risk must be made with the best possible knowledge of probable results. While the degree of acceptable exposure is a responsibility of the military, it is also the responsibility of industry to conduct system analysis to determine reasonable safety parameters. The problem does not end with the establishment of safety criteria, however.

The success in avoiding inadvertent launch or detonation of a nuclear device must be determined before a weapon goes into operational service. Therefore, industry must develop the ability to predict quantitatively,

with accuracy and confidence, the degree of safety that can be expected from a given system design. Industry has undertaken this task, and thus far experience has shown the safety measures have been adequate. New systems, however, require greatly improved safety controls.

A review of the Minuteman system will illustrate how a safety program was developed and is managed at Boeing.

Initially, general system requirements and specifications were developed by the Air Force. These were evaluated by space technology laboratories and transmitted to Boeing as general design criteria. Boeing formed a Minuteman Safety Committee to study the technical design criteria and to more fully define and detail safety requirements for the design engineers. This committee had representation from all company organizations concerned with the program. Included were representatives from medicine, fire, security, human factors, safety engineering, industrial hygiene, training, manufacturing operations, systems test, ordnance, and design engineering.

These groups spelled out specific safety requirements which were considered feasible from a design standpoint. A conscientious effort was made to avoid dictating design but to establish safety limits and parameters within which the designer would have freedom of selection. Within these safety limits, the designer produced optimum items consistent with the state of the art, performance, weight, configuration and environment. In those areas where recommended safety considerations could not be incorporated in the design, the Committee recommended alternate safety criteria

and procedures to achieve safety objectives established for the system.

Since several contractors are associated with this program, Boeing recognized the need for an integrated approach to the safety problem and presented a proposal for a system safety management program at the Air Force-Industry Missile Safety Conference in Los Angeles in September, 1959. The Air Force concurred in the proposal and negotiated a contract with Boeing to provide centralized administration and direction for an integrated weapon system safety program under the policy direction of ballistic systems divisions and space technology laboratories. Boeing then established a weapon system safety management office.

A Weapon System Safety Group was established for the purpose of providing the affected Air Force commands and contractors, participating in the Minuteman program, with a uniform method of defining, controlling, and managing the weapon system safety program.

In summary, we may conclude that system safety can be integrated into the design and development of a weapon system by:

1. centralized direction and management,
2. determining risk factors,
3. establishing design parameters,
4. providing technical skills,
5. documenting procedures, and
6. operator/hardware integration.

The Minuteman safety program to date has been very successful. We believe that this success adds validity to the system approach to safety.

SAFETY IN THE MACH NUMBERS OR ELSE

By RICHARD WILKINS

Administrator, Industrial Hygiene & Safety
North American Aviation, Inc., Los Angeles, Calif.

A tremendous explosion presents a graphic picture of the accident potential which we are now facing. Imagine that no injuries occurred to personnel during such a holocaust; this was no accident. Many months

of study, planning, and action paid off in the saving of death or serious injury to operating personnel. Bunkers and block houses afforded barrier-type protection. Breathing protection was provided by venti-

lating systems, as well as self-contained breathing equipment. Protective clothing was used to prevent chemical and thermal burns. Last, but certainly not least, procedures assured that personnel were not exposed during critical periods of the test run.

Our profession has jumped from a status where speed could be measured in miles per hour to a position where it must be measured in mach numbers. Many seemingly insurmountable problems were faced at the start. An example of this was the selling of eye protective equipment to management. We were constantly faced with objections to the use of safety glasses or goggles by supervision and workers alike. By the same token we suffered many serious eye injuries because of a lack of this type of equipment.

The requirements for putting over a program of this nature were tenacity and salesmanship. I believe all of you will agree that eye protection is not one of our greater problems of today.

Another example of one of our trying problems was the selling of supervision on safety. Our reception by supervision ran the gamut, from halfhearted acceptance of safety responsibilities, all the way up to a threat of physical removal of the safety representative from the area. Here again, it was necessary to employ a lot of stamina, grit, and follow-through to overcome this problem. The technical requirements were not great, and here again I feel that we, as a group, have done a tremendous job in obtaining the cooperation and help of our supervision.

I can recall when the formation and functioning of a safety committee was almost impossible to attain. In one instance, the chairman of a supervisory safety committee had extreme difficulties in attending these meetings. It so happened that this general superintendent was provided with a company car, and some special trip in this car was almost always necessary when the meeting was scheduled. This had a very bad effect on other members of this committee, and soon a condition existed wherein no one attended the meetings.

Two signs were made up with the wording "Supervisory Safety Committee Today at 2:00 P.M." One of these signs was placed on the Chairman's office desk, and the other was hung on the controls of his company

car. When it came time for the meeting, our chairman was seated at the head of the table grinning sheepishly and saying, "I get the message." From this time on, this committee became very effective, with good attendance and participation by all members.

I believe all of us can appreciate by now, through review of these examples, that it would not require a brilliant person to make great headway when we could gauge our progress in miles per hour.

We have suddenly had to face sweeping challenges in our profession. Two major fields have appeared which are forcing us to change from a sub-sonic approach to our safety problems to a super-sonic necessity.

The hydrostatic testing of pressure vessels used to be our salvation when we were battling to obtain safe operations, as well as a limited budget. Should failure occur in the vessel being hydrostatically tested at 100 psi, no more hazard was presented than a stream of water, should the vessel fail. Now that we are testing in the area of 10,000 psi and above, we no longer have a safe, simple technique for pressure testing.

Let us look briefly at the change in magnitude of our responsibilities. We can all remember the problem presented with sand blasting operations in our beginning. The silica sand generally used presented a definite, known, hazard. We were blessed, however, with instrumentation which could be used to monitor the hazard and assure us that we were working within safe limits. In addition, we could engage in fistfuffs with our purchasing department and sell a substitute material which fell into the nuisance category at a higher price than the silica sand.

Compare this to some of the exotic materials which we are now using. In many cases, the allowable limits are so low that it is almost impossible to obtain instrumentation capable of adequate measurements. In addition, nine times out of ten, there is no reference literature to guide us. The material itself must be used with no possibility of a non-toxic substitute.

Another example of changing exposures in which we must deal is radiography. Many years ago our radiographic equipment was used in a well protected booth. Our industrial work which had to be subjected to this type of inspection could be easily trans-

ported to the booth, which was equipped with interlocks, shielding, and other protective measures.

Now we are faced with the problem of using either X-ray equipment or radioactive sources on the floor, without the luxury of being able to transport the product to an enclosed area. We are also faced with the dilemma of not being able to require an entire production force to leave the area while these operations are taking place.

We can easily see that if we failed in our job during the first stages of our safety development, we probably would have affected one person. Now, however, we must have performance in the mach numbers, or there is every likelihood that our failure will result in a catastrophe. We must qualify ourselves to measure up in our current responsibilities.

If we fail to provide intelligent practical services, we may rest assured that other groups will of necessity take over and offer safety services. During the early years of aircraft development, an engineering department's concept of safety was a factor which had to be built into the aircraft because of specifications. This safety factor was in no sense comparable to the safety factor which we had been accustomed to. As a matter of fact, it was a tremendous bugaboo to the engineering profession, because it represented additional weight.

Now, through the use of exotic fuels and materials, elevated temperatures, extreme pressures, etc., the engineering people have had to become cognizant of safety requirements through necessity. As a matter of fact, specialized groups, such as human factors and research teams, have been specifically developed, in order to cope with the current safety and industrial hygiene problems.

Quality control groups, who seemed to have one assignment in the early years, that of slowing down production, are presently engaged in extensive non-destructive testing operations. As an example of this type of testing, we have the radiographic work. There is a constant desire on the part of this profession to handle its own monitoring and safety requirements, in order to expedite the job.

Our production departments, who once felt safety was a necessary evil, recognize the fact that it is next to impossible to clear complete buildings, in order to conduct safety or structural integrity tests. They also know that, due to the size of many of our products, it is not possible to pick them up and transport them to a protected area for these tests. They, therefore, are extremely interested in controlling safety precautions, in order to eliminate production slowdowns as much as possible.

Let's face it, safety is now recognized as a necessity, in the present state of the art. We must either accept this challenge and keep up with the times, or another group will do it for us.

For years and years we have all been exposed to harangues and a desire to upgrade our profession. Many attempts to bring about this upgrading, through acceptance of additional job responsibilities and improvement in the personnel who have entered the field, have been tried. We do not have to try to upgrade the safety profession any more. The upgrading has been thrust upon us and the question now is whether we can live up to this upgrading or not.

I seriously question management's current interest in hidden costs, or any of the other old hackneyed approaches that we used during the early 40's. Even rising compensation costs have difficulty in competing for interest with situations which could result in a catastrophe, should something go wrong.

We know that we must still cover our routine safety responsibilities, involving such things as strained backs, hernias, and falls. We must add to these responsibilities and change our thinking from a miles per hour concept to a mach number concept, or face either a catastrophe through inability to provide proper safety coverage, or the assumption of safety responsibilities by other groups. If either of these two situations come to pass, we will undoubtedly stagnate with the routine safety job as we have known it for many years.

Our opportunity has arrived. Let us attain the same fine results that we have in the past.

INTRODUCTION TO GUIDED MISSILE AND ROCKET SAFETY PRESENTATION

By COLONEL RICHARD H. PETER
Commanding Officer, U. S. Army Ordnance Field Safety Office

We would like to make Army Ordnance safety facilities available to personnel of the Chemical and Aerospace Sections of the National Safety Council as well as to the Armed Services. This is in consonance with the desire of the chief of ordnance to carry out the safety policy of the President of the United States which is to have all federal agencies cooperate with management, labor, state and local governments and safety organizations in developing and applying modern safety standards.

You can't very well make use of our facilities and activities unless you know what they are, so I am going to devote a few minutes to telling you about them, with the help of slides.

1 & 2. Our office is located at Charlestown, Indiana, which is near Louisville, Kentucky.

3. One of our principal activities is the operation of the U. S. Army Ordnance Safety School.

4. This slide shows the courses which are available to your personnel during the balance of the 1961-62 school year.

We have courses in guided missile, rocket and nuclear weapons safety scheduled for November and February which you may be interested in attending.

Copies of a brochure which contains complete information on our safety courses is available. The brochure contains descriptions of these courses and how to apply for attendance at them. Your personnel may attend the missile courses or any of the others on a space available basis. We are already close to capacity for all courses, so I would like to suggest that your people get their applications in soon. Their applications will be processed on a first come, first served basis.

Applications should be forwarded through the ordnance district in which your company is located.

5. This is a photo of our air-conditioned

classroom, which is completely equipped with the latest training aids.

6. This is a photo taken during the industrial safety course which we conducted during the past two weeks. Courses are taught by safety engineers who are assigned to our inspection and investigation divisions. These engineers conduct safety inspections and investigate accidents at 92 ordnance activities and 120 privately-owned plants.

7. This photo shows the chief of our inspection division and three of his safety engineers planning inspection schedules for 1962. By inspecting Ordnance Corps installations and privately-owned plants, we try to prevent accidents through the elimination of unsafe equipment, facilities and practices.

I would like to show you four of the latest color slides which are typical of the training aids used in our school.

8. This photograph shows what was left of the inside of a mixer room after an explosion at an Army Ordnance plant last July. Damages were estimated at \$700,000 but only 11 minor injuries resulted. If this had not been a remote control operation, all personnel in the mixer room would have been killed. Preliminary investigation indicated that the probable cause of the explosion was friction between metal parts and propellant in the packing gland areas of a Baker-Perkins mixer. Adjacent buildings, separated by the required quantity distances, received extensive blast damage.

9. The walls surrounding the mixing bay were constructed of 12-inch reinforced concrete—three feet apart. The space between the walls was filled with earth.

This photograph shows the damage to the walls surrounding the mixer. Notice the complete severance of the concrete walls in the center of the photo.

10. This photograph shows torn and twisted structural members and complete cracking the concrete wall.

11. This outback building was located approximately 210 feet from the explosion. Transite siding and Corloz panels on this building were destroyed. Two persons working in the building at the time of the explosion received minor injuries.

12. The U. S. Army Ordnance safety equipment exhibit, which was established recently, is a valuable source of training aids for the school. Leading manufacturers of safety equipment who are genuinely interested in promoting safety have furnished over 300 items for this exhibit.

13. Students at Ordnance Safety School courses are given a complete conducted tour of the exhibit and selected items are used for instructional purposes in the classroom. A conducted tour of the exhibit is a safety education in itself. You do not have to attend the safety school in order to visit the exhibit. We will be happy to have you drop in to see this exhibit whenever you are in the Louisville area. It is the largest permanent display of safety equipment in the world and it has been completely air-conditioned for the comfort of our students and visitors. Safety personnel and operating personnel should be thoroughly familiar with the latest safety equipment in order to prevent accidents and fatalities.

14. For example, this is a photograph of a routine Jupiter missile operation which resulted in a fatality. The crane operator was lowering the spreader bar which was attached to the crane hook. The spreader bar caught on one of the small nose cone projections and slipped off the hook. A workman standing below was struck on the head by the spreader bar and killed. He wasn't wearing a hard hat and he had no business standing under the crane.

15. However, a safety latch like this on the crane hook would have saved his life. It costs only \$2.75.

16. We have several different types of safety latches and hooks in our exhibit. Three of them are shown on this slide. None of these cost more than a few dollars. The use of any one of them would have saved a man's life.

Safety items such as these safety latches and hooks are demonstrated to students in our courses and shown to exhibit visitors.

We also have the latest resuscitation equipment, fire fighting equipment, deluge sys-

tems, machine guards, non-sparking tools, warning devices, safety hats, safety shoes and protective clothing.

17. This slide shows one of our safety engineers demonstrating the latest protective clothing for missile fuel handlers. He is wearing a rubber suit and a rubber mask with a plastic window. The rubber gloves have a slip joint fit which seals them to the suit.

18. This slide shows seven hands belonging to seven men employed at one Ordnance installation. These hands were involved in accidents which could have been prevented by the use of guards like these.

19. Students attending our courses are shown how to use these guards and—what is more important—how to get others to use them.

20. Army Ordnance publishes three monthly safety periodicals. The Safety Information Letter specializes in short articles and the latest safety news.

The Safety Digest contains longer technical articles on all types of safety, including the manufacture, transportation and storage of chemicals and high energy solid propellants.

Statistical information on accidents, fires, explosions, injuries and fatalities is published in the Statistical Summary. This information is analyzed in an effort to spot accident trends which may be developing at our installations. Corrective action can then be taken before too many accidents occur.

21. These publications are distributed monthly to Ordnance installations and companies having Ordnance contracts.

22. With the world situation as it is, we must do everything in our power to prevent accidents, injuries, fatalities and property losses. We can't afford to lose trained personnel or essential production facilities as a result of accidents.

The objective of our presentation is to pass on to you as much practical safety information as possible on the manufacture, storage, transportation and handling of guided missiles and rockets.

We are fortunate to have personnel on our staff who have a combined total of 300 years of ammunition, missile, rocket and explosives safety experience.

SAFETY IN STORAGE, TRANSPORTATION AND HANDLING OF GUIDED MISSILES AND ROCKETS

By RAY L. MYERS
Deputy Chief, Inspection Division
U. S. Army Ordnance Field Safety Office
Charlestown, Ind.

The safety of a plant must be a constant consideration of those in charge of it from the conception of the original idea around which it is designed, and throughout the entire period of its construction and operation. Safety must begin on the drawing board, as otherwise its necessary consideration later becomes a matter of increasing difficulty and cost, and the latter all too often becomes prohibitive.

Safety in the storage, transportation and handling of guided missiles involves several important factors; i.e., (a) the determination of the hazards inherent in the operations, equipment, buildings and areas; (b) the development and adoption of a proper protective procedure to eliminate these hazards, if possible; (c) to reduce their effect in the event of an accident, if they cannot be eliminated; and, (d) the establishment and continued application of methods of inspection to insure the maintenance of these protective measures.

The safety engineering approach to the general problems of guided missile and rocket safety has been a large factor in the remarkable record of the U. S. Army Ordnance Corps establishments that store, transport and handle guided missiles and rockets.

As an example, during World War I, 240 persons were killed for every billion pounds of propellant and explosives processed; whereas in World War II, this figure was reduced to five persons.

These statistics interpreted simply mean that the lives of more than 10,000 persons engaged in these operations during World War II were saved by safety measures that were put into effect.

Without these safety precautions, a billion dollars' worth of plant facilities might have been lost and, what is more important, our combat troops would not have received the

kind and amount of ammunition that they needed when they needed it!

The storage, shipment and handling of packaged missiles, rockets or their components, at present, poses no serious problem. However, the advent of ever-larger missiles and heavy rockets will create correspondingly greater challenges in storing, packaging, transporting and handling.

The type of storage facility provided guided missiles and heavy rockets or their components, is controlled by the hazard, or potential hazard, of the component itself. Explosive components, such as war heads, rocket motors, igniters, etc., require igloo storage. Liquid propellants, including both fuels and oxidizers, may be stored, properly segregated, in liquid propellant storage areas, in properly designed and constructed buildings.

The storage of present and future missiles containing solid propellant rocket motors however, takes us into an additional problem area—that of explosive safety. The presence of these explosives—loaded rocket motors—demands that the safety of personnel handling, storing and shipping this material, the protection of government property and the safety and protection of the lives and property of surrounding communities will have been carefully pre-planned and is rigidly enforced.

How is this done?

First, safe distances must be provided between locations containing explosive materials. This includes operating buildings, storage magazines, loading docks and any other explosive facility. Inhabited building distance must be maintained between explosives locations and inhabited buildings. Intraline distance is the minimum distance permitted between any two buildings within an operating line. Magazine distance is the mini-

mum distance permitted between any two storage magazines.

Guided missiles and rockets are classified according to the expected damage if they explode or ignite. The maximum amount of explosives permitted in any location is specified in the quantity-distance tables, Section 17, ORD M 7-224. It is mandatory that local limits be established in amounts no greater than those consistent with safe, efficient operations.

Keep in mind that the cardinal principle to be observed in any location or operation involving guided missiles and rockets is to limit the exposure of a minimum number of people, for a minimum time to a minimum amount of hazardous material consistent with safe and efficient operations. All operations should be scrutinized to devise ways and means of reducing the number of people exposed, the time of exposure or the quantity of material subject to a single accident.

Guided missiles, rockets and their components are stored in accordance with applicable Ordnance Corps storage drawings. War heads, motors, igniters and other explosive components require igloo storage. An igloo magazine means an arch-type, earth-covered magazine which may be constructed of concrete, metal or wood. A "standard igloo magazine" means an earth-covered, reinforced concrete, arch-type magazine, with or without a separate floor barrier, constructed according to approved standard service drawings.

Liquid propellants (fuels and oxidizers) must be stored in an area separate from all other activities. The facilities must comply with the requirements and standards for various propellants. All buildings, tools and equipment must be compatible with the various chemicals. The propellants will probably either be stored in approved shipping containers or bulk storage tanks meeting all the safety requirements. Among some of the liquid propellants used today are hydrazine, hydrogen peroxide, unsymmetrical dimethylhydrazine, nitrogen tetroxide, liquid oxygen and nitric acid.

At present, the shipment of large guided missiles and rockets, regardless of their hazard classification, is offering no particular problem. Future missiles may reach 15 to 20 feet in diameter and 75 to 100 feet in

length and weigh as much as 100 tons or more. Such dimensions offer not only new problems in packaging and handling but also in shipment irrespective of the mode of transportation. The size and weight of these future components will necessitate further revision of the loading and blocking concepts.

The advent of these ever-larger explosive-loaded items will probably cause revision of the ICC Regulations to permit their movement by common carrier. The ICC Regulations are published in the 1949 edition of the Code of Federal Regulations, Title 49, parts 71-90, Transportation. Those regulations are also published in various freight tariffs.

Our present public highways have a maximum height clearance of 13 feet, six inches; yet, as has been pointed out, components of the new large missiles may be as large as 15 to 20 feet in diameter. Not only are our highways as presently constructed inadequate for the transportation of items of this size but the railroads will also have difficulty in handling any item whose loading height, plus the car height, exceed 15 feet, one inch. Such items usually require special handling and special routing.

Present guided missiles, heavy rockets and their associated components are loaded, blocked and braced in accordance with Department of the Army Ordnance Corps drawings. Truck and rail loading drawings have been developed after many tests to insure the best possible protection during shipment of the guided missiles and rockets. All of the Ordnance Corps drawings are approved by the Bureau of Explosives, Association of American Railroads, and are binding upon all shippers of guided missiles and rockets by, for and to the Ordnance Corps.

Shipments of guided missiles, rockets and liquid propellants must comply with the following regulations:

1. Interstate Commerce Commission Tariff Books;
2. Army Regulation 55-355;
3. U. S. Coast Guard Regulations and Instructions;
4. State and Municipal Laws and;
5. Ordnance Safety Manual, ORD M 7-224.

The handling of guided missiles, rockets and liquid propellants involves much more than the mere off-loading and out-loading of these items as packaged. In many cases, special handling equipment must be designed and fabricated for these operations. The handling of any item depends on the hazards involved. The handling of the unpackaged guided missile body, rocket motors and other associated components and/or hazardous material present special problems. In this connection, the size and weight of the component of the new missile, which the future may bring us may exceed the safety limits of the material handling equipment now being used.

It is of utmost importance that the nature and characteristics of the various items be fully understood by all who are required to handle them. Established rules have been developed as needed to fit actual cases. In general, all operating personnel must be taught the nature of the hazards involved in the handling of the guided missiles, rockets and liquid propellants.

The three basic hazards to be dealt with in operations involving these items are:

1. Fire;

2. Explosions; and,

3. Toxicity poisoning or chemical burns. Any or a combination of these hazards may be present in a given situation.

Fire protection and prevention are a must at all times. Areas used for storage of combustible materials, fuel and oxidizers must be kept separated. Fire fighting equipment and extinguishing agents must be available to the type of fire which may occur with a particular fire and oxidizer. Where flammable vapors are present, electrical equipment must be of the approved explosion-proof type, and equipment and containers must be grounded. Non-sparking tools, shoes, and non-static generating apparel should be provided where required.

The principles guiding the elimination and control of fire hazards are generally applicable to explosion hazards as well. Shock-sensitive materials must be handled carefully and protected from vibration, friction and impact.

The protection of personnel from poisoning and chemical burns involves:

1. Engineering prevention to minimize spills and leaks and insure adequate ventilation;

2. Use of appropriate personal protective clothing and equipment and;

3. Conducting of periodical health surveys;

4. Periodic physical examinations;

5. Constant education of supervisors and employees regarding safe procedures and practices.

In summation, the storage, transportation and handling of guided missiles and rockets involves, in general, highly hazardous materials. Consequently, in order to do the job safely the hazardous properties of each item must be fully known, recognized and understood. Specific and detailed safety standards to be followed in all operations involving these materials have been established. These safety standards are outlined in various publications in a manner adapted to the needs of the safety engineer, plant superintendent and operations supervisor.

Supervisors must devise and enforce a system of inspection to ascertain that all operations are being conducted in accordance with the prescribed safety requirements. Unless successful control for the hazards involved in the operations is maintained, sooner or later a fire, explosion, poisoning or chemical burn will occur at the plant. Therefore, during the storage, transportation and handling of guided missiles and rockets close adherence to all safety requirements is a must, and demand constant alertness to every new indication of a need for a change in the safety standards through actual experience.

SAFETY IN ROCKET PROPELLANT MANUFACTURE

By ROBERT J. SHIROCK

Deputy Chief, Evaluation & Investigation Division
U. S. Army Ordnance Field Safety Office
Charlestown, Ind.

The cardinal principle of hazardous operations; i.e., "In any location or operation involving explosives, ammunition, severe fire hazards or toxic materials, exposure must be limited to the minimum number of people for a minimum time to a minimum amount of hazardous material consistent with safe and efficient operations," must be the basic premise for all propellant manufacturing operations.

The introduction of rockets and guided missiles into the nation's weapons system for defense of our country has raised a question—what changes have resulted in the safety requirements for manufacture, handling, storage, and use. The assumption that the term rocket propellant connotes the unusual; therefore, the hazards must also be unusual is wrong in most cases. Most often, careful and objective study of the material discloses the hazardous properties. Thus, there have been few major changes to the basic safety requirements. Specific changes due to chemical and/or components have resulted. Each of these require individual research in order to formulate the necessary safety requirements.

Rocket propellants are, in general, highly reactive materials designed to deliver large amounts of energy in short periods of time. Fuels and oxidizers, and their reaction products possess hazardous properties which must be fully understood by all who handle them in any manner.

Missile propellants are grouped according to the physical state in which they exist. At present, only two types are in general use—liquid and solid.

The hazards of liquid propellants are fire, explosion and toxicity. In the case of fire and explosion, the principles guiding the elimination and control of each are generally the same. As to toxicity, prevention of poisoning and chemical burns of tissues of the body require (1) proper engineering design of operations, (2) personal protective equipment, periodic health surveillance procedures and (3) trained supervision.

The hazardous properties of liquid fuels, oxidizers and starting mixtures can be easily determined.

The manufacture of solid propellant motors for guided missiles and rockets has introduced many potential hazards. The safety requirements for the manufacture of single, double, triple bases and cast and composite propellant have been developed over many years. Now, however, the ingredients of each are being combined. This has created new safety requirements.

Safety in manufacturing operations must start during the research and development stages of a particular item.

Many of the explosions which have occurred in the manufacture of rocket propellants are a direct result of the lack of complete and adequate research and development.

Solid propellants are basically high-energy mixtures of a fuel and oxidizer which, after certain process steps, are a solid mass possessing properties consistent with the manner in which they will be used. Because of their composition, combustion progresses in the absence of air or other externally supplied oxidizers. The fuel and oxidizer are either chemically bound or in solution as in single and double base propellants, or are chemically separate entities consisting of a generally elastomeric fuel and crystalline inorganic salts. Other ingredients are normally added to impart and control desired physical and ballistic characteristics to the propellant.

The particular chemical and physical differences of the propellants being developed and manufactured require a wide variety of process methods. These methods can be catalogued into major functional processes; i.e., raw material preparation, mixing, casting, curing and motor finishing.

The physical conditions such as increased size, sensitivity of ingredients and ability to detonate are important.

This has meant redesign of present equipment and development of new, unique types of equipment.

No single factor exerts more effect upon a solid propellant operation than the safety procedures under which the work is performed. The objectives of safety are well understood, but the impact of safety measures themselves tends to be underestimated by persons unfamiliar with explosives and industrial operations.

The Ordnance safety manuals are the regulatory explosives safety publications used at Ordnance Corps plants and private plants operating under Ordnance Corps contracts. The rapidly changing nature of solid propellant formulations results in areas for which the safety requirements have not been developed.

The safety manuals in the explosives and chemical field have been written in "blood." This was after the fact safety. Now we must, of necessity, build safety into our propellant operations before the fact.

The custom of designing and installing equipment and facilities and then examining it for hazards is obsolete. Consideration of safety after development becomes a matter of increasing difficulty and cost. The cost factor all too often becomes prohibitive.

The mechanization and automation of processing and loading techniques have gone

forward. Many things have been accomplished in the field, but the most important insofar as safety is concerned is the reduction in the amount of explosive materials which might be subjected to a single accident.

Advances in the art have been so rapid in the propellant and explosives field that there are many instances of equipment and processes becoming obsolete before they are actually put into production.

The explosions which have occurred during mixing, curing, finishing and testing of solid propellant motors have been the result of make-shift equipment and lack of complete knowledge. Technical advances have increased the efficiency of our propellants; however, this increase can result in disastrous results because of improper procedures.

Safety involves the determination of the hazards inherent in the processes, equipment, buildings and areas—the development and adoption of proper protective procedures, either to eliminate these hazards or, if they cannot be eliminated to reduce their effect in the event of accidents and to minimize the frequency of such accidents, and last—the establishment and continued application of methods of inspection to insure the maintenance of these protective measures.

SAFETY BEFORE THE FLIGHT

By WILLIAM F. MAHONEY

Manager, Development Jet Engine Test, General Electric Co., Lynn, Mass.

100 people die in plane disaster!

This is the type of headline that we are trying to avoid. But if we are to be successful in the quest for air safety, we must spend several years developing and perfecting our jet engines.

When you read in the newspapers that a new aircraft has been unveiled, it means that years of effort have paid off, that trial and error, success and failure, have been climaxed by completion of a project.

From the very inception of an engine program reliability and safety are very important factors. Before the engine is allowed to fly it must pass a pre-flight rating which is generally of 50 hours dura-

tion. The next official milestone is the completion of a 150 hour model test which, if completed successfully, allows engine shipment. However, in the time span between these tests the engine model is run for several thousands of hours. All of these test hours are accumulated for the purpose of insuring the best performance and engine reliability.

The most valid test, certainly the toughest, is long-term endurance. Most engines run about 200 hours each time they are installed in a test cell. The major portion of this being 150 hours of endurance testing to military specifications.

In a view of one of our propeller en-

gines just prior to the start of such a test, you note that the engine is mounted in the same manner as it will be on the aircraft. Also, this same model engine will be run for 1000 hours. We use a typical aircraft propeller so that the engine will be subjected to the same vibrations it will receive on an aircraft. The orifice or band, behind the plane of the prop is used solely for the purpose of preventing recirculation of air in the test cell, as this would raise the prop stress level. Such a problem is not encountered in flight.

A second view shows another 1000 hour engine on test. Actually the view shows the test man running the engine. The face of the clock in the foreground is painted to coincide with the test schedule to help prevent human error in the running of the test. This test calls for running 2000 half-hour cycles that typify a helicopter flight such as might be flown by Chicago Airways, which employ gas turbine helicopters. The engine is shut down for five minutes between each cycle, thereby allowing it to cool down before restart, which, of course, subjects it to the worst possible conditions.

Although endurance testing is the most meaningful and time consuming part of any program, there are many aspects to the testing business which insure flight safety.

For example, many of the components that make up an engine are tested separately and are given very extensive tests, especially to make sure that there is a more than adequate safety factor in the design. A good example of such a test is that given engine rotating parts such as turbine wheels and compressors. A high speed pit is used to run rotating parts at well over their design speeds to prove their integrity. A small engine compressor is lowered into a pit where it will be run at 3000 rpm above the maximum top engine speed.

A step further toward proving turbine integrity is a power turbine destruction test. In this case, an engine shaft was intentionally blown up by an explosive charge, so that the turbine could be purposely overspeeded to determine at what speed engine parts would fail, and to make sure that the engine turbine casings would contain

the failed parts. This action was recorded by high speed cameras and other very accurate measuring devices. The people running the test were protected by sand bags and wooden beams.

A very important factor in component testing is that concerning the combustion system. There is a combustion facility which has the capability of testing combustion tests at both sea level and altitude conditions. This enables us to develop a liner and find out if there are problems at altitude before the engine is flown.

On a main fuel control stand facility, the fuel control, one of the most complex parts of the engine, is developed. This particular engine part not only schedules fuel to the engine but varies the geometry of the engine compressor, thus controlling the flow of air through it. Because the main fuel control is the heart of the engine, it must be subjected to more extensive testing than other parts.

In our new power control facility we must prove that the control is capable of going through rigid requirements set by the Government. A panel houses the controls of the test equipment. The stand has other features such as automatic cycling provisions, and a fuel system capable of delivering fuel from -65 to 150°F.

The chamber that the control is tested in, running at a speed of up to 3000 rpm, will maintain an ambient temperature anywhere from -65 to 275°F. It has a special safety feature of a blow-off roof to protect the operator.

This specific control test consists of some 900 hours of running which includes: 500 hours of cyclic testing, accelerated aging to dry out "O" rings, room temperature running for 250 hours, 150 hours of contaminated fuel running, introduction of a salt solution into the control, a hot soak of the control at 200°F; also the control must be soaked at -65°F for 72 hours and then run for 20 hours at the same temperature, including 10 starts and shutdowns.

Many other jet engine accessories are also put through various acceptance tests; for example, an ignition system is checked out. Items such as cables, spark plugs, generators and alternators are tested. They are checked out at both sea level and altitude conditions, and the ambient tempera-

ture in the chamber of this stand can be controlled from -100°F to 200°F .

Oil pumps are also tested. I could go on and on, as there is a test facility for each engine accessory. All components are tested for thousands of hours so that all of the faults can be detected and corrected. Just another step in insuring flight safety. Of course, in proving the value of a product, the final answer lies in testing the entire engine.

As I pointed out earlier, most cell testing is of an endurance nature whereby various engine models are put on test stands and run until they break. In fact, in the early days of a program we run units to break them so that we can find out where the faults are. However, we must go a step beyond this and run engines under extreme conditions; every conceivable problem that can take place in flight must be paralleled in a test cell. For example, an engine must be run for 50 hours on contaminated fuel.

A tank truck is located beside the engine test cell. The contaminate, consisting of such items as acid, iron oxide and lint, is put into the fuel, which is thoroughly mixed by a circulating system so that the contaminate will not settle; and the engine continually receives the bad fuel. You will note that the truck is parked a safe distance from the cell and the system is properly grounded.

By conducting such a test we not only accumulate data about the engine's performance, but also what adverse effects these contaminants might have on engine parts.

Another sea level test we conduct is to spray salt water into the inlet of a jet engine compressor to see what amount of deterioration is caused by salt spray. A simple type of spray rig is used to inject ocean water into the engine. In conjunction with this test, we are experimenting with various methods of cleaning compressors after they become contaminated. Also, different types of coated blades are being used in an effort to minimize the buildup of deposits on blades.

One of our latest test sites is an outdoor facility which houses an ice ball gun. The proper name for this test is hailstone ingestion. The gun is used to propel an

ice ball at a running engine. The gun consists of a 20 foot length of 2-inch diameter brass pipe. The pipe is attached to a frame which can be adjusted by two jacks to give elevation and traverse. The propulsion force is compressed air, which is stored in a coded pressure vessel and released by a quick-operating air valve. Air travels from the receiver, through the fast acting valve and into the breach of the gun behind the shell and projectile.

In our particular test, the projectile is an iceball or hailstone which varies in diameter from $\frac{1}{4}$ to 2 in. The gun is lined up on a track in the cell, located directly in front of the engine. Prior to such a test target practice is actually taken so that a predetermined area is hit and also that the proper velocity is attained. (By regulating air pressure in the air receiver, it is possible to achieve a wide variety of velocities.) To record the test results, high speed motion pictures are taken of the firing shot. (A 16 mm camera is used operating at 8,000 frames per sec.)

The gun's muzzle has two photo-electric high speed traps located directly under it which give an electrical impulse that is used to determine velocity measurement. Also, an engine might be seen in the stand with visible damage from an ice ball. From this test facility we hope to gain important data concerning compressor ingestion. This, of course, will have to include bird ingestion, if we are to cope with the problem of wild life flying into jet engines.

Still another test just recently completed is illustrated in the T64 engine, equipped with inlet duct and cowl, G3E60 propeller and spinner, and the aircraft oil system, which is located in the exact position it will be in the aircraft in relationship to the engine. The purpose of this test was two-fold: (1) to get engine running time in the test cell with the actual components that will be flown in the aircraft, and (2) to run investigative tests on the oil system before the flight. Incidentally, one such system did fly up in Canada.

To further improve jet engine credibility before the flight, many other approaches are made. Climatic tests are run in such places as Mt. Washington and the Navy's aircraft engine laboratory in Phila-

delphia. This allows us to investigate further problems which could occur at altitude or during adverse weather conditions. For example, testing an engine in an altitude chamber to check starting characteristics is very important to an engine program.

In fact, such a program has borne out the need for using ethylene oxide for making altitude starts. One of our engines in a missile is launched from a B52 at high altitude and needs help to start. E.O. will ignite easily and act as a pilot light to start the engine. An example of such a need is the fact that our U-2 plane, shot down over Russia, had to lose altitude after engine flame-out in order to re-start its engine. Low atmospheric pressure and temperature make high altitude re-light difficult.

While on the subject of ethylene oxide, I would like to point out the fact that it not only assists jet engines but also, of course, it creates a handling problem for us in the test business.

We use a cage to house a 50-gal. drum of E.O. The cage is sand bagged and of course is equipped with a water spray and an emergency CO_2 system. Double check-valves are used to prevent reverse flow; also we use nitrogen to pump the E.O. Safety steps are also taken at our remote storage site, namely, a continuous water spray in warm weather and a 40 psi nitrogen pump on the tank.

One of the most important phases of testing is the subject of vibration; therefore, I would like to discuss some of the aspects concerning this problem. Many vibration investigations are undertaken by the engine maker for the purpose of establishing the mechanical integrity of the engine such that the users can be assured that they have maximum quality, safety and comfort in the end product.

First, engine components are studied separately, such as compressor blading and turbine buckets. Normal mode frequency characteristics are calculated and experimentally determined to ascertain their reliability. These studies are undertaken on model blades, and design changes can be made compatible with the aerodynamic and mechanical configurations required.

Having established a final design on the blades and buckets and the material to be used, the endurance characteristics are then

established. This is done experimentally by simulating the mounting conditions of the specimen and exciting it to vibrate in various normal mode frequencies by an external driving force. The amplitude of the specimen is increased until failure. In this manner, the endurance of each blade or bucket configuration is established for the principal normal mode frequencies.

To determine the areas of maximum stress for these normal modes of vibration, strain gages are applied to the blade and/or buckets. The specimens are then vibrated in their normal mode frequencies and stress distribution curves are obtained.

Having eliminated or minimized the possibility of mechanical excitation of the specimens from known engine generated excitation, studies are made of the blades and buckets during actual engine operation to determine if they will be exposed to any excessive aerodynamic excitation. Strain gages are applied in the optimum location to give maximum information. Strain data from the rotating members is transmitted through a slip ring and displayed on suitable electronic equipment.

I might mention that to measure these and other engine parameters, requires that we maintain approximately one million dollars worth of instrumentation. It is only through instrumented tests that you can determine if theoretical calculations are sound.

The entire operating range of the engine is explored, and the vibration stress behavior of the blades and buckets is investigated. Once a satisfactory configuration has been established, the above investigations are undertaken in altitude test facilities for final approval.

Next, the natural frequency characteristics of each compressor and turbine wheel are calculated and experimentally measured, to determine if any critical frequencies fall in the operating range of the proposed engine.

Having satisfied this requirement, the individual wheels are high speeded separately to check out their mechanical integrity.

Accessories such as fuel controls, ignition boxes, actuating systems, etc., must perform their function in the vibration environment of the engine. To insure that these components will perform satisfac-

torily, they are subjected to vibratory surveys. Each component is mounted on a shaker table and a frequency survey is made over the operating range of the engine. The component is then vibrated at twice the amplitude anticipated in service, over the entire speed range in each of three mutually perpendicular axes.

Having eliminated or minimized resonant frequencies in the various engine components that could cause troublesome vibration problems, we then become concerned with the vibration behavior of the system as a whole. The engine is mounted in the test dolly in the cell and a series of vibration shake tests are undertaken. As a result of these tests, an optimum vibration pickup location is selected, and a maximum allowable vibration limit is established.

After a period of time in which we are able to obtain the vibration history of a particular engine design, the vibration limits are reviewed and adjusted, if necessary, to be compatible with safe operation of the engine, to further illustrate the importance of the subject of vibration.

Endurance tests are conducted on propeller engines to find out just how much propeller imbalance an engine will withstand. This type of running is called an abusive test. It is accomplished by placing known amounts of tape on various positions on each prop blade thus inducing specific amounts of imbalance. Concurrently, engine vibration is measured resulting in the establishment of limits for varying amounts of prop imbalance.

Another form of testing is that area covering inlet distortion. It is extremely important to determine how an engine will react when the inlet is obstructed. It is not only necessary to find out aerodynamic characteristics but also how the blades in the compressor will react to this different type of loading.

A screen is mounted to the bellmouth at the forward end of the engine (compressor entrance). To properly conduct a distortion survey, small segments of various screen meshes are attached to the bellmouth screen. Several static and total pressure probes are located aft of this screen so as to establish a pressure profile at the compressor inlet. Also, during such a test, strain gages are attached to the

compressor blades to determine what effect distortion has on the blades mechanically, and also establish a stress limit, or what the maximum allowable stresses will be.

There is still another very basic and important step that is taken to insure maximum safety. This comes under the heading of quality control requirements for material. The raw material supplier must give results of tests on all properties. Tests such as ultrasonic, radiographic, magnetic particle and fluorescent penetrant inspections are just a few of the many tests that have to be performed to demonstrate material quality.

Furthermore, the processes involved in these tests have to be approved. Heat treating and welding techniques are clearly spelled out in a specification; in fact, all work performed on engine material must be done so, in accordance with very strict rules.

Finally, the vendor of the material must issue a statement of conformity certifying that all specifications have been met. If any parts do not meet requirements such as dimensional discrepancies they must be submitted to a material review board for disposition. It is only through this medium that a part that is only slightly inferior could possibly be accepted.

In line with checking materials, we in test run endurance tests on various metals, rotating them at high speeds and temperatures. This is accomplished by running these materials, shaped in the form of a disc, in a vacuum vessel. This vessel includes a steel rupture guard and a refractory lining. Heating is accomplished by radiation from calrod elements with a total input of 6650 watts, resulting in a maximum temperature of 1200°F. Also this facility is equipped with a drive turbine capable of 60,000 rpm.

Safety is even emphasized in still another manner and that is the orientation of personnel who are to work on these engines. If qualified, well trained people are not employed in the maintenance of engines then air safety is in jeopardy. To prevent such a problem, several classes are conducted. Also, literature pertaining to the engine and its operation is published.

While on the subject of orientation, we make it a practice to brief test personnel

on the subject of safety; consequently, we have experienced a good safety record in the factory.

Of course one of the final steps that has to be taken before commercial flying is the flight test phase. For this purpose several flight test centers throughout the country are used, two of the most popular being G.E. Flight Test Center in Schenectady, N. Y., and Edwards Air Force Base in California. In fact, at both of the locales, G.E. has its own aircraft. A helicopter is used quite extensively in New York to further improve the in-flight reliability of the Navy's T58 turbo shaft engine; and in California a T38 Air Force trainer is putting the turbo jet engine through its paces.

Flight testing is very necessary, as fac-

tory testing cannot simulate gyroscopic moments nor help predict the effects that altitude has on the lube system. Therefore, many thousands of flight test hours are logged annually.

The subject of flight safety is very important to us in the jet engine manufacturing business. It is indeed a tremendous challenge, one that must be successfully met if we are to stay in business. I have tried to give you a brief description of some of the steps that we take to help insure engine reliability, and in turn make aircraft safe to fly in. I am sure that you will agree that flight safety will become one of the most important aspects of this general subject of safety. And that it is of greater importance for us to guarantee safety before the flight.

FORMING PRACTICES WITH HIGH EXPLOSIVES

By JOHN J. DOUGLASS

Technical Representative, E. I. du Pont de Nemours & Co., Inc., Gibbstown, N. J.

The object of this paper is to discuss current practices in the use of high explosives for shaping a variety of metal parts. The comments are derived from the Du Pont Company's four years experience in this field, and illustrations are presented which show some of the actual forming jobs that we have done. A variety of commercial explosive devices are available to those desiring to do explosive forming, and some typical pieces that can be formed from each of these explosives are illustrated.

Although the state of the art is infancy, relying quite heavily on trial and error methods, a start is made towards (1) an engineering approach to the charge requirements for producing a given piece, and (2) the die design requirements to withstand the required explosive forces.

It should be emphasized at the very beginning that we have not found any radical departure in the metallurgical or mechanical properties of explosively formed metal pieces that would not be expected from mechanically formed pieces. For ex-

ample, we found that the rated static elongation properties of a metal are still the confining limits as to how much a piece may be formed before requiring annealing.

It should be emphasized that in our opinion explosive forming should be used only after a complete investigation of currently available facilities show that conventional forming techniques cannot be used to fabricate the desired shape. In general, explosive forming cannot compete economically with conventional forming techniques on a high production basis.

There are, however, definite advantages to the explosive forming process that give it a role in industry today and give the design engineer a new degree of freedom. Among the disadvantages are:

(1) Reduced die cost, since only a single female die is used rather than a complete punch and die set (this is not to imply that in all cases low-cost die materials can be used).

(2) Large capital investment for presses can be eliminated.

(3) Springback of metal being formed is minimized although not completely eliminated.

(4) Some shapes that are difficult or impossible to form mechanically can be formed explosively.

(5) An assembly can frequently be formed in one piece to replace a number of small pieces welded together.

(6) Improved surface finish can be obtained, since a punch (which may scratch the piece) is not used.

(7) Intermediate anneals required in mechanical forming can often be reduced by increased utilization of the available metal elongation properties.

(8) Explosive pressure can be distributed uniformly over the entire area of a surface, thus eliminating localized stress concentrations that may be encountered when using mechanical systems.

All comments in this paper are directed to the use of high explosives rather than low explosives, such as black powder and smokeless powder. We have used high explosives exclusively in our forming development work because the die arrangement is simple. High explosives can do their work independent of confinement because of their high rate of pressure development, whereas a gas tight arrangement is needed when using low explosives. Hence, the size of the piece that can be formed with low explosives is somewhat limited—while with high explosives forming there seems to be none.

The typical high explosives forming system consists of an explosive charge, a die, and a metal preform. First, there is the explosive itself which is immersed in a medium, usually water, to transmit the pressure generated by the explosive to the work piece. The explosive charge can be in many forms and many sizes. They may range from a small blasting cap to several pounds of high explosives in the form of a tube, rod, or ball.

The shape of the explosive used can largely determine its effect on the piece to be produced. For example, a point or spherical charge can be used, or a linear charge, or perhaps a disc of EL-506 sheet explosive, depending on the shape of the piece to be formed.

The effect of standoff, or the distance between the explosive charge and the piece to be formed, is of great importance. Actually, we have found it a more critical factor than the weight of the explosive charge itself. The pressure acting on a metal surface is approximately inversely proportional to the standoff distance between the surface, and the explosive charge while pressure-generated varies with the weight of the explosive charge to the one-third power.

An interesting phenomenon was noted during one of our basic studies on the cupping of various metals; it developed that when using a disc charge of sheet explosive (EL-506), the closer the standoff, the better the cupping results. Actually, with a greater standoff distance, fractures occur.

Yet by bringing the disc charge closer, hemispherical cups were obtained. It is hypothesized that the closer the explosive disc is to the plate to be formed, the flatter is the shock front, thus eliminating the possible high pressure peak in the center.

Another variable in the explosive forming system is the transfer medium itself. In general, water is used since it is the most readily available and cheapest of the liquids. Air can be used, but it is much less efficient than water, and the noise of a shot made in air can be objectionable. When a water medium is used in explosive forming, the noise is reduced to a great degree. Very slight improvement was obtained when such liquids as glycerin, kerosene, etc. were used.

Some typical case histories drawn from our experience are detailed below to illustrate the wide range of explosive charges that are available and their typical applications.

Blasting Caps as Forming Charges

The smallest charge used is an initiator or the blasting cap. There are a great variety of commercial blasting caps available with varying charge loads ranging from one to twenty grains of high explosive. Generally, for explosive forming use, electric blasting caps are preferred over fuse type—primarily for safety reasons. With electric blasting caps the operator has control over the exact instant of charge initiation.

In Figure 1, we see a diagrammatical sketch of a typical setup using a blasting cap in explosively forming a cylindrical piece. In this case, the cap containing approximately 20 grains of high explosive was immersed in the center of a 3" diameter tube of .010" thick wall of AM-350 stainless steel. The simple die arrangement was used (as shown); sealing was accomplished by setting the die on a rubber pad with a grease seal on the bottom.

FIGURE 1
BELLWOWS CONFIGURATION
3" O.D. X .010 WALL AM-350

Forming a small flat object can be accomplished by using a blasting cap as in Figure 2. Here an expendable container, such as a cardboard cylinder, is mounted above the flat object to be formed. Alternatively, the entire die and charge system can be immersed in a shooting tank or pond. Again, approximately 20 grains of ex-

FIGURE 2
FUEL FILTER DISC
.006" THICK 302 STAINLESS

plosives two inches away from the piece produced the configuration. The piece, made from .003-inch thick 302 stainless steel, is used as a fuel filter for a jet engine. The detail and sharpness of the explosively formed piece were greater than that obtained when conventional pressing techniques were used.

Mild Detonating Fuse (MDF)

The next step up the ladder of explosive force is obtained with Du Pont mild detonating fuse (MDF). This is a high explosive core encased in metal tubing, and can be obtained in strengths ranging from 1 to 20 grains per foot. A typical system where this type explosive charge can be used to advantage is formation of a corrugated cylinder six inches in diameter from .010-inch thick A-286 stainless steel. The mild detonating fuse was suspended along the axis of the piece, and initiated by an electric blasting cap. The die conformity obtained was excellent and tolerances obtained for this piece were $\pm .002$ -inch on diameter.

"Primacord"

Again, stepping up our explosive ladder we come to the use of "Primacord" (manufactured by the Ensign-Bickford Company, Simsbury, Conn.), which is a string or cord-like explosive available in various explosive loadings from 30 to 400 grains per foot. Typical applications for such an explosive charge are in the forming of medium-sized cylindrical pieces. One example is the sizing of a missile motor case. In this operation, a welded missile tank, slightly undersize, was placed within a die. Normal welding techniques could not meet the tolerances required by the missile manufacturer so it was desired to expand the tank and produce good dimensional tolerances both diametrically and axially. The piece was .010" thick AMS-6434 steel and a tolerance of $\pm .005$ " was met.

Du Pont EL-506 Flexible Sheet Explosive

The most versatile explosive we have used for forming is—Du Pont EL-506 Flexible Sheet Explosive. This material resembles vinyl tile in form, texture, and flexibility. A great variety of explosive shapes can be fabricated from this novel material such as dies, rings, tubes, etc. Pellets or cylindrical shapes can be made by simply

cementing together several cut discs of sheet explosives. Du Pont EL-506 Flexible Sheet Explosive is relatively insensitive and, therefore, safer to handle than many other explosives used in forming work.

A single bladed cutting instrument, such as a lineoleum knife should be used to cut sheet explosives to insure against metal rubbing against metal and creating a spark. Do not use scissors.

All of the following examples have utilized EL-506.

One way of utilizing this explosive is in the forming of heavy cylindrical parts. A seven-inch diameter by three-eighths-inch thick wall tube of 8740 steel was expanded to a maximum diameter of nine and three-quarters inches on an eccentric axis. This is an example of an operation where it would be extremely difficult and probably impossible to form this piece in one operation by mechanical means. (The previous method of manufacturing this piece consisted of welding two forged ends to a cast cylindrical mid-section.)

A central loading of a cylinder of sheet explosive was used. The sealing was obtained by welding a metal bottom on the piece to produce a watertight "can." The tolerances obtained here on the main cylindrical portion were $\pm .003$ -inch. Intermediate annealing was required in forming this piece.

In forming flat corrugated sections, a pellet-shaped charge was obtained by cementing together several layers of EL-506. One of the versatile features of the sheet explosive is that during the experimental stages, when endeavoring to obtain the proper charge weight, it is a simple matter to add or subtract discs from the pellet configuration.

The same general system was used to form another shaped piece. The six-inch diameter dished head was formed from a flat sheet of .090-inch thick "Vasco-Jet" 1000. For this job it was found that by using several stacked two-inch diameter discs of sheet explosive, satisfactory forming results were obtained.

In the forming of large diameter dished heads, we have found that it is an advantage to use a ring shaped charge of EL-506. This system minimized the metal

wrinkling obtained when central point charges were used. This piece was difficult to form mechanically because of the high ratio of diameter to thickness, and normal pressing or spinning operations tended to wrinkle the metal.

Another operation utilizing EL-506 was the sizing of mechanically formed dished heads. In this case, the heads were preformed to nearly the dimensions required but were purposely left undersized by approximately one per cent. Again, this was a missile application where dimensional tolerances were rigid and could not be met by mechanical pressing alone.

The preformed head was placed in a die and sealed. Water was pumped into it and by detonating a ring charge of sheet explosive (average weight one-third to one-half pound) near the flange area of the head, the required dimensional tolerances of $\pm .010$ -inch were obtained. After trimming, the tolerances were $\pm .003$ -inch on pieces up to four and one-half feet in diameter and .110, .250 and .350-inch thick.

To give an insight into what is involved in designing a charge and a die necessitates a discussion of the static and dynamic pressures involved in the high explosive forming system. We know that at the instant of detonation pressures as high as 35 million psi are generated within the explosive. We know also that as we move away from the central core this pressure diminishes. Although the pressure is still very high, it acts only for a matter of microseconds.

Experiments were designed to obtain data so that we could better estimate our charge weight and design dies to withstand explosive forming pressures. Using tubing of known mechanical properties and detonating linear explosive charges axially located within it, the explosive charge was gradually increased until the tube just yielded plastically. This point was indicated by strain gages mounted on the tube. Thus, the explosive load in grams, which just yielded the tube, was assumed to be generating a dynamic pressure equivalent to static yield pressure of the tube.

Numerous experiments were run until a curve was obtained. Utilizing this curve, one can determine what explosive load will just yield the tube. These data have been

checked out quite well with tube diameters up to 24".

The die for explosive forming applications is perhaps the most important single element. We have heard much about low cost die materials and have used them, but we find that these relatively low strength dies can be used only for short runs and for pieces where tolerances are not critical. Our experience with cast materials for dies has, in general, been poor, usually because of casting defects. If possible, wrought materials should be used. These do not have to be tool steels but, if possible, should be designed with higher yield strength than the pieces being formed. The surface finish of the die is extremely important and controls the finish of the finally formed piece. In many cases, the configuration of the piece will necessitate a split die construction. We have successfully used standard high strength socket head screws for fastening such split dies. Quick opening devices such as channel designs may be desirable for production runs.

In general, no allowance for springback is made, although some may occur. In the head sizing example, we found that the cast die was actually growing after repeated shooting. Although the die had expanded diametrically .095 inch, with the proper adjustments of explosive load, the tolerances of $\pm .003$ -inch could still be obtained.

General considerations for forming applications include among other things the evacuation of the air from the die cavity. In the forming of deep drawn shapes, for example, it was necessary to evacuate the air from the die cavity to prevent deforming the piece. A vacuum of 26 inches to 28 inches of mercury was usually necessary for deep drawing of pieces with a single shot. Lubrication definitely assists in the amount of forming that may be obtained. One word of caution, however, is that the lubricant must be confined to an area where trimming is done so any entrapment of the lubricant between the piece and the die will not mar the finished surface. In the forming of deep drawn objects, such as dished heads, a hold-down ring was required to control the wrinkling and thinning of the piece. Prevention of water leakage between the die and the forming piece was an absolute necessity because leakage results in a deformed piece. Numerous meth-

ods have been used successfully for sealing such as "O" rings or rubber pads, gaskets, tape, or putty.

The general trend of those interested in explosive forming has been a desire to set up their own facility. Many companies have established either experimental or production explosive forming facilities at their own plant sites.

One of the initial considerations before starting explosive forming should be that of legal and insurance matters. Local ordinances usually regulate the use and storage of high explosives in populated areas so responsible officials should be contacted and their advice followed. The insurance companies should also be contacted to determine how explosive facilities can be built and operated within their regulations.

The extent of the facilities depends in a large degree upon the size and number of pieces that are to be produced. Some of the smaller pieces, which can be formed with small explosive charges, can be produced inside existing plant buildings. Larger explosive charges may sometimes be used indoors if sufficient barricading is provided and remote locations selected.

Outside forming facilities, the usual selection, may range from a simple sand bag barricaded shooting table to extensive underwater tank facilities with elaborate materials handling equipment. Again, the extent and complexity of the facilities installed depends upon the size of the pieces to be formed and the scope of the program.

The storage requirements for commercial high explosives are usually determined by local and state regulations. The Institute of Makers of Explosives has compiled and published the "American Table of Distances for Storage of Commercial Explosives" which has become a part of many state codes. The distances between the storage magazine and various installations such as other magazines, inhabited buildings, highways, and railroads are well defined. Separate storage magazines for the initiators and explosive stocks are required.

As previously mentioned, water is usually used as the pressure transfer medium in outside locations. Detonating explosives underwater tends to minimize the noise problem considerably. The general procedure in forming medium to large size pieces con-

sists of immersing the die and preform, with the explosive charge properly located, into a tank or pond of water. In some cases, however, a separate shooting pond is not required. An example would be in the forming of cylindrical or conical shaped pieces where the die itself, along with the preform can act as its own reservoir for the water. For applications where the explosive charge must be placed above the blank, as in dish head forming, a practicable solution is the use of expendable containers such as open-ended fiberboard drums mounted above the blank.

Of course, equipment suitable for handling the dies as well as the pieces to be formed is essential. This equipment may be in the form of a monorail or crane system or portable lift trucks.

Safety for operators and near-by workers should be the main consideration when setting up explosive facilities. We cannot emphasize too strongly that unless properly handled, explosive charges can be extremely dangerous. It is essential, therefore, to have a person in the forming crew who is trained in the safe handling and use of explosives. In some states licensed blasters may also be required.

The distance from the shooting area to the blaster's station will vary somewhat depending upon the amount of explosives shot and setup used. A barricade of some sort is recommended for the blaster. The preparation building for the makeup of explosives charges should be separate from tool storage area so that any impact and friction from

the striking of tools will be well away from explosive charges. The bench where explosive charges are prepared should have a smooth soft surface. Clean rubber belting with no cracks or crevices is satisfactory. Blasting caps should be kept separated from the main explosive charges until the last possible moment. A check for stray electrical currents should always be made before using electric caps.

Personnel should be chosen for explosive handling with emphasis on maturity, intelligence, and common sense. Explosives have been used in industry for years and the record for safety is an admirable one, but it is only through constant surveillance and supervision that this record is maintained.

In summary, we wish to point out that in our opinion there is a definite place for explosive forming in industry. There are a great variety of explosive charges that can be used and selection should be made after careful analysis of the forming problem. Properly applied, explosive forming can supplement present commercial forming processes and give the designer a new design dimension, because of the intricate and accurate shapes that can be formed with explosives.

ACKNOWLEDGMENTS

Grateful acknowledgment is given to the personnel at Eastern Laboratory, Explosives Department, E. I. du Pont de Nemours and Co., Inc., Gibbstown, New Jersey, who contributed to the data for this paper. Special credit is given to Dr. C. H. Wroning for his work in high speed photography and to Messrs. J. P. Sved and Bruno Chudzik for their work in the cupping tests.

AIR TRANSPORT SESSIONS

SOUND FILMS AT BARGAIN BASEMENT PRICES

By IRA THATCHER
Training Film Specialist
United Airlines, Inc., San Francisco, Calif.

Probably many of you have already made an excellent safety film. I have no doubt that any of you could make just as good a film as I can. I say this because I know that you, as safety engineers, have a great deal of creative skill, a large amount of initiative and unparalleled zeal in your work. If you did not have these qualities, you would not be safety engineers.

Good, economical, sound films can be made by your in-plant film maker, or by a commercial film maker in your area. The in-plant unit can be in your department or some other department in your plant. I would like to set the record straight from the very beginning. I believe that a good film must be made by a film maker, no matter how small his operation may be, and not made by a suggestion man, a personnel man, engineer, even a safety engineer, if he intends to make more than a single film. I have heard it stated that nearly one-half of the in-plant motion picture units have started in a safety department. That certainly is the way our unit started.

I started out making training films because we needed them in safety work, and all of a sudden I was making movies—not being a safety engineer. A safety engineer has a full-time job and so does the movie production man. If you go out and buy some equipment and start to make your own sound films, you will be starting a film unit in a small way, with a low investment, and as it gains acceptance, I am sure it will be expanded, but who, then, will do the basic safety work in your plant?

I still think safety engineering is a very rewarding work and you can continue in your profession as safety engineer and still have motion pictures at bargain basement prices. You will get them in exactly the same way that you get any bargain

basement price. I think you will agree that this is accomplished only by knowing what you are looking for, where to look and quite a good deal about the item you want; that is, how it is made, what kind of material it should have in it, and also, just as important, what you don't need in the item.

With some basic knowledge of what it takes to make a film, you will be able to get the help you need to make the film and not pay for help you do not need. You can do much of the work yourself without special equipment and techniques. You can provide help for the professional, that will reduce time and effort which are costly.

Here is a list of twelve steps in film making that must be taken into consideration by you to control costs: 1) your specific problem; 2) research; 3) creative work (story script); 4) studio and set rental; 5) locations; 6) electrical needs (lights); 7) camera and crew—motion and still; 8) film stock; 9) actors and props, narrators; 10) retakes; 11) laboratory processing (cutting, editing, recording, music); 12) animations.

With this basic list in mind, acquire one or two of the many books available from photographic stores or public libraries on movie production to help you determine just how to proceed with the parts of the production you can do yourself.

(1) Looking at number one on the list, what is the specific problem for which you need a film. Find it, analyze it, determine who your audience is to be and specifically, what is the purpose of the film. Never forget this point . . . is it to change an attitude, to teach, to get someone to take action? . . . determine your purpose. Get realism in the film. If this is clear and well defined, it will greatly cut the cost of any film regardless of who makes it.

(2) The second item is research. Actually, you are the only one who probably has already done all the research necessary, but you must know how to effectively pass the information on, or sum it up. When is the best time to shoot? Where is the best place? Where can the necessary props be acquired? Can you eliminate extra sets? How should the sequence of events be shot and how will they best show what you want of the operation in mind.

(3) The third item, creative work, is really important to cost. You, or someone in your plant can do this. Find a story, get a rough script, determine what will interest the audience, keep them interested, and explain your purpose in the simplest terms. What will show the action in the clearest way and what are some effective comparisons. Costs are in direct proportion to the amount of creative work you do and what you expect the producer to do.

(4) The fourth item is acquired studio rental, set design and construction. If you can't eliminate it, keep it to a minimum as it is an expensive item. Use your own plant work area and natural surroundings.

(5) The fifth item is location expense. In the air transportation business we sometimes lose sight of what it costs to travel from one location to another. But I am not talking about a film taken all over the United States. You can waste a lot of money in location expense if you have to move the camera and lights to several new locations right in your own plant. If possible, eliminate as many locations as you can. You will save expense and time.

(6) The sixth item is lighting. If the film can be made out of doors, you have completely eliminated a very big item. Lighting equipment is expensive to buy and use. I recently came across a list which someone composed which he maintained was the minimum lighting needed for an industrial film unit. It consisted of 23 lights in the \$100 to \$500 per unit class, a total of 30,000 watts. I know you engineers do not have to get out your slide rules to know that this would take better than 500 amperes, and where would you get juice like that in your plant? So, find out about lighting and you will make great plans to eliminate as much of it as possible from your film.

(7) Camera and crew—motion and still. This is where you need professional skill and professional equipment, but you can give assistance if you understand the problems. One of the problems you will have to deal with is the people in your plant who are absolutely sure that anyone can take an automatic camera, aim it, give a coast down, fire at all his eyes can see, and all the thoughts he is thinking will come out of the can in perfect picture and concise, clear, sound.

Another problem is the fellow who knows all about taking motion pictures. He has a home movie camera. There is nothing to it. He has been taking pictures since last Christmas. Don't think I am bitter—these are big problems and it will take skill and diplomacy, as well as knowledge, for you to convince these people, who may control the purse strings, that here is one place to spend what little money you have for a film.

Shoot a home movie of your vacation trip and the scenes, when projected, can bring back to you the town you stayed in, the delicious dinner you had, the sunset that day, the sunrise you saw to the east, the station where you got gas at gas-war prices, and many other memories, but only to you and those who were with you. Any training film, safety or otherwise, must show and tell, in complete detail, its story. The viewer relies on the film to understand the story.

Your eye is a marvelous thing—it sees wide angle, telephoto, close up—all at the same time in very good or very poor lighting conditions. Everything is in focus. Now try to take that picture with a camera. It would require many different lenses and cameras, special lights and editing skill to present it, and would require about ten times as long to put the same image on the brain.

(8) Item number eight is raw stock. This is the least expensive item in making a film, regardless of whether you make the film by shooting five times what you need or 500 times what you need. But, you can make terrific savings if you know what type of film is available and will be best for your specific situation. There is very little difference in the cost of using black and white and color, and there are several

color films for good light or poor light. The type of film available in 8 mm is limited.

(9) Actors, props and narration. If the film has realism in it, the actors are the people who do the job, and the machines and shops are theirs, an audience of them will be very interested. You also save the expense of hiring actors and constructing dummy props. With a little practice on a tape recorder you, or someone in your plant, can probably do a better job of narration than the local news commentator on the subject of your film.

(10) Item number ten—retakes. This is where you can save money on a film. Be careful, when a scene is taken, that it is the way you want it. You will find that an in-plant film can tolerate some imperfections. So try to use a scene, or part of it, rather than rushing out and retaking.

(11) Item number eleven is laboratory processing of the film. This includes many things and nearly every one of them requires expensive equipment and specialized personnel. There are hundreds of these labs all over the country competing with one another to do this work, and I assure you that the prices in most cases are very, very reasonable. These include developing, printing, trick photography, fades, dissolves, enlargements, reductions, recording, cutting, editing, dubbing and music. Many film pro-

ducers specialize in this part of film making. They will be very glad to help you with the phases you can do yourself.

(12) Item twelve is animations. There are many places where they can be effectively used, but are probably the most expensive item in making a film. Special equipment and art work are required to make animations.

I have not touched on 8 mm sound movies as they have absolutely nothing to do with the subject we are discussing. They are a new and marvelous step forward for the home movie field and will some day move into many phases of industry. But, the basic principles of film making are the same, regardless of the film size. Today, even the most ardent advocates and manufacturers of 8 mm sound equipment recommend shooting industrial films in 16 mm and reducing it to 8 mm.

In most cases, you can make sound motion pictures for your safety programs at bargain basement prices when you have a basic knowledge of the art of film making and take into consideration the twelve items we have discussed—doing for yourself those things you are capable of doing, buying from experts the things you cannot do without special equipment or skills, and realizing what the frills or accessories are which you do not need in an industrial film.

STORES TRAINING—RIGID PURPOSE, FLEXIBLE METHOD

By D. B. LANE

Supvr.—Stores Training & Packaging, Trans World Airlines, Inc., Kansas City, Mo.

This presentation on Stores Training systems, methods and facilities, as applied by TWA, was described and demonstrated by the use of projection slides and tape recordings.

The following is a verbatim copy of the narration.

The requirement for technically educating and training personnel assigned to the meticulous task of maintaining and protecting the physical inventory of the multi-

million dollar supply stores for TWA, became apparent.

When the company was young, the manpower markets provided personnel with adequate qualifications. Training involved only the teaching of procedures, which were peculiar to the company along with a minimum of technical information related to the physical handling of materials.

As the industry grew and the transport aircraft became more complicated, the man-

power market thinned. Technically qualified personnel became increasingly difficult to hire.

Supervisory workloads increased. — Procedures became more involved with the advanced steps toward automation and machine accounting. — Time available for adequate detailed on-the-job instruction became less and less.

When the new TWA overhaul base was activated early in 1956, the requirement for "wall-to-wall" training became a "must".

New procedures, methods and equipment — placed in use simultaneously with the new base activation required a change-over from the old systems to the new systems within a relatively short period of time.

To implement the changes and establish an effective means of educating new employees as replacements for vacancies created by promotion, etc., — a specific section of main stores was originated and entitled "stores training".

The stores personnel are scheduled through training courses in three phases: Phase One is designed to make a new employee with the stores department a productive employee in only five days.

This phase of the training program does not teach the exceptional procedures (which require experience with the department to permit understanding). It provides the basic routine, which covers the majority of production by any job assignment.

Phase One is presented in four steps—receiving, binning, order filling and shipping. Each step involves three hours of classroom training, followed immediately by approximately five hours, on-the-job indoctrination and practice, carefully audited by the instructor.

Phase One is completed with a written examination which was carefully developed to assure that the passing grade is a direct measurement of retention equivalent to knowledge gained by approximately five years with the department, without formal training.

Phase Two of the stores training program is presented to the trainee no earlier than sixty days later and is more comprehensive. Given to the employee when his job assignment has stabilized, it is a

course in which he receives the instructions on specific materials handling, exceptional procedures, and the "hints and kinks" of the specific job.

The titles of some of the Phase Two courses are: metals and raw materials, hardware, radio & electrical, airframe, engine, instruments and hydraulics, R&R procedure, catalogue reading, unit of issue, packaging.

There are many others, but these titles will give you some idea of the detail studies presented as Phase Two lectures.

Phase Three is presented every six months and is comprised of the changes to published procedures and methods, which have taken place within the past six-months' period. Designed for updating the employee, it provides refresher training in the areas necessary.

Special courses, training classes and presentations are being developed consistently as the requirement is recognized. Special courses are generally included in Phase Two training.

To fully understand the systems and methods used in teaching, as applied by the stores training facility, we look first at the classroom training.

For those persons who have had teaching experience, this explanation is not new . . .

A human being capable of mental acceptance and retention can be depended on to form opinions and make decisions which is guided by education.

That! is the prime purpose of classroom training. It provides opportunity to study the details and background of the job, which is necessary if accuracy is to be gained with peak production.

In the classroom, the trainee receives technical lectures and participates in discussions which enhances his mental guidance and reasoning when applying his physical efforts on-the-job.

Hence, the old saying when defining training as applied:

"You educate a man—you train a horse."

On-the-job training is given to the trainee after leaving the classroom. Based on retention percentage versus time, the trainee is placed on the job in a productive position. On-the-job instruction is given to assist the trainee in adjusting physically to the

assignment area and location of the tools used on the job.

Physical motions involved on the job are demonstrated and the trainee's duplication of trained efforts are audited for efficiency. Reports of audits are furnished to the supervisor in charge.

To repeat this in brief form . . . the trainee is given the why and how in the classroom and converted to habitual motions on the job.

To teach in the most organized manner and provide the trainee with the best opportunity for self audit and understanding: all courses are developed in the order of material flow. For example: the Phase One basic course for the new employee starts with receiving and is followed with binning. Therefore, when studying binning procedures, the trainee reviews and notes the errors he made previously during the receiving operation. The same applies during the entire processing cycle.

There are twenty-six separate types of mechanized and powered material handling equipment in use by the TWA main stores department.

All employees have been given an operator's check on each type. All individuals assigned to operate specific pieces of equipment, repetitively on a job, are given experience evaluation checks, and qualification records are maintained perpetually.

Such items as road checks for truck drivers, are given over frequently-traveled routes. Lift truck and other equipment operators are checked over hazard routes. The "do's" and "don'ts" described in the classroom are pointed out and demonstrated during this on-the-job check procedure.

On the subject of training aids—Within the stores training classroom, the complement of visual audio aids, and their operation is of prime importance to the over-all stores training operation and the following is a brief description of the facility and aids.

The classroom will seat a maximum of seventeen trainees, although classes of one are sometimes necessary when scheduled presentations have taken place during a vacation or period of illness. Returning employees must be updated to be able to do their job correctly.

Exhibits of parts, materials and forms are classified, categorized, grouped and wall-mounted for convenience.

Generally a new employee has had little, if any, experience or exposure to parts, materials, procedures or handling information, as applied to the airline business.

Recognition of metals by color, gram, measurement systems, etc., are taught from these exhibits and sample displays.

General hardware exhibit is categorized and displayed for easy recognition and basic guidance.

Radio, electrical and electronic parts are sampled and used for demonstration of proper handling, protection, recognition, etc.,

Textiles and fabrics are exhibited for recognition, special handling and measurement techniques described.

Material flow forms—their color codings—and informational forms—their applications, procedures and standard color codes—are exhibited and consistently studied for improvements in design and handling compatible to better training.

The blackboard—to aid the instructor during extemporaneous discussions and portrayals—instructor techniques in training aid use and development require extensive and continuous instructor training.

In addition to wall-mounted charts and exhibits, visual audio aids used during classroom presentations involve the use of 16MM sound motion pictures, primarily for showing commercially available films for supervisory technical training.

The 8MM motion picture equipment is used for showing films produced by the stores training section. Correct or incorrect methods, involving job motions, are shown for study and discussion.

The 35MM slide projection equipment is of the magazine load type which is synchronized with tape-recorded narrations, and can be used for detail studies of procedures and associated forms, processing, etc., when discussion between scenes is necessary, but motion demonstrations are not necessary. (Updating the recordings after repetitive showing permits editing to include the answers to most questions before they are submitted.)

Cameras of several types are used . . . the majority of them are available as by-

products of the business—obtained as unclaimed articles from the lost and found department.

The stores training permanent library includes three 16MM films—45-8MM films and 110 slide tape packages. These films and packaged courses are continuously updated to include all changes to be ready for class presentations, as required. All recorded presentations are retained and filed when superseded by updated packages.

This has been of considerable advantage when reviewing previous showings for referee use or debate purposes.

The use of slide-tape packages for detailed study has become increasingly convenient to use by providing masters for duplication and assignment to field stations for their repetitive review of subjects too comprehensive for retention by one-time viewing, or extensive manual study.

For example:—system training of the IBM 650 R&R material control procedure was duplicated twenty times and the twenty packages have been assigned system-wide for repetitive showing as required.

Proper development and editing of recorded presentations are found to be particularly advantageous because the normally monotonous monotone voice of the instructor, who is required to read prepared pas-

sages is replaced with the advantages of recordings to include sound effects, etc., when desirable. In addition, all employees hear and see the instructions identically without exceptions and instructor variations.

Classes can be held several months apart without forgotten points and factors.

Classroom sessions are more accurately and efficiently timed by tape-time standards.

More presentations can be given per instructor by reduction of fatigue factor.

The stores training section of TWA main stores maintains an extensive set of records to provide supervisors with information relative to each employee's training and his capabilities.

Studies are currently in progress toward development of a measuring system, which will indicate an employee's production gains throughout successive steps of training, as compared to production levels without training.

The purpose of the study is to provide proof of value received and the justification of training given.

To summarize . . .

This is:
Why We Do It
When We Do It
How We Do It

OFFICERS OF THE

AEROSPACE SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—KENNETH L. STEBBINS, Dir. of Safety, Locomotive Div., AVCO Mfg. Corp., Stratford, Conn.

Vice Chairman—JOHN D. DONOHUE, Supv. Safety & Employee Services, Rohr Aircraft Corp., Chula Vista, Calif.

Secretary—W. H. STAPLES, Safety Supv., TEMCO Electronics & Missiles Co., Dallas, Texas

Newsletter Editor—HERBERT S. NATH, Chief of Employee Services & Safety, General Dynamics Corp., Pomona, Calif.

Associate Newsletter Editor—JOSEPH A. YOHMAN, Safety Engr., General Electric Co., Flight Propulsion Div., Cincinnati, Ohio

Senior Program Chairman (West)—CLAY W. LOWREY, Supv. Health & Safety, Space Technology Laboratories, Inc., El Segundo, Calif.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

AUTOMOTIVE AND MACHINE SHOP SECTION FERNANDO'S HIDEAWAY

By BRUCE PODZIUS
Safety Director, Detroit Diesel Engine Div., General Motors Corp., Detroit, Mich.

The Fernando that I am going to discuss is not a character in a song. Fernando is a machine operator at Detroit Diesel. Fernando's Hideaway was the inside of a machine and the object that he concealed was a tobacco can containing six small Allen wrenches. Every morning at starting time for four hundred eighteen (418) consecutive work days, Fernando would carefully remove four screws and take off a cover from the side of his boreumatic machine. Next, he would reach inside and retrieve his tobacco can treasure chest which he had hidden at quitting time the previous day.

On the morning of November 18, 1952, Fernando's luck ran out. As usual, he first pressed the starting button for the motor in order to cycle and warm up the hydraulic system for the machine wherein the tobacco can was hidden. Next, he removed the cover. As he reached inside, his left third finger was caught and amputated between a revolving "V" belt and a pulley. Fernando's Hideaway had finally been discovered!

It was almost incredible that a General Motors employee working in a safety-minded plant could perform a flagrantly unsafe act twice a day for four hundred eighteen (418) consecutive days without ever having been detected or corrected by his supervisor, his fellow employees or his safety department. It makes you stop and think, doesn't it?

We in the safety department did plenty of thinking. At first we consoled ourselves by saying, "It is difficult to control the human factor." Next, we reminded ourselves that the business of building Diesel engines is classified as heavy industry and serious accidents are more likely to occur in heavy industry operations.

Then came the thought that in spite of the fact that our safety program provided an hour and a half safety induction talk to each new hire, in spite of the fact that

supervisory safety meetings were regularly held, in spite of daily five-minute safety talks to employees, in spite of safety inspections, safety procedures, safe job instructions, safety rules, signs, slogans, bulletins—in spite of all this and more, it could not be denied that Fernando's unsafe action climaxed an entire year of several serious accidents at Detroit Diesel. Somewhere we were missing the boat. Four conclusions were finally reached:

First: All people perform unsafe acts.

Second: If one employee with better than average intelligence and with a previous accident-free record was able to perform a flagrantly unsafe act twice a day for nineteen months, it would involve higher mathematics to determine the number of unsafe acts that three thousand employees in the same plant would perform in the same time interval.

Third: In many instances a history of an employee's unsafe practices was discovered after actual injury took place. We needed a plan of action to detect and correct unsafe practices before an actual injury would result.

Fourth: The safety department needed help—plenty of help.

Early in 1953, the Detroit Diesel "Unsafe Practice Observation Plan" came into existence. Management, traditionally safety minded, accepted the "Unsafe Practice Observation Plan" as a supplement to the safety program based on the General Motors "Six Basic Principles of Safety."

It was decided to try the plan in the manufacturing division first. The energies and talents of thirty men were made available. These men were thirty manufacturing division foremen. Overnight the safety department had been enlarged 750 per cent. These foremen were the first recruits enlisted in an all-out war against the dangers of employee unsafe practices.

A letter from the works manager informed all manufacturing foremen that an

"Unsafe Practice Observation Plan" was going into effect immediately. The purpose and function of the plan was explained to the foremen by their general foremen. Each foreman was asked to observe, correct and describe in his own words a minimum of three unsafe employee practices each month. Each foreman was supplied a form to aid him in this work. On the back of this form were listed 44 reminders which serve as a thought stimulant to the foreman. The foreman after listing his observations and corrective measures would submit them to his general foreman.

After being reviewed by the general foreman, the unsafe practice observations, as described by the foreman, are compiled and sent to the printing department. Every foreman knows that his written safety contributions are being read each month by all supervisors in the manufacturing division from the foreman all the way to the works manager. This supervisory exchange of corrected unsafe practices and unsafe conditions is actually a take-off on the corporation "Safety Idea Exchange" plan.

By 1957, the "Unsafe Practice Observations" program had undergone two major changes. First, the original group of thirty foremen had been reinforced by seventy additional foremen. Manufacturing, material handling, inspection, toolroom and maintenance foremen had joined the ranks to combat the endless numbers of human errors. The second change for the better was brought about when the foremen streamlined the somewhat lengthy title of "Unsafe Practice Observations Plan" by nicknaming it "U.P.O."

The most astonishing aspect of "U.P.O." after its first five years of existence was the unaltered enthusiasm that the foremen themselves had in carrying out the three-way role of private eye, educator and author. This was reflected in the ever increasing numbers of items submitted by supervisors. In the minds of the participating foremen, this was not just another safety drive. They believed in "U.P.O." Fernando's tobacco can had become a plant-wide symbol for an employee unsafe practice. By 1960 it had become a matter of record that supervision at Detroit Diesel in seven years discovered over 15,000 unsafe practices.

To keep the record straight, it must be said that not everyone at Detroit Diesel welcomed "U.P.O." with open arms. A certain department head and his supervisors felt that to describe on paper something that was a part of their daily work was wasteful from the time standpoint and, furthermore, had a boastful tone. Traditionally, this particular department had averaged three lost-time accidents every two years.

There were times when we in the safety department felt a need to solicit the persuasive ability of top management to alter this department head's thinking, but we did not yield to this impulse because we subscribe to the belief that you cannot compel or coerce safety consciousness—it must be won. The passage of time solved this particular problem. In September, 1957, the above department head retired. His successor readily accepted "U.P.O." The results were amazing.

The new department head has yet to experience the heartache that accompanied a serious disabling injury to one of his people. Better than three years without a single disabling injury is truly a unique experience for this department.

At this point, I would like to describe an example of "U.P.O." at work. On August 1, 1960, Foreman Jim McCook submitted a "U.P.O." item wherein he stated, "While making a check for miscellaneous materials being stored inside electrical control panels, a panel was found with the 'on' and 'off' switch inoperative. The machine could not be locked out for maintenance employee safety during repairs. Condition was corrected."

The next day I asked Jim the reason for his safety inspection of electrical panel boxes. He replied that he read of foreman Al Voegel's experience in a "U.P.O." item written two months previously. I dug out the May 31 edition "U.P.O." and read Voegel's report, "Made a safety survey of electrical panel boxes in department. Found towels, tools and grinding wheels stored inside. Explained to all my employees the danger of this unsafe practice."

Foreman McCook's reaction to foreman Voegel's experience is the same reaction that you and I get when we read Ken Hedge's "Safety Idea Exchange" bulletins.

It is the same reaction that motivates you and me to look at our own plant operations so that we would not experience a repetition of the accident described in the corporation bulletin.

"U.P.O." through the medium of thought exchange builds hazard awareness in the minds of foremen.

I remember a few weeks ago, a visit that was made to our plant by Ben Gieslik and Ralph Deeds. Ben is Ken Hedge's right arm and also his left arm. Ralph had just become a member of the corporation labor relations staff. Ben and Ralph listened to an explanation of how a typical General Motors safety program operates. "U.P.O." was briefly mentioned. Later, while out in the plant, Ralph expressed a desire to meet and talk with a departmental foreman.

The first one we encountered was Ziggy Dombrowski. Ziggy is in charge of engine block machining. He was asked to explain the manner in which he operates his departmental safety program. Ziggy took off with all the enthusiasm of a hungry Detroit Lion football player chasing a Chicago Bear fumble.

Ziggy unloaded. He talked about his 100 per cent eye protection program. He talked about safety shoes, safety rules, safety guards, and then he said, "Oh, yes, I almost forgot unsafe practices. I always carry my 'U.P.O.' reminder sheet with me so that I can jot down observed items the moment I see them."

Ziggy took his "U.P.O." sheet out of this pocket and handed it to Ralph. Ralph proceeded to read out loud, "Jobsetter informed me that he had observed a machine operator place his fingers too close to a pinchpoint at an automatic indexing machine. A plant work order was issued to guard the hazard."

Cooperation on the part of the foreman is the very heart of "U.P.O.". This cooperation is obtained by employing the technique of job recognition. The various department heads at Detroit Diesel take careful pains to publicly demonstrate their approval for the "U.P.O." efforts of their line supervision. In addition, the safety department takes every opportunity to praise their "U.P.O." efforts through the medium of plant-wide bulletins. I have in my hand an example of how this is done.

Automotive and Machine Shop Section

In the Safety Idea Exchange Bulletin dated August 4, 1960, the last grim sentence states, "This is the fourth fatality in G.M. in 1960 due to a fall and again emphasizes the importance of using every precaution when working overhead."

Attached to this corporation bulletin is a Detroit Diesel intra-plant bulletin addressed to all supervision, which reads:

To: All Supervision

The attached Safety Idea Exchange describes the fourth General Motors fatality this year due to a fall. This type of tragic mishap has been singularly absent from Detroit Diesel.

After reviewing recent "Unsafe Practice Observations" by Detroit Diesel supervision, the writer takes this opportunity to thank fifteen supervisors. These fifteen supervisors corrected conditions that could have caused fatal falls similar to those that took place earlier this year in four G.M. plants. Listed are three typical examples of excellent supervisory safety alertness:

Foreman R. Dillaha: "Found 18 foot wood ladder with badly split side rail from the bottom to first rung. Ladder was removed. Condition was corrected."

Foreman E. Verkerke: "Observed millwright working approximately 15 feet above the floor. He was standing on top of a three inch diameter pipe safety railing which was part of a work platform. I warned him of this extremely dangerous practice. He came down and obtained another work platform of proper height."

Foreman R. Matchko: "Observed employee #712-122 standing precariously on top of lift truck while installing cable into a hoist approximately 12 feet above floor. He obtained a ladder."

This bulletin was concluded with "Please be alert for similar unsafe practices and unsafe conditions in your department. The life you save may be a co-worker's."

All General Motors plants have made tremendous progress engineering safety into methods and machinery. The principal plant problem in safety, therefore, is no longer methods or machinery. The principal problem is people. In order to reduce accidents, we must do a better job of engineering safety consciousness into the minds of people.

We believe that "U.P.O." has made our foremen much more safety conscious. Many of our foremen have told me that they particularly enjoy the correct-it-themselves aspect of this program. This is understandable when you consider that any foreman in any plant would prefer to personally correct employee mistakes and unsafe conditions in his department rather than to have some other member of management

do the correcting. "U.P.O." has helped make our foremen more responsible and more valuable members of the management team.

At this point it might be appropriate to look at the record. Seven years of "U.P.O." will be compared with the seven years that preceded "U.P.O." The comparison concerns itself with severity and frequency rates and accident compensation.

The average severity rate (number of days lost for every million hours worked) in the seven "U.P.O." years has been reduced 80 per cent.

The average frequency rate (number of lost-time accidents for every million hours worked) in the seven "U.P.O." years has been reduced 71 per cent.

As you know, accident compensation costs in recent years have risen enormously throughout industry. In our plant "U.P.O." has helped to reverse this national trend of soaring costs. Accident compensation paid at Detroit Diesel in these past seven "U.P.O." years was 72 per cent lower than the seven preceding years. This reduction represents substantial savings, but — more important — it indicates a minimum of disabling injuries to our employees.

This look at the record would not be complete without referring to the year 1957. For it was in 1957 that the men and women of Detroit Diesel worked ten consecutive months without a disabling injury. This accomplishment of 6,000,000 man-hours worked without a disabling injury established a national record in the field of engine manufacturing. This record still stands.

Do not interpret these references to the record as an indication of self-satisfaction or complacency. In the first nine months of 1960, Detroit Diesel supervision described more "Unsafe Practice Observations" than any single year in "U.P.O." history. The sober realization and reflection that accompanies page after page of recorded unsafe actions received each month makes complacency impossible.

As you know, the first of the seven General Motors "Basic Principles of Safety" emphasizes active top management support. It might interest you, therefore, to hear the reaction of three members of

top management at Detroit Diesel relative to "U.P.O."

Mr. Eugene Kelly, works manager, has said: "Unsafe Practice Observations are the backbone of our safety program. One half of safety is awareness of unsafe acts and unsafe conditions; the other half is prevention and precaution. These two needs are fully met by unsafe practice observations as we use them."

Prior to the discovery of Fernando's Hideaway, we at Detroit Diesel did not have this awareness of unsafe acts that Mr. Kelly mentions. We were forever locking the barn with corrective measures after the horse had been stolen, after the accident had happened. Today, we believe that "U.P.O." locks the barn before the accident takes place.

Mr. John McKenna, production manager, stated: "Our safety record in the material division, we feel, has been exceptionally good inasmuch as we have had but one lost-time accident in the past seven years. We feel that this is unquestionably due to our constant observation and correction of unsafe practices."

Mr. Stanford Varblow, chief inspector, declares: "The use of the plan has made every member of the Inspection Division a more active member of the 'safety team.'"

A little over two years ago, I attended a meeting with George Humphrey, safety director, at the Cadillac Motor Car Div. During intermission I told George of our "U.P.O." success story on five years of experience. The question was raised: "Will 'U.P.O.' work in another General Motors plant whose operations are vastly different than those at Detroit Diesel Engine Division?"

If this same question is in your mind, the answer is: "You will never know unless you try it."

Cadillac Motor Car Div. did try it. Cadillac titled their program "Before The Accident." At the present time the energies and talents of over five-hundred supervisors are being successfully employed in discovering the unsafe actions of Cadillac's Fernandos.

Do you recall our concern back in 1952 as to the potential numbers of unsafe actions that three-thousand employees might

perform in nineteen months? Do you recall that Detroit Diesel supervision uncovered over 15,000 unsafe practices in seven years? It therefore should not surprise you that supervision at Cadillac in six months uncovered 9,466 unsafe practices. When I received those figures from George Humphrey, I phoned my thanks and asked him: "George, three years ago if someone would have had the nerve to make a statement to the effect that close to 10,000 unsafe actions and unsafe conditions would be discovered in your plant in a six-month period of time in 1960, what would you have said?"

"I would have had serious doubts regarding his sanity," was George's reply.

Cadillac with their "Before The Accident" program is experiencing the same unexpected phenomena that we experienced at Detroit Diesel with "U.P.O." I am talking about the enthusiasm that all levels of supervision have for this "do it themselves" safety approach. Typical of several top management testimonials to their new safety concept are the words of Mr. R. L. Pratt, assistant superintendent, final assembly.

Mr. Pratt said: "We at Cadillac for many years analyzed all accidents. Not just the major or serious accidents, but also the minor scratches and cuts. Every hospital pass we investigated with reports, charts, records and statistics. We still continue this after the accident activity. With the 'Before The Accident' approach, we feel that we are preventing accidents before they happen instead of analyzing an accident after it happens."

George Humphrey sums up the Cadillac adaptation of "U.P.O." in this manner: "Our 'Before The Accident' program has greatly contributed to a gratifying Frequency and Severity record this year at Cadillac. In addition, we went four months — March, 1960 to June, 1960, inclusive — accumulating over 7,000,000 man-hours worked without a single lost-time accident."

Incidentally, I might add that George has

set up some spirited competition between participating divisions, wherein the total number of items submitted per division is divided into the number of man-hours worked within the division. Supervision in the material control division are currently submitting the amazing average of eighteen "Before The Accident" items a month per supervisor. This competition between divisions must be working when you analyze the fact that almost 10,000 potential accidents were prevented by Cadillac supervision in six months. This is foremanship motivation at its best.

The Frigidaire foremen participation program is titled "Job Observations." One of Frigidaire's plant managers came up with the idea. Although Frigidaire had never heard of "U.P.O." or Fernando's Hideaway, they discovered that they had their share of Fernandos also. Frigidaire reports over 1,000 "Job Observations" per month.

All plants have their share of Fernando Hideaways. Our concern should be to discover them. Frigidaire, Cadillac and Detroit Diesel supervision are aware of the fact that people with all their human shortcomings will perform unsafe acts. This awareness, coupled with determined action, definitely prevents accidents.

It would be most pleasant to conclude the story of "Fernando's Hideaway" with the words: "and as a result of the 'Unsafe Practice Observations Program' accidents ceased and they lived happily ever after at Detroit Diesel." Of course, this is not the true ending. All of us know that there will never come a time when anyone can say: "This is it . . . now all accidents will cease."

We do believe, however, that "Unsafe Practice Observations" have made Detroit Diesel a better and safer place to work for our employees. I wish to thank you for your attention, and I sincerely hope that you have been given an idea or two that might be of value to you.

TRADIN' POST

Presiding: LEWIS R. MORRISON, Corporate Mgr.-Safety, ACF Industries, Inc., New York City.

BOB REEVES, Mgr., Safety Services Sect., Ind. and Comm. Relations Dept., Allis-Chalmers Manufacturing Co.
Subject: Safety Modifications of Standard Push-Button Controls

Here are two gimmicks on push-button controls that we have made standard at our West Allis Works and which may be of interest.

Overhead Doors — Normal controls are "Raise, Lower, and Stop," momentary contact push buttons permitting the door to be stopped at any height. This is tough on floors, and possibly personnel, from dislodged loads when clearance is misjudged and door is struck by a truck.

We corrected this exposure by eliminating the "Stop" button and requiring the "Raise" control to be automatic. (The latter is standard on many units.) Under this arrangement, a single actuation sends the door to its top height with no way of over-riding or stopping it. The "Lower" button requires continuous pressure so the operator must stay at the control where he can make sure no one is caught under the lowering door. Removal of pressure on the

"Lower" button stops the door at any point. Of course, it's possible to bring the door back down to less than maximum open height on cold days, but we have found no tendency to do so.

Electric Elevating Platform—These are normally equipped with both a floor-operated set of controls and a platform set. If the operator leaves the platform while in up position, it is possible for a person on the floor to bring the platform back to the floor, leaving the upper man stranded. Also, the platform could be moved while in use. We require a selector switch on the platform control by which the operator can lock out the set of floor controls so the platform cannot be taken away without his knowledge.

These are both simple wiring operations that are easily accomplished. We find that several hazards have been eliminated by requiring them as standard hookups.

II

CLARENCE E. JOHNS, Safety Supvr., Canton Works, International Harvester Company, Inc.

Here are two ideas that we have used with success for the past year.

1. Captive wrench for acetylene cylinders. The assembled unit is attached to the

acetylene cylinder under the regulator mounting nut. The wrench has the distinct advantage in that it is always in place when it is needed.

2. Replacement for oil cans. Oil cans may cause trouble due to puncture wounds

The can may be damaged easily. We have replaced our oil cans with plastic containers, such as liquid detergent bottles. To make them into an oiling unit, we merely drilled a hole in the cap. The bottles are economical, easy to replace, remove an injury potential. Even more important, our employees like them and they become quite proficient with them.

III

E. SKINNER, Safety Administrator, St. Louis Assembly Plant, Chrysler Corp.
Subject: Trailer Safety Jacks at Shipping and Receiving Docks

This is one solution to a problem that I think we have all had in the past. You've noticed the different methods that are used for securing the trailers when they come in so they won't jump up in front when the fork lift goes in. We've made a set of jacks that we secured to the face of our loading dock or receiving dock. These

jacks swing out when the tractor or the trailer comes into place. They can be raised to any elevation. One problem—aluminum trailers. When we first used these, we were bending the structure underneath some of the aluminum trailers. To eliminate this, we put on a wood adapter which covers more of the trailer surface.

IV

H. L. KIRK, Mgr., Personnel and Safety, ACF Industries, Inc., Berwick Plant.
Subject: Air-activated Safety Gate

The walkway leading from one of the doorways of one of our buildings (Freight Erection) is located beneath the truck-carrying crane which travels past this door-

way to supply trucks to the track. Due to the usual amount of noise in this building, and the fact that the crane is overhead, workers stepped through the doorway

directly beneath the passing crane. In order to eliminate this hazard, we installed an overhead air-activated drop gate.

This gate consists chiefly of a round bar from which is suspended straps of asbestos. When the crane nears the doorway, contact is made with a third rail, which energizes the air-activated piston, which in turn

causes the drop-gate to lower. The asbestos straps on the gate are approximately 2½ feet long and swing freely on the bar from which they are suspended, so that if a worker should be immediately under the gate as it drops, he would not sustain any injury.

V

E. JAMES, Safety Dir., Sunstrand Corp., Rockford, Ill.

Subject: Relocation of Cooling Fans

Our air circulating fans mounted on pedestals were being placed in hazardous locations such as aisles and other areas having heavy traffic.

Our hydraulic division's plant engineering department picked up this problem, studied it, and solved it this way. They removed the fans from their pedestals. They then placed the fans on permanent mounts which

had been attached to selected building columns. The building columns used were those selected on the basis of air movement needed during the hot summer months.

This change not only removed a serious injury potential, it also eliminated a lot of controversy over who was going to use or place the fan.

VI

J. K. SKIPTON, Safety Supvr., WKM Div., ACF Industries.

Subject: Shaving Shield on an Engine Lathe

A shaving shield on an engine lathe protects the operator from flying shavings thrown off by the chuck jaws or the revolving work.

The principle used here is a curved horizontal 12-inches-wide shield on roller

bearings that can be pushed left or right on a ¼ inch by 2 inch angle iron track the length of the lathe carriage. It can be pushed over the engine housing to the operator's left when he needs to chuck his work or to his right clear of tool post. The operator uses the shield as work dictates and at whatever point needed depending on location of the cutting tool. It has a removable plexiglas window to have work and tool visible. Where a coolant is used, it contains it within the machine. The skirt on back of shield under the ¼ inch angle track protects adjacent operations and helps balance the front overhang.

The roller bearings make it very easy for the operator, with a fingertip touch, to move the shield freely without interference to his production.

The shield has been successful in preventing burns and other injuries from the flying chips.

VII

ARRON COX, Supvr. Safety & Fire Prevention, ACF Industries, Inc., Albuquerque Div.

A. Magnesium Extinguishing Powder Cart

This piece of fire protection equipment is basically a garden and lawn cart with an attached lid and leg tray. The lid is attached

to disallow contamination of the extinguishing powder with metal chips and other debris. The leg tray is added to the cart to support a 2X shovel blade while the shovel handle rests on the cart handle.

This magnesium fire extinguisher has proved to be a very useful piece of equipment. It is very portable, holds 50 to 60 pounds of extinguishing powder; the wide opening of the lid makes the powder very accessible, and the 2X shovel provide an ample amount of powder plus being a useful tool to remove burning particles and for clean-up operations.

The cart and shovel are both painted red and marked "FOR MAG FIRES ONLY" in white letters.

B. Crane Hot Line Lights

Two red lights extending from a 440 volt to 110 volt transformer which is tied directly in line from the crane power supply act as caution lights to crane operators and maintenance personnel. There are two hot line stations on each crane circuit mounted above the crane rails, and are clearly visible in the crane operators and other personnel.

The hot line lights are not used to indicate the crane power line hot or not hot, but are used mainly as caution indicators and disconnect monitors.

C. Magnesium Scrap Cans

The magnesium scrap can is a safe means of controlling magnesium scrap and in providing a system of control for the fire potential involved in magnesium scrap within a plant area.

The can is made of ½-inch steel plate. It is 36 inches deep and 30 inches in

diameter. At 90 degree segments there are braced 2½-inch pipes extending 5 inches from the wall of the can. With this construction, should a fire exist in a magnesium scrap can, a lift truck or crane can easily and rapidly remove the can to a safety area without danger of the burning magnesium being contained in a shop or spreading it about while attempting to remove it from a shop area.

While a magnesium scrap can is in a shop, it is provided with a lid made of rolled one-inch angle iron and 1/16-inch sheet steel with a large handle attached to the lid center. The lid is basically used to disallow scrap contamination with other materials and to hold back the fire potential from cigarettes and lighted matches.

D. Lever Drop Lock

The machine lever drop lock was installed on an engine lathe housing between the high and low range back gear lever positions to prevent accidental range speed change of the back gear. The drop lock is set on an angular plate with an offset pin in the drop lock arm base to always cause it to be extended. In order to change range

speeds, it becomes necessary to raise the drop lock arm before repositioning of the back gear lever can be obtained.

The drop lock not only acts to prevent accidental change of the lever but also is a reminder to the lathe operator that he is changing operating speeds.

In the case of this installation of a drop lock the ratio of speed change was about 8 to 1.

E. Special Welder's Glove

A glove designed to meet a dual purpose. To allow operators of automatic welding equipment touch control and positive feel of the equipment's operating panel and to safeguard against ultra-violet rays causing damage to the operator's hands.

The glove hand is made of thin goat skin to which is attached a heavy five inch leather gauntlet to provide protection between glove and sleeve.

F. Welding Snood

A welding snood, made of black wool, is used to prevent ultra-violet ray burns to the back of the head and neck of welders working inside of cylinders and bowls of bright metals where reflections are prevalent. The welding snood is made to be attachable to the headband of the welding helmet easily. There are only two snap hooks involved in the attachment.

Along with use of the welding snood, the welding helmet is equipped with a fresh air plenum to supply the welder with

a constant supply of filtered fresh air removing possible heat, smoke, and fume problems.

G. Fire System Indicator Board

The purpose of the fire system indicator board is to mark attention to any part of the plant sprinkler and fire main system

that may be reported non-operational. With the marked attention to a non-operational part of the fire system, the plant security force and the plant fire protection section can maintain a closer vigilance over the indicated section, and be prepared to operate under a secondary system in advance should it be necessary.

The indicator board is a photo copy of the drawing of the plant fire protection and sprinkler system. The purpose of the photo copy is to reduce the board to a more suitable size. In this case it was reduced from a drawing 36 inches by 126 inches to 14 inches by 34 inches.

The photo copy was marked with colored indicators to represent the various valves and equipment of the system and each

indicator was numbered or lettered to correspond with its actual valve or equipment. Hydrants are indicated by a fluorescent green triangle; sectional valves on the main are indicated by a fluorescent orange square, and building sprinkler valves are indicated by a yellow circle.

The fully indicated and marked photo copy is mounted over a plywood back and under a piece of clear plastic glass. Below each marked indicator a 1/16-inch hole is drilled through the mounted board so that a non-operational indicator could be placed if needed. The non-operational indicator, a

round fluorescent red plastic tack with a 1/16-inch shaft, is placed in the mounting hole of the corresponding non-operational equipment. The easily noticed red indicator when placed on the board becomes a caution notice that a part of the system is non-operational.

A procedure requiring the reporting of any change in any operation of the fire protection system, either repairing, construction, testing, etc., to the plant security force and plant fire protection section is the first step of functional value for the basic purpose of the indicating board.

VIII

WILLIAM F. PITCHER, Safety Administrator, Kokomo Plant, Chrysler Corp.

Subject: Limit Switch for Electric Carts

We found that the employees using an electric cart had a tendency to ride with their foot out of the left hand side of the cart. This practice resulted in a four-day lost time injury earlier this year. To eliminate this source of injury, we substituted a limit switch for the ignition switch.

The limit switch is located on the left floor board. The employee must keep his left foot on the switch to maintain a closed circuit so that the cart will run. This is a simple change and cost us about \$12.00.

IX

MILTON RATHERT, Personnel and Safety Dir., Hages Hinge Co., St. Louis, Mo.

Subject: Metal Drum Check and Disposal

Our metal drums through hard use become ragged or torn at the top; and, as a consequence, created quite an injury potential. We frequently had difficulty in removing the ragged drums from our operation due to the fact that as soon as they were empty, they would be re-used. The procedure we set up to eliminate the re-use of bad drums consisted of:

1. Having our safety engineer mark a yellow X on the torn or ragged barrels he found.
2. The foreman sends all barrels marked with an X as soon as it is empty to the scrap bin.
3. An electric magnet is dropped on the drum, thus removing it from further use.

X

A. CAVANAGH, Safety Dir., The Budd Co., Inc., Detroit.

Subject: "I'm a Bug"

We had a problem. We went through a period which many of you have gone through and many of us are starting to limp back out of—a process of changing people from being of nervous individuals, people who are unsure. In short, I'm saying

we went through a period of a potential grave hazard, the changing around of people within a plant.

We had tried quite a number of things, the same things that I know most of you fellows have tried—posters, "Safety Every-

where . . . All the Time," "Knowing is Not Enough," etc. We had posters all over the plant; we had safety committees: everything you can think of, but we still had a problem because these things had been used. They were no longer new.

I had a brain storm, and this is my baby. He did a terrific job for us in four of our Budd plants; and, because he did a terrific job, we want to hand him to you. The program is entirely new, is attention getting, is talk-inspiring, is interest-arousing and includes everyone from the president to the newest sweeper if you want to make it do so.

Our program follows four basic steps. We call this the "I'm a Bug" program. I called together my executive plant safety committee, and I proceeded to make them "I'm-a-Bugs." This little character, "I'm a Bug," is symbolic. Here's the idea. "I'm a bug on safety. That's all he is, and it is easy to guess, but you'll be amazed at the number of other answers that it generates as you unfold your purpose.

I called this executive safety committee together, and I proceeded to outline to them the four steps we would follow, and I made them "I'm a Bug" simply by putting on their lapels an "I'm a Bug" pin. They became at that moment a bug on safety. Then, we hit the personal side by saying, "Fellows, as executive safety members, you are now bugs on safety and you are the stepping stone in our program that is going to take four weeks to cover. In that time you must, to make the program successful, follow implicitly the outline. By that, I mean for the next week you cannot tell anyone what that pin means. You have only one answer. The guy comes up to you and

says, 'I'm a Bug.' What's that about? What's it mean?' You say, 'You'll find out.'"

You know, that came to be a watchword overnight. "You'll find out." Pretty soon everyone was saying, "You'll find out."

During the first week, our executive safety committee, comprised of our top management in the plant, including our plant manager, wore pins that nobody knew anything about. The following week, we conducted our monthly foremen's meeting, and at that meeting we decided to bounce this program to them. We made them "I'm a Bug" simply by handing them the pin, telling them to put it on, wear it all the time you are in this plant. Further, don't tell anybody what this is about; just say, "You'll find out."

At the end of our second week with all our foremen and all our executive safety committee wearing this pin, there was no one who knew what it was all about except the wearers. We had a lot of curiosity aroused in our plant. At the beginning of this program, the first poster appeared on a Sunday afternoon throughout that plant anywhere there was a spare piece of blank wall, poster board or anything else. That poster appeared on Sunday afternoon with nobody in the plant. People coming in on Monday morning or Monday afternoon or Monday's third shift, everywhere they looked they saw an "I'm a Bug" staring at them. And it was talked about.

The second week, as far as the employees were concerned, foremen were wearing the same pins that were appearing all over the plant on posters. During the third week, our instructions to our foremen were that they would receive as many pins as they had employees working for them. We told them, "We want you to make your people 'I'm-a-Bugs.' This is how you can do it. You can make an "I'm a Bug" out of one of your employees if you see him doing something about which you have cautioned him and he is doing it right and he is doing it safe; or, he comes to you with an idea to prevent an accident in any way or form. We don't even care if it's a good idea or a lousy idea. As long as this man is thinking and has an idea that is acceptable or not, he is thinking safety. He is a bug on safety. Make him an "I'm a Bug." Tell him why, and tell him don't divulge it but

say, 'You'll find out' to any employee that asks him who is not wearing an "I'm a Bug."

Most important we had people talking, and we had them talking about something that, to them, was important. Those in the know thought they were pretty sharp. Those who were not in the know, we double crossed; we really double crossed them.

At the end of that third week, I sent a letter to all employees in our 6,000-man plant and this included our officers. The letter stated: "We suspect that the Budd employee in your family has already let you know about the little fellow, 'I'm a Bug.' He has become well known to all our people as 'I'm a Bug' born at the Budd Company's Detroit plant less than a month ago. He gained immediate acceptance by all who met him. In the campaign he has been conducting, he gained scores of followers every day.

"The only way in which we can describe him is to say he is an idea which has grown into an attitude and that is what an 'I'm a Bug' is. 'I'm a Bug' simply means 'I'm a Bug on safety. I am such a bug on safety that I am constantly alert for those things that cause accidents. Since most accidents occur because someone does something wrong, I'm always taking a look at the way I do things. I'm finding ways to do them better and more safely. I believe in bugging other people too if I find them taking chances, but such an idea is not confined to work out at the plant.'

"A fellow's wife bugs him until he cleans up that fire hazard in the basement, gets rid of the tripping hazards on the basement stairs, puts a new bulb in the dark closet, and many more too numerous to mention; but we can retaliate by pointing out that matches should be placed out of reach of children, high heels should not be worn on highly waxed floors, the radio should not be played in the bathtub and you know how it goes; but, when it comes to being a bug on safety, just think how we bug our children, teaching them to cross the street safely, teaching them to ride their bikes safely, and teaching them to live a full life safely.

"The Budd employee in your family is probably wearing a bug pin already. It was

given to him by his foreman in recognition of a fact that the employee believes in and practices safety. (Here comes the double cross.) If he hasn't received his pin yet, maybe he hasn't earned it by using safe practices."

I never heard such repercussions as we received from that letter. We had women calling, "What's my husband trying to do, kill himself over there? Does he practice safety, does he want to get hurt, can you control him? Make him do it."

We had men coming into my office, the plant manager's office, and the superintendent's office saying, "Look I want a doggone pin. I don't want to get hurt. What's this thing all about?"

That was the fourth week. These letters went out at the end of the third, so we told our foremen the plan of operation for the fourth week. The last week you have about 40 per cent of your people who are not "I'm-a-Bugs." As yet, they still don't know what it's all about until they read that letter. Now, you take five minutes and talk to every man who doesn't have a pin on. Explain why. You watched him for weeks trying to find one thing right that he was doing safely. One little extra thing or the fact that he didn't come to you with anything concerning a safety idea. Explain to him why "I'm a Bug" is important.

Now you give him a pin. Join the group. Become a bug on safety. We finished up those four weeks and very truthfully not because of my efforts, but because of the efforts of our foremen who ran this and the employees who loved it. We had a far better program, far more results, far greater and far revealing results than we ever would have anticipated.

The Greater Detroit Council is now handling this program. It is available to you. They in turn are going to make a little bit of money on it, not much, and they are going to use it for civic projects. During the week, our foremen received their pins.

One foreman in our tool shop had at home a little six year old daughter, who asked, "Daddy, What's the pin about?" So, he told her, "This is an 'I'm a Bug' pin. The safety man gave it to me over at work today, and I'm supposed to bug people on being safe so they don't get hurt. That

means I've got to watch what they are doing. I've got to get them to work safely," and with that he closed the subject.

He came up to my office on the second day. He said, "Look, I gotta have another pin." I said, "Only one to a person. That's what we agreed. Unless you can give me one whole of a good reason that you have to have another pin, that's the only one you get." He said, "Okay; my little daughter took that pin to school with her and she wore it, and the teacher wanted to know what it was about. So she told him, 'My Daddy got this over at Budd Company and that means he is a bug on safety. He's gotta watch people and he's gotta bug them

on safety.' The teacher took the pin and put the class to work, and she proceeded to copy that little guy up on the board as closely as she could and from that day on, she started teaching safety to those children for just a few minutes a day. They became 'I'm a Bug.' 'Remember, when you go home tonight, I'm a Bug on crossing streets. Remember tonight, when you go home and you play, I'm a Bug when I'm riding my tricycle.'"

There's a big wide open field. It's quick, short, inexpensive probably less than ten cents per employee, and I hope if you use them that you'll find the results even better than what we did.

ROBERT H. CROSS, Supvr., Safety, Ternstedt Div., General Motors Corp., Flint, Mich.
Subject: Band-cutting Tool

As a result of an employee suggestion, a workable tool was developed for cutting bands on carton materials and coil steel. Present methods of cutting bands is to use some object, usually a hinge, to support band and to hammer band until it breaks. When cutting shears are furnished to the job, they disappear in a few days. The tool

developed as a substitute is much safer, is not attracted to other uses, and remains on the job.

A hardened drill rod is split, welded to a 1/4-inch pipe, and threaded for coupling to a handle. The tool is slid over the band, backward and forward motion being used until the band is sheared.

XII

HARRY A. HARRIS, Engineering Safety Coordinator, Farm Equipment and Research Engineering Center, International Harvester Company, Inc.

A. Test Engine Safety Clamp

The metal bands used to fasten our engines to skids were replaced with safety clamps to reduce the hazard of band cutting. The safety clamps fit on and become part of the skid. It is fastened with a spring loading nut, which secures the engine to the skid. The clamp can be moved back and forth along the skid to give maximum use

B. Spring Loaded Drums—Good For the Last Drop

Drums on storage racks frequently have to be tipped to empty the fluid. We put a spring loaded clamp on the rear of the drum. When the drum is full, the spring is down. As the drum empties, the spring raises the rear of the drum enough to allow the drum to empty as desired.

XIII

K. L. LEWIS, Safety Engineer, Delco-Remy Div., General Motors Corp., Anderson, Ind.
Subject: Center Post for Tumbler

This idea is for the employee who gets his clothing caught on the outside of the tumbler. The idea involves adding a center post in the tumbler with a bolt attached.

A nut is attached to the cover. This allows the lid to be fastened at the center, thereby eliminating the projections on the side of the barrel.

XIV

ROBERT BEESON, Supv., Safety and Training, Perfect Circle Corp., Hagerstown Plant.
Subject: Fluorescent Tube Disposal

Our chief electrician saw the need for a way to dispose of used fluorescent tubes. We had been placing them in a drum and hauling them to the dump. As we began using longer tubes, this was a real problem because of breakage and the tubes being difficult to handle. The machine is placed

over a steel drum for the broken glass to drop in.

We require the men to wear eye protection and gloves when operating this machine but have had no trouble with it. It really does the job.

XV

PAUL KRAMOS, Chief Safety Engineer, Butler Mfg. Corp., Kansas City, Mo.
Subject: Safety Trip Bar for Plate Bending Rolls

An emergency safety trip bar was designed and installed on a 14 inch by 14 foot plate bending roll. This roll was originally equipped with an air cylinder operated end cap and interconnected top roll lifting mechanism. With slight modifications, this safety feature can be adapted to other makes and styles of rolls.

The heart of the mechanism is the limit switch installed above the trip bar at the center of the roll. The "up" or normal position of the lever on the limit switch

has the upper contacts closed and the lower contacts open. In the "up" position, the contacts are in series with the "stop" button on the magnetic switch for the motor. On the "down" position, the contacts are in parallel with the "down" button for the solenoid operated 4-way valve which operates the end cap.

The safety trip bar has spring plungers below and stop bars above to balance the weight of the bar and to prevent vibration

from tripping it. When a foot is placed on the bar, anywhere along its length, the top contact of the limit switch is broken which breaks contact on the motor starter holding coil and stops the motor. As the bar goes on down, the bottom contact of the limit switch is closed and the solenoid on the 4-way air valve is energized, allowing air to flow to one side of the air cylinder. This forces the end cap from the roll, and in turn through a rod linkage also raises the top roll.

The solenoids for the 4-way valve, which operates the end cap cylinder, are normally

controlled by two push button stations, one at each end of the roll. After the safety trip has been operated, it is necessary to push the "up" button at one of the two stations to close the end cap or the roll. Then the "start" button can be pressed to close the magnetic starter circuit and start the roll motor.

The approximate cost of this installation is \$125 material and \$125 labor.

If additional information is desired, contact Clifford Holt, Butler Manufacturing Company, 7400 East 13th Street, Kansas City 26, Missouri.

LOW VOLTAGE SHOCK HAZARDS

By T. W. McCREADIE
Div. Staff, Liberty Mutual Insurance Co., Chicago

If I were to say that high-tension electricity deserves the utmost respect, there would be no disagreement with the statement. Let's review some of the factors involved in the injuries and fatalities from voltage less than 440 volts which is usually called low voltage and see if some of this respect cannot be extended from the high to the lower voltages.

To illustrate my first point concerning the hazards of electric shock from low voltage electricity, I'd like to review two accidents involving electricity which were written in the daily paper a short time ago.

The first case involves a girl who had a habit of listening to the radio rather constantly and had even formed the habit of carrying the radio into the bathroom. The reconstruction of the accident estimated that the radio was on the side of the bath tub and accidentally fell in the tub and the girl grabbed hold of it to lift it out receiving a fatal shock from the standard house current.

Let's move on to another newspaper item. This concerns a Charles Brown, lineman for an eastern utility, who had been working on a de-energized 66,000 volt line, using ground chain and all standard precautions. At end of job he removed the chain just as the line was energized and received severe

burns of hand arm and neck through his leather jacket. He was thrown clear, he came to, drove his car 6 miles to a hospital and then spent 6 months in the hospital recovering from his burns.

Why did Charles Brown live through an attack by 66,000 volts while the girl taking a bath and many others you have read about in the newspapers die with ordinary house current of 120 volts?

The difference between the two incidents is contact. By the law of electric circuits called Ohm's Law, current equals voltage over resistance. To rephrase this law as it might apply to a shock condition we can write this law as follows: Current through body varies directly with the voltage applied to body and the resistance of that body. Resistance in turn is dependent upon amount and condition of body contact.

Current through body

Voltage applied to body

Resistance of body and contact

By means of an illuminated meter and electrodes I will illustrate this principle.

If you will watch the movement of the needle on the meter you will see how much current flows through my body under dif-

ferent contact conditions although the voltage in the circuit is consistent throughout, 90 volts. You notice that when I touch the two contacts together the needle swings to about 100.

Now as I gingerly hold these contacts with the fingers of each hand you will notice that there is a movement on the needle but it is not very high. As I contact more of each hand onto the electrodes you will notice that there is an increased amount of flow and as I grip the electrodes tightly with each hand I get rather closely to the direct contact reading that we had initially.

What have I been doing? The voltage has been constant, there has been no change in the internal resistance in my body and this highly variable shock current has been produced merely by changes in the contact resistance.

We can now see why low voltage shock varies so much from a trifling tingle to a severe jolt and sometimes to a lethal dose of electricity depending upon how poor or how good the contact resistance is that connects us to the circuit.

Take a situation in your own home. Under what conditions are you likely to be making good connection to ground and at the same time a good contact to some defective electrical device? Your basement is a somewhat dangerous place because basements are damp, but of all places your bathroom is the most dangerous.

If you get into a tub of water you have a very large area of wet contact with ground through the water in the tub and piping eventually leading to the earth. If you handle any portable electrical device whatever, whether it be a defective curling iron or a defective portable heater or a defective motor-driven device or a radio that had fallen into the tub you may touch a part that has become charged and your resistance of the body and its contact will be extraordinarily low. You will get a correspondingly severe shock to your body.

Now to illustrate to you how accidental electric shocks may occur through use of common electrical devices we have what I will call a Robot. This Robot is an associate in a uniform, on which are fastened strings of small lamps. These lamps will show how the flow of electricity would pass through his body when handling defective

devices. You may be sure however that we carefully insulate both of his hands and both of his feet from the contact in this demonstration.

These wands that I hold are now connected into the circuit supplied by the lighting system of this building. The most common form of contact is hand to hand, across one arm crossing near the heart and down the other arm. Again, the current may enter by the right arm, travel down the whole torso and leave by the right leg, or could cross over and leave by the left leg.

Now the Robot stands on two strips of metal, one foot on each and the wands are touched to the strips. Now this goes up one leg and into the torso and down the other leg and out. This is the type of shock received by a man stepping from the running rail to the third or live rail of a rapid transit system.

Now the Robot has both feet on a metal strip that represents a wet floor or ground outdoors and his right hand grasps a wand the other wand being moved down to the metal strip. Note this carefully as it is the most common way in which people get electric shocks. Standing on the ground they take hold of some electrical device that is defective and receive a charge in this manner. As you see, the current comes in through the hand and the current flows down the torso and slips into two branches, one going down each leg to each foot to ground. You will note that the lamps on the arm burn more brightly than those on the two legs.

The question of how electricity kills is one to be answered more properly by the medical profession, however, there seem to be basically two causes paralysis of the respiratory center and fibrillation of the heart muscles. The paralysis of the respiratory center has probably been well proven by the many instances of successful artificial resuscitation. This is a situation in which manual movement has overcome the paralysis of the respiratory center.

The situation in fibrillation is that when the stimulus given heart muscles by the electric current the heart is caused to flutter and operates so rapidly that it cannot perform its normal function and death follows very shortly. There have been instances of laboratory control. I am told, when the application of an equal and opposite electric

shock has successfully stopped fibrillating action, but this is only under precisely controlled laboratory conditions. In most instances a heart that goes into fibrillary contraction seldom comes out of it again.

Before we go into the demonstration of the equipment which we have on this panel I probably should first cover the point that has been made by some people that their house circuit is protected with fuses of rather low capacity 15 amps. In this equipment we have a 6 ampere fuse and I shall not depend on it for protection. In experimental conditions 220 volts with 1/4 amp. has killed a cow and I don't feel I am quite that strong.

Now I would like to show you the normal grounding circuit usually found in homes. The public utilities ground all their equipment, and the house equipment is usually grounded at the meter.

I have displayed on this board a variety of lamp sockets very commonly used for different purposes, and all are plugged into receptacles for operation on the supply line coming to this table. This demonstration is not a criticism of any manufacturer nor of any product.

These metallic sockets, for example, are perfectly safe to handle where the person using them is not grounded and where the live parts inside them have the insulation in the manner originally constructed, and have not become defective through moisture or damage. Also they must have been properly and carefully wired so that not even a single strand of wire is carelessly contacting the outside metal shell. To be certain, it is considered better judgment not to have brass shell sockets where it is possible to grasp the socket and be standing on ground of any kind.

On this next brass shell socket we have a pull chain. You will observe that the shock current continues whether the light is on or off. Please observe that the shock current continues even though the robot leaves the shell itself and starts down the pull chain. Of course when he passes the insulating link he is in a protected area.

We have seen a newspaper article concerning an overhead lamp in a boiler room in which a wire had been used to lengthen the pull chain and there was no insulating link. When an employee with wet shoes

attempted to light this lamp he received a fatal shock. The insulating link is not expensive but is very important. It is preferable to have these installations operated from wall switches.

The porcelain type socket should not be used where it would become subject to physical damage. On this next socket with a pull chain the porcelain is an excellent installation but any metal on the outside of that socket tends to make that socket potentially dangerous. None of the four sockets demonstrated thus far should be used under moist conditions.

This next socket (rubber covered, with pigtail) is one that should be used where moisture exists, such as in a laundry or basement and similar places. Even though this next and last socket is a safe one, it still requires proper maintenance and care to prevent damage to it. I observe that the Robot has indicated a shock current. I see that the socket is damaged. Apparently it was struck by something and the rubber got torn.

Now let's consider some industrial applications of electricity and the hazards of fixed and portable electric devices. First we'll wheel in our facsimile of a 50 hp motor. Any motor this large, of course, is securely bolted in place on a frame. Power is usually supplied in conduit. Installation is in accordance with the National Electric Code, and the frame is grounded.

However, as in the case of the electric lamp sockets we would like to show you that this motor will operate whether it has a defect in it or not. The Robot will step forward, please, and hold this motor. The motor is operating satisfactorily. This motor has a defect in it. The internal insulation has been damaged and has contact with the case of the motor.

The Robot will now put his foot on the grounded plate. Note that the motor does not change speed but that the lights come on, indicating a shock current from the motor through the body to ground. The National Electric Code requires grounding of the metal frame of the motor either through continuous conduit connection to ground or separate metallic connections to ground. This is a standard practice. This required grounding protection should be checked at intervals to be certain that it has not deteriorated and become useless as protection.

When we were talking about the contact through ground we frequently mentioned moisture. The Robot and I would like to demonstrate how little water is necessary to create this current-conducting moist condition. Notice that I have now fixed the ground plate so that there is a piece of blotting paper between the ground connection that we have to the water faucet and the plate on which the Robot is standing. I will now take about, oh, say a quarter teaspoon of water and place it in the holes on the top plate on which the Robot is standing. (At this point the lights on the Robot come on gradually.)

You will notice that not much water was used and there is now a complete ground circuit in operation. At this point it might be well to mention that several studies made at a munition plant during the last war proved to their satisfaction that concrete was a good conductor for relief of static charges, so let us, for purposes of electrical installations, not consider concrete automatically as insulation. Wood, rubber, leather are consistently better.

I have heard of instances where multiple deaths were due to electric shock because the person or persons observing the initial accident rush to help without taking proper precaution of disconnecting power or insulating themselves from the shock current. One incident that comes to mind is the one that occurred a short time ago in a coal yard where a coal loader which operated on 220 volts was being moved to a new location in the yard by two men and in the maneuver the supply cord which had not been disconnected was twisted in such a manner that the frame of the loader became charged.

The two men were instantly killed and two others observing the accident ran over to lend assistance and also were killed. There also has been a recorded instance of an employee teaching another employee how to operate an electric drill, the drill was defective and while the men had their four hands on the drill their feet touched a grounding source and both were killed.

In talking about electric drills, let's see our expensive half inch drill so that we may demonstrate the addition of a ground wire and the benefit which can be derived from such protection. As I said on the

sockets and as I have repeated, when manufactured the equipment is in good order and is safe to use, but through abuse, misuse, moisture or some other contaminating influence the case of the machine can be electrically charged. Now you will notice when the Robot holds this drill it continues operating regardless of the fact that it is defective and some current is passing through the Robot's body.

Let's change the equipment so that we can demonstrate the benefit of a grounding device. Now we are placing this ground wire on the frame of the drill and we will plug it in so that it will operate. You notice that a fuse has blown and that the lights on the Robot did not light up.

Through the use of this ground wire we provided a path for the electricity which was easier for the electricity to travel in than through the body of the user.

Check your equipment to make certain that the additional wire which the manufacturers are supplying as standard equipment on portable tools is always used for a continuous circuit to ground and is not being considered as that "little pigtail that is in the way" and is snipped off. It is a life-saving feature that can only save a life when it is utilized.

To summarize: control the situation of one hand on a faucet and one hand on a bare pull chain—get an insulating link in those pull chains, if you cannot put in a wall switch.

Electrical devices used in the bathroom should not be near the tub, that is the point of the maximum low resistance contact.

Portable tools should be grounded, extension cords should have a third wire so that they can carry the ground back to the proper location when a portable tool is used at a distance from the socket. Large portable machines should have polarized plugs so that they cannot be used without being grounded first—like this type of outlet. (Hold up polarized plug).

Electricity can continue to be your best servant if you do not let it get to be your master. Use the protective devices available, make sure that all others do too. Spread the gospel that electricity should have respect whether it's high voltage or whether it's low voltage.

POWER PRESS AND FORGING SECTION HOW POWER PRESS OPERATORS GET HURT

By E. D. SALLEE
Mgr., Safety & Industrial Hygiene, American Can Co., New York City

Even to a neophyte in the business of attempting to improve effectiveness of a power press safety program, the title of this presentation may seem somewhat trite. Everyone who has seen a power press in use undoubtedly has some definite ideas of the types of personal injury hazards involved, and how the press operators might get hurt unless effective preventive measures are maintained.

It is probable that most such opinions are correct. It certainly isn't difficult to arrive at the conclusion that getting hands or fingers under a descending press punch can result in tragic, bloody injury. This is the picture, apparently, that commonly enters the mind during everyone's first consideration of power press safety. But this is far from the complete story. Keeping hands out of the area between a punch and die is of cardinal importance. However, it is only one of a great number of aspects that are essential in a good power press department accident prevention program.

American Can Company has been both a manufacturer and a user of power presses for the past sixty years. We have learned a great deal about power press safety during that time—and there is much more to be learned. A check with several other major users of power presses indicates that their accident facts, and development of preventive measures, closely parallel ours. Sharing of this experience may spark some ideas on how you may improve your accident prevention effectiveness.

The purpose of this presentation, therefore, is to review the facts about causes of accidents among press department workers in my company. From such analysis we get pertinent and helpful information on who gets hurt, where they get hurt and how badly; and most important, how and why they get hurt. Facts on these salient points then lead to logical steps on how most effectively to go about eliminating the causative factors.

The study covers all power press department accidents reported in our metal operations last year. Some 2810 of the presses are for punching out and forming the ends for metal cans at rates up to 400 strokes per minute. About one-third of these are automatic, the operator's main task being merely to keep the feed hoppers filled with stock. About 2000 of the total number of operators work at either semi-automatic single-action presses in which the plate is fed and positioned by hand and the press activated by a foot treadle. Plate fed into the presses ranges up to 24 gauge, although the bulk of it is in the order of 0.006 to 0.009-inch thickness.

We consider our presses well-guarded. Each of them is provided with a point-of-operation barrier, the flywheel is totally enclosed and there are no exposed gears. Where the point-of-operation guard is the hinged type it is connected to an electrical interlock to shut off power when the guard is open. Die blocks and appropriate tools for cleaning scrap or "jams" from the dies are provided with each unit. Scrap and product ejection or stripping is automatic whenever the press is practical.

A great deal of time, effort and money has gone into the attempt to make the presses free of significant hazard. We are convinced that this has paid off. Despite this, however, we are far from satisfied with our press department injury rates.

In view of the money and effort spent toward eliminating hazards, it is sometimes a little difficult to explain why accident costs and frequency rates are not lower. The answers, of course, can be found by digging out the accident facts—the causes or reasons for the accidents that result in employee injuries.

In this quest for accident causes it would seem only natural to turn to the persons who are closest to the operations—the press department foremen and their long-service employees. One would think, certainly, that

the individuals with many years of direct on-the-job experience would have some clear-cut opinions on who gets hurt, how and why.

We find, however, that even among these experienced specialists there is divergent opinion. The operators and mechanics themselves are prone to attempt fixing the blame on the machine, the materials and tools furnished or the working conditions, but rarely on the possibility that they made an error or committed an unsafe act. The foreman, on the other hand, has a tendency to over-emphasize employee shortcomings and generally play down any unsafe conditions, since admitting to the latter would be largely self-criticism.

On many occasions we've asked press department foremen for their opinions on the greatest sources of employee injuries in their respective departments. Despite the fact that their departmental accident records were essentially the same and the equipment and working conditions practically equivalent, we usually get varied answers to this question. The following opinions are typical:

"Operators swing the guards away and stick their fingers between the dies to clean them out, rather than using the picks or longers."

"Mechanics neglect to use the die blocks."

"Operators now-a-days just aren't careful."

"Operators 'jimmy' the limit switch so they can open the guard with the press still under power. Get jimmy-proof switches and we won't have any more injuries."

"Despite all the care taken to assure good clutch maintenance, brake motor maintenance, etc., once in a blue moon something goes wrong and we get a 'repeat'. Eliminate repeats and you've solved the problem."

"The mechanics get in too much of a hurry and put their fingers between the dies before the flywheel has stopped, even though the power is turned off. The press repeats and they get hurt."

"The set-up men often want to try out the machine before replacing the guard. Make sure the guard is always replaced before the power is on or the flywheel can be moved, and you'll have no accidents."

Most of these are good observations. Even though they're varied, they have one thing in common—there is universal concern for prevention of the exceptionally severe injuries, the bloody and tragic amputations. The cases in which descending dies chop off hands or fingers are the more morbidly dramatic or spectacular type, and it is natural for these to stick in the supervisor's mind.

But these are certainly not the complete picture. If press department supervision's preventive efforts are limited to forestalling such injuries, largely neglecting the myriads of other potential sources of accidents, then trouble in large doses is bound to result. Any really successful preventive program must be well-rounded, and it must be based on fact. The general impressions related by individuals, even those with direct work experience, can be misleading.

Accordingly, we have made extensive effort to establish the facts about our accident prevention needs. We find that proper use of past experience is a major aid in getting the needed facts. For that reason for the past several years we have been using a business machine system for correlation of information obtained in accident investigations. Each accident that results in injury of such severity as to warrant a doctor's attention is thoroughly investigated, with particular emphasis on the accident causes and the preventive action taken to prevent recurrence. The information is then coded and transferred to punch cards, from which correlations of company-wide experience can be obtained conveniently for any type of operation, type machine, type injury, etc. It's a good tool for getting maximum use from accident investigation information.

Use of such means of data correlation requires, of course, that the numbers involved be large enough to warrant business machine tabulation methods, and that the information fed into the machines is valid and representative. We find that correlation of all "doctor case" accidents satisfactorily meets these requirements. With respect to accident causes the information on the sequence of events or circumstances culminating in a particular type accident does not necessarily vary with severity of injury. It's the severity of the injury that is frequently influenced by chance, not the prime causes of the accidents.

For purposes of this particular study our 4262 press department employees were grouped in three categories according to their work duties: (a) 66 per cent are operators whose duties are to feed the press or off-bear, (b) 22 per cent are mechanics whose duties include all die-setting and direct maintenance, repair and adjustment work, and (c) the remaining 12 per cent are other press department employees with various miscellaneous jobs such as operation of equipment auxiliary to the press operations, bringing stock to the press area, packaging finished product, janitor work, quality control inspectors, electricians, etc. No employees in this third category work directly on or with the press machines, although all of them are engaged full time in the immediate vicinity of the presses.

Last year our press department employees made a combined total of 40,000 individual visits to our plant first aid rooms for occupational reasons. These same employees suffered a total of 610 doctor-case injuries, of which 42 were disabling. Detailed analysis was made of the accident investigation information on the 610 doctor cases and results of the correlation are summarized in the accompanying charts.

Fig. 1—Press Dept. Accidents—How They Got Hurt

Figure 1 shows the incidence of doctor-case injuries for the three categories of press department employees. For convenient comparison purposes, incidence of these cases has been converted to the familiar frequency rates—the number of injuries per million man-hours worked. Bear in mind these are doctor-case frequency rates, not disabling injury frequency. Note that per unit of time worked operators get hurt significantly less often than mechanics. Other workers in the department also get hurt

more frequently than operators and at practically the same rate as mechanics. The press machines themselves, however, are not involved in the accidents to the miscellaneous workers in the department.

The relative magnitude of the overall preventive or corrective attention required is a function of the product of frequency rate times number of employees in each category—66 per cent are operators, 22 per cent are mechanics, and other workers in the department comprise 12 per cent of the department population.

Fig. 2—Press Dept. Accidents—How They Got Hurt

Figure 2 shows who suffers the extremely severe or disabling injuries. For purposes of this discussion we have further classified these in terms of frequency rates for (1) the so-called dramatic or spectacular injuries (permanent partial disabilities), and (2) all other disabling injuries. The latter involved no permanency of disability, just lost time only. Note that all the spectacular injuries were suffered by press mechanics and operators, none by other department workers. Four operators and two mechanics had fingers amputated—all during work directly at the presses. The remaining four spectacular injuries (permanent partial disabilities) were severe lacerations and fractures, all of which occurred during work at the presses. However, only 10 of the total of 42 disabling injuries, or 1.6 per cent of the total doctor case injuries, were of the spectacular type—the type that foremen and many others tend to remember, and to base preventive action accordingly.

Figure 3 is summarized information on where the employees were working when they got injured, shown as doctor case frequency rates, in which the power press

Fig. 3—Press Dept. Accidents—Where the Injuries Occurred

itself was directly involved. This is compared to incidence of accidents when the press machines were not involved. Note that with all categories of press department workers, far more accidents occur at activities away from their machines than at them. While the spectacular injuries are more likely to be suffered at the presses, the large proportion of other injuries incurred away from the machines warrant commensurate preventive effort.

The next four charts, Figures 4-7, present more detailed basic information on the nature of accidents and injuries to these same employees. Again, the data are expressed in terms of doctor-case injury frequency rates. Only the more important factors are shown. The several additional miscellaneous items involved in the accidents and resultant injuries, while important individually, are too few in number to influence general direction of a preventive program. For general comparison purposes, data on these same factors are given for all plant employees, to give a better idea of how press department workers rank in our overall accident prevention program.

Figure 4 gives relative incidence of the various Parts of the Body Injured. Fingers and thumbs are the most frequently injured members in all of our operations, but note that incidence of such injuries is considerably worse for press mechanics than for the average plant employee. Press mechanics also give their hands a bad time. As will be noted later, much of this is due to mishaps in their use of hand tools, which is an obvious hazard in common with duties of mechanics in all departments.

Injuries to wrists, arms and elbows among press department personnel are only slightly

Fig. 4—Press Dept. Accidents—How They Got Hurt

higher than the general average, but press mechanics again have the worse record.

For other press department employees (those that handle the material skids, pallets and other bulky items), there is a prevalence of damage due to their dropping these materials on their feet and toes.

Figure 5 is a summarization of the nature or type of injury suffered. As might be expected where the major material handled

Fig. 5—Press Dept. Accidents—How They Got Hurt

is sharp-edged plate, cuts are the most common injury. As might be expected, incidence of these lacerations among press operators is higher than the company average—press operators have higher than average exposure to tin plate, in feeding the presses, off-bearing, piling and unpiling it, clearing jams and wrecks from the machines and conveyors, etc. But incidence of cuts suffered by mechanics is surprisingly high despite the fact that, by comparison, they handle plate relatively infrequently. Indications are that since handling plate is not part of their regular routine, they have not developed the knack of handling it safely.

Miscellaneous press department employees are out of line with respect to incidence of bruises, strains and sprains. This too is in keeping with the fact that they handle the bulky and heavy materials.

Fig. 6—Press Dept. Accidents—How They Got Hurt

Types of accidents in which these workers are involved are recapped in Figure 6. Accidents in which employees inadvertently "strike against" (objects, surfaces, machines, materials, etc.) are the most common type. Mechanics are again the bad offenders in this category. Mechanics seem to have a rough time in inadvertently banging their hands against machine parts, guards, etc., when their wrenches or other hand tools slip.

For other workers in the press department,

the accidents involving "sliding and falling objects" are the most common. This is plausible since these are the workers that are occupied principally at material handling and transporting jobs—work around stacks and piles of raw materials, skids, finished product, etc.

The "caught in (on, or between)" category includes, obviously, our few spectacular injury cases as well as the accidents resulting in less severe injuries. Mechanics have the poorest experience, getting fingers caught under dies, or lacerated or bruised in plate feed or product discharge mechanism. Note, however, that incidence of such accidents is comparatively low for operators, which speaks well for our guarding effectiveness. These are the factors, of course, that make good guarding imperative, with particular emphasis on employees' effective use of the guards.

Note, also, that even with the press mechanics the "caught in" type of accident is not the most common. They represent only one-fifth of all injuries suffered by mechanics. Obviously, it is a highly important proportion of their mis-haps, but it should not be over-emphasized at the expense of overlooking more frequent types of injury.

Figure 7 is a recap of the item most closely associated with the accident. It is that agency or item which was used improperly

Fig. 7—Press Dept. Accidents—How They Got Hurt

or could have been corrected. Note that both operators and mechanics get hurt more frequently than the average employee due to handling plate. Other employees in the department don't routinely handle plate—their mis-haps with plate are primarily due to inadvertent brushing against stacks of it or in handling the scrap. But these miscellaneous employees routinely handle or are exposed to various materials other than plate, such as trucks, skids, cartons, packages, etc., and their accident experience is influenced almost proportionately.

As mentioned previously, mechanics have a comparatively high incidence of accidents in which hand tools are involved, the most common type being improper use of wrenches in tightening or loosening a nut—the wrench slips off and they bang their hands on the machine or other objects. Also as might be expected, the mechanics have relatively high incidence of accidents in which machines are involved. This "figures" since most of their work is with machines.

Up to this point in our discussion we've reviewed facts about *which* press department employees get hurt, where they get hurt and how. It's sometimes hard to differentiate between *how* people get hurt and *why* they get hurt. Let's now examine some of the reasons *why* press department workers get hurt, as shown by analysis of information obtained on their accidents last year. These are the unsafe acts, the unsafe conditions and other factors which contribute to the sequence of events and circumstances resulting in accidents.

Starting with the unsafe acts, Figure 8a lists the most common incorrect actions that led to the various injuries suffered by our press department workers last year. Taking an unsafe position, with respect to the work being done or the particular activity in which the employee was engaged, was the most common error resulting in injury. This includes a variety of unsafe acts, such as: climbing on, over or around machinery or other items; sticking hands and fingers too close to a recognized hazard; standing, walking or sitting in the way of department traffic, trucks or other workers doing their jobs, etc. In each instance such actions were entirely unnecessary to perform the work and are in violation of established safe practices. They are not the type of hazard that can be controlled by further guarding

Fig. 8a—Press Dept. Accidents—Unsafe Acts

or practical alterations in production processes.

Unsafe lifting and carrying results in a significant number of accidents but press department workers are no worse than the average plant worker in this respect. Using equipment, tools, etc., unsafely is also a significant causal error although, again, press department people are no worse than others.

Cleaning, adjusting or repairing equipment while it is in motion results in comparatively few accidents but we are particularly critical of these since such accidents are almost invariably the bad ones—the spectacular injuries mentioned previously. It is a cardinal rule to do this work only when the machine is stopped and power turned off—but, obviously, there is not always strict compliance.

There are, of course, several other specific types of unsafe acts, not listed, accounting for a combined total of about one-quarter of the total unsafe acts committed by press department workers, but the numbers of these additional individual types of unsafe acts are too few to be statistically significant. As indicated, there are also a number of accidents in which no unsafe act was committed, the mis-hap in such cases being due entirely to an unsafe condition or other contributing factor other than an error by the injured employee.

Fig. 9a - Press Dept. Accidents - Unsafe Acts

Figure 9a gives further breakdown of common unsafe acts committed by press department workers. Note that operators are better than average in refraining from positioning themselves or parts of their bodies in vulnerable positions. But mechanics, and particularly the other press department workers, frequently get out of line in this respect.

In unsafe use of equipment and tools, mechanics and miscellaneous workers are the frequent offenders.

Violation of the rules prohibiting work on machinery in motion is most common among mechanics, but in view of the relative proportion of time spent in direct work on machines, they are probably not worse than the average employee. This particular unsafe act gets our safety men hotter under the collar than any other rule violation, because of severity of injuries involved, but "machinery in motion" accidents actually account for only 7 per cent of the total.

The influence of unsafe conditions in our press department accidents is summarized in Figure 9b. These data corroborate our justifiable pride in our guarding program, and the success achieved in controlling unsafe conditions. Unsafe acts are involved in 88 per cent of our accidents in press departments; unsafe conditions in 30 per cent. In 18 per cent of the cases a combination of unsafe act and unsafe condition is involved.

Fig. 9b - Press Dept. Accidents - Unsafe Conditions

If we could eliminate all unsafe acts our accident toll would be reduced 88 per cent. This, obviously, is where major preventive effort is in order.

Fig. 9c - Press Dept. Accidents - Unsafe Conditions

Figure 9b gives further breakdown on the major unsafe conditions encountered by our press department employees. Housekeeping, congestion of equipment and materials, or their hazardous arrangement, are the prime factors in this category. Housekeeping is critical with respect to mechanic accidents—it is sometimes difficult to maintain good housekeeping when machines are torn down for repair or overhaul. Hazardous arrangement of materials, of course, is

significant in the safety of the miscellaneous department personnel that handle bulky packages, skids, etc.

Fig. 10 - Press Dept. Accidents - Contributing Factors

In many instances there are readily discernible reasons why unsafe acts are committed or unsafe conditions develop. We call these contributing factors and they are recapped in Figure 10. In any good investigation of an accident, effort should be made to find these underlying reasons. Not all accidents, of course, have recognizable contributing factors, but where they are known, such information can be decidedly helpful in programming preventive efforts. Known disregard of instructions, for example, plays a significant role in the unsafe acts and resultant accidents occurring to mechanics and miscellaneous press department workers, indicating need for further enforcement. Lack of knowledge or skill points up deficiencies in getting workers adequately trained. In our press department this training or skill deficiency accounted for a total of 6 per cent of our accidents. We were able to recognize definite contributing factors of one kind or another in only 40 per cent of the press department factor-case accidents. Others, not detailed on the chart because of their relatively small number, are physical deficiency of the injured person and unsafe actions of persons other than the injured person.

Summarizing the highlights of this entire study, our experience shows:

- Press operators get hurt less frequently than either press mechanics or

the other miscellaneous workers in power press departments.

- Almost half the press department injuries are suffered by employees other than the machine operators.

- In only one-quarter of the total press department accidents was the press itself directly involved. The remaining 75 per cent were suffered at activities other than press operation or maintenance.

- All of the extremely severe injuries were suffered at the presses although these account for only one-quarter of the total number of disabling injuries in the press department.

- Cuts and bruises from handling stock and other materials are by far the most frequent type of press department worker injuries.

- Unsafe conditions are the cause of relatively few press department accidents. Unsafe conditions alone resulted in only 12 per cent of our press department injuries. Unsafe acts alone resulted in 70 per cent of the accidents. In 18 per cent both an unsafe condition and an unsafe act were involved.

The foregoing is *how* power press department employees get hurt. But there is little point in digging out the facts on how people get hurt unless this is followed up by what's to be done to keep them from getting hurt. The only real purpose of getting accident facts, such as those just examined, is to point out the most effective means of prevention.

In our war against accidents one of the fundamental points requiring further emphasis is *our defense*.

We are all familiar with the benefits of emphasizing defensive driving in street and highway traffic safety—the driver is expected to be on the alert at all times for any damnable thing any other driver might do to trigger an accident. And the driver is charged with a preventable accident if he fails to do everything he possibly can to avoid or prevent the accident.

Certainly, in our war against accidents in our plants we should do no less than to take the same *defensive* stand. We must be on the

alert at all times to any factor—unsafe act, unsafe condition, improper attitude, or whatever it is—that might lead to an accident. And knowing as we do that almost every accident in one way or another is preventable, we can't be satisfied with our efforts until we have done everything we possibly can to forestall an accident.

Keep in mind too, the old adage that in war the best defense is a good offense—we have to be aggressive in going out looking for those unsafe factors and attitudes to be successful in rooting out the hazards and potential troubles before they cause accidents.

To do everything we possibly can to prevent the wide variety of pressroom accidents means doing a lot more than merely putting guards on the presses and keeping them in good condition. Even though these factors are all-important, a lot more must be done. It means that in addition to controlling unsafe conditions we must work out safe operating methods, improve employee safety attitudes, effectively enforce safety rules, and a host of other items—in short, a "complete" accident prevention program.

Well then, what is a "complete" program?

You've undoubtedly seen a great number of write-ups on this subject. I don't have any startling simple, new or magic formula. I don't believe it's possible for anyone to come up with one. It still takes a lot of work to get optimum effectiveness in prevention of accidents. However, there are several fundamentals that I consider imperative for a program to be adequately effective and I'd like to re-emphasize these.

I Get the Facts

Every good program must be based on facts.

What accidents are being experienced, or are potential?

Who is likely to have them? Where? When? How? Why?

This calls for observation, study, investigation, analysis.

II Use the Facts — Promote Safety Awareness

There must be a purpose and aim of the fact-finding, and appropriate planning of how the facts are to be used. This calls for clearly defining

the purpose or aims of the preventive program and communication of the facts—the accident data, the causes, the *why* is. They must be communicated upward to top management, and back down in appropriate form to the people charged with carrying out the detailed preventive action, the foremen and employees. The facts must be used as tools for building accident prevention awareness and safety-oriented attitudes on the part of everyone—the top boss, foremen, employees.

III Eliminate Unsafe Conditions

Having gathered the facts and communicated them properly, specific action must be taken—what we must *do* and get others to *do*—to prevent accidents. Such action includes the safety engineering — improving or changing equipment and layout, guarding, improving job processes, minimizing potential hazards, etc.

IV Eliminate Unsafe Acts

This phase of detailed action calls for general safety indoctrination, specific job instruction, and their appropriate follow-up. The latter includes enforcement of safe practices—all the time.

V Get the Right Safety Organization

This is the all-important part that makes or breaks the entire program. Active acceptance and support of the safety program by top management is essential, since only management can make other parts of the program possible. The safety engineer does not by himself create a safe plant—he must get other people to think and work safely. The "safety organization", therefore, includes top management with his insistence that accident prevention be an integral part of every job, from manager on down through staff, supervisors and employees. Included in management's responsibility for seeing that there is proper organization to implement the program—management must (1) provide the safety specialists charged with the task of gathering and using the facts and coordination of acci-

dent-prevention functions and (2) management must see that all supervisory personnel and employees have

opportunity and facilities for carrying out their accident prevention responsibilities.

Furthering the simile that our job is to war against accidents and injuries, this five-point program can be shown graphically in the geometric figure illustrated in Figure 1. It is the "Pentagon" from which our war is directed.

Several conclusions can be drawn from this graphic presentation of the program:

1. The center or core is accident prevention. This helps us keep our sense of proportion—there is no point in an elaborate safety "program", as such, unless it prevents accidents. And the most informal of programs can be the

best one, if it does the best job of preventing accidents.

2. This geometric picture illustrates the theorem that, formal or informal, our safety efforts are incomplete unless all five parts are there. Any single missing element weakens or destroys the whole structure.

3. And in common with all symmetrical figures, it looks the same from any angle. It's possible to start from any angle and still wind up with a balanced, effective program as long as you make sure that all five parts are included.

I prefer to start with the facts of the safety problem, then use them to get the purpose of the preventive effort clearly understood. From there I would proceed toward getting the detailed action done—correcting unsafe conditions and unsafe acts. But no part of the program will proceed properly unless we have proper management interest and direction.

One closing comment on points III and IV, the action phases—in this entire discussion I have attempted to emphasize the point that it is essential to have a complete, well rounded program for prevention of accidents in the power press room. Persons who feel that the only really important factor is making the equipment or physical working conditions as safe as practical are most surely due for a rude awakening. Certainly, if your presses are unsafe, you can make a big dent in your accident record by correct-

ing the unsafe conditions. But if you do only this, you'll still wind up with far too many accidents and injuries. The best guarding program in the world won't stop all accidents. Remember, by far the majority of them are caused by unsafe acts.

Please understand clearly, however, that it is not my intent to de-emphasize in the least the importance of guarding or maintenance of safe presses. This is of cardinal importance and tempo of such action must be increased, never reduced. My plea is that for optimum effectiveness include all the important factors in your program. Even though unsafe acts may cause more accidents than unsafe conditions, don't expect employees to cooperate fully in correcting their errors unless it has been demonstrated first that every reasonable effort is being made to control unsafe conditions—which is the exceedingly important theme of the panel discussion to follow.

THE NEW POWER PRESS SAFETY CODE

(An interpretation and discussion of the 1960 revision of the American Standard Safety Code for Power Presses, B11.1-1960.)
Moderator: ARTHUR S. KELLY, Asst. Mgr., Industrial Dept., National Safety Council, Chicago.

(a) PURPOSE AND SCOPE OF THE CODE SECTION II—DEFINITIONS SECTION III—REFERENCES TO OTHER CODES

By ARTHUR S. KELLY

This revision of the B11 Code was finally completed in December of 1959. It was approved as an American Standard on January 19, 1960 and was published the middle of this year.

The American Standard Association is really a federation of national organizations brought together in the interest of standardization. It includes engineering societies, federal and state agencies, trade associations, representatives of employees through the A.F.L.-C.I.O. organization and it is administered by a staff of about 110 people. It is made up of a series of boards and com-

mittees that are responsible for the development of these standards. The top group in the American Standard Association is the Standards Council. ASA is made up of what they term representative member bodies.

Operating as an arm of the Standards Council are some 18 Standards Boards. There is an Electrical Standards Board, a Mining Standards Board, a Nuclear Standards Board, a Safety Standards Board, etc. Each one of these Boards develops and approves the standards within its particular scope of interest. In some instances there is an overlapping of interest between two

Standards Boards, in which case they set up a coordinating committee to cover the particular problem.

Individual safety standards are controlled or sponsored by trade associations, engineering societies, government agencies and others. Please keep in mind that any standard is a voluntary standard. The basic requirement for approval of a standard is that the standard represent a favorable consensus of the committee developing it. I will probably use the phrase "consensus" repeatedly.

Anyone who has an inherent interest in the scope of a standard may have representation. Usually this representation is through an organization to which the particular person's company belongs. Nevertheless it is entirely possible for an individual company to be represented if it cannot be represented otherwise.

The membership of a committee developing a standard by the sectional committee method includes six basic groups: (1) manufacturers of equipment, (2) users (purchasers) of equipment, (3) government agencies, (4) representatives of employees (labor organizations), (5) independent specialists such as technical and professional societies and associations, and (6) insurance agencies.

The interest of the members of a committee, as well as everyone concerned with the code, are further protected by the ASA requirement that not more than one third of the total membership of a sectional committee may be made up of one of these particular classifications or groups. In other words, there is no way to load a particular sectional committee, a policy very carefully controlled by the Standards Council.

It is true that standards can become the basis or background for safety regulations. In fact, some states adopt a standard almost verbatim and make it a matter of law within their particular state. I should like to point out however that the B11.1 code was first published in 1922, and in the intervening 39 years only 9 states have adopted this code in its entirety. Other states have adopted portions of it and have written laws concerning the safe operation of power press equipment which vary from the code.

This code has been revised four times since 1922, the last time in 1948.

The need for further revision was realized several years ago. The large number of press amputations which continued to occur and the past experience with press equipment clearly showed the need to give serious thought to improving safety in press operations.

The press manufacturers have done much, particularly during the last ten years, to improve the safety of press operation. Such improvements have included better frames, improved clutch mechanisms, the development of better press control systems which made it possible to apply tools and dies that permitted automatic, semi-automatic or even remote feeding.

Power press design features developed within this decade also have facilitated the application of safety devices that insure operator safety on those operations which have to be fed "under the punch."

While this improved technology is now available, it will be years before the total effect will be apparent in press operations. The average age of the more than 250,000 presses in operation today, is about 20 years. By converting clutches, air valves, limit switches and control systems, many of the older presses can be brought up to date.

To return to the American Standard Association for one reference, I want to tell you that the Review or Steering Committee, which developed the draft of the present revision was maintained in proper balance insofar as the six classifications of membership were concerned. The Review Committee was divided into five subcommittees, and the chairmen of these subcommittees had the privilege of going outside the B11.1 sectional committee for the members of his subcommittee.

Also I want to say a word about the Appendix. The Appendix is not a part of the code. The Appendix is intended to interpret the code provisions and to explain and illustrate how the requirements of the code can be complied with by companies with press operations. It gives many examples and many hints that will help apply the standard.

Now I should like to refer to the Foreword of this code. It, also, is not a part of the code itself. For one thing, previous editions of this standard dealt with hand and foot presses as well as power presses. It was felt by the committee that a separate stand-

ard dealing with hand and foot presses should be developed and this project is under consideration. Mr. L. A. Faulkner whom I have introduced to you has been selected as the general chairman of the B11.1 committee to succeed Mr. Henry B. Duffus.

Safeguarding of power presses has never been considered an easy accomplishment. Safeguarding has been complicated by the wide variety of operations and operating conditions due to variations in size, speed, and type of presses; size, thickness and kind of pieces to be worked; design and construction of dies; required accuracy of the finished work, skill of operator; and length of the run. Because of these varying factors a wide variety of feeding methods, point-of-operation guards, and devices have been covered in the standard.

The revision has been developed on the premise that maximum safety can be obtained by providing the means that make it unnecessary for the operator to place his hand or any other part of his body in the point of operation. Improvement of press design, performance and a wide range of safety devices kept influencing the Review Committee on Revision against setting safety standards that would assure operator safety under most operating conditions.

The committee felt that the objective of this code could be accomplished by:

- (1) Automatic or semi-automatic loading and unloading of the dies, with proper point-of-operation enclosure guard; or
- (2) Limiting any point-of-operation opening to one-quarter inch; or

- (3) If the methods outlined in (1) and (2) cannot be applied, auxiliary protective devices should be used to control access to the point of operation.

In addition to the use of safety devices, full consideration also should be given to the use of hand tools for feeding and stock-removal methods which would make it unnecessary for the operator to place his hands into the point of operation.

The three most significant changes in the 1960 standard are:

- (1) The revised standard covers only power presses.

- (2) There is now a clean-cut definition of a guard and of a safety device. A guard is defined as a physical barrier between the operator and the point of operation—either

a permanent part of the press or die, or interlocked into the press control circuit so that the guard must be in place to make the press operative.

A device is a machine control or an attachment which allows the operator access to the point of operation for loading or unloading the die. It either prevents normal operation until the hands are removed, or automatically removes his hands from the point of operation as the press slide descends. Or, it may be a barrier device which does not meet the definition of a point-of-operation guard.

- (3) A more complete definition of hand tools and hand-tool feeding is provided.

It is recognized that the B11.1 standards are the minimum requirement for safe operation of power presses. As with all other American safety standards, this standard has been developed under the consensus principle, so that each party having a reasonable interest in the standard has a voice in its acceptance. Again let me point out that the Appendix is not part of the standard; it is used to describe and illustrate other suggested means of protection for press operators and to define or describe any parts of the standard that might be misinterpreted.

My first assignment in the discussion of the code itself is to cover the scope and application. The scope is as follows:

"These requirements apply to those powered machines which shear, punch, form, or assemble metal or any other material by means of tools or dies attached to plungers or slides, but do not apply to bulldozers, hot-metal presses, forging hammers, or hot-bending presses."

This code applies to all power presses, all dies and all auxiliary equipment installed subsequent to the adoption of this B11.1 code. Power presses, dies and auxiliary equipment installed prior to its adoption, January 19, 1960, need not be modified to conform to its rules unless the supervising authorities having jurisdiction consider that sufficient hazard exists to warrant such action, or definite improvement is made in the existing law. What I have just said constitutes the "grandfather's clause."

Further provision is made for cases of practical difficulty and unnecessary hardship. In such cases, the enforcing officers or body may grant exception to the literal requirements of the standard or permit the use of other devices or methods, but only when

it is clearly evident that equivalent protection is thereby secured.

Section II of this standard covers definitions. The committee spent considerable time in making this section of the code inclusive enough to satisfy everyone. Further, the committee consulted many authorities to arrive at reasonable and understandable definitions. An example is the term "slide." The question arose, should we use the term "slide" or the word "ram." Should we use some of the other terms that go along with it and try to pick out words that would increase in usage and apply them. Then in determining what we were to use we looked pretty much to the trade associations and trade publications and the technical societies to give us a clue. We spent considerable time in differentiating between "hand feeding" and "hand-tool feeding," again to show the difference between these two particular terms, and in the hope that it would be accepted.

I have already given you the definition for a guard and a device. In this section you will also find definitions for the specific types of devices, such as the adjustable press-barrier device, the electronic-control

device. We have also defined guard, point of operation, die-enclosure guards, fixed-barrier guards, and interlocked-press barrier guards.

Specific comment on the difference between guards and devices as applied to power press safety will be discussed in more detail by Mr. Kraklow when he covers Section V, safeguarding at the point of operation.

Another section I want to comment on is Section III, references to other codes. I mentioned to you earlier that there are some 170 safety codes, standards, recommended practices, and specifications. Those which apply to the operation of power press equipment are listed in Section III.

Briefly, some of the other codes which have equal application to the operation of a power press include codes for industrial lighting, portable and fixed ladders, mechanical power transmission apparatus, compressed air machinery and equipment, conveyors, pressure piping, both the national electrical code and the national electrical safety code and others. Copies of these standards may be obtained from the American Standard Association, 10 East 40th St., New York 16, N. Y.

(b) SECTION IV—

PRESS CONSTRUCTION AND INSTALLATION

By NORMAN DUNLAP

The Minster Machine Co., Minster, Ohio

Mr. Kelly stated that there was no way of loading the sectional committee developing an American Safety Standard. I want to verify this as a definite fact. I tell you that I felt rather lonesome as a member of the review committee serving with the men on this panel and four or five others.

When we started working on a revision of the 1948 code it was soon obvious that everyone on this committee not only had a tremendous amount of experience to draw from but was also dedicated to the job. It was a real education working with these fellows and I want to thank the National Safety Council, the National Machine Tool Builders Association, and our fellow press builders for the opportunity of working on this committee.

The N.M.T.B.A., which I represent on the committee, was very much interested in becoming a part of the revision of this code because of the continuing and increasing number of accidents that we see in our day to day operation. When you dig into these accidents, the investigation almost always reveals that one or more simple, basic rules had been violated, too often with a serious accident and injury resulting.

The first approach to Section IV of the code was drafted on the basis of covering all phases of press construction and the many approaches to each phase—such as the proper construction of clutches, counterbalance cylinders, frames, drives, etc.

It was immediately apparent that this ap-

proach would be entirely too voluminous to be used as code material.

After many discussions the obvious solution appeared to be a pretty big lump for press manufacturers to swallow, in that it was completely against human nature and the practices of any product manufacturer. We had, in effect, to tell what could go wrong with our products, where and how they could wear out.

With this approach, it soon became apparent that much of our material was not code material, but material that would best serve the cause of power press safety in the Appendix. Actually, this material now appears in the code portion of the 1960 revision of B11.1 in few basic major points, the bulk of the material remaining in the Appendix.

The major points in the code itself that differ from the 1948 version concern the insertion of new coverage, such as air clutches and brakes, methods for disconnecting power, and control circuits and current interruption.

Without trying to read Section IV, I want to mention a couple of points. Power presses equipped with fly wheels, shafts, clutches, and gears not confined within the press frame are required to be arranged with guards or brackets with such a design,

construction and strength as to retain twice the weight of any broken gears, shafts, clutch parts, or fly wheels. In discussing the strength of a bracket, which is the determining factor more than the gauge of a metal used for the guard, it was determined that a bracket made of one-half inch by two and one-half inch steel, of whatever length was desirable, and secured to the frame with two or three three-quarter-inch cap screws would do the job.

Usually with this setup, a fly wheel breaking from the shaft will spin harmlessly within the confines of the guard itself. It is only when the fly wheel falls clear to the floor and gets a purchase against the floor and then with the terrific inertia and momentum rolls through the shop, that we have the destruction and injuries that are so feared from this particular mishap.

One last point I want to mention concerns air-friction clutches and brakes. Pneumatically operated friction-clutch and brake units are required to be designed and constructed so that the brake is applied and the clutch disengaged in the event of an air or power failure.

As I said the bulk of the material developed by the subcommittee working on Section IV has been put into the Appendix. I am sure you will find it interesting and helpful.

(c) SECTION V—

SAFEGUARDING AT THE POINT OF OPERATION

By THEODORE A. KRAKLOW
Dir. of Safety, Deere & Co., Moline, Ill.

Needless to say, this section of the code received a lot of reviewing, debating, changing and compromising before an agreement could be reached.

Well informed, aggressive safety men and management people are all generally agreed that it is not enough to assign a worker to a power press and tell him he must work safely and not put his hands under the die when the press is in motion. We have learned not to rely on this method. We have learned, in fact, that no human being is entirely reliable.

Guards and devices designed to keep hands out of dies were developed for this purpose. Devices are two-hand controls, sweeps, pull-backs, electric-eyes, and gates. Some of these have been on the market and used on punch presses since 1920-21. Yet, punch press accidents and amputations continued in spite of these efforts. Why? Because of the simple fact that most people, buying and installing these devices do not follow the manufacturer's instructions, provide no continuing maintenance, mount them on presses for which they were not intended,

or allow operators to tamper with them or disconnect them, or just do not enforce their use.

The manufacturers of this equipment furnished data and booklets stressing the need for providing inspection and maintenance of these devices to assure their satisfactory performance. However, usually, this was more or less ignored and when the device failed, the accident was blamed on malfunction of the device or malfunction of the press, forgetting that a press is capable of turning out 6,000 to 8,000 pieces per day, some two to two and one-half million strokes a year. It isn't hard to visualize what happens to equipment subjected to this kind of use without any continuing adjustment, inspection or repair.

With this as a background, I would like to give you the reasoning behind the material written into Section V, safeguarding at the point of operation.

If a man's hands are never required under the slide or between the dies (in the point of operation) to place or remove stock, then he will not be injured if a malfunction of the press or device occurs.

The opening statement in Section V is the key to the entire section. It says, "Each press shall be equipped with a point-of-operation guard or a point-of-operation protection device for every press operation performed except where the point-of-operation opening is limited to $\frac{1}{4}$ " or less." This simply means that one of these methods must be provided in order to give protection at the point of operation.

An attempt has been made in the Code to spell out performance requirements for guards and protection devices.

A "guard" must be an enclosure attached to the press or the die with openings to permit stock feeding, but designed and arranged to prevent hand entry into the point of operation by reaching over, under or around the guard.

Four examples of guards include: (1) point-of-operation opening limited to $\frac{1}{4}$ inch or less; (2) a die enclosure guard; (3) a fixed press barrier guard; and (4) an interlocked press barrier guard.

A "device" on the other hand, is a method, control or attachment to the press or die that permits entry into the point of opera-

tion for loading or unloading the dies. The device either prevents normal operation until the hands are removed from the point of operation or automatically removes the hands from the die area as the press slide descends or it may be a barrier device which does not meet the requirements of a point-of-operation guard.

Six examples of devices include: (1) adjustable barrier; (2) the gate or movable barrier; two-hand controls; the pull-back device; the sweep device; and the electronic or "electric eye" control.

Hand feeding tools are not accepted as guards or devices but are intended to be used as accessories or auxiliaries on all point-of-operation devices.

A review of the Code material will readily give you the performance requirements intended to be followed in providing guards or protection devices on power presses, stressing certain do's and don'ts in order to provide maximum and ultimate safety for press operators.

However, I want to stress the Appendix. Do not overlook it when you run into a statement in the Code that appears to be difficult to interpret. In the Appendix, which is not Code material (that is, not enforceable), more detail is supplied and there is a wealth of information answering the questions concerning why guards and devices must be installed in certain ways, why they must be inspected, maintained, and otherwise kept in good operating condition.

The Appendix material supplies the answers to questions of why openings in adjustable press barrier devices must be a certain size.

Other questions that are answered include why gate or movable barrier devices must be in place before the press is tripped and how this can be accomplished. The Appendix explains why two-hand controls must be located at least 21 inches apart and why they are not recommended on positive clutch presses unless certain precautions are taken. The reason for pull-back devices needing adjustment for each operator and each press setup are given as well as the importance of frequent inspection.

The advantages and limitations of sweep devices are presented and you will learn why sweep devices are most effective when used on small dies and slow-acting presses,

and also you will learn the reasons why timing with the press stroke is important. The Appendix also explains why electronic

control devices should not be used on positive clutch presses and other precautions that need to be taken.

(d) SECTION VI — POWER PRESS AUXILIARY EQUIPMENT

By GEORGE A. STILES
Engineering Dept., Aetna Casualty & Surety Co., Hartford, Conn.

My discussion of Section VI will be brief. In this Section, we cover what is termed auxiliary equipment. Auxiliary equipment is a very important part of power press safety. So many times one goes through a plant where one sees, for expediency's sake or because somebody is convinced that nobody should do this or that, that press pedals are not covered with a guard. I think it safe to say that no responsible person acquainted with the problems or preventing injuries on power presses will attempt to defend the fact that a pedal cover isn't a mandatory requirement.

This Section also includes requirements for pedal-return springs, and I think you will recognize that there is considerable chance that there might be a malfunction of a press because of a broken spring.

When you consider the millions of strokes that occur on any press over a period of time, you must recognize how easy it would be for springs to break. The Code requires that such springs shall be of a compression

type, operated on a rod or guided within a hole or tube. When operated on a rod the inside diameter of the spring shall be no greater than the diameter of the rod plus $\frac{1}{16}$ inch. When guided within a hole or tube, the inside diameter of the hole or tube must be no greater than the outside diameter of the spring coil, plus $\frac{1}{16}$ inch. Further, each spring, in its initial compressed position, must be wound so that the space between the coils of the spring is less than the diameter of the wire used in the spring.

The single-stroke mechanism, covered in this Section, is important. During the development of this revision, committee members argued long and loud and there was considerable soul searching before we were able to say precisely what we wanted to say and as it now appears in the code. This happened, because, for one thing, there is a misconception between a non-repeat device and a single-stroke mechanism and we have tried to spell out the difference so that there will not be any question.

(e) SECTION VII — DESIGNING, CONSTRUCTING AND SETTING OF DIES

By L. A. FAULKNER
Supvr., Industrial Plant Service, Liberty Mutual Insurance Co., Boston, Mass.

Section VII was prepared primarily as the result of the cooperation of a group of people from the American Society of Tool and Manufacturing Engineers, who within the last five or six years have given considerable attention to safety in tool and

die design, and this attention is very much in evidence in their society's handbook. The A.S.T. & M.E. have scheduled a session on safety in tool and die design on the agenda for their annual meeting for this year. Personally I think they should be congratulated

for giving the thought they have to this problem, and I hope they will continue to do so.

This particular section was needed, we felt, because the initial step in the provision of safe and efficient operation of a power press is in the planning of the method to produce a particular stamping. Obviously, there are certain fundamental factors to safety of pressroom personnel which must be considered and incorporated into the design of a particular die.

I am quoting at the moment from the introductory paragraph which will become part of the Appendix of the Code Section. "This part of the Appendix is prepared with the general idea in mind that there are certain elements of tool design necessary if the overall objective of this particular Code is to be achieved." It includes, as you will on reading it, only those items of tool design which are closely related to safety and discussed in other sections of the Code. There is no attempt to include in the Code or in the Appendix of the Code the fundamental principles of tool design as such. It is only in relation to the safety factors involved in the design of a specific tool.

The Code recognizes semi-automatic and automatic feeding devices and therefore this section describes the various types of semi-

automatic and automatic feeding devices which are available and which should be given consideration by the tool and die designer at the time he is planning the processing of a given piece.

The Appendix includes diagrammatic sketches and pictures of the various items in the code as a means of helping in the interpretation of the Code. You will note this particular section also includes, in addition to the designing and construction of dies, the setting of dies. It was decided by the committee that this was the place in which to provide some basic information in relation to die setting, but only in relation to those hazards involving the die setter which could be eliminated as much as possible by giving them consideration at the time the tool was being planned for processing.

As an example, die fastening and die handling problems, work measure and stroke designations, are being included as a part of the responsibilities of the tool and die designer in relation to minimizing the possibility of accidents and injury to the die setter, or the employee who is required to operate this particular machine if such information is not available to him. The section includes other items such as the necessity for turn-over bars, inclined-press stops, safety blocks, and others.

(f) SECTION VIII — INSPECTION

By NORMAN DUNLAP

I want to go back and add some further explanation to the remarks I made about Section IV, Press Construction and Installation. In Section IV we refer to the American Standard Safety Code for Mechanical Power Transmission Apparatus, B15.1-1958. This Code covers the guarding of gears, chains, levers, belts, arms, etc. But we elaborate somewhat or deviate from that code in that, on the press construction phase, we wanted to tie in the necessity of making guards cover twice the gravity weight of the rotating parts, such as shafts, fly wheels and clutches. There was considerable discussion on this point among the committee present today as well as on the sub-

committee of which I was chairman, that developed this section. We didn't feel we had to cover the energies involved. In other words if you would try to make a guard that would handle the energy of a 60-inch fly wheel turning over at 100 rpm, you would have a tremendous guard.

Actually, the experience in the field has been that fly wheels seldom have a tendency to take off and go through the building unless they are dropped. So we felt that making a guard to take twice the gravity weight would prevent them from dropping far enough to get the traction required to propel them through a brick wall. This has happened—we know. But it isn't too

much of a job I checked on a 60-ton machine which has a 1200-pound fly wheel on it, a fly wheel type machine at 100 rpm. Two brackets at the bottom of the fly wheel guard that are $2\frac{1}{2}$ inches by $\frac{1}{2}$ inch securely fastened to the frame with at least three $\frac{3}{4}$ inch cap screws would fill the Code requirement. On clutches, we have mentioned positive type clutches in conjunction with springs. There again, the wording is such that we are asking for a spring design so that if the spring does break, the broken ends will not wind into the other part of the spring and lose the effect of the spring entirely.

We mentioned brakes for positive clutches, primarily for the safety of the die setter. There is no need to go into the hazards which exist when the brake on a machine will not hold the slide at mid-stroke. In discussing air-friction clutches or other types of drives we mentioned brakes again in conjunction with counter balance cylinders and surge tanks so that you will not have a condition which will result in the slide falling.

We felt that hydraulic presses could be covered very well if we followed the code for pressure piping, B31.1-1935. This is an

extremely important code in the safe operation of power presses and we feel that every safety man or management representative having responsibility for power press safety should have a copy of this code and should make certain that the piping setup complies with it. In a hydraulic press we have a plunger similar to the slide in a mechanical press. The speeds are different but basically the same amount of safety can be obtained by using the same safe practices as on a mechanical press.

We discussed controls to some extent. I think we are all familiar with the hazards of low voltage under certain conditions and we tried to cover that.

Now so far as Section VIII is concerned, the inspection and maintenance section of the Code, I would like to say that the Appendix is devoted almost entirely to recommended inspection sheets. We made quite a survey and all the companies we contacted were very free in giving us the information from their records of inspection and maintenance. We feel that if you have a record of your troubles you will do something about them. I think this covers Section VIII. If you have any questions, please let us have them.

A NOTE ON SECTION IX — OPERATION

Mr. Kelly, Section IX, Operation, is really quite simple. It has two provisions. One is that no one under 18 years of age shall operate or assist in the operation of machinery covered by this Standard. The other point has to do with instruction of operators and specifies that before starting work

on machines covered by this Standard and before starting work on any operation with which he is not completely familiar, the operator shall be carefully instructed in the particular operation and a safe method of work.

QUESTIONS AND ANSWERS

Question, Please explain what is meant by applications. How does this requirement affect my 30- or 40-year-old presses.

Mr. Kelly, Any of us can answer that but as long as I am on my feet I shall. Basically, the code doesn't affect those presses inasmuch as the Code says specifically it is applicable after the date of adoption or approval, which was January 19, 1960.

As I mentioned earlier, this Code and all

other American Standard Safety Codes are developed for voluntary adoption by the people concerned with the subject of the Code. There is no legal status whatsoever so far as this Code is concerned until it has been adopted in part or completely by a state.

The states have not been too quick to adopt this Code. There are some 20 or more states that do not have any regulations at all

for the safe operation or safeguarding of power presses. This goes back clear to 1922, almost 39 years.

To answer your question specifically, I would say the Code would affect your older presses only insofar as new dies—built after January 19, 1960, are concerned.

Question, Can a press be purchased that will comply with this Code? Will it be completely fail-safe?

Mr. Dunlap, Well, to answer your first question, yes, a press can be purchased that will comply with the Code. Fortunately, Minster is not the only company that builds such a press. I think all press builders will come up with a machine that does a beautiful job complying with the Code, and can even go further. Most of the press manufacturers are doing this now, and that is adapting control circuits to handle point-of-operation guarding and the many other items that are covered in the code. So if you want to comply with the Code, one of the best ways of doing it is to start out with a new machine.

"Will it be completely fail-safe?" No. Unfortunately, these presses seem to run forever. It has been my experience to run across a group of machines that are 35-40 years old or older, but as long as you are subjecting a piece of metal or equipment to the shock that is involved in exerting anywhere from a 5-ton load to a 100-ton load or sometimes over, you will be involved with stresses. When you get involved with stresses in a machine, you get involved with flexure-life. The way you train your disetter, the way you design your dies, all control the amount of flexure life you will get out of a press.

We would like to feel that we design them so they are fail-safe. But for us to make the claim would be foolish, because it seems like the smarter our engineers get, the smarter the people become in getting around the safeguards that we design into the press in the first place.

Question, What is meant by a "fail-safe" valve?

Mr. Dunlap, A fail-safe press valve is a multiple valve arrangement wherein a failure of any valve part, or a failure of the protecting arrangement, will result in either immediate or normal top of stroke stopping

of the machine, and also prevent further operation.

The Minster random valve with macro-current detector accomplishes this by arranging two three-way valves in series with a valve position detecting assembly mounted in each valve and a control for these assemblies mounted within the press control. Both position sensors must be in the off position to initiate a press cycle, and both must shift to operated condition to maintain a press cycle. Thus both valves and both sensing arrangements must be working normally not only to initiate a cycle, but to maintain it, since both valves must operate to start a cycle, but either shutting off will stop the cycle.

Question, Why should a device be used, when hand tools are used and the tool does not require the operator's hands to be placed into the point of operation? And why aren't hand tools recognized as devices?

Mr. Kraklow, Hand tools are not attached to the press in any way. They can be laid aside and just not used. As a result they do not comply with our definition of a device. As far as the first part of your question is concerned, I refer you to the opening statement in Section V, safeguarding at the point-of-operation, which I read to you. It says, "Each press shall be equipped and operated with a point-of-operation guard or a point-of-operation protection device for every press operation performed, except where the point-of-operation is limited to $\frac{1}{2}$ inch or less."

Question, Does the Code recognize that a point-of-operation guard can be effectively used to establish an "out of bounds" area for hands when the feed opening must be too large to be considered as an effective barrier?

Mr. Kraklow, Yes, the Code does take care of this. What you have described is a barrier device and not a guard, because of the size of the opening that would permit the hands to be placed between the dies. The Code specifically says in Paragraph 5.3.1.2, "If it is necessary to feed manually within the point-of-operation, hand tools should be used as an accessory to all point-of-operation devices."

Question, Although several powered machines similar to power presses, such as

bulldozers and forging hammers are specifically excluded, neither power brakes or riveters, both of which fit the definition as mentioned, are included.

Mr. Kelly. Let there be some misunderstanding, there is an American Standard Safety Code for forging and hot-metal stamping, B24.1. This would take care of the first part of your question. A power brake is not within the scope of this Code as outlined unless power press dies are fitted into it. I know that some power brakes are now manufactured specifically for the utilization of power press dies. I would say very definitely that in such cases it is no longer a power brake but a power press and this code would apply to any metal stamping or forming operations performed on it. Riveting machines do not comply with the scope of this Code.

Question. What is the difference between applying two-hand control devices in regard to positive and friction-type clutches?

Mr. Kraklow. As we have tried to point out in the Appendix, the difference between positive-type clutches and friction-type clutches is that, on the positive-type clutch, two hand controls are nothing more than operating mechanisms because, once the press starts the cycle, there is no way in which you can stop it until it has completed its cycle.

I might quote from the Appendix on that particular point: "On positive-clutch presses, hands are free the instant the slide starts down. Therefore, the tripping device must be located so the slide completes its downward travel before the hands can reach into the point of operation, if maximum safety is to be achieved."

"On presses with friction-type clutches, or any type of slide cycle which can be interrupted during its stroke, maximum safety can be obtained if the controls are adjusted to require constant pressure of the operator's hands until the slide has descended to a point where there is no longer a hazard."

So we made that definite distinction, because a lot of people would purchase two-hand controls and stick them on a positive clutch press and then assume they had a safe press and give no consideration to the fact that a malfunction of the device or a malfunction of the press, as the man

was reaching into the point-of-operation area, would cause amputations.

Question. How do we get our die designers to give more thought to safety? What reference material is available?

Mr. Faulkner. I think this is an important question. I have heard it said that there would be a hell of a change in the type of die design if the die designer himself or his wife or his daughter had to run that particular job with the particular die he had designed. You see badly designed dies in practically every plant you go into. But more and more as time passes, we are getting increasing interest on the part of the die designers; they are getting into this overall picture to a greater extent. This interest is not only in the production of a given part in a certain way, but also in the safety of the employee. I could cite two or three plans recently adopted which have been fairly successful and which I believe would be more or less the answer to this particular question—the general idea being that where the designer was brought into the picture some minor change of that particular die has resulted in a safe operation.

In one plant, they have a committee which meets periodically to discuss the planning of a given die in relation to the types of safety devices or safeguards that are to be incorporated into that job. As an example, the design of a special die for the use of a particular type of device involves certain considerations. If you are going to provide the operator with a pull-back device, for example, there are certain things that should be taken into consideration in the designing of the particular die. If you are providing a two-hand trip and hand tools, obviously there are certain other things that should be taken into consideration. So, basically, it is a question of getting this overall interest in this particular subject accepted on the part of the various management people who should assume the responsibility. It starts with creating some kind of management policy within a given company as to the type of devices that are to be used, and consideration given to the die designers at that particular time so the device can be used effectively.

Question. Mr. Dunlap mentioned that the Code stated that the brake capacity should be sufficient to hold the slide and die at

mid-stroke. How is the press manufacturer expected to determine the weights of the various dies which the press user might insert in this particular press in years to come?

Mr. Dunlap. Actually this requirement has been in the specifications of individual companies for some time. It was treated in the Joint Industry Committee. Normally, we consider the weight of the moving parts in the press itself, and I think J.I.C. now stipulates one-fourth of the die area in steel.

Question. How can you set a brake tight enough to hold on mid-stroke with the press power off on a 200-ton press that makes 60 strokes per minute and does not burn up the brake or cause too much drag?

Mr. Dunlap. I think this question is answered in paragraph 4.1.3.2 of the Code. On larger machines where it is not normally possible to hold the slide at half stroke, check valves should be used in conjunction with counter-balanced surge tanks to prevent slide and die from falling in the event of an air or power failure. What we mean here is counter balances with surge tanks that have check valves so that if you have an air failure you do have trapped air.

On the larger machines, 200 tons on up to the very largest, I would say that the press manufacturer designs to this J.I.C. Standard or that the standard is accepted pretty well, in that 25 per cent of the available die area is solid steel. However when you get into higher speeds, large presses, 200-ton machines running at 60 strokes a minute, there are many design modifications which would give you a problem of holding all this weight plus the weight of the extremely heavy parts in the press itself. I can't see where this 60 strokes a minute in this machine would give you a problem, because if you can run a 200-ton press at 60 strokes a minute, you are going to have plenty of brake on to stop it from coasting.

You do have a tremendous problem of stopping the press as speed increases. As a matter of fact, inertia has to be calculated on the basis of the square of the speed; and when you are talking about ratios on these machines, around 8:1 or 9:1 and use the W/R square factor, you will have to have plenty of brake on the machine. If you stop such a machine properly at 60

strokes per minute, you won't have any trouble with your static loads for the setting or at mid-stroke. Counter balances can be used to offset problems which you run into, designwise.

Question. Some parts, particularly large drawn parts, must be fed by hand for subsequent redraw, trim, etc. operations. While the hands are in the die area during feeding or removing the stock from the dies, would the use of two-hand trips meet the requirements of the Code?

Mr. Faulkner. The answer could be yes, if the two-hand trips were installed on the particular machine in accordance with the requirements of the Code I would assume, however, that since they are talking about a large press on redraw operations, it would be a type of two-hand control that could apply constant pressure in relation to the friction drive, or a machine that could be stopped within the stroke. If, for example, it was a large positive-clutch press and two-hand controls were installed, it would not meet the requirements of the Code.

Question. Using pull-back devices, what is the company's position when some mechanical failure occurs such as a pin dropping out, a leather strap breaking, etc.?

Mr. Kraklow. Well, that is the point that we have been trying to stress throughout our discussion of this Code insofar as devices are concerned. You just don't buy something and hang it on a press and walk away and forget it and say, "We have accomplished our purpose." It is just like anything else. It has to be maintained. It has to be adjusted and it has to be inspected periodically to see that everything is satisfactory.

If these things are not done, then you are going to have a malfunction of the device because there is nothing—no device made that will not wear out. No one claims that they won't wear out.

We tried to spell this out quite fully in the Appendix because this has been the greatest problem that industry has experienced with such devices on presses. We think they will accomplish exactly what the manufacturers claim they will accomplish. However if the purchaser doesn't follow the advice and counsel of the manufacturer, he certainly can't blame the device if it doesn't perform properly.

Mr. Faulkner. I would like to add one point, since we are talking about pull-back devices. It is of the utmost importance when you decide to buy or install pull-back devices that you obtain from the manufacturer, and use, the material and the instructions that come with the device so that you can get the most effective use out of it. These companies have booklets and instructions, very well illustrated on all phases of installation, adjustment and maintenance and the information is available. As a matter of fact, most of the companies manufacturing these devices will help train your people in the proper maintenance and inspection of the devices.

Question. What is meant by "regularly scheduled" inspections? Would you tie in a definite specified time to "regularly scheduled?"

Mr. Dunlap. By "regularly scheduled" we feel, rather than put this on a time-interval basis, that it should be on a usage basis. Let's take an air valve, for instance. Most air valves have a life expectancy of from 6 to maybe 30 million cycles. Now if you are using an air valve on a single or double geared machine that runs 25 strokes a minute, and you operate it at the rate of 15 strokes a minute, then your frequency of inspection wouldn't be as often as if you used this same air valve on a 35-ton OBI that is running at the rate of 130 strokes a minute.

You could, conceivably, single stroke this machine up to 60 and 70 times a minute—and there are cases where presses are single stroked that fast. Then again you would have to take the number of cycles that this unit is being subjected to into consideration in your regularly scheduled maintenance.

I think the best answer is to go back to the manufacturer's criteria of the critical components. I am sure they all have minimum life expectancy and it is a matter of simple calculation to project your frequency into the inspection period. One of the points we cover on installation is making sure the basic supplies to the machine are in good shape. You have to consider that point, too. If you have, for example, an air-conditioner in which large, mildly aged air pipes are subjected to a lot of shock and vibration, or if they go out of one

plant and into another one so that they are subjected to a lot of temperature change, and if you have water and scale conditions, then you have to check your filters in accordance with the experience that you have in your own operations.

Question. 1. Do press manufacturers have recommendations available relative to inspection and maintenance of their product?

2. Even with frequent scheduled inspection and overhaul, loosening of screws, guards, braces, etc., is a constant problem on presses in constant use. Press manufacturers seem to be lax on this point. Why?

Mr. Dunlap. I would say "yes" to the first question. All manufacturers have service and operating instructions, and they are readily available. Most of the manufacturers make it a practice to mail instruction manuals along with the machine when it is delivered.

However, we know these manuals end up in the purchasing department or in the general manager's office, and the fellow who is supposed to do all the things we recommend in the manuals never sees them as he should.

The second question is "loaded." Actually, in plants that have a regularly scheduled preventive maintenance program, the problem as described isn't as acute as the question indicates. In plants where maintenance is done on the basis of necessity, where you have trouble with loosening screws, gibs, connection barrels, there is a trend developing. The days of greasing the squeaky wheel are fast disappearing. Preventive maintenance is very important, more so with newer machines than with the older ones. If you have a condition or situation in which guards, bolts, and screws are loosening up, it is quite possible that that press is not being used for the purpose for which it was designed.

In some plants I have run across an old, positive-clutch machine with a block clutch geared and it was designed to run at 30 strokes per minute. Someone put a bigger sheave on it and really wound it up. Well, the shock and impact is going to increase, naturally, and it is obvious that something has to give, and the strains and stresses are going to increase.

PRESS FORGING WITH SAFETY

By HAROLD J. ALLOR

Quality Control Mgr., Detroit Forge Plant, Chrysler Corp., Detroit, Mich.

Now for a conducted tour of the crankshaft operations at the Detroit forge plant. Previous to this setup, all of our crankshafts were made on 12000-pound steam hammers. By the use of the forging press we have made our operations safer, have reduced costs and improved the quality of our product.

Our plant consists of ten buildings, including a die shop, maintenance building and power house.

Steel comes into our plant via trailer and railroad gondolas. Steel from which crankshafts are made is unloaded for storage by use of a crane and electro-magnet. The magnet is powered by a 230-volt generator set of which we have two, with one on standby service. At no time do we permit loads to be carried over the heads of employees. The magnet is used for ease of handling and for safety as no hook-up man is required.

Each heat of steel is checked by the metallurgical laboratory to make sure that it meets the specifications of the engineers in order that quality and safety will be built into the forging. Many tests are necessary before a heat of steel can be released to production.

When approval is given, the stock is removed from the storage area and the handling straps are broken. The steel is then aligned on the ground. A lift of steel is then picked up by the crane and placed on the stock rack of the normalizing furnace, or oven, where the steel is heated to prevent shear cracks. It is then pushed through the oven by a hydraulic cylinder onto the conveyor to the shear.

Wherever possible we use mechanical handling devices to eliminate strains and burns, which are common in a forge shop.

All gas furnaces are equipped with safety valves which operate on a gas, combustion air or electrical failure.

After shearing, a quality control man checks the multiple for size. The multiple then moves along a conveyor to an elevator which raises it to the height of the furnace

hearth. It is then placed on the hearth of the rotary furnace by means of a water-cooled, hydraulically-operated loading boom. The furnace is brought to heat using natural gas, then switched to a fuel oil. Stock multiples are placed side by side on the hearth and, as the furnace revolves, is brought to forging heat, approximately 2200 degrees.

The multiple is now removed and placed on a chute-type conveyor which brings it to a water descaler. It then passes through a preforming roll which prepares the billet for forging. As it passes an electric eye the roller is turned over to bring the tone end towards the operator.

The billet is now positioned on the block-and-press of the die by means of an air-operated cylinder controlled by the operator. The press strokes, after being actuated by a foot pedal controlled by the operator, then the billet is rolled into the finishing impression. The press strokes again and the forging is rolled onto the conveyor as the right of the die which carries it to the next operation, which is trim.

Water-cooling spray and die lubricant are applied without the operator placing his hands in the die area, another way in which we have built safety into our operations.

At the trim press, the flash is removed and placed on a beneath-the-floor conveyor, which conveys it to a gondola for return to the mill. At the back of the trim press, an operator removes the trimmed crankshaft from beneath the die and transfers it to the twister operation. Suspended tongs are used to eliminate muscular strains. In this twister, the crank is twisted 90 degrees to give correct pin position. Since this film was made, we have gone into a 100 per cent hard hat program, which to date has saved six employees from head injuries. I can sincerely recommend the filming of any operation to bring out the hazards which might otherwise go unnoticed.

Following the twister is a restrike operation, where the forging is struck in two positions, then hung on the cooling line. Note

1961 National Safety Congress

that the tong jaws are replaceable in case they are bent or broken.

At regular intervals a quality control man takes a crankshaft from the restrike for a routine check, after which it goes back on the cooling line if the check shows no flaws.

From the cooling line the forging is transferred to the heat treat line, where employees wear steel foot-guards.

Three sets of gas-fired furnaces process the forging through hardening and stress-relieving cycles. Each furnace is controlled by pyrometers and guarded by safety valves, which close on gas, combustion air, electrical failure, etc.

After passing through the hardening furnace, the forging is quenched in water. At this point a crankshaft is removed for a hardness test by a quality control man. Records are kept of the readings.

From the hardening furnace, the forging moves into the stress-relieving furnace, after which a sample is taken for another test.

The forging is taken from the conveyor after stress relieving, and placed on a conveyor, where it is transported to a wheelabrator for removal of scale.

Our sample forging is now centered, and marked for a location point for the engine plant who will machine it. The operator stamps an identification mark on the crank which makes him responsible for the work done on the locating spot.

The crank is now checked again by placing it in a fixture equipped with a dividing head. This check completes the inspection of the crank, except for a visual check just before the loaded container is shipped to the machining plant where the engine is made.

OFFICERS OF THE

AUTOMOTIVE AND MACHINE SHOP SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—R. M. Cox, Safety Dir., Goodman Mfg. Co., Chicago, Ill.

Staff Representative—ARTHUR S. KELLY, National Safety Council, Chicago, Ill.

*Former General Chairman

PLAN NOW - -

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

**See the Latest in Safety Equipment
At the Greatly Expanded Congress Exhibit Hall**

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

SAFETY ASPECTS OF GROUNDING PORTABLE TOOLS

By E. J. MATOUSEK
Mgr., General Engineering
International Minerals & Chemicals Corp., Skokie, Ill.

My discussion will not be concerned with the why or how portable tools can become a hazard, but in the event they do, what steps should have been taken to prevent any personnel hazard.

The National Electric and Fire Codes have directed industries and residential construction into safe and reasonable avenues. However, there are certain aspects that may need a bit of historical explanation. Most 110-volt single phase systems have one line grounded. This grounding procedure grew from the prevention of fire caused by lightning primarily in residential construction. There are other valid reasons for grounding 110-volt systems, but to digress into the pros and cons of grounded versus ungrounded electrical systems, would be beyond the scope of this discussion.

We are concerned with grounded electrical systems powering portable tools. In some respects the addition of the ground tends to increase the shock hazard because it brings in one lead of the two necessary to close the circuit and cause the shock. What I mean by this is—in order to cause a shock, the human body must be inserted in the circuit.

Normally a person will not intentionally touch a hot line, but this is exactly what happens when a workman uses a portable electric tool, which has the hot line shorted to its metal frame. The system and the man are both grounded; the man becomes a part of the circuit and is subjected to a shock.

Basically, the human body can be considered as a salt solution encapsulated with a thin insulated membrane which is the epidermis portion of our skin. This is why intensity of shocks is increased in the event that hands become moist or minor skin wounds are involved. In other words, the skin's larger resistance breaks down and the current flows readily through the "saline solution."

The severity of the shock depends upon the vital organs that are affected, namely the

heart and the brain. This is why shocks between arm and arm, or between arm and leg, are much more hazardous than between leg and leg, or let's say—hand and elbow of the same arm.

Another aspect worth considering in this understanding of shocks is that normally, voluntary muscles operate from electrical impulses generated in the nervous system and usually respond to a frequency of about 50 cycles per second. Hence, contact with 60-cycle extraneous voltage causes a saturating signal that tends to lock the various muscles involved. This is why some shock victims cannot let go of a hot wire, but must fall away from it.

This saturating effect blanks out normal signals; if this occurs in the vicinity of the heart or brain, artificial respiration is required to keep the oxygen entering the body until the paralyzing effect is dissipated and the normal functions of the body take over.

With this brief resume of the physiology of the shock, and applying this understanding to the elimination of a shock from a portable hand tool, it seems obvious that the solution is to prevent the man from becoming a part of the circuit. How is this done? One answer is to completely insulate all metal or current carrying exposed parts. The advent of plastics and the extension of its physical characteristics of strength and temperature resistance, makes this possible. I am sure that in the future the insulating technique will provide solutions for many portable tool problems. However, with the existing tools and appliances, which have exposed metal parts on their exterior, we must provide another answer.

The best solution is to ground all metal exposed parts of an appliance with a separate conductor, thereby providing a low resistance path for the stray ground current. Electricity, like humans, will take the path of least resistance. The ground wire protects the man, by taking him out of the ground return circuit. The fuse will blow because

of the excessive ground current, and the defective unit will be isolated.

The ground wire has become almost standard in industrial construction for the last ten years. Generally the ground return circuit is formed by a conduit system and receptacles are provided which connect the separate grid. Standardization of plugs and receptacles has been difficult to achieve, and even the solution now accepted does not necessarily solve all problems. Receptacles now in common use provide the ground connection. A major problem is that many tools and appliances do not have three-conductor cords and cannot be used in some receptacles unless an adapter plug is provided. Similarly, a tool with a three-conductor plug cannot be used in a shop which is equipped with the out of date two-wire receptacles. The accepted solution is by a plug and receptacle that is adaptable to both two and three plugs. If the tool does not have a ground wire, it can be used, but the safety aspect of the three-wire receptacle would be lost.

In a sense, the ground wire in the three-conductor cord is your insurance policy for safety on portable tools with the metal exposed parts. The problem here however, is that one never knows when this insurance policy will expire. Ground wires break or become disconnected, and when this happens—and it happens all too frequently—the user of the tool is exposed to a possible lethal shock.

This happened to a construction worker doing work for a major company some years back—even though they had a strict grounding policy. As a result of this accident, a tool checker was devised to automatically check electrical tools before they were issued. This device acted primarily as a "go—and no go" test for a storekeeper who issued tools. The checker automatically passed a high current through the ground wire and maintained this high current long enough to burn out any whiskers, if that was all that was left of the ground wire. After passing this test, the tool was then

subjected to a high voltage test, approximately 500 volts, to check deteriorating insulation. It also tested for a short circuit in the motor armature. If the tool passed these tests, the tool would then be subjected to run voltage and a run test, if the "on" switch of the tool was pressed.

Another feature of this tool checker was its built-in safety factor. In order to operate the tool tester, the tool had to be pressed against a spring plate on the vertical portion of the test panel on the tool checker. Pushing the tool against this panel, besides assuring a good ground connection, the tool frame operated a micro-switch directly behind the panel to initiate the test procedure. If the tool was faulty, an audio and visual indication was provided and the test would not proceed to the point of applying voltage to the tool. Accessories for testing existing cords were also provided. This automatic tool checker has never been produced commercially, although a unit that uses the same tests but on a manual basis is being marketed.

The essential steps for safe operation of portable 110 volt single phase electrical equipment can be summarized as follows:

1. Use a grounded power system with adequate overcurrent protection for all feeders.
2. Maintain a good ground grid. This can be either a properly installed conduit system, or a supplementary ground wire network.
3. Use standard three-wire receptacles and make sure the ground wire is connected to the ground grid.
4. Use three-wire cords for portable tools and appliances.
5. Periodically check portable tools to be sure that your ground wire insurance is in force.

If these steps are followed, needless loss of life by electrocution from defective 110 volt portable equipment will be prevented.

GROUND FAULTS IN QUARRY ELECTRICAL SYSTEMS

By H. P. CASSEL
The Whitehall Cement Mfg. Co.

Well-planned installation of electrical equipment takes for granted that such equipment will be well grounded, at least to the minimum requirements of the National Electric Code. In the application of both large and small portable electrical equipment, we have at times been negligent in the installation and maintenance of proper grounding.

The use of large, portable, electrically driven equipment in quarries, such as draglines and shovels, usually requires operation at voltages of from 2300 to 13,000 volts. The fact that such voltages are used, plus the uncertainty of obtaining good grounds in areas such as quarries, demands that we carefully examine our grounding practices in this area.

WHAT IS A GROUND FAULT?

When one of the main conductors of power accidentally touches the framework of the machine involved we speak of this as a "ground fault." This accidental contact may be caused by the breakdown of insulation anywhere on the machine. It may be at the point of entrance of the portable cable, in the switches or wiring on the machine, or in the windings of the motor or generators driving the machine. Such a breakdown may occur at anytime and without warning.

When such ground faults occur, personnel standing on the ground and touching the frame of the equipment involved may be subjected to electric shock ranging in intensity from slight to fatal. Since even the best insulation, installed in the most expert manner, is still subjected to occasional breakdown the safety problem involved concerns control of the intensity and duration of the shock hazard when such breakdowns occur.

WHAT CONSTITUTES A SHOCK HAZARD?

A good deal of investigation has been undertaken to determine the limits of human

reaction to electric shock. Due to the great variations in individuals and their varied reaction to shock, and to many other variables, the evidence of these studies is only generally conclusive. However, broad limits may be set which will apply to most cases and conditions.

All investigations agree that the severity of any electric shock is a function of intensity and duration.

The intensity of the shock depends on the voltage encountered and the bodily resistance of the individual in that portion of the body through which a particular electrical current may pass. Investigations in this area have set values ranging from 500 to 1000 ohms.

The amount of current flowing through the body having such resistance will depend on the potential or voltage encountered. The following is an indication of what probably will happen with varying amounts of current flowing through the body:

1. 1 milliamperes—No sensation.
2. More than 5 ma.—Painful shock.
3. More than 10 ma.—Muscle contraction—25% of population will freeze to contact.
4. More than 15 ma.—50% of population will freeze to contact.
5. More than 30 ma.—Breathing difficult—unconsciousness may occur.
6. 50-100 ma. Possible ventricular fibrillation of heart.
7. 100 ma.—2 amps.—Certain fibrillation of heart.

With these results in mind the mining industry, some years ago, set 100 volts as the maximum allowable potential that should exist between the frame of a machine and the earth during a ground fault.

WHAT HAPPENS WHEN GROUND FAULTS OCCUR?

Let us now examine what might happen when ground faults occur under various types of installations.

A. An ungrounded system:

With an ungrounded system, a single line may be the ground. There will be no interruption of service and unless special ground detection equipment is installed such a ground may go undetected indefinitely. A second ground fault in the frame of a shovel, for example, will cause a fault current to flow through the frame of the shovel, through the treads where they contact the earth and thence through the earth to the original fault. The amount of current flowing will be determined by the total impedance of the system. Since a large part of the total impedance will consist of the rather poor contact between the shovel treads and the earth, a large portion of the full line potential will appear between these two points. Any person standing on the ground and touching any part of the frame would be subjected to this potential. If the line potential would be 2300 volts and the body resistance taken as 500 ohms, almost 4 amperes could flow through the body, with almost certain fatal results.

B. Underground distribution system—with frame of machinery grounded.

There has been some thought that the addition of a ground connection to the frame of the machine, running to a ground rod would eliminate hazards due to ground faults. Actually, such protection is far from adequate. With such a ground connection and a ground fault to the frame of the machine plus failure of another phase wire, ground fault current will flow through the machine, the ground connection, to earth and so to the fault. Since the total impedance of this path has been reduced by the lowered resistance to earth of the ground rod, a larger ground fault current will flow than in the previous case. If the ground rod resistance path is in the order of 10 ohms (which seems to be a reasonable value to expect in most quarries) fault currents could be in the neighborhood of 50 to 100 amperes, on a 2400 volt system, and thus a potential of from 500 to 1000 volts would appear between the machine frame and ground. Again assuming the body resistance to be in the order of 500 ohms, this would indicate between 1 and 2 amperes of current through the body, again a fatal dose.

C. Another system makes use of a solidly grounded neutral in a Wye-connected distribution system, with the point of transformer ground being carried along with the power conductors to the frame of the shovel. With a ground fault, a large ground fault current will again flow, which should cause the protective relays to trip out the power circuit. However, during the time necessary for these relays to operate, the frame of the shovel will probably be at a dangerous potential for a short period of time.

D. Having looked at the previously described system, it may be seen that a high degree of protection may be secured by:

1. Providing the lowest practical resistance between the shovel frame and ground.
2. Limiting the ground fault current to such a value, so that the voltage drop between the frame and ground will not exceed a voltage which is ordinarily considered dangerous. The mining industry has set this limit at 100 volts.
3. Disconnecting the power feeders when a ground fault occurs with as little delay as possible.

It is to secure these benefits that modern installations are using impedance or resistance grounded neutral transformer distribution systems. In the event of a ground fault, the ground fault current will flow from the transformer terminal through the main conductor to the shovel frame, returning through the ground conductors to the neutral resistance and thence to the neutral point of the transformer. Under these conditions the ground fault current is limited by the neutral resistor to such a value so that, under the ordinary conditions encountered in quarries, the voltage drop between shovel and ground would not exceed the safe limit of 100 volts. In addition to this, protective relaying is installed in the neutral of the transformer, that will immediately be responsive to ground fault currents and remove the entire feeder circuit from the system.

Summary

Adequate protection of human life and health against electrical shock hazards can be provided. It will consist of these features:

1. All electrical installations to be made with the highest degree of skill possible.
2. Neutral point of Wye-connected trans-

formers to be grounded through a resistor which will limit ground fault currents to 50 amperes or less.

3. Ground connections from this resistor to be carried through the portable cable and terminated on the frame of the machine involved.

4. Relaying to be installed in the neutral of the transformer which will remove the faulted circuit from the source of supply.

5. Ground connections, cables and rods

to be periodically tested to insure the lowest possible resistance in the ground circuit.

To accomplish this may add somewhat to the cost of installations. It will certainly require some effort, time and money to maintain in working order, but unless we agree to do the job to the best of our knowledge and ability, we cannot say we have done everything in our power to make our plants a safe place in which to work.

HAZARDS CAUSED BY IMPROPER APPLICATION OF KNIFE SWITCHES

By G. J. REYNOLDS

Tech. Mgr., United States Gypsum Co., Chicago

The United States Gypsum Company has had several serious accidents in the past several years through the closing of inadequate knife-type so-called "safety" switches on stalled motors or short circuits. This is the greatest single cause of electrical accidents in the company.

Many of the knife switches have been applied in the past as safety lockout devices ahead of motors. The hazard exists in that the knife switches are usually of the lightest type available as intended to be visual disconnect only and to be opened or closed only with the power off, not to interrupt energized circuits. Our main objective is the elimination of the knife switch entirely where possible, where a lockout switch is required. If it cannot be locked out conveniently because the main breaker is too far away, a safety lockout circuit breaker should be added for this purpose.

The purpose of this switch is only to visually open the circuit for safety reasons after the power is off. The reduced voltage starter for the motor is at the lower right and the starter stops and starts the motor by means of a push-button above. Therefore, after the motor is stopped, theoretically, it should be perfectly safe to open or close the knife switch as there is no load on the circuit at that time.

In one case the starter contacts had fused when inching the motor but the knife switch

was safely pulled without damage. Later when it was closed on a starting load, because essentially the starter contacts were fused shut, the switch was closed on a load which the switch did not have capacity to take and the switch exploded.

A maintenance mechanic had been assigned the job of servicing the rollers of the White Raymond mill. He serviced them by positioning them manually in line with a port in the side of the housing and had completed four of the five rollers in this manner. He experienced difficulty in getting the fifth roller into position for servicing. He pointed this out to another mechanic who was walking through this area. The latter said he would "inch" the motor for him. The first mechanic removed his lock on the safety switch and then returned to the Raymond Mill so that he could observe the positioning of the rollers.

He signalled to the second mechanic when he was ready. At the signal, the second mechanic closed the safety switch, pressed the starter button momentarily and only long enough to allow the fifth roller to turn into position. This would have meant that the mill made only one fifth of a revolution before the operator released the starter button.

The first mechanic states that the mill made no more than a fifth of a revolution and that the fifth roller stopped in the

With the co-operation of our safety director, Mr. E. C. Beuthin, the program was reviewed with management and their support and approval for future appropriations was obtained.

Our next step was to disseminate the information to our 60 plants in the field through channels that would set up authority for execution and to assume the responsibility for compliance. This was handled through our operation managers, through

their production managers and plant works managers.

The seven-page Information Bulletin #604, referred to above, was compiled to cover classification, survey and alternate methods of making correction and was issued to all plants as an operating bulletin for execution.

Completion of each separate plant project, in accordance with the above, is being followed up by the production managers.

FALLS DURING BULK MATERIALS LOADING OPERATIONS

By JAMES M. CHRISTIE
Safety Engineer, Portland Cement Assn., Chicago

My paper is directed to a problem in our industries that is certainly not new. As a matter of fact, in my research I ran across an accident report describing a fatality in this same type of situation back in 1920—just a few years before I was giving any thought to safety work. The title of my paper, "Falls During Bulk Materials Loading Operations," is intended to be specific to a current problem. And I believe it accomplishes this. However, as I stated, this problem is not new. It is merely being brought to our attention most recently, because of an increased usage of trucks for bulk hauling of our products. And, naturally there have been many injuries sustained by our employees.

I wish to tell my point with a few case histories. The case of the fatality I mentioned earlier involved a fall from atop a rail car. A 15-foot fall, the approximate height of a rail car, is certainly a potential fatality whenever it may occur.

Essentially, our problem involves falls to a lower level—whether loading into truck trailers or rail cars. However, it is not necessarily limited to this. One injury that I learned of involved an operator loading a trailer with bulk lime—he tripped and fell on top of trailer and fractured three ribs on his right side. But this accident did not exhaust all the possibilities for injury. He could have fallen into one of the

open hatches on the trailer—with the resultant possibility of suffocation.

This happened to a worker loading finely divided material—he tripped while on top of a rail car and fell into a loaded section of the car. For a brief interval he was completely submerged in the material. Fortunately, quick action on the part of another employee saved his life.

Or—another case—this time on a truck. The employee stepped into the opening on top of truck with one leg—suffering severe bruise in groin.

Now the fall to a lower level. Basically—from the top of the rail car or truck trailer to the ground—distances ranging from 10 feet to 15 feet. Would you condone a situation in which an employee regularly works on an irregular surface near an unguarded dropoff of 15 feet? There is much condemnation of such work practices in our industries. It appears that the thinking has been something like this—railroad men and truck drivers do it why can't we? Does this sound familiar? Or, the safety equipment creates more hazards than it alleviates—hogwash. I'm sure you have all heard these excuses many times.

In plants where these and similar excuses have been allowed to prevail, we know of many injuries resulting from the falls that occurred. An interesting sidelight is the fact that in almost all cases, after an in-

jury has occurred, some action is taken to prevent further injuries. But only after someone has been injured.

These are the case histories of some injuries sustained in falls during bulk loading:

A bulk car loader lost his balance and fell to the ground when a hatch door that he was pulling open released quite suddenly. He fractured his heel. Another case of lost balance and a fall to the ground from a rail car resulted in multiple fractures, bruises and brain concussion—both of these are similar as the start but the consequences are vastly different.

On truck trailers, I learned of a case where the truck driver drove away from the loading point while the loader was still on the truck. And yet another case of lost balance—this time from a truck trailer—the loader suffered a broken arm when he tried to jump to a platform 8 feet below to avoid a fall.

These case histories certainly are not all inclusive in either number or types of accidents. They do lead us in the direction of solving the problem, however. At the risk of over-simplifying this problem, let me say it in this manner. We have people working in locations where they are exposed to injuries from falling. Our job is to prevent these falls—How? By tying the people in place or by building a fence around them.

By way of explanation, my organization, The Portland Cement Assn., has established certain safety precepts that our members use to guide their safety efforts. We call them "model safe operating practices." The one that is specific to this situation states, in part, "A safety belt and line properly attached, adjusted and incutted shall be worn by each person working on an unprotected perch more than five feet above a lower surface."

I might add that this model safe practice, and all the others, is intended as a minimum requirement for job safety in the cement industry. Our members find need to expand these and to make them specific to certain work locations and situations. We believe this model safe practice covers both the "tying in place" or "building a fence around" situations.

Directly, if a man is on top of a rail

car or truck he is working on an unprotected perch—more than 5 feet above a lower surface, and needs the protection of a safety belt and line. On the other hand, if a fence is built around his work location, his chances of falling to a lower surface are negligible. So, I say again, "Tie him in place," or "build a fence around him."

Now, gentlemen, I would like to show some specific examples illustrating the two points I have mentioned.

1. Man on car with belt and line attached to horizontal overhead cable.

You will recall that I told you of a case involving a loader who fell into a hatchway and was momentarily submerged in lime. This picture involves the same type situation. Except, this man was using the belt and line shown and only went into the hatchway to around his knees. There is quite a difference in the potential consequences of these two similar cases.

In attempting to apply the principle of "tying the man in place" you will encounter some physical difficulties at your loading points. It amounts to answering the question, "What can we tie the man to?" With a roof overhead, a cable can be extended horizontally over the length of the loading area. As in this case, the life line can be permanently attached to the horizontal cable. Also, a ring attached to the top of the life line allows your bulk loader to work the entire length of the car or truck trailer.

2. Silos or buildings on both sides of loading area.

If you don't have a roof or structure over your loading area, you may have structures on either side, as shown in this slide. Here you will note the cables extended over and across the loading area that support the cables extending the length of the loading area. To these, then, the life lines are attached. Please note that these life lines are pulled up and tied off. This is to allow for the 22-foot vertical clearance requirements over the top of the rail.

3. Pole installed as upright support for one corner of cable arrangement.

This is intended to show the extent to which one plant has gone to provide a place to tie the bulk loader to his job. They didn't have adequate overhead structure or buildings on both sides of the loading area.

so they installed this post as the corner support for their cable. Again, note the life line pulled out of the way for rail movement.

4. *Boom pivoted from side of silo for truck loading.*

One plant has solved the problem of what to do by installing a boom on the side of their silo. The boom is pivoted at the silo and is actually a monorail. The life line is attached to a carriage on the monorail and the user can safely traverse the entire length of the boom.

5. *Platform over truck loading point.*

This platform is designed to virtually eliminate fall hazards during bulk loading. It illustrates the point of building a fence around the work location. At this plant, the loader never goes onto the truck trailer. However, the problem is not completely eliminated because someone (in this case the truck driver) must open and close the hatch covers. This practice appears to be quite common around the cement industry. The employer of this worker needs to attend to his protection.

6. *Handrailed walkway alongside silos.*

This is an illustration of the fencing principle as used in loading aggregate from silos. The discharge chutes can be lowered into position and the flow of materials controlled from this handrailed walkway.

7. *Pivoted walkway to get out to truck.*

This situation does not fit neatly into either of the categories I have tried to establish. However, it does involve need for both fencing and tying the loader. The platform on which this employee is standing is hinged and counterweighted to keep it out of the way when a truck trailer (or railroad car) is being spotted. Then it is used as the access to the truck or car. It has handrails; however, once an employee goes beyond these he lacks protection. So, this represents a situation in which both tying and fencing may be applicable.

8. *Suspended handrails at a truck bulk loading point.*

An example of applying the "fencing" principle to a truck bulk loading situation shows the slatted grating leading to the trailer, then the handrail that extends around the working area.

An additional safety innovation is evident in the stairs and catwalk that are used for access to points where maintenance work will take place. I think you will agree that a great deal of thought has been given to these work situations.

9. *A situation that is not common all over the country.*

On a trip into New York State I saw a type of rail car that I had never seen before. It is called a bottle car and consists of 4 or 5 large metal containers on flat bed rail car. There are no ladders on the sides of the "bottles," and no catwalk from one "bottle" to another. As a partial solution to the problem of how to position a man for loading these cars, one plant installed hinged grating alongside the loading area. These are kept in a raised position until a car is spotted. Then the platform is lowered and it offers a convenient working surface for the loader. I might add, that this arrangement could be improved by installing a cable overhead for use with a safety belt and life line.

There is one other mechanical device regarding bulk loading that I want to discuss. In many of the examples above, you will recall that the bulk loader had to climb up the ladder on the rail car or truck and then hook up his safety belt to the life line. This allows for exposure to falls during the climb up and down the ladder, and momentarily while he is not hooked up to the life line.

I don't want to be accused of advertising a commercial product and I don't have any stock in this company, but I do want to tell you about a product that is being used in some cement plants. It amounts to a life line that is mounted on an automatic reel. The reel contains 16 feet of steel cable that extends or retracts automatically with the normal movement of the user. Then, should he lose his balance and start a rapid extension of the cable, a locking mechanism in the reel stops the movement in about one foot.

To use this device in a bulk loading situation for example, you still need a cable extended horizontally over the loading area. Then, the reel containing the extendable and retractable life line, should be attached to the horizontal cable. It will slide on the horizontal cable allowing free-

dom of movement the length of the rail car or truck trailer.

The life line will allow for safety during the loaders vertical movements getting on or off a rail car or truck. In answer to possible questions, I would like to explain that I do not know of any tests that have been made on this device—other than by plant people—one plant has dropped a 250-pound weight and the locking mechanism worked properly.

Falls during bulk loading of materials can result in serious, even fatal injuries. They have happened in the past and will happen again unless we exert efforts to provide work situations where fall potential is either eliminated or drastically re-

duced. And, this won't be an easy task. You are all familiar with the resistance one encounters when attempting to institute any new safety practices or equipment. You may expect such resistance regarding fall protection—both from management, supervision, and employees. However, there are many plants in which the employees are protected from falls and they are still producing efficiently.

I'm sure you realize that I have not covered every conceivable situation—I'm certainly not knowledgeable about all of them. I do hope, though, that I have been able to stimulate you to review your bulk loading situations with an eye towards reducing fall potential and eliminating these injury sources.

BELT CONVEYOR HAZARDS

By LESLIE S. VOLTZ

Safety Engineer, Consumers Div., Vulcan Materials Co., Chicago, Ill.

My remarks are pointed primarily to the management of the smaller companies who do not have actively organized accident prevention programs, and to the larger companies who do have such programs but fail to make them effective because of the poor attitudes of operating personnel. As a safety engineer I cannot be honest if I judge our progress as an industry by a code of legalistic moralism. I must judge the results on our success in preventing all personal injuries.

The tragedy of belt conveyor accidents is that we do know how to prevent them. We do know the essential rules, on the mechanical and electrical devices and their operation, to eliminate such hazards to our employees. We do know the necessity of specific rules and regulations which must be hammered (and this can be taken literally for some employees) into the minds of our management and men concerning the operation of belt conveyors.

Some of the things I say here may make you angry and I hope they do—in fact I wouldn't care if you got so mad you pushed me out the door—if in so doing I could only convince some of you of your lack of

an intelligent approach to belt conveyor safety.

Possibly many of you have stood by a belt conveyor and watched it roll along quietly with its load, the occasional click of the splices passing over the rollers being the only sound you heard. It doesn't make a lot of noise to put fear in your mind and seems so innocent as it travels along at 350 to 450 feet per minute. This very characteristic makes it fascinating and seemingly harmless.

In fact, I have often thought of this type conveyor in the same manner as a person might think of the waves that roll in so quietly and peacefully at a beach. Yet we know in many cases beneath all this serene beauty there is a deadly undertow. You may be only a few feet from danger . . . and so it is with a belt conveyor. You may be only a few inches from a serious personal injury.

The following should never let you forget one basic rule of belt conveyor accident prevention, that is, provision for an effective "lock and tag" system. I have called this "Death Takes a Holiday."

A working foreman about my size and age was instructed to repair the chute at the bottom of a 42-inch belt conveyor from the screening building to the load out bins. The conveyor was not running and, according to the man's statement, he pulled the emergency cord to make it inoperative. He then proceeded to get on the belt and start the repairs.

All head and tail pulleys should be guarded, but the wing type tail pulley is a particularly dangerous type; however it did not contribute to this accident. A general view up the conveyor from the tail pulley shows the emergency cord. This is the long trip our man will have to take—220 feet to the head pulley at a belt speed of 400 feet per minute.

A view of skirt plates at the chute to be repaired would show the emergency cord on the left which the foreman said he pulled at this point. The employee was standing between the angle supporting the skirt plate and the conveyor cover when the belt was started from the control center at the load out bins.

He was knocked down by the cover and started up the conveyor head first. As he was traveling about seven feet per second, he could not pull the emergency cord.

He was flattened by the 3/4-inch belting, used to shape the material on the belt before it comes to the weighing device. The clearance from the bottom of the 3/4-inch angle supporting this is 21 inches and it is only 11 inches from the trough of the belt to the crown of the belting.

Again, he entered the conveyor covering to continue his journey. His last view of daylight was at the weighing device, where once more he went under cover. Surely, at this point, "death was his companion."

At the chute to the screen, where the employee went over the head pulley and into the chute, there was only a 12-inch clearance. He was able to get out by himself and walk from the tower with some assistance. Examination at the hospital did not disclose any fractured bones or serious lacerations. His body, however, was so severely bruised all over that he was disabled for 22 days.

No one can deny that this man was blessed and that "Death" did indeed, "take

a holiday!" But why did it have to happen? The plant had been provided with danger tags. Only the previous week locks had been received to institute lock-out systems. The employee had three separate places to tag out, lock-out, or both tag and lock the power to this conveyor, as follows:

1. At the emergency switch at the head pulley of the conveyor.
2. On the control panel at the load out bins.
3. The circuit breaker for the unit under the load out bins.

However, none of the tags were placed at any of these points. Who, then, was responsible? You can each answer these questions for yourself and your own operation.

1. Had the employee been instructed personally on the use of these tags?
2. Had management and supervision insisted *every single time* on the use of the tag out system?

A two hundred foot walk on the part of the employee would have insured his security. Yes, Death took a holiday but don't depend on it! Good management cannot afford to gamble with such odds.

If you are interested in seeing an excellent film on lock out systems get "Lock and Tag." See the June 1961 issue of *National Safety News* for the source for this film.

The next series lists some of the hazards encountered in the process of repairs, or as the result of repairs or maintenance. Please review your own operation as these are given.

1. Guard not replaced following repairs.
2. Ladders incorrectly placed or used.
3. Conveyor walk-ways with openings, no toe boards and absent or missing cleats. The latter are a necessity where frost, or freezing water can accumulate.
4. Falling Hazards—Man trap, material left on stairs or platforms.
5. Pinch bar left on walk-way.
6. Removal of bearing race with 8 lb. sledge hammer.
7. Compressed gas cylinder—unsupported oxygen tank.
8. Tools in bad condition—mushroomed chisel. Note oxygen tank in background.

9. Unguarded platforms, openings, absence of cleats, etc.

10. Unguarded flexible couplings, motor to speed reducers.

11. Unguarded conveyor drives.

12. Incomplete guarding.

13. Unguarded back stop.

14. Unguarded wing type tail pulley.

15. Overhead dangers. "A Safety Hat Saves a Life."

A quarry mill employee, age 29, was cleaning the tunnel floor under a 42" belt on the tight side, (opposite the emergency cord) where there was an 18-inch clearance between the conveyor structure and the wall. He was using a long handled scoop shovel and throwing the spilled material back onto the top run of the belt. A troughing idler was involved in the accident, and a vertical angle supported the skirt plates. The handle of the shovel was caught between the operating belt and idler, pulling the left arm and shovel blade under the belt. The throat of the shovel held part of the weight off of the employee's arm, and prevented the idler from turning. The employee's statement was as follows:

"It seemed to me an eternity before I was found, although I think it was between two and three hours. I hollered from time to time as loud as I could whenever the conveyor was stopped and on one occasion I unlaced one of my shoes and wedged it between one of the rollers in an attempt to lessen the pain. I also took a shoelace out of the shoe and wound it around my arm as a sort of tourniquet to stop the loss of blood. When released by my fellow employees I fainted and woke up in the hospital."

The report of medical treatment was as follows:

"He was treated for 3rd degree burns of the left forearm and hand. This involved the tendons, muscles, nerves, arteries and veins. He had multiple debridement of the left arm. In order to prepare the arm for the skin grafting, his right thigh was chosen by the doctor as the donor site, and from this area three strips of split thickness skin was taken and placed on the defects. Approximately 75 per cent of the forearm was covered, leaving the other 25 per cent which was composed of dying and exposed flexor

tendons in the area of the wrist. Iodoform gauze was packed into the wound and extended proximally down between the radius and ulna in the lower third of the forearm. Vaseline pressure dressings were applied followed by fluff dressings."

He was discharged from the hospital 103 days later, but had to report to the hospital three times a week as an out patient for further debridement of the skin and conditioning of the skin graft. The donor site dressing was changed after two weeks and revealed this wound to be completely healed with no particular difficulty. The only thing remaining is the volar area of the wrist in which remains some of the fibers of the deep flexor tendon which should be saved to give him a pinching mechanism of the thumb and index finger. Therefore, it was impossible to graft over these areas. Enclosure had to be achieved by secondary intention. After 46 more days, the man was sent to a sanitarium for physical therapy treatment to help reconstruct the function of what remains of the power in his left hand.

Seven and one half months after the accident the employee was re-examined and it was reported that the wounds were healed except for two small areas on the volar aspect of the wrist.

"His fingers reveal very little, if any, active motion and almost no passive motion. He does have 25° of active flexion of the distal phalanges of the thumb and 15° of active flexion of the proximal phalange of the thumb. He has a loss of sensation compatible with injury to both the median and ulnar nerves. This hand and forearm, in my opinion, represents a 100 per cent disability because of the marked stiffness of the joints of the fingers. I believe there is little hope of obtaining active motion by further ten's surgery. If it were possible, by continued physiotherapy, to obtain some passive motion, there would then be some chance for further surgery. The gap in the median nerve is so great that nothing short of nerve graft would be of any value."

"It would be my impression that either the total disability should be accepted, or to continue with a trial of physiotherapy and splinting to try to mobilize the small joints of the hand. If these small joints can be mobilized, one would then have to plan a large pedicle abdominal flap to replace the scarred tissues on the volar aspect of the

AN M.D.'S USE OF ELECTRONIC DATA PROCESSING IN HEALTH AND SAFETY

By BERT W. BROOKS, M.D.

Dir., Industrial Health, The Upjohn Co., Kalamazoo, Mich.

Electronic data processing has, in recent years, become almost routine in industry. Most of you here today, I am sure, have had some contact, in the various industries that you represent, with representatives of your data processing departments. Records of sales, sales forecasts, shipping, the various accounts and payroll data, even supplies in many maintenance departments, and sums of available stock are a few of the functions of such a data processing department. The ease, accuracy, and speed of the reports from this type of department save hundreds of man power hours each month. If such facilities are available, why then shouldn't we in medicine and safety utilize them to assist us in not only day-to-day work, but also in long range planning and forecasting?

I am sure most of you know the concept of modern occupational medicine. Man power conservation is growing more important each and every day. There are few industries today that are not looking for some way to conserve their man power. I believe that health and safety parallel each other and, because of this, we should look at some medical statistics; and in this way, perhaps, gain further insight into the total problem of safety.

Within the past five year period, I was a consultant to Occupational Health Service, and during this time had the opportunity to study the results of over 60,000 physical examinations done at many locations on working people. The results to me were astonishing. Utilizing mobile equipment, over 30 different industries were visited in 16 states. For example; a paper corporation in Texas, a candy company in New Jersey, coal miners and quarry workers in Virginia and West Virginia, employees of one of our largest electronic firms in Ohio, and a utility corporation in New England.

As you can see, we had representation in many geographic locations as well as representation of many various types of industry. These were voluntary examinations done during working hours and paid for by management. Of the industries visited, none had less than 90 per cent participation of their employees, from top executives to the lowest rated employee. I think it important to mention that these examinations were done on supposedly well people, because if an employee was not at work he was not examined.

Also, to add to the statistical significance of these examinations, the same laboratory technicians performed the tests in each location, as well as the same board specialists for interpretation of such things as cancer smears, X-rays, electrocardiograms, etc. This, I feel, gives us a valid statistical base.

Electronic data processing played its part in this study. Without the use of electronic data processing adapted to medical records and laboratory results, little information could have been learned from this study. Each aspect of the medical examination was tabulated utilizing IBM equipment and from this data we quickly were able to produce accurate statistical reports of our work.

Let us briefly go through the various procedures that were done on each examination to give you an idea of the depth of this study. With each of our physical examinations:

A. A medical history was taken, utilizing a modification of the Cornell Index. Type History, including past medical history, present medical history, family history, operative history, and social history. An individual completed his history form with the aid of a nurse and a "marked sense deck of cards," including the above mentioned history. At the same time the individual was given 100

grams of glucose in orange juice for a more accurate blood sugar determination.

B. The height and weight were recorded and classified according to Metropolitan Life Insurance Tables based on body build, sex, height, and age.

C. Visual testing included the use of the Harrington Flocks method for visual field screening and the Ortho Rator for near and far vision, color vision, depth perception with and without glasses.

D. Because of the importance of hearing conservation, each individual was given threshold screening evaluation from 250 to 5,000 cycles per second.

E. A 12 lead electrocardiogram.

F. A routine physical examination which included neurological evaluation, rectal and pelvic examination, and papanicolaou smears in all females.

G. A routine chest X-ray.

H. In the laboratory the following laboratory procedures were performed: hematocrit, hemoglobin, blood sugar, serology, routine urinalysis, cholesterol.

I. Yes, I am sure you will agree, is more than a typical screening-type medical examination.

What were the results of these examinations? Twenty-five per cent of the people examined, regardless of job, age, geographic location or industry involved, showed a medical condition that might limit their survival in an industrial environment. One out of four of the people we examined, therefore, were found to have a serious or potentially serious medical defect. This fact alone might not shock you, yet 70 per cent of the individuals found to have a serious medical defect did not know it existed. The incidence of asymptomatic disease was found to be quite high. It is no wonder, therefore, that we are confronted with so many problems in our safety work. Certainly a sick individual is more prone to accidents than a healthy one.

When one considers minor medical defects, the results are again shocking. As high as 50 per cent of the individuals examined exhibited minor defects. Minor medical defects, in my opinion, are those which if left unattended might develop into more serious findings. I am speaking here of allergies, hemorrhoids, low back syndrome,

the myriads of fungus, etc. When you add the minor medical defects to the major findings in this study, approximately 75 per cent of the working population examined had recognizable medical defects, and yet most of them thought they were well.

Many other studies such as this have been reported and I am not presenting these statistics as the last word, yet this was a unique study done under rigid medical conditions and I feel should give you some basic medical insight as to the causes of many accidents.

I think it is interesting to note the increase of chronic debilitating disease from 46 per cent around 1900 to 81.4 per cent in the mid-1950's. On the same graph is noted the decreasing incidence of acute disease. This statistical evidence may be confusing.

Actually, the point to remember here is with the advent of the so-called miracle drugs, such as the potent antibiotics that physicians have in their hands today, acute disease is much better controlled now than it was in 1900 and if this is the case, it is the chronic debilitating disease that presents the challenge today. This is why the occupational medicine prevention or preventive medicine is assuming such an important role.

Of interest too is the percentage of accidents. This figure is relatively unchanged since 1900, and it is my opinion that illness plays an important role in keeping this figure at that level.

You all know that accident is the number four killer in the United States and for every person killed at work, three are killed at home and four are killed by automobiles. As late as 1957, 14,000 men were killed at work and 83,000 were permanently impaired, and in 1960, 13,800 were killed and there were 1,946,000 lost time injuries causing 84,000,000 days lost from work. You are also familiar with the fact that physical hazards cause only about 15 per cent of our accidents, human behavior 85 per cent.

Why do 4/5 of the accidents happen to 1/5 of our employees? Why are there so many repeaters year after year? I feel these can be predicted if we analyze records of their job, health, credit, and even social service records. Here is where electronic data processing can step in and play an important role.

DESIGN AND TESTING OF A NEW HIGH PRESSURE CELL

By

HOWARD C. BROWNE, Structural Engineering Consultant, Research and Engineering Div., Monsanto Chemical Co., St. Louis

HAROLD J. HILEMAN, Group Leader, Research and Engineering Div., Monsanto Chemical Co., St. Louis

LOWELL C. WEGER, Safety Dir., General Offices and Research Center, Monsanto Chemical Co., St. Louis

JOHN P. WEBER, Eng., Sandia Corp., Sandia Base, Albuquerque, N. M.

Chemical research activities today are vastly different from those of previous years. Many new technologies are being utilized to produce new products and processes. Among these new technologies is the use of high pressure, and the application of high pressure techniques has moved the chemist from his laboratory into many types of barricaded structures.

The types of reactions conducted at elevated pressures are quite varied, but usually involve a pressurized vessel in which an exothermic chemical reaction is carried out. Any pressure vessel or exothermic reaction presents some hazard. When the two conditions are combined, as in an exothermic reaction under high pressure, a considerable hazard may be involved. This is particularly true in research activities where the reaction and reaction rates are not known.

The possibility of the rate of reaction, being carried out at high pressure, approaching those found in explosive decompositions is very possible; therefore, extra precautions are required to provide proper safety for personnel. Some of the safeguards that should be employed include specially trained personnel, well-designed and engineered equipment, proper safety devices such as relief valves and rupture discs, provision for control of exothermic reactions, adequate barricading.

Each of the above mentioned safeguards is of considerable importance in the safe operation of a high pressure laboratory. This paper deals primarily with the subject of adequate barricading.

There are two general approaches to the use of barricades. In the first, personnel are placed in the cell with the equipment

placed in the open. This system is used in rocket and missile test work, and in the testing of conventional and nuclear explosives. In the case of high pressure chemical research it is conventional to place the equipment inside the cell. The primary function of the cell is to protect against missiles, and for hydrostatic test work the cell wall is usually made of steel or a combination of wood and steel.

A second type of missile, resulting from a runaway chemical reaction, is more difficult to stop. Under this condition a concrete cell wall is generally preferred. In the case of a chemical explosion, it is also necessary to protect against the resulting shock wave. For protection against missiles a completely closed cell would be preferred, whereas for the relief of the blast pressure a wide open area would be ideal. Cell design, therefore, is generally a compromise between the two. An additional function of a barricade is to isolate incidents, that is, prevent the involvement of adjacent areas.

Since high pressure laboratories are often operated in close conjunction with other laboratory facilities, protection of adjacent buildings is important. Mechanical failure of an experimental unit may allow the release of considerable volumes of combustible gas inside the cell. Because of the large energy release possible from the explosion of a gas-air mixture, it is necessary to guard against this condition by the use of forced ventilation.

Data on cell design were collected from many sources including other chemical companies engaged in similar work. The design we have chosen is based upon a com-

bination of the information received from U. S. Army Ordnance Proving Ground, Terminal Ballistics Laboratory, Aberdeen, Maryland and the high pressure laboratory of the Union Carbide Plastics Company located at Boundbrook, New Jersey.

The design objective was to build a cell that would minimize the effects from a runaway chemical reaction operating under pressure. Therefore, the design must satisfy five basic premises in the event of an explosion. These are as follows:

- (1) Prevent injury to personnel by fragments and missiles from vessels and accessories.
- (2) Prevent the spread of gases throughout the laboratory by an explosion or rupture of a pressure line.
- (3) Isolate the incident within the barricade so that adjacent facilities are not affected.
- (4) Contain an explosion without significant damage to the cell. The barricades must be capable of withstanding the effects of a sudden energy release of 25,000 BTU.
- (5) Confine fire.

The work done on a barricade wall by an explosion is a function of the cell venting. This venting is most easily done with an open top cell arrangement but because of the need of a roof, which would cut down the effectiveness of the vent, the open top approach for the cell design was abandoned. Literature has indicated the best protection against missiles is afforded by a wall constructed of a heavy wood panel between two steel plates.

However, since investigators also disclosed that a 12" minimum concrete wall gives excellent missile protection, along with more mass in cell walls with the corresponding increase resistance to shock waves, concrete was chosen. The recommended ratio of volume of experimental equipment to

volume of cell is 1:1,000 with 1:10,000 preferred.^{1,2} The small cell in the high pressure laboratory has a volume of 820 cubic feet. It is anticipated that equipment size will be limited to one gallon capacity thus the ratio will be 1:8,100.

Those familiar with the present day construction practice of high pressure barricades or cells will recognize basic sketches (1), (2), and (3) of Figure 1.

The energy release is designed to break through a panel of light construction, (rigid plastic, wood, light sheet metal, masonite, etc.) which is lightly fastened in position. This method depends upon hillside or wide expanses of unused and unoccupied land to absorb resulting missiles. Missile and energy absorbing type mats were rejected as not solving the problem in addition to not being functional.

An obvious and somewhat simple solution is to direct the shock wave and missile discharge to an unoccupied position. The easiest and best location is down into sand placed in front of the cell. Aberdeen's terminal ballistic laboratory confirmed this idea by showing us their labyrinth of concrete cell passages connected to their cells for venting and reducing the sound of each explosive charge.

From our cell the shock wave will change direction (see Figure 2). It will move around

the curved section 180° to the sand and then out of the cell at about 45° upward. Some portion will reflect from the "safe" wall but its dissipation back to the main cell building will be generally of lower order. Missiles will be absorbed in the sand.

Once the inside curved shape was agreed upon it was decided to square off the top exterior making it much thicker at the corners. By doing this we have a cell which lends itself to multi-cell construction if desired. At the same time it provides a wall for a second floor of a connecting structure to house laboratories and auxiliary mechanical facilities. These are important adjuncts to high pressure operations. The additional mass of concrete also provides an ideal absorption medium for blast energy.

It will be noted that this cell (Figure 2) has no so-called blowout panel. There is definite reason for this which has been borne out by experimentation and by our own tests of the prototype cell. The reason we desire the blast wave to go instantly out of the cell is to prevent the build-up of pressure from the rebound of detonation waves and after burning effect. A build-up of pressure could have detrimental effect on the cell walls by its quick pressure rise.

While this feature requirement has been recognized before in cell design, it has been always tied in with a detailed description of the blowout panel, termed the venting area. This is a new feature to be pointed to here. There should be no material of rigid stability, even though light in nature and insecurely erected, in the vent space. The forces from the energy release move so fast (a few milliseconds) that the panel hasn't the least conception it had been struck; thus, it contains the force and allows pressure to build up.

The reflecting forces from the detonation wave could move back and forth many times, building up pressure with the hot unburned gases, before the blowout panel moves out.

For an explosion in an enclosed space two mechanisms are important: the initial detonation which gives rise to a shock wave, and after burning of the detonation products in air.

The shock wave reverberates between the walls of the cell transferring energy con-

tinuously to the atmosphere through the irreversible processes occurring in the wave front. Also part of the shock wave energy escapes to the outside through any wall openings or vents which exist. The after burning is a relatively slow process which causes a general rise in pressure in the room or sustains pressure for a longer period of time.

The two processes together result in the transfer of some part of the total heat of combustion to the room atmosphere, the fraction of the total depending upon the percentage completion of the after burning reaction. This energy is in turn dissipated to its surroundings by heat of conduction to the walls, by release of pressure through vents, if any, and also in an important practical sense, by work done in damage to the structure.

Our cells are designed for installation of a plastic curtain which can be rolled down from the arched ceiling. In extremely cold weather the curtain can be dropped while setting up the experimental equipment. When the experiment is under activation and personnel are out of the cell this curtain is to be drawn up to its top rolled position in order to provide clear venting conditions.

Authoritative articles on high pressure cell venting recommend the ratio of vent area to cell volume to be between 1:20 and 1:30 in order to reduce pressure roughly to that obtained from an open air explosion and take care of decreasing the effects of after burning.^{1,2,3,4}

Our small cells have a ratio of 1:16 which is better than recommended. Our larger cells have a ratio of 1:22 which is equivalent to the recommended venting. Dr. W. E. Gordon⁵ considers 1:50 as being sufficient to effectively reduce the pressure.

Having established the shape of the cell, it was necessary to determine the structural material, thickness and reinforcing required. The choice was between using reinforced concrete or double steel plate construction. While there are many proponents in the literature^{6,7} for the use of two steel plates separated by an energy absorbing material it was our conclusion that reinforced concrete would be more advantageous to us for the following reasons:

(1) Multi-cell construction lends itself readily to mass pouring of concrete.

(2) Steel plate construction requires much extensive welding since all joints should be continuous. A preliminary estimate of the cost of each showed no advantage to steel plate even with its thinner walls.

(3) The large mass per unit area of concrete is highly advantageous in energy absorption and ability to resist shock waves.

(4) Anti-missile penetration can be achieved by use of at least 12 inches of concrete for this type enclosure when parts of reactors, rocket bombs, etc. become explosive propelled missiles.

(5) Internal and external maintenance in relation to the two story integral supporting research building definitely favored concrete.

In the preliminary design we determined the thickness of the concrete wall using a nomograph furnished to us by U. S. Army Ordnance. Using the calculated energy release of 25,000 BTU, roughly equivalent to 8-12 pounds of TNT placed 1.5 to 2 feet from any cell wall, the prevention of severe damage by a missile requires 15 inch walls of concrete. Since the exact energy release is indeterminate we added 3 inches more to the wall thickness as a factor of safety and for more mass protection from blast effect.

The additional 3 inches is not very costly, and the potential hazard to life and property would not be worth the insignificant savings in money and space resulting from the construction of 15-inch walls versus 18-inch walls.

The intermediate wall at the center of the cell space over the blast wave vents was made 12 inches thick since it was not a factor in personnel or property safety.

There are two methods of designing the walls to resist the pressure caused by the sudden release of energy. Both are simple design procedures which give reasonably conservative results. A more rigorous detailed method would be difficult to justify since there is seldom sufficient information available to determine the true character of the blast forces which the cell might be required to withstand.

It is extremely difficult to predict a pressure effect from the vast range of

high pressure chemical experiments which could result in blast forces from rupturing of a pressure vessel or a high pressure line, or from the ignition of explosive gases or vapors escaping from an operating system. These methods are equivalent static pressure, and blast resistant design by dynamic response and plastic action. Details of these two design methods are covered in a technical paper presented at the American Chemical Society meeting in September and can be obtained from the authors.

In applying the second method to our design we found the amount of steel required was conservative. Later in this report the results of the field test of the prototype cell show this to be true. Serious wall distress was evident only after energy releases of more than 35,000 BTU.

The 12-inch safe wall, nine feet behind the mouth of the cell, was designed as a cantilever wall by the dynamic response and plastic action method. The test of the prototype cell did not use a concrete safe wall but rather a light wooden wall constructed of the concrete form lumber. Shock wave effect on the weak wood wall confirmed the need of a concrete safe wall which contains mass and resisting strength. It is of interest to note that high speed film of this action proved definitely the fact that a weak fragile wall did not move when first hit by a shock wave of super-sonic velocity. It rebounds a portion of the shock before it knows it has been hit.

Mention should be given to the one-fourth-inch plate on the outside surface of the cell at the operation side, called an anti-spall plate. Its function is to prevent the exterior surface of the concrete cell from spalling off chunks of concrete when the inside cell surface is hit by a high energy missile coming from an explosion. The one-fourth-inch plate, held in place by one-half-inch continuously threaded coil rods nine inches long used in form work. The test of the prototype cell indicated that the studs and plate held firm and performed their function perfectly.

In normal operation it is often necessary to keep cell doors closed for extended periods. Safe operating practices preclude entry to the cell while high pressure experiments are in operation. If leaks should develop

in the operating system at such time, toxic or explosive vapors could be released which would present a hazardous condition unless the cell is well ventilated.

It is not practical to design a cell of sufficient strength to withstand the energy release from the detonation of a cell full of combustible gas mixture. While it is difficult to imagine how this situation could arise in normal operations, the possibility of this happening is guarded against by a forced ventilation of one air change every two minutes.⁶ This is considered as a minimum requirement. Many installations are constructed with one air change per minute. However our cell design makes use of a large direct vent area so the necessity of one air change per minute was dropped to two. Each standard cell has two exhaust fans.

The fans are split between exhausting air at the ceiling and at the floor line. The upper fan handles lighter than air gases and the lower fan the heavier than air gases.

An individual ventilating system is provided for each cell. It is felt that the use of a single fan with a system of ducts to serve more than one cell is less desirable because of the possibility of an explosion in one cell causing the failure of ventilation in other cells at an inopportune time or spreading flame or toxic materials.

At the completion of the cell design considerable research time, money and effort had been expended. It was felt that the only reasonable way to ascertain if the design were adequate, meeting the five basic design premises, was to prove it by building a prototype cell for test purposes. Therefore, Monsanto entered into an agreement with Armour Research, Foundation of the Illinois Institute of Technology, to test a full scale model of the cell.

This organization is experienced in similar explosive-type testing work since it is continuously doing work for government agencies, in the field of nuclear explosives for the AEC, and ballistic missile testing for the U. S. Army Ordnance. The Explosive Research Section of the Fluid Dynamics and Systems Research Division of ARF conducted the tests at the ARF explosives test site, Coal City, Ill., in February and March, 1960.

The test program was intended to determine the effects of 8 to 12 pounds of TNT detonated within the cell. For convenience in charge preparation, handling, and firing, DuPont 50 per cent dithene dynamite was used in place of TNT. The heats of detonation of TNT ($p = 1.59$ gm/cc) and the dithene dynamite are 2010 BTU per pound and 1880 BTU per pound, respectively. The heats of combustion are 6520 BTU per pound for TNT and 2500 BTU per pound for dithene dynamite.

The large heat of combustion of TNT results from an oxygen deficiency. The after-burning of the detonation products does not contribute to the air blast pressure, but it is of importance only in creating rise of static pressure in a completely closed system.

Since the test cell has a large vent area per unit of volume, pressures within the cell are not sustained, and the increases due to afterburning will probably not be of sufficient duration to cause increase in structural damage. For this reason the heat of detonation more truly represents the sudden energy release, and is the better criterion for predicting air blast damage to the cell and its surroundings. Thus, it can be seen that a given weight of dithene dynamite is only slightly less effective in causing damage than an equal weight of TNT.

Electronic and photographic instrumentation were employed to obtain air blast peak pressure measurements in the immediate neighborhood of the cell, shock velocity measurements in the immediate neighborhood of the cell (for pressure and shock position calculations), and air blast pressure measurements at greater distances.

In order to determine directly whether windows in adjacent buildings might be damaged by air blast, three glass windows were mounted in the test area. These windows were located at distances of 280 feet, 500 feet, and 800 feet.

For some of the shots, a 16mm Fastax camera was used to observe shock propagation from the cell, and the response of the cell and the safe wall to the blast. Framing rates were between 725 and 4600 frames per second, depending on the exposure times required for the existing light conditions.

The gauges used for obtaining pressure measurements were of the piezo-electric type employing barium titanate. They were one-fourth-inch in diameter and were flush mounted in the centers of rectangular steel baffle plates having dimensions of three-eighths by four by seven inches.

A foil-break probe system was used to detect the shock front. Holes two inches in diameter were drilled about three-fourths-inch deep at two-foot intervals along a two-by-four. One-half-inch wide aluminum foils, notched down to one-sixteenth-inch in the center, were taped across the openings. Pieces of Saran film were then taped over the foils. The breaking of the foils unshorted resistors, resulting in voltage changes on the output cable. The circuit was balanced, so that an up-and-down step function resulted as various foils were broken by the shock front.

Because only one Tektronix 551 dual beam scope was available for the first few experiments, three of the pressure gauge signals were amplified and recorded on an additional four-channel oscillographic unit. A sequence timer was used to synchronize the recording camera on the four-channel unit, the Fastax camera, and the firing of the charge. Shock arrival probes were used to trigger the sweep of the two Tektronix scopes.

Six one-pound charges were detonated in the cell, followed by one two-pound charge, one four-pound charge, three eight-pound charges, one sixteen-pound TNT charge, and a fifty-pound charge. The charges were all located near the center of the cell floor, and were supported about two feet above the floor by a wood four-by-four. Number 6 electric blasting caps were used to initiate the dynamite charges, and firing voltage was supplied by two six-volt "hot shot" batteries in series.

To permit synchronization with the instrumentation, the firing circuit was closed automatically at the instrumentation trailer. When high speed photography was employed, the firing circuit was closed at the camera remote control unit. The wood wall in front of the cell, simulating the concrete safe wall, did not withstand the effects of charges of two pounds or more. The wall was rebuilt twice, and after the first eight-pound shot it was no longer used.

Except for damage to the side door

mounts (cinch anchors into the concrete), no damage to the cell was detected until after the first eight-pound test. In this shot, some concrete fell from an area across the top of the vent opening or mouth of the cell. The discolorations in the concrete in this area indicated that the concrete had been improperly mixed or settled.

The second and third eight-pound charges caused only slight additional damage to the cell. The 16-pound TNT charge caused several cracks in the side walls and the interior wall, but no significant deformation of the basic cell structure. The 50-pound charge, which was considerably in excess of the energy design limit of the cell, did cause extensive structural damage, however, fragments from steel members placed on the charge were not projected from the cell.

The motion picture records of the TNT test show afterburning of the product gases outside the mouth of the cell. It is also apparent that much unreacted carbon was present. This information supports the opinion that afterburning within the cell does not result in significant additional damage to the cell structure and that the energy release criteria should be the heat of detonation rather than the heat of combustion.

In the experiments involving charges of four-pounds and larger, the pressures recorded from the gauges located near the cell seemed too low, and the shock propagation velocities indicated by the foil break probes were only slightly above sonic. Fastax films of the experiment revealed that the recorded pressures were lower than expected because two shock waves were produced. A weak shock preceded the strong shock from the mouth of the cell. This weak shock apparently is caused by leakage around the edges of the baffle plate on the vent pipe near the bottom of the interior wall.

Pressures of the strong shock were calculated in some cases from measurements of the shock velocity taken from the Fastax film. In the shots for which pressure gauges were located seven feet and eleven feet from the cell mouth, the weak shock signals were recorded, but the strong shock drove the traces off the scope. The time of arrival of each shock at each gauge was known, and therefore, the propagation velocities and shock pressure could be calculated.

SAFE HANDLING OF CRYOGENIC FLUIDS

By R. M. NEARY

Safety Eng., Linde Co., Div. of Union Carbide Corp., New York City

What is cryogenics? The word itself is derived from the Greek words meaning "to produce icy cold." In current usage, "cryogenics" generally means the science of producing and utilizing extremely low temperatures. The temperature range involved is usually from about -150°F . down to absolute zero (-459°F), but this is arbitrary, and the recognized groups working in the field have established various other temperatures to define the upper limit of the area of cryogenics.

For the purposes of this paper, we will consider cryogenic temperatures to be those where special cryogenic equipment, such as double-walled vessels, extended stem valves, and related hardware is required. Practically speaking, this is what distinguishes the handling of cryogenic fluids from the handling of ordinary low-temperature fluids.

Cryogenic techniques have been used for many years in the low-temperature separation of air into oxygen, nitrogen, argon, and other gases used throughout industry. In recent years, however, the emergence of new industries and processes has given a tremendous boost to the field of industrial, or applied, cryogenics. The missile and rocket industry, for example, uses large volumes of liquid oxygen, hydrogen, nitrogen, and fluorine. The chemicals industry is making increasing use of cryogenic tech-

niques for purifying methane and other gases, used in producing high-purity chemicals in commercial quantities.

Cryogenics also promises to play a major role in low-temperature physics (particularly in electric computers and microwave communications), in the preservation of biologicals, in the refrigeration of foods, and in many other applications.

The large-scale growth in the use of cryogenic fluids in recent years has been paralleled by a large increase in the number of users of laboratory quantities of these fluids. Since handling small quantities presents some safety considerations different from handling larger volumes, these subjects will be covered in separate sections of this paper.

The Cryogenic Fluids

Handling cryogenic fluids safely is largely a matter of knowing their properties and using common sense to avoid hazards. Potential hazards stem from three important properties:

1. These fluids are extremely cold.
2. Small amounts of these liquids vaporize to form very large volumes of gas.
3. In the case of liquefied hydrogen, the released gas is highly flammable.

Some of the important properties of the most common cryogenic fluids are listed below:

	Bolling Pt. $^{\circ}\text{F}$	Liquid Density lbs./cu. ft.	Conversion: cu. ft. of gas from 1 cu. ft. of liquid at 70 $^{\circ}\text{F}$, 150 psia	Heat of Vaporization Btu/lb.
Ethylene (C_2H_4)	-184.7	35.31	737	207.7
Methane (CH_4)	-258.6	24.48	237	218.2
Oxygen (O_2)	-297.3	71.3	562	91.7
Argon (Ar)	-302.6	87.53	847	70.2
Fluorine (F_2)	-306.8	84.3	869	74.1
Nitrogen (N_2)	-320.3	50.46	656	82.2
Neon (Ne)	-410.6	78.35	1,415	37.1
Hydrogen (H_2)	-422.2	4.42	864	192
Helium (He)	-452.1	7.8	754	8.8

Handling Laboratory Quantities

More accidents, and more potentially serious accidents, have been reported with laboratory quantities of liquefied gases than with large volumes. This makes the proper

handling of small quantities especially important.

Liquid nitrogen, liquid hydrogen, and liquid helium are the cryogenic fluids most widely used in laboratory quantities. Liquid

neon is also coming into the picture, since it provides more than three times as much refrigeration as an equal volume of liquid hydrogen, and more than forty times as much as liquid helium.

Liquid neon, like liquid helium is inert and therefore the same safe practices that apply to handling helium (to be discussed) would apply to neon with due allowance for the higher rate of gas conversion of liquid neon.

Small Containers. The containers usually used for laboratory handling of cryogenic fluids are made from materials which can withstand the rapid changes and extreme differences in temperature encountered in working with these fluids. In a typical container, the inner liquid vessel is supported within the outer casing by the neck tube and, possibly, one other support. The wall of the neck tube is made as thin as practical to minimize heat leak into the inner vessel. Since liquid hydrogen is only about 1/12 as heavy as liquid nitrogen, the neck tube on a liquid hydrogen container may be designed to support the container when it is filled with liquid hydrogen only.

Thus, cryogenic containers are filled only with the liquids for which they are designed, and are handled carefully to prevent damage to the inner container support system. If a container has design limitations affecting the net weight of content, or which otherwise make it unsuitable for use with all cryogenic fluids, suitable warning must be given to the user.

Incidentally, the Compressed Gas Association is considering revisions of Interstate Commerce Commission Specification 4L (the insulated cylinder for pressurized liquid oxygen, nitrogen, and argon) to provide for a cylinder (such as the LSH 150) to transport liquefied hydrogen. The ICC 4L containers suitable for use at liquefied hydrogen temperature (-423°F) will be stamped with the maximum weight of the contents to warn the shipper against filling them with a heavier liquid.

Many cryogenic containers used in laboratories vent to the atmosphere through neck tubes. This type of container has been used successfully with liquid nitrogen for many years with only a couple of incidents reported where the neck tube was plugged. However, several instances have been re-

ported where the neck tubes of liquid hydrogen and helium containers have become plugged.

It has been surmised that, since the boiling points of hydrogen and helium are both well below the freezing point of air, solidified air contributed to this plugging. Thus it is imperative that all containers for liquid helium, hydrogen and neon be protected by a device which permits the escape of vapor, but precludes the diffusion of air back into the cold neck tube.

A relief valve that maintains the contents at 1 to 5 psi is often used and it is installed downstream of a short tube so that it remains at essentially ambient temperature. An inverted "U" tube is not considered adequate to prevent back diffusion of air.

Plugging is particularly critical in air shipments because changes in atmospheric pressure as the plane goes up and down cause erratic boil-off rates. To overcome this problem on liquid helium containers, Linde uses a copper tube heat exchanger ahead of the safety device to warm the released helium gas to ambient temperature before it reaches the relief valve. In laboratories, the tube may be much shorter.

Filling Containers. Before the initial filling of a warm container with liquid helium or hydrogen, it is precooled with liquid nitrogen if possible (contact the container manufacturer for the maximum weight of liquid nitrogen which may be used). Precooling with liquid nitrogen minimizes the volume of flash-off gas when the container is filled with liquid helium or hydrogen. It also purges air from the vessel.

Since the low temperatures of liquid helium or hydrogen can solidify any other gas, it is imperative that all of the nitrogen gas and air be removed from the container before it is filled. Solidified air in liquid hydrogen presents an explosion hazard because of its oxygen content.

Because air will condense into them, liquid hydrogen and helium are always (except in special cases) handled in closed systems and never poured from one open container to another. In addition, all liquid hydrogen equipment is electrically grounded and the operator touches the grounded equipment to eliminate static before making or breaking any connections.

Many cryogenic containers used in laboratories are not equipped with safety relief valves, since the containers normally vent through the neck tube. During filling, a tube is inserted into the container, often leaving only a very small annular space between the fill tube and the neck tube through which the flash-off gas can escape. If transfer is being made from a pressurized container (above 10 psi) through a closed system, a relief valve is installed in the transfer pipe to protect it and the receiving container from excessive pressure.

Design of the Laboratory. A conventional laboratory with good ventilation is suitable for handling non-flammable liquefied helium or neon because a principal hazard is the release of sufficient inert gas to reduce the oxygen concentration in the room below the level necessary to support life.

Laboratories for liquid hydrogen are well ventilated with several (20 to 60) air changes per hour. The density of hydrogen gas escaping from boiling liquid is about the same as air so it tends to spread somewhat. However, it warms and rises rapidly and thus exhaust ducts are provided above the equipment and at the ceiling.

Although the literature assures us that unconfined hydrogen-air mixtures will not detonate, confined mixtures are detonable over a wide range. Spills are avoided by using the proper equipment, including metal dewars rather than glass. All sources of ignition, such as flames and spark-producing electrical equipment are avoided or controlled.

Since hydrogen is odorless, colorless, and tasteless, leaks may not be detected promptly. Therefore, laboratories where liquid hydrogen is handled are equipped with combustible gas monitoring systems, which sound an alarm when a fraction of the lower flammable limit is reached.

Personnel Protection. People, of course, are most important, and their protection is our most important assignment. Since leaks or spills may occur even with well-designed containers and apparatus, the people involved wear personal protective equipment. Cryogenic fluids are extremely cold and contact with the eyes or skin will cause burns similar to thermal burns. Thus eye protection is a must at all times. Gloves are worn when handling anything that is or may recently have been in contact with a

cryogenic fluid. Asbestos is preferred, but leather may be used. The gloves fit loosely so that they can be thrown off if liquid is splashed into them. Cuffless trousers are worn outside shoes.

Since hydrogen is flammable, and the release of any hydrogen within a laboratory creates a hazard, personnel are instructed to leave the laboratory rapidly in the event of a significant spill. At Linde's main hydrogen laboratory the employee can trip an alarm in the hallway, warning all personnel to vacate the building, if it becomes necessary.

Handling Large Volumes

Improved insulation, better materials of construction, and the availability of cryogenic valves, pumps, pipelines and transport equipment, have made it economical to store and handle large volumes of "permanent" gases as cryogenic fluids. With cryogenic fluids, the pressure is low and the volume small. One cubic foot of liquid oxygen, when vaporized and heated to atmospheric temperature, expands to produce 862 cu. ft. of oxygen gas. 0.37 cu. ft. of gaseous methane occupies only 1 cubic foot as a liquid. Cryogenic fluids may be transferred by pressure or pumped in much the same manner as L.P. gas, ammonia, or even water, except that the containers and equipment are well insulated.

Large Vessels. In general, all large volume cryogenic storage is in double-walled vessels with the liquid container supported from the outer casing through long slender tie-rods having low thermal conductivity. Thus, the insulation casing is a part of the liquid container support system. This is the chief difference between cryogenic tankage and conventional tankage, where the liquid container sits directly on the support and the casing merely keeps the insulation in place and dry.

The liquid container or pressure vessel is fabricated of material suitable for use at the boiling point of its contents at 1 atmosphere. Such materials include austenitic stainless steel, aluminum, copper alloys and nine per cent nickel steel (the latter down to -320°F.). Carbon steel and some ferritic stainless steel are brittle at these low temperatures. When applicable, the liquid container is designed and stamped in accordance with the ASME Code, Section VIII for

Unfired Pressure Vessels for use at the proper service temperature, (-320°F. for oxygen and nitrogen, -423°F. for hydrogen, etc.). It also complies with local codes and regulations.

Piping, supports, and other appurtenances likewise are fabricated of materials suitable for use at low temperatures. In addition, all liquid lines from the container are trapped to prevent liquid from continually draining toward a warm surface. This would cause surging and increase heat leak. All lines within the casing have sufficient flexibility to accommodate movement caused by thermal contraction and expansion. Furthermore the outer casing connections to cold lines are designed to prevent the steel in the casing from reaching its brittle range.

The outer casing is usually fabricated of carbon steel and is sealed to positively preclude the entry of atmospheric air. At cryogenic temperatures, frozen water vapor and carbon dioxide would destroy the high efficiency of the insulation. In most cases, the outer casing is designed for 15 psi external pressure because a vacuum is maintained in the insulation space.

Insulation. The space between the outer casing and the liquid tank contains non-combustible insulation and, in most instances, a very high vacuum (1/100,000th of atmospheric pressure) is maintained. Powder insulation, such as perlite, is used in most large tanks, and may be as much as 5 ft. thick, if vacuum is not used. The typical powder-vacuum insulation (6" thick) has a thermal conductivity of about 0.002 Btu per hour, per square foot, per degree F., 35 to 40 times lower than 4" of cork.

Safety Devices. The liquid container is usually protected from overpressure by two safety devices connected to the vapor phase; a relief valve set at or below the design pressure of the container, and a frangible disc set to function at a somewhat higher pressure (but below the test pressure of the container). Although this is very unlikely, if the vessel should be exposed to severe fire or the relief valve should stick, the frangible disc would function and blow the tank down to atmospheric pressure.

The relief valve discharge piping on tanks containing flammables is vented upward away from the tank, at a point at least 5 feet above the tank and unobstructed to the

open air in such a manner as to prevent any impingement of the gas upon the tank; loose fitting rain caps are provided. Also relief valves may be piped to a vent stack.

In sizing the relief devices to prevent overpressure in a vessel subjected to fire, it is assumed that the vacuum is lost and that the insulation space is filled with the contents of the container (gaseous phase) at one atmosphere. Gaseous hydrogen, for example, has about six times the conductivity of air. The insulation space is protected from overpressure by a safety device in the casing usually set to function at a few pounds positive pressure.

Containers are not filled beyond a certain point. If a container were entirely filled with liquid before the pressure reached the setting of the relief valve, the valve would vent liquid instead of gaseous product. Contents of the container are checked either by weight or by means of a full trycock.

Location of Storage Tanks. In determining site locations for cryogenic tanks, the properties of the contents, as well as the construction of the tanks, are considered. As previously mentioned, liquid converts to a large volume of gas. Liquid oxygen, nitrogen and argon, the large volume cryogenic fluids, are all nonflammable, non-toxic and odorless. Thus the primary considerations in locating tanks for these products are to protect them from other fire exposures and provide good ventilation.

The location of liquid oxygen tanks is covered by NFPA Standard 566, "Standard for Bulk Oxygen Systems at Consumer Sites." Among other things, Standard 566 points out that tanks should be located, diked, or graded, so as to prevent any nearby flammable liquids from running under or around the tank. Local building and fire department regulations must also be considered.

Flammable Cryogenic Fluids. Liquefied hydrogen, ethylene and methane, of course, are flammable cryogenic fluids.

The properties of liquefied hydrogen have been thoroughly investigated under an Air Force, Air Research and Development Command contract. After examining all available data, experts have concluded that liquefied hydrogen is not as hazardous to store and handle as corresponding quantities of L.P. gas. Radiation from a hydrogen flame is

only a fraction of that from a propane flame, and the peak emissivity lasts for only a few seconds with hydrogen as compared to minutes with propane.

In view of the above, it appears reasonable to use, with *direction*, industry standards for LP gas and flammable liquids (such as NFPA 58 and 59) as guides. Containers are mounted on concrete pads or saddles. Structural steel supports or legs may be used when they are protected against fire in an approved manner. When the casing is part of the support system for the liquid container, as mentioned above, adequate fire protection (water) is available to keep it cool in the event of fire. The steel casing protects these tanks from "hot spot" failures of the liquid container that occasionally occur in the vapor area of bare liquefied gas tanks in fires.

Low dikes or curbs may be employed to keep traffic away from the tank and contain liquefied gas in the event of a spill. Large dikes do not appear necessary since they are not normally used with tanks of LP gas which is less volatile than liquefied hydrogen. Because of local regulations, however, the authority having jurisdiction may require a dike. Crushed rock may be placed under the tank to supply heat and extra surface area to quickly vaporize spilled liquefied gas, thus reducing the exposure time.

But vaporizing the liquid quickly creates a larger flammable vapor cloud that will travel a longer distance to a potential source of ignition, and there may be situations where slower vaporization would be safer.

Excess flow valves are not used at these low temperatures, so an insulated remote-controlled shutoff valve is located adjacent to the casing to shut off the flow of liquefied gas in the event of damage to the pipeline. A remote controlled internal shutoff valve is also a very effective means of shutting off the flow in the event of a pipeline break.

Electrical Equipment. In locations where the use of explosion-proof equipment is required, the National Electrical Code calls for Group B equipment for hydrogen service. This equipment is often not readily available. However, where (a) there is good ventilation, (b) the possibility of a hydrogen spill is remote, and (c) a flammable mixture would exist for only a short time,

Group C and D equipment is usually adequate. This is checked with the local authority having jurisdiction.

In explosion-proof electrical equipment, a spark-producing element is encased in a steel box with a sealed cover. If a flammable mixture within the box is ignited, the seal will prevent the escape of sufficient fire to ignite a flammable mixture outside of the box. Thus, proper maintenance of the seal is most important.

If the steel electrical box is allowed to reach cryogenic temperatures, it will become brittle, and the cover seal may be damaged, depending upon its design. Under these conditions, conventional explosion-proof equipment may not contain an explosion, but may fly like shrapnel, creating a serious hazard. Inside cold boxes and wherever low temperatures may occur, continuous purging with nitrogen is often used to keep hydrogen out of electrical equipment.

Transportation. The transportation of cryogenic fluids is not new. Regular tank truck shipments of liquid oxygen were begun by Linde in 1932. Total truck mileage since then is estimated at 175 million miles with truck capacities ranging from 5 to 20 tons. Railroad tank car movements started in 1939. Last year Linde tank cars operated in excess of 10 million miles with each car carrying 40 tons of liquid oxygen.

Liquefied hydrogen is being shipped from Florida to California in 30,000-gallon tank cars without loss of product enroute. Liquefied hydrogen is also transported in 8,000-gallon tank trucks capable of going from coast-to-coast without loss of product enroute. Liquefied hydrogen is by far the coldest flammable cryogenic fluid. This indicates that equipment can be designed to transport any cryogenic fluid safely from coast-to-coast.

An amazing fact about these tanks is that the insulation space is only two inches to three inches thick. The insulation is a new, highly efficient aluminum glass-fiber lamination, plus a very high vacuum. The thermal conductivity per inch is about equal to the conductivity through 40 inches of powder-vacuum or 1500 inches of cork.

The ICC Regulations at the present time do not provide for the transportation of liquefied hydrogen, but the ICC has issued special permits to shippers authorizing

its transportation in accordance with the terms of the permits. It is the practice of the ICC to prohibit the venting of a flammable gas from tank cars or tank trucks during normal transportation.

The tank cars described above are equipped with a mixing device. Should the car be delayed so the pressure in the container builds up to the setting of the pressure control device, the released hydrogen is mixed with sufficient air to reduce it to 50 per cent of the lower flammable limit for hydrogen-air mixtures.

The Compressed Gas Association, whose membership includes most of the industrial

producers of cryogenic fluids, is preparing proposed amendments to the ICC Regulations to permit the transportation of liquefied hydrogen in cylinders, tank trucks and tank cars.

Cryogenic fluids have been handled safely by a few companies since the early part of the century. Their use, and the number of people handling them, have increased tremendously in recent years. To ensure safety, old and new users alike require a thorough understanding of the properties of these fluids and a willingness to make use of reasonable safeguards in handling them.

JOINT SESSION WITH OCCUPATIONAL HEALTH NURSING SECTION

PSYCHOLOGICAL ACCIDENTS — THE INDUSTRIAL PHYSICIAN'S VIEWPOINT

By Dr. J. KILIAN, M.D.
Medical Director, Texas Division
Dow Chemical Co., Freeport, Texas

Throughout the years that I have treated occupational injuries it has become increasingly apparent that the vast majority of the accidents were not due to mechanical failure of equipment, or faulty protective devices, but due to the human failure of not doing the proper thing at the proper time. When I was a neophyte in this field, I logically assumed that such was due to day dreaming or perhaps just a chance, but as my appreciation of the human psychological mechanism became more acute I began to realize that here was something far deeper and more basic in many of these accidents. This human understanding has progressed until at the present time I am firmly convinced that a significant number of our occupational injuries are due to basic psychological mechanisms, the patterns of which are just as real as the mechanical equipment that we use.

It is time that the folks who work in the field of safety develop an increased awareness of this and, also, realize that many of these psychological mechanisms must have their protective devices just as certain machinery has to have its protective devices. Today through the presentations on this panel I hope that you will develop this increased awareness of the necessity to understand people and recognize certain emotional danger signals if you expect to make a real impact in the field of safety.

I do not intend to bombard you with a barrage of psychological gobbledegook, but I would like to point out to you some fundamental facts about everyone's personality and illustrate how certain psychological mechanisms may have a bearing upon certain accidents. In all of our minds we have certain areas which we must un-

derstand before we can begin to comprehend this problem of the psychological influence of the human mind on industrial accidents. It is a well recognized fact that the human mind can be divided into three parts: the conscious, the preconscious and the unconscious mind.

The conscious portion is the part that does our everyday thinking. It is the part that I am using at this time in presenting this speech to you.

The preconscious is the area of the mind which we do not ordinarily use, but from which facts can be brought up to the conscious mind rather easily.

On the other hand the unconscious mind is the deeper, inner reserves, which is composed of material not immediately available to our conscious thinking, but is composed of stored experiences and conflicts that have occurred throughout our whole lives. The influence of each of these areas is extremely important to the man on the job, but the thing that should be extremely enlightening to all of you is that fundamentally our lives are governed, moulded and influenced by our unconscious thought processes.

Let me illustrate it in this manner. When one learns to drive a car he consciously thinks about taking his foot from the accelerator and applying the brakes during this training period. After awhile this becomes automatic and now when one approaches the stop sign this particular act does not enter one's conscious mind at all. It is in the preconscious area where it can be easily recalled if one puts his mind to it.

If the brain did not function in this manner, our lives would be completely occupied by all sorts of irrelevant thought

processes everytime we did something. These things must function at a lower level and on an automatic basis in order that we may devote our conscious thinking to the important things. The unconscious mind on the other hand is buried material, deep within the inner recesses of our thought processes and can only be brought out by certain psychiatric techniques that we cannot concern ourselves with today.

There is one fact that I feel is extremely important, that I have discovered from experience. It is that people who work in safety, as well as members of supervision, have a difficult time accepting the concept that the unconscious mind can really influence an individual's actions to the extent that it will produce serious accidents and disabling injuries.

When one mentions psychological causes of accidents most of the people think in terms of the man who is consciously trying to hurt himself to gain a certain advantage, or that a man is preoccupied by his emotional problems and he does not realize that danger is creeping upon him. If one just considers these aspects of psychologically motivated accidents he is indeed missing the boat on the vast majority of cases. Let us take a few examples to try to drive across the point.

Case number one: This case involved a man who was working on an extruder press in which the equipment was well guarded in a manner that made it virtually impossible for the man to get his hand in the extrusion mechanism and throw the switch at the same time. However, early on Monday morning this happened and the man was brought to the medical department with a seriously crushed hand. During his anguish and state of semi-shock he confided in the industrial physician that he really did not much care what happened to him since he had been having marital difficulty and his wife had run away two days before with another man. At no time after this revelation would he again discuss this situation. The wife was located, however, and within a short time she was at the bedside of the victim crying and feeling a great deal of remorse towards the injury.

Now what did this accident accomplish for this man? Obviously it served the purpose of getting his wife back (at least

temporarily), and I think one should really ask himself the question, "Was this really a mechanical accident of a psychologically-induced accident?" When the accident reviewing committee made a study of this particular situation they reported with their analytical, conscious, thinking that they could not understand how this individual could override the guarding mechanism and have this happen.

The question that all of you are probably wondering about is, "Did this man do this deliberately?" To this I would like to add my unqualified "no" he did not! Preservation of life and avoidance of pain and injury is a powerful instinct, and this man's unconscious mind was fundamentally driving him to this solution of his problem. How many times we see highway accidents where there is no logical explanation of why it occurred and it is a matter of statistics that mechanical failure of the equipment plays a minor role in the overall problem. The problem is people and most of these problems involve psychological mechanisms which cannot be understood by the conscious portions of our mind.

Now, let us look at another case and perhaps we can more clearly bring out some other of these unconscious underlying factors that are so important. This man was working in an area where they were temporarily short handed, and his foreman asked him to roll a 400 pound drum out of the aisle. This normally was not the employee's job and he conveniently forgot the order for several hours. Later the foreman again reminded him that the drum in this area was a safety hazard and should be moved. Again the individual chose to ignore this command, and a short while later the foreman became rather disgusted with this turn of events and sternly commanded that the man had better get the drum moved, or else! The employee then went out, seized the drum, and, with a tremendous strain which was conceived in anger and executed with hate, moved the drum out of the aisle and, in the process, produced a severe lumbosacral strain in his lower back.

The man was disabled over a year and intensive investigation revealed no evidence of a ruptured disc or any physical disability which would account for the prolonged loss

of time from the job. Many months after the original injury, I got into the act as his physician and found out that at one time he and his foreman had been hourly employees, vying for the same job as foreman and that the other fellow eventually got. In my discussion with him he literally exploded resentment towards this man when given the opportunity.

This incident that I pointed out to you reminded me of a little child who deliberately threw himself down and tried to sustain an injury and thereby punish his parents who were the symbols of authority to him. This man's back pain (which I am convinced was a simple muscular strain) became a symbol of the festering resentment that he had towards this figure of authority. The eventual outcome was that the more his back could bother and disable him the more he could blame his foreman for what had happened.

This type of thing is happening all the time in industry. Many times the industrial physicians are not treating an organic injury, but are treating a serious inter-personal relationship between a worker and the chain of authority above him. We have to recognize this and do our best to deal with it effectively. I also feel very strongly that you who deal with safety should likewise recognize it and do your best to deal with it effectively.

I have presented this approach of the consideration of the psychologically motivated aspect of occupational injury to many people in management and invariably I have received the same reaction, which I think is a very healthy one, and I am sure all of you in the audience will be asking the same question. "So there are underlying psychological reasons which truly can be on an unconscious basis for many of these things, but just what good is your talk doing? It is one thing to tell you why something happens, but it is a horse of a different color to say what you are going to do about it. After all, we cannot all be psychologists, or psychiatrists, or physicians, and how can we as supervisors and safety people hope to prevent psychologically-motivated accidents?"

My answer to this is, first of all, there needs to be an awareness all the way up and down the line of management that this business of the psychologically-motivated accident is a very real thing. Secondly, there needs to be training so that these people understand how certain emotional conflicts can express themselves in various physical ways of having accidents. With this should come skill in recognition and assigning people to sublimate many of these emotional conflicts into constructive channels.

Let me give you an example. Each of us has the very primitive emotion of aggression and the skillful supervisor should direct the individual who manifests signs of over-aggression into some form of activity which will be useful in allowing that man to work off his aggression. For example, if he is an outside worker he might be given an ax to clear shrubbery from the edge of a road so that he can work off his aggression by wielding the ax against the trees and shrubbery. This will go a long way towards preventing him from wielding a venomous tongue against his fellow employees or his supervisor. It may prevent him from an unsafe act, because his hostility may seek expression in mentally unhealthy channels to punish his boss.

Do not lost time accidents really do a very effective job of punishing the boss? People must be taught that everyone in supervision should be an emotional first aid station and allow the employee to ventilate his problems, and to recognize that when this becomes insufficient he should refer the man on to those who have the special training to deal with these problem cases. The days of the old hard nosed sergeant are over and experience has shown that management gets more productivity, fewer accidents and a healthier and happier worker, when he is dealt with in an environment of understanding, sympathy and genuine concern for the employee. People in safety work can help a great deal by promoting this philosophy and pointing out to management the important factors that we have discussed here.

THE OCCUPATIONAL NURSE'S ROLE IN THE DIRECTION AND REFERRAL OF EMOTIONAL PROBLEMS

By ANNE KLOIBER, R.N.
Supervising Nurse, Pabst Brewing Co., Milwaukee, Wis.

How many times have you heard said, "don't pay any attention to him—he hasn't got all his marbles?" Or, how many times have you discussed an occupational injury or disease with the foreman or supervisor only to have him inject in the conversation somewhere, "that guy's nuts—he doesn't keep his mind on his work—something's bothering him."

Yes, that is precisely the point! SOMETHING is bothering him! And, it's up to us, as occupational nurses, to steer him in the right direction so that he receives proper help.

We nurses in industry, of course, shouldn't have to wait until an injury occurs or until the man's apparent emotional problem is brought to light by the foreman or supervisor. We should, because of our personal knowledge of people at work, be able to detect certain signs and signals which should alert us to action. For this reason, it is vitally important that the nurse maintain a professional, yet warm, relationship with all employees so that they will come to her willingly with their ailments and injuries. Through her adequate medical records, the nurse will then be able to see patterns of behavior which perhaps even medical people outside of the plant could not detect.

It might be well at this time to add that these people with problems—these people who are "different"—not only call attention to themselves in the Medical Department. They are known to Personnel, the Credit Union, and in other areas of the plant as being in one jam after another. It seems almost as if they're enveloped in trouble.

One can't help but wonder if these situations—these difficulties they create, aren't actually S.O.S.—signals for help. What a pity then if, we, who are in a position, at least to, give them some guidance, close our eyes and ears to these situations—perhaps give them something for their nerves, or offer them another job or a few rationed words of reassurance—just to satisfy our conscience.

This problem, as you are all aware, is not confined to industry alone. All one needs is to look about him—be it in a super market, church, school, or what have you. Emotional outbursts of all kinds are visible almost daily in society at large.

Dr. Gerald Gordon of the DuPont Co., in his paper on "Industry's Problem Children," states:

"People are not either sane or insane in the same sense that a woman is or is not pregnant. Whereas it is impossible to be a little bit pregnant, it is quite commonplace to be a little bit crazy. Some degree of mental illness is present in all of us normal people. Inasmuch as we all suffer from it, we find it difficult to see in others, and all but impossible to see in ourselves.

"The diagnosis of mental illness may be made early from apparently trivial and unrelated signs and symptoms if we are willing to be realistic and objective, even about ourselves. Dr. Dershlimer once wrote that industry constitutes one of the most realistic situations existing in our modern world. As such, it is the testing ground on which the strength and weaknesses developed by the early training of individuals become clearly apparent.

"It is, therefore, in industry where many of the earliest signs of failure or mental illness may be seen. This situation gives management and supervision an opportunity, found almost nowhere else, to do a real job of mental hygiene which will benefit the employee no less than industry."

In keeping with the fast pace we have set for ourselves today, with the result, of course, that there is really never enough time for everything we would like to do, I suppose we feel justified in effecting a job transfer for someone who can't get along in a certain department or where a specific problem exists. But we cannot keep shrugging off these responsibilities in this manner—we must face these issues squarely and give them the time that they truly deserve.

Let me tell you of a problem which existed in our plant recently. This problem, I am happy to say, was resolved with the patient coming out as the victor—one of those "happy-ending stories." This young man has no vision in one eye as the result of a childhood injury. Needless to say, he protects his remaining good eye more than one would do normally. Because of his low seniority, he is occasionally placed in a transfer pool to areas where caustic solutions are used for cleaning. Protective equipment is issued this man, as is to all employees. However, when this transfer arrangement first started, this man would be in the Medical Department constantly with one caustic burn after another—his self-diagnosed caustic burns. Actually, most of the time they weren't burns at all.

During every visit he would beg us for a transfer to another department where this hazard was not present, but the doctor and I both felt that we would try to help him face the problem and not run away from it. We knew that if we gave in to him this one time, we would set off a chain of transfer requests. At any rate, the course was slow and at times quite stormy. There were two or three times when the foreman called us and shouted, "get this guy out of my department—he's getting everyone jumpy."

But we hung on a while longer and were victorious. We tried to educate him as to the proper equipment to wear. We tried to instill in him a respect not only for caustic soda, but for all harmful chemicals. We spelled out to him the proper first-aid measures in the event he did come in contact with them in spite of his caution.

Recently, he came in to see us, and thanked us for making a man out of him. His foreman has told us that he has become a more industrious and safe worker. Not only are we thankful that he's not running to the Medical Department three or four times a day with apparent chemical burns, but more important, we are glad that he faced up to the problem and did something about it.

Happy endings such as this are not always possible. We shall continue to have the overly fearful worker or, conversely, the careless worker—the guy who says, "I can take a bath in the stuff," but who continues

to be a threat because of his deep ulcerations from strong solutions. We shall have to realize that lack of attention to the inanimate things about us often involves us in accidents and that this lack of attention is usually conditioned by our mood or preoccupation with other things at that time.

We shall have to stop using that expression, "he's just accident prone," and, instead, learn to appreciate that accidents to a large extent are the result of the person being unable to cope with the situation in which he is placed. We shall have to realize that our physiological well-being can go up or down like a thermometer, that everyone has regular periods of exhilaration and depression—that it's just not women with "estrogen imbalance."

It is suggested that the nurse include in her history, following an occupational injury, the mood the person was in prior to the incident. She might even go a step farther by asking this same question of the foreman or supervisor. At least it might alert him to the fact that maybe this business of emotions isn't just something you read in a book.

In going back over our more serious and disabling injuries of the past year or so, we came up with the following moods or things employees were thinking about just prior to the time of the accident:

One man, who sustained very serious caustic soda burns to 30 per cent of his body, including his eyes, admitted to the doctor that he and his wife were having marital difficulties—that on the morning of the accident, they had an unpleasant scene which was witnessed by their youngest child, who apparently was the apple of his eye. He admitted to the doctor that this argument had left him nervous and jumpy—and that he just wasn't thinking when he dumped the water into the powder instead of vice-versa.

Another man who sustained a traumatic thumb amputation said afterward that he found he was in an ornery mood from the time he got up in the morning—you know, one of those days when everything goes wrong! Still another man claimed the foreman was nagging him constantly on the morning of the accident.

Is there little wonder then that these people become highly vulnerable to accident

proneness? An industrial nurse recognizes the fact that tension and conflict among workers, or between workers and foremen, often causes a rise in accident frequency. Her knowledge of industrial health counseling in such instances can be used most effectively.

While we're touching on the subject of counseling, let me say here that industrial nurses can make themselves responsible to a certain degree for teaching health to the employees. Nothing can replace an intelligently administered health program. Work habits of the employees are influenced by their mental processes and by the help or hindrance offered to them, be it in their homes or at work. It is helpful to the nurse to observe not only how the employee behaves under unusual circumstances but to observe his customary everyday behavior.

Management, of course, also must share in this responsibility. Management should know the physical capacities of the worker, his home situation and his personality traits. Pre-placement physical examinations are a must, as well as routine annual re-examinations. Matching up the job requirements with the individual so that a happy medium is reached is another of management's responsibilities.

I would also like to stress the importance of confidentiality of medical information. While it is generally accepted that management must know of existing physical capacities and limitations so that proper job placement can be effected, there is no special reason why all the details have to be spelled out. If the examining physician interprets his findings into a physical capacities appraisal and sends this to management, this should be sufficient. One of the most tested attributes of the industrial nurse is her ability to maintain confidences. If she is to do well as a counselor, this must continue to be of prime importance.

In summation, then, I would like to offer that nurses, because of their personal knowledge of people at work, because of their background (fortified with courses in psychology and counseling, and because of their thorough medical records, are able to see patterns of behavior and emotional problems which can then be referred to the proper people for care.

Having the psychiatrist in mind, did you hear about the two psychiatrists who met on the street? One said, "Hello, there! And how are you today?" After which they parted and the other one said, "Hmmm, I wonder what he meant by that."

A NEW CONCEPT OF ACCIDENTS

By SANFORD G. ROGG, M.D.

Medical Division, E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

There can be no questioning of the fact that, as long as we remain human beings, we will become involved in accidents. Obviously the more we understand the multiple factors involved in accidents, the better prepared we will be to prevent the avoidable ones.

There has been an increasing awareness regarding the fact that our continuing nationally high accident rate is a reflection of personal rather than machine failure. Certainly the engineers who design machinery and in particular, those whose task it is to pay attention to safety features

and operational control, have all done an extremely competent job.

As a matter of fact, they have done their work so well, that the continuing high accident rates we see quoted yearly throughout our country, can in no sense be called a responsibility of poor design features. At the same time, it would be foolish to infer by any means that continuing effort on the part of design engineers would be unrewarding. The fact to be emphasized is that even if we designed to theoretical perfection, we undoubtedly would still have well over 80 per cent of our accidents occurring.

TABLE I
Leading Causes of Death by Age Groups
1. Age 14-24 2. Age 25-44 3. Age 45-64 4. Age 65-74 5. Age 75-84 6. Age 85-94 7. Age 95-104

Age Group	Accidents	Heart Disease	Cancer	Stroke	Pneumonia	Cholera	Tuberculosis	Diabetes	Alcoholism	Drugs	Other
1. Age 14-24	100	10	5	5	5	5	5	5	5	5	5
2. Age 25-44	100	10	5	5	5	5	5	5	5	5	5
3. Age 45-64	100	10	5	5	5	5	5	5	5	5	5
4. Age 65-74	100	10	5	5	5	5	5	5	5	5	5
5. Age 75-84	100	10	5	5	5	5	5	5	5	5	5
6. Age 85-94	100	10	5	5	5	5	5	5	5	5	5
7. Age 95-104	100	10	5	5	5	5	5	5	5	5	5

Table I, while contributing no new knowledge on the subject, does emphasize the place that accidents hold as a cause of death in our country.

Without becoming too involved in figures, the National Safety Council's statistics list approximately 40,000 people killed in automobile accidents, 14,000 in industrial accidents, 27,000 in home accidents, and 16,000 public deaths. We can define public deaths to include train accidents, airplane accidents, public fires, etc. or whatever else might happen to a person in a public situation. To this, add an untold number of injuries, possibly running as high as 24 million of the type that brings itself to the attention of a physician or limits a person's activities for at least one day.¹

Perhaps the question arises as to why the medical profession is becoming so concerned about safety. Certainly any condition that kills about 97,000 people a year and leaves over 400,000 with permanent residual injuries, varying from the minor to the most severe type, should of necessity command the attention of the profession that has the responsibility of caring for these people.

In my opinion, most of the problem is to be found in the emotional status or even in its broader aspects, the personality of people who become involved in accidents. And to digress for a moment, we can define personality in the sense that it is being used here by labeling it as consisting of the habitual patterns of temperament, intelligence, desires and behavior that distinguish us as individuals. We can readily appreciate the problem in that it is difficult to delve into and obtain an understanding of these factors. This can be easily understood if we realize that we are dealing with personal motivations and conflicts of thought, wishes and desires of people, combined with all the frustrating situations with which they are confronted.

It should be emphasized that there is no

desire to leave the reader with the implication that the problem of accidents is a narrow concept, a psychiatric one, in that mentally ill people who require treatment are the ones who become involved in accidents. It would be much better and more easily understood, if all of us were to acknowledge that we are liable to accident situations at various times throughout our lives.

What is overlooked in a good deal of the work that is being done, is the fundamental factor that looms as most important in all of our dealings with people. This is, that although we like to think of man as an intelligent, rational, coherently reasoning and consistently logical individual, man in reality is predominantly guided by motives and feelings of which he is most often unaware. These logical powers only serve as a means of allowing the individual to reach goals that are created by more deeply placed emotions. This in turn could lead us to realize how we must look at, and deal with, these feelings if we are to be successful in our safety endeavors.

We must realize that becoming involved in an accident is basically the same as any other condition about which people become involved in difficulties. These individuals could just as well solve their problems by developing stomach ulcers, severe headaches, spastic colitis or the numerous other entities that are diagnosed as psychogenic illnesses. The accident-involved person is, in a very unsuitable, and from the viewpoint of our society, in a totally unsatisfactory way, solving the emotional problem by becoming involved in an accident situation.

It appears suitable and advisable to go a little further at the present time and state that the emotions we are discussing arise from the whole life of the individual, the twenty-four hours of each day that he lives, and by no means only the eight hours that he spends in gainful employment.

We have all heard the expression many times over, that so and so tends to take his work home with him. Well, we can reverse this and state that everybody tends to take his home to work with him.

My interest in the factors producing accidents was aroused while discussing one with a safety engineer. He was describ-

ing an accident that had just occurred and in the course of the conversation said "I just don't know what happened. This man has been doing the job for years and knows it perfectly well. As a matter of fact, in the usual course of events, we checked over everything, the switch controlling the machine, and the machine itself, and they were in perfect operating condition; still, the man became involved in an accident that resulted in the amputation of his finger."

After this discussion my thinking went along the lines of what could have involved the man in this accident, and broadening things a bit, began to wonder what could be going on in the mind of a person just prior to his having an accident.

By accident, we are referring of course to the common garden variety where the individual alone is responsible. Technically we could call this a "personal accident" with the primary cause to be found in the individual in contrast to the "impersonal accident" with the primary cause in the environment. It is possible to be even more precise here and state that this study was not directed towards an exploration of the basic personalities of these individuals, many such studies have been done and the literature is replete with articles describing the personalities of people who become involved in accidents. Attention was focused on the thinking occurring in a person's mind prior to becoming involved in an accident and by prior is meant half an hour, a minute, or even moments before the event happened.

After becoming interested, it was considered advisable to have reference to what had been written by others on this subject and the literature was searched. This led to the conclusion that very little had previously been done where a trained person sat down with someone involved in an accident and tried to find out what thought processes were going on in the mind of this person just prior to the occurrence of the accident. This was somewhat surprising and indicates a field that has been badly neglected. We thing learned, however, was the interesting assurance that we are neglecting a very important phase of accident prevention by limiting the study of the subjective of human behavior and merely measuring a statistic.

Chemical Section

To investigate this matter, a procedure was set up whereby the men who were working in a large plant and had been involved in an accident would be seen by me. The sampling was a non-directed one, the men being picked on a consecutive basis by the receptionist. The attitudes of the men were mainly cooperative. They spoke freely and at times gave more information than was being looked for.

It was felt that to interview someone whose accident had occurred more than three days past would be a useless procedure in that many things would start fading from the individual's mind. Human nature being what it is, when things start to fade from one's mind, the person then tends to supply facts that he actually thinks would fit the situation. It is not meant by this to imply that the individual would deliberately construct misinformation. It is a matter of knowledge that as our memory fades and we are asked to recall an incident that has occurred in the past, a good deal of the information that we bring to recall in information of a type that we ourselves have formulated. The technical term for this would be retrospective falsification.

An excellent article, "Accident Statistics and The Concept of Accident-Proneness," by Arbous and Kerrick,² states that it is conceivable that with our present instruments of analysis, we may yet succeed in pinning down the personal factor in accident-causation in terms of some strict definition, but this may involve so many restrictions in a mathematical sense that the concept will bear little relation to the real factors in everyday industrial life. The above comments do not constitute a denial of the usefulness of statistical procedures in investigations of this type, nor is it suggested that the research worker can ever dispense with them altogether. The conclusions indicate rather the limitations of these techniques and emphasize the fact that statistics can never do your thinking for you.

The above considerations may well lead me into a state of dependency and frustrated resignation, were it not for the fact that a different approach to the problem seems possible. This approach may not enable us to analyze accident liability in terms of universal principles, laws of dis-

tribution, etc. with reference to human behavior in general, but it may well enable us to reduce the incidence of accidents in our community by enhancing our knowledge of the mechanisms at work causing individuals to have accidents. And surely this is the ultimate objective of all this work.

Before getting into the actual cases seen, it appears pertinent to mention the work of Vinales,⁴ who emphasizes the fact that another limitation of the statistical viewpoint in accident prevention is the emphasis upon isolated aspects of the individual personality, in contrast with the concern, in the clinical approach, for the total relationship. The clinical approach recognizes that there are many different causes of accidents and that they may combine in different patterns in different individuals.

Several things became apparent after the procedure of interviewing was started and led to the realization that my thinking was not in agreement with much that had been previously written about accidents.

The first concept with which there was disagreement was that of a man being "an accident-prone individual." The initial studies on which this was formulated were done in England in 1919.⁵ The term itself (i.e., accident-prone) was coined in 1939 by Farnier & Chambers.⁶ For various reasons, one of which undoubtedly was the fact that the concept of "accident-proneness" relieved or lifted the burden of responsibility from where it belonged, this idea immediately attracted attention. Other workers in this field, then began to formulate lists of traits that could be found in these "accident-prone" people. Somehow it was presumed, that armed with such a list of traits, one could then more suitably place or even avoid hiring a person falling into this category.

The obvious fallacy of this type of reasoning is that all of us have accidents, whether at home, at the office, at the plant, on the road, or anywhere, and throughout our lives probably will have many times more than one accident. It seems that there are times when all of us are in a state of increased susceptibility to having an accident without it necessarily being a life-long pattern of behavior. Therefore, the type of personality of the accident involved in-

dividual, is as wide as the range of our entire population.

Of the people seen, only those with sub-major injuries were considered. It was found that the employees having accidents were mainly experienced men. It seems that the younger plant population is helped by the elasticity of youth in dealing with their problems. They also are more attentive to work hazards and still have "open-ears" at safety meetings. Since no control groups on considerations of hazard exposure could be statistically validated, it would be foolish to attempt to read too much into this.

TABLE II
Comparisons Between Injury Group and Plant as a Whole

	Injury Group	Plant
Average Age	45	44
Average Length of Service	16	17
Average No. Dispensary Visits per Year (Excluding Injuries) ..	1.4	2.2
No. Minor Injuries per 100 Person-Years	67	25
No. Previous Major and Sub-Major Injuries per 100 Person-Years	1.6	0.9

From a review of Table II one might be tempted to hypothesize regarding the number of minor injuries in the injury group as compared to the whole plant. Arbous & Kerrick,⁷ in their admirable statistical study, strongly conclude that "minor accidents do not enable us to make any prediction with relation to major accidents."

Many people feel that once the accident train is set in motion, there is no real difference between a major and a minor accident and that the resulting injury was the one chance element in the situation. A mathematical example might demonstrate some of the hazards involved in the deductions obtained from collected statistics.

For example, in studying accidents that result in sub-major injuries (a sub-major injury is one that results in loss of time from one's work) it would seem that there are two liabilities to be considered: (a) the liability of the individual to have an accident, and (b) the liability of this event to cause subsequent injury—resulting in its being recorded. It is conceivable that if the injury were not chance determined, the following results may be obtained as illustrated in Table III.

TABLE III

a—Represents unplanned events without injury.
e—Represents unplanned events with sub-major or major injury.
In the case of two individuals, the results will might be:
Individual X had a, e, e, e, e, e, e = 1 reported sub-major or major accident.
Individual Y had e, (e), (e), (e) = 3 reported sub-major or major accidents.

In the records Y would obviously be considered more accident prone than X, but this would not be a reflection of his proneness to unplanned events (near accidents) since Y has only 4, whereas X has 8. It would rather be a reflection of the liability of such events as he had, to result in injury. This may well be determined by factors beyond his control and the study of (e)'s would give little indication of the individual's susceptibility to (e)'s.⁸

Another deterrent factor bearing on Table III is the inability to equate exposure hazards between the injured group and the plant as a whole.

Referring back to Table II it can be seen that there is a valid statistically significant difference between the average number of dispensary visits per year for the injury group and the rest of the plant. Possibly the people having injuries are settling their emotional problems via this route while the plant group is discharging its emotional problems via psychogenic symptomatology.

TABLE IV
Accidents with Demonstrable Psychological Factors of Recent Origin

Psychological problem of recent origin	Number	Per Cent
No evidence of emotional disturbance	12	44.4
Subtotal	15	55.6
Non-assignable, multi-party responsibility	27	100.0
Not cooperative	8	
Total	35	

Roughly 70 per cent of the psychologically disturbing factors were job-connected, 30 per cent non-job connected.

Table IV might on a clinical basis substantiate my hypothesis. It is, however, a fundamental piece of knowledge that it is never possible in any science to prove a hypothesis.

It may be informative and interesting to transcribe the notes made after interviewing three people who had been involved in accidents.

Case No. 1, a male employee age 21 with two years of employment as a driver for a parcel delivery concern. He sustained a severe twisting injury of his right ankle that required the use of crutches and kept him from regular work for five weeks. The safety bulletin listed the following description.

"This injury was sustained during normal operating conditions. The weather was clear and cold. The concrete surface was level and dry and free of any foreign body. The truck running board was clean and dry, with all door attachments in excellent condition. The injured stated that he looked before stepping down and noticed nothing out of the ordinary." This man in talking to me said that he realized as he was getting off the truck he was headed to go around the front of it. Realizing this, it then became necessary for him to turn so that he would be facing towards the rear and be able to walk around the back of the truck. The sudden shifting of his body after it had already established the direction in which it was going resulted in the accident.

"He went on to talk very freely and stated that he was hit by a truck as a child at about nine years of age and ever since that time he has been afraid to walk in front of any vehicle even to the present moment. Even now if a car or truck is parked at the curb with no one in it, he still will not walk in front of this vehicle but will walk an extra fifty feet if necessary, in order to go behind it. He says at any time he absolutely cannot avoid walking in front of a truck or car, the picture of his being hit by the heavy truck when he was a youngster still comes to mind. "Several times a year," he continued, "I still have nightmares where I wake up screaming and soaked with sweat, dreaming that the truck was coming down the street and about to run over me again. All that I know is that I still can't get over the fear of walking in front of any car or truck."

Case No. 2. This case that I am going to describe, is I feel, an interesting one although it did not actually result in an accident in which somebody was hurt, but very nearly did and would have created an extremely serious situation had the accident itself actually occurred. The man in question was sent to the plant medical building because of an acutely upset condition following the incident. His job is to put an allow-

into a chemical process. He has been doing this for two years and is a first-class operator. In the past four weeks he has had a new helper. This helper and he evidently were extremely incompatible. He feels that this man was negligent and had a careless attitude towards his work. The operator had spoken with his foreman twice asking for a new helper, giving the above reasons for his request. He told his foreman that sooner or later such carelessness would lead to an accident.

No action had been taken up until the day in question. The morning of the incident, he was particularly annoyed by his helper. In violation of all operating rules he dropped his charge of pellets into an agitator following routine procedure except for the very serious omission of not checking to make sure that the agitator was cleared of its previous charge. Fortunately (and in no way could the man know this) the agitator happened to be clear at that time. If not, a violent explosion would have occurred. When the man realized what he had done, he began to suffer an acute panic reaction and his foreman sent him to the medical building. The man was able to pinpoint his thinking when talking to me—"I was so mad with the helper, I knew something would go wrong. I tried to get rid of him but they wouldn't transfer him. I guess the strain was too much for me waiting for him to do something wrong so I went ahead and did it myself."

Case No. 3, a 36 year old man with sixteen years of service fractured a finger while working on a machine. This was the man's first recorded accident in all of his years on the plant. He had worked a double shift the previous day. He said he was asked to do this a few hours before quitting time. He and his wife had made arrangements to go out that evening, this of course entailed the usual difficulties of baby sitters, etc. Although he very much wanted to say "No" to supervision's request, he has always been too compliant an individual to be able to voice his own feelings and therefore, said he would do the extra work. As far as supervision was concerned, their request was routine with this man, since he was usually asked first when there was some extra work available. The next day the man was thinking about the previous evening and was pretty much "burnt up inside" about what

had happened. In addition to his normal resentment he had experienced a difficult situation with his wife when he explained to her that they were not going out. As a matter of fact, he stated his wife was "as boiling mad as he had ever seen her." While dealing with these feelings of extreme resentment, the man suffered an injury.

One of the things that can be seen here is that in the cases quoted we have a fairly clear idea of what was going on in an individual's mind just prior to his becoming involved in an accident. As to how this might be of any benefit in helping us to prevent accidents in the future, several implications can be drawn. First, we should learn all that we possibly can about the fact that such motivations exist in an individual. By this I do not wish to imply that all safety engineers should become amateur psychologists but they must at least have some basic idea of the facts of how human behavior and emotions at times may influence our susceptibility to accidents.

To this end safety educational material could perhaps be reviewed, to emphasize this fact. The advertising industry in the past ten or so years has been doing a good job in some respects with what is called motivation research. Perhaps orienting our safety education somewhat in that direction might be fruitful. In our study of accidents we should try to find out from the people involved how they felt about the accident at that particular time, so that we may learn something about the problems and distractions that have diverted the individual's attention from the safety hazard. By doing this, we may also get some hints about what things distract and disturb people and also some idea of how we may be alert to similar problems in others. Perhaps with a better understanding of the human factors involved in accidents, we can make safety education even more effective.

After a recent talk which I gave to a group of safety men and supervisors, someone in the audience asked me a question—"What would you do with a man who continually and knowingly violates established safety procedures? He insists that he will do the job in the way that he desires." I gave the question back to the audience for an answer and several members stated—"I would fire him." The man who originally raised the question sadly said—"I can't, we both work for the Government."

Another interesting facet of human behavior here is that the employee himself, the individual who stands most to lose through an accident, is the last one to accept the fact that safety is as much a part of doing his job as any other area of performance. Of course, a safe worker will aid management, but openly and directly the safe employee will primarily benefit himself. Be that as it may, and this cannot be too strongly emphasized, we can certainly see that there has been a tendency to be tolerant towards the continued irresponsible actions of people involved in accidents.

We also must realize that stronger demands for an adult standard of behavior will be necessary. Our society as a whole must insist on adherence to effective lines or behavior in regards to safety. Certainly it does not make sense to lightly gloss over the irresponsible, the immature, the careless and negligent individuals who cause accidents. It is a rather grim prospect that the irresponsible actions of people who refuse to follow our rules are yearly causing increases in our national statistics of people who are killed and injured. It appears that the least we should do is to learn more about the factors leading to people becoming involved in accidents, so that we can be in a position to work out ways for lowering the frequency of accidents that can be avoided.

My feeling is that the medical profession must assume more responsibilities in developing these effective ways to help in accident prevention. Since I am firmly convinced and feel that most of us who deal with safety agree that the emotional factors are the cause of the greater part of accidents, our approach must become more meaningful and must consider the emotional life of the people concerned in order to effect any changes.

EYE SAFETY IN CHEMICAL PROCESSING

By JOSEPH GUELICH

Safety Dir., General Chemical Div., Allied Chemical Corp., New York City

Among those who are wearing glasses there is a good chance that most are safety glasses, with hardened lenses. If you have a small child who wears glasses, these are probably safety glasses. If you have children in chemistry laboratories in high school or college, the schools probably have a rule that the students must wear safety glasses. If you wear glasses and engage in such activities as squash racquets, the chances are that you have equipped yourself with safety glasses.

These are all indications that today there is a clearly discernible trend toward universal eye protection, off the job and on. Of course, you will agree that a complete eye protection program in chemical processing neither begins nor ends with a safety glasses program. We have, you might say, four lines of defense: preventing the accident, preventing the injury, guarding the person, and minimizing the injury.

Preventing the Accident

One of the most familiar examples of preventing the accident is something you learned in high school chemistry, to the effect that sulfuric acid should be added to water and not vice versa. I am sure you can think of other examples.

One user of caustic soda found that he was having trouble in making up caustic solutions by adding solid caustic to water. Despite repeated admonitions, the operator would add the solid caustic too fast and the heat of solution would cause the vessel to spit and boil over.

An acceptable solution was found by replacing purchases of solid caustic with liquid caustic. While there is a hazard from heat of dilution of 73 per cent or 50 per cent liquid caustic, the hazard is not anywhere near so great as the heat of solution produced by suddenly dumping large quantities of solid caustic into water.

In preventing accidents which involve the eyes in chemical processing, one fairly good rule of thumb is that the chemicals you can't see are usually the safest. An example would be in filling containers. If the fill

pipe ends at a point above the top of the container, the liquid is available to the eye—that is, it can splash or bounce or in other ways be diverted from the container to the face. On the other hand, if the fill pipe extends into the container there is considerably less chance that the chemical running out of the pipe can reach the face.

Prevention of eye accidents in chemical processing does not stop at chemicals themselves. Let's take a simple example, that of a pipe rack. Where are you going to put it? If it is in the middle of the yard and open at both ends, pipes sticking past the end of the rack present eye hazards to passersby and to anyone who is getting pipe from the rack. You can automatically reduce this exposure by 50 per cent by the simple expedient of putting one end of the rack up against a building or fence. You can eliminate the hazard to passersby by completely enclosing the rack, so that the exposure is limited to those who actually enter the enclosure for the purpose of obtaining pipe.

You can see that any consideration of new processes or even reviews of present processes can profitably include the query, "What are the potential eye hazards and how can they be reduced or eliminated?"

Preventing the Injury

When you consider the prevention of injury to the eyes you must make the assumption that the accident has occurred or will occur, and that your endeavor is to keep whatever happened out of the faces of your people. In most instances this consists of imposing a barrier between the accident potential and the individual.

A familiar example would be the window in a laboratory hood. Indeed, right here we might discuss the hood window, as it is one of the most abused objects in chemical processing. I am sure that you have all seen hood windows that for all practical purposes were inoperative. Perhaps they were badly etched from months and years of HF determinations. Maybe the glass was old and opaque. Maybe services to the hood,

such as nitrogen, were introduced from outside the hood through lines that entered at mid-hood levels.

All of these things preclude the proper function of the hood window, which is to protect the person and confine the fumes except when an operation is actually being performed in the hood. If you made a study of what this work consists of you would probably find that in an eight-hour day not more than half an hour is spent by the chemist in standing with his hands in the hood. But if the conditions we have just reviewed are present the hood window will remain open the other seven and one-half hours.

Lately there is a new trend in hood design which protects the eyes and indeed all of the body except the forearms during the time the chemist is actually working in the hood. This design consists of transparent panels which slide horizontally on an overhead trolley and overlap in front of the hood. The chemist is able to thrust his arms around the edges of the panels, which are not secured at the bottom, and do his work much as he would in a glove or dry box.

Remembering that we are talking about preventing the injury, which means imposing a barrier, this barrier can very often be simply part of the process equipment itself.

I invite you to consider a gauge glass on a tank. Let us assume that for some reason this is a gauge glass which cannot be quarried, which is fragile, and which is installed at eye level. This clearly constitutes a hazard to the eyes. Now where are we going to put this glass on the tank relative to the area?

Usually one would imagine that the gauge glass would go at a spot most available to the operator who needs it, which would mean at the point of heaviest travel, such as an aisle. If the glass is put in this position it constitutes a potential hazard not only to the operator but to everybody that passes the tank. If we put the gauge glass on the opposite side of the tank it is harder for the operator to read it, but it constitutes practically no hazard to anyone but the operator.

In investigation reports on eye injuries in chemical processing, perhaps one of the commonest phrases is a variation of, "He

turned the wrench and acid squirted out." The chemical industry has learned that this type of accident, which we call a line-breaking accident, is very nearly 100 per cent preventable, because we can impose barriers. A barrier can be as simple as an old vinyl raincoat. You loosen the bolts on the flange a quarter turn or so and then continue your work with a raincoat or rubber sheet between you and the wrench and the flange. If the product in the line squirts out it is going to be deflected by the barrier.

Another barrier can be as primitive as a bucket of water. I wonder how many of you know that something as simple as a plug cock, taken off a process line, can still constitute an eye hazard. If you will examine drawings of plug cocks or many other different types of valves, you will notice that in the closed position in a line considerable product is contained within the valve.

If the line is drained and the plug cock removed, the product goes right along with it. If the valve is subsequently opened, as for example in the act of working on it in the machine shop, the product can squirt out. One simple method of preventing this type of accident can be insisting that the valve be in an open position before it is removed from the line, and that it be immersed in a bucket of water and opened and closed several times before further work is done upon it.

Guarding the Person

Our next line of defense in eye protection to some degree resembles our second, that of imposing a barrier. In guarding a person we provide a barrier on the person himself. This consists of something in front of his eyes such as safety glasses, mono-goggles, face shields or masks.

I would like to tell you about my own company's eye protection program, because I think it works very well and could be easily adopted by almost anyone interested in preventing eye injuries in the chemical processing industry. The program is based on one simple rule, which calls for the wearing of safety glasses by everyone all the time.

These safety glasses are conventional frames without side shields and are plano for those people not requiring prescriptions. For people wearing prescription glasses we provide prescription safety glasses. All these

glasses are provided at no cost and we have no limitations on the number of glasses per person per year.

We think there are some very definite advantages to this program, even though we accept the fact that safety glasses provide only about 90 per cent protection as compared to cup goggles or face shields. We use face shields and cup goggles, and I will mention them a little later. We think that safety glasses when worn all the time dispense with two serious objections to cup goggle programs.

As you know, no workman can be expected to wear cup goggles or mono-goggles or face shields eight hours a day. In plants which rely upon this type of eye protection, some system must be evolved to determine when the workman must wear the goggles. This determination seems to have taken three separate courses: the concept of an eye protection area, the decision of the employee's foreman, or the decision of the workman himself.

In a so-called "goggle area" signs are usually posted to inform that goggles must be worn in this area. However, this does not protect the people working or passing adjacent to this area, and historically people have suffered eye injuries when they have entered the area, as they put it, for a short time.

Programs which depend on the foreman or the worker to determine whether goggles should be worn really place too much responsibility on the foreman or workman. Probably neither of these individuals is competent 100 per cent of the time to say whether a significant eye hazard exists. Furthermore, this type of program leads to arguments between management and the workman, usually with agreements that are only temporary.

I should like to say something about the introduction of a 100 per cent safety glasses program. This is not something which can be installed overnight. One usable method is to begin by announcing to the supervisory staff that at a future date you intend to introduce safety glasses, first on a permissive basis and later on a mandatory basis. At this time you can request the foremen to begin wearing safety glasses and to equip wearers of prescription glasses with prescription safety glasses.

Even at this early stage you will encounter some resistance from the foremen. This resistance can be met in many ways, such as pointing out the frequency of eye accidents in your company and comparing safety glasses with other safety equipment commonly in use, such as rubber gloves and aprons and gas masks.

When you equip your workmen with safety glasses you will initially encounter both resistance and high initial cost. The cost will come from the fact that your people are simply not used to wearing safety glasses and will break them, lose them or leave them at home. You should be prepared to replace these glasses and you will find that initially you will need to carry a comparatively large inventory.

Later on you will find to your satisfaction that your supply problems will diminish considerably, as the employees become accustomed to wearing glasses all the time. Glasses which are worn on the nose don't get lost or broken. The way glasses get lost or broken is by being sat on, falling out of the pocket, or getting knocked about in a tool box.

You will eventually find some unexpected dividends in a 100 per cent safety glasses program. One of them is the psychological reaction of the workman who wears safety glasses. By the very act of his equipping himself with a protection device he becomes more safety conscious and will perhaps unconsciously consider other hazards in the plant more closely. Furthermore, a workman who wears safety glasses is inclined to kid a fellow workman who for some reason has left his glasses off.

Another dividend consists in a reduction of off-the-job eye injuries. As workmen become used to safety glasses and convinced of their value they will wear the glasses off the job when doing things that carry a degree of risk to the eyes. This is particularly true on do-it-yourself projects. In my company we frequently get testimonials from workmen who say that their eyes were saved by their glasses in accidents involving power tools in their own work shops. I personally wish that the Wise Owl Club would include these incidents as qualifications for membership, since at the present time only work-connected accidents are considered.

I said a little while ago that our eye safety program does not stop at safety glasses. Some of our operations require more complete protection. For example, in line breaking operations our minimum requirement is a full face shield. We require that this be worn over safety glasses in order to protect the eyes when the shield is removed or momentarily raised. Chipping, welding and other high-hazard jobs likewise require additional protection such as mono-goggles or cup goggles. These additional requirements are best spelled out in safety manuals or posted in high hazard areas.

I would like to say a word about the future of eye protection programs with relation to safety glasses. We think that better glasses can be made, that they can be better fitted, and that delivery schedules can be improved. It is obvious that some standardization of safety glasses is needed. At the present time not all safety glasses parts are interchangeable. For example, there are J, S, and 7 barrel hinges, and variations in the shape of lenses.

In a large chemical plant there may be two or three different brands of glasses, and the lack of standardization makes it difficult to replace broken parts. As for delivery schedules, these are not much of a problem on plano glasses, but delivery promises, so far as prescription glasses are concerned, have to be taken with a grain of salt. I think we are within our rights to insist upon minimum periods between placement of orders and delivery of prescription glasses.

Concerning the fitting of safety glasses, it is obvious that the better they are fitted to the individual the more likely he will wear the glasses all the time and the more comfort he will enjoy. There is a trend toward initial fittings by oculists or other members of the profession. These services cost money but they increase eye protection and additionally they relieve the busy safety engineer from the purely mechanical job of fitting and dispensing glasses.

Minimizing the Injury

We come at last to the important subject of treating the eye injury after it occurs. In a chemical plant the answer, which is deceptively simple, is water. The first aid measures for a chemical injury to the eye consist solely of the application of water,

lots of water, and for a long time. The best place to administer this water is as near to the scene of the injury as possible.

This calls for lots of hoses as a minimum, many safety showers as a median, and adequate eye wash fountains as an ideal. We personally like home-made eye wash fountains. A simple design consists of three conventional shower heads each mounted 90° apart and at about waist level. Such an eye wash fountain takes care of the entire face and the position of the face relative to the ground is such that it provides for a maximum of dilution and run-off.

I saw an excellent arrangement at an RCA plant recently, which protects bench workers. This consists of nothing more or less than a kitchen type of hose spray on a reel, with a spring loaded nozzle at the end. If materials are accidentally introduced into the eyes the bench worker need only reach for the nozzle, pull it toward him, and direct the stream into his face.

Following the use of water at the point of injury it is usually necessary to continue eye irrigation in the first aid room. Very often other parts of the body are involved, and many first aid rooms use tubs for immersion washing. These tubs should include spray hoses similar to home shampoo hoses so that the eyes and head may be irrigated at the same time.

Some of your workers may be exposed to chemical burns of the eyes away from your plant. Examples would be truck drivers and those performing services at customer locations. Trucks should carry supplies of emergency water, in the glove compartment or in one or five gallon cans kept in the cab of the truck. Lately we have found an ideal place to keep water in acid tank truck transports. These transports are equipped with roll-over bars. The bars are actually hollow compartments, which can be filled with water and fitted with a nozzle.

As for work at customer locations, your people should be instructed to look for emergency sources of water as soon as they enter the location, and to report to you if such sources of water do not exist. We have sometimes found that customers receiving our products do not have safety showers near the point of unloading, and we have also found that uniformly the customer has been cooperative in providing such showers when requested.

Eye wash fountains and showers should be periodically tested and a record of such testing maintained. No valves should be permitted in these lines. Fountains and showers in cold climates can be protected against freezing in various ways, such as using warmed circulating water, installing the piping below the freeze line, or using dry pipes issuing from a warmed building. The showers and fountains should be marked with signs and distinctive painting and it is a good idea to use a green light at each shower.

Some companies are using "drills" for the reason that it is probably against instinct to get under a shower with your clothes on. We have seen many instances in which a man contaminated with a chemical splash would use a hose or even a basin instead of an easily available safety shower. Drills, which might take the form of getting under a shower just before quitting time, will condition the workman to use a shower when he needs it.

A final word is necessary relating to water substitutes and the fight we must make against them. In almost any plant you will find individuals who feel that certain types

of chemical burns are best treated not with water but with special solutions. For example, some people want to treat acid burns with sodium bicarbonate solutions or weak ammonia. There are serious deficiencies in these routines.

For one thing, the so-called special solutions are never as readily available as water nor in the large quantities necessary to flush away the offending chemical. Even more important, the so-called neutralizer very often produces a secondary injury in that in the process of neutralization a new chemical product is formed in the ocular tissue. This not only increases the injury but makes the treatment more complicated as the physician who ultimately sees the patient will find it necessary to remove the chemical which has been formed before he can treat the injury.

To summarize the modern concept of eye protection in chemical processes, we have four lines of defense: to prevent the accident, to prevent the injury, to guard the person, and to minimize the injury. These lines of defense are inter-dependent and each must be carefully planned for maximum eye safety.

FUNDAMENTALS OF PRESSURE-RELIEVING DEVICES FOR UNFIRED PRESSURE VESSELS

By H. V. MODNICK

Safety Engineer
General Electric Company, Lamp Division
Lamp Metals and Components Department, Cleveland, O.

I'd like to mention several examples which show abuse and negligence of safety valves and rupture discs:

- 1) A relief valve that couldn't operate if it had to—the spring and frame are corroded, the spring has been repainted several times and the lever arm used for manual testing is inoperative.
- 2) A "pop" valve installed on a 60 psi hydrogen line—the discharge opening with a metal plug installed—in this plant, they were in a hurry to get the hydrogen equipment in operation, so they delayed in install-

ing the discharge line. No, nothing happened.

- 3) A rupture disc installed on an HCl tank, using 60 psi for the acid movement—this rupture disc was a flat sheet of lead, but after four weeks of service it has bulged from the pressure. Four weeks before this, the lead disc ruptured—no one was hurt, but a large amount of HCl was spilled in the area.
- 4) Under two cans are "pop" valves on a steam line. Reason for the cans—the valves were popping off and spraying a large area.

By placing these cans on the valves, the steam was directed downward—a smaller area was involved.

I've seen worse rupture discs and safety valves in my tour of plants, but I'm sure there aren't any scenes like this in your plant—or are there?

This afternoon, I'd like to discuss the fundamentals applicable to pressure-relief devices for unfired pressure vessels. An unfired pressure vessel as you know is a pressure vessel that is not subject to direct application of heat from the products of combustion, i.e. it's the reverse of a boiler, which is an example of a direct fired vessel.

This lecture will not make rupture disc, safety and relief valve engineers out of you, nor will you be able to solve complicated relieving problems, but it should explain the most common types of relieving devices that are used for unfired pressure vessels.

Generally speaking, there are four basic types of safety devices: rupture discs, pop valves or safety valves, relief valves, safety-relief valves, and combinations of safety valves and rupture discs. Each has its purpose, but the pivotal point is cognizance of the fact that every pressure vessel in your plant is a potential bomb.

Before discussing the basic types of valves, I'd like to emphasize one point: all unfired pressure vessels constructed in accordance with the ASME code for unfired pressure vessels and according to paragraph UG-125 shall be provided with pressure-relief devices. In this code, there are five pages of precisely worded rules devoted to pressure-relief devices. These rules state how, when, and where you should install the relief devices, which will be adequate to protect against overpressure, chemical reaction or other abnormal conditions.

If you haven't already done it, it would be to your benefit to obtain a copy of the ASME code for unfired pressure vessels and peruse paragraphs UG-125 through UG-134. These paragraphs relate to pressure-relief devices only.

The simplest safety device is a rupture disc, which is merely a thin metal sheet designed to burst when pressure exceeds a given value. It is held between flanges and is inserted either in the wall of a pressure vessel or in a line connected to the vessel.

Consider a flat disc installed in a flange.

When subjected to pressure, a flat disc starts to take on a bulged shape. When this happens the disc has a tendency to work-harden and as a result, it will fail from shear or fatigue at a pressure lower than would be expected. As a result, frequent maintenance can be expected with flat-type discs.

Experience has shown that for uninterrupted service during normal operations of a pressure system as well as for rupturing within a 3 per cent (plus or minus) range of the marked rating, a pre-bulged disc is most desirable.

Frequently in the chemical industry we have vessels that operate under alternating pressure, i.e. vacuum and positive pressure and this presents a problem. How do we prevent the crumpling of the disc under negative pressure and resultant leakage at the intersection of the creases? This is accomplished by equipping a pre-bulged disc with a vacuum support. Height of the supports corresponds to that of the disc, restricting its movement when negative or backpressure is encountered.

Rupture discs are available in a variety of metals—stainless steel, inconel, monel, nickel, platinum, silver, copper and aluminum. Sizes normally range from 1/4" to 24". What is probably the largest rupture disc ever manufactured was used at the end of a wind tunnel.

Size and temperature are two big factors that effect the rupture pressure of discs. Stainless steel has a rupture pressure of approximately 2700 psi for 1/4 inch disc at 72°F and decreases to 65 psi for a 24 inch disc at 72°F.

Temperature limits have been established on all ductile metals that are used in fabricating pre-bulged rupture discs. For example, for aluminum, copper and silver, the maximum operating temperature is 250°F; for platinum and stainless steel, 600°F; and for monel 800°F.

For use in corrosive atmospheres, various plastic coatings and linings are available for rupture discs.

The rupture pressure of a disc should not be greater than the code rating of the protected vessel. Expressed in other terms, the rupture pressure of a disc should be at least 50 per cent greater than the normal operating pressure of the vessel. Conversely,

the normal operating pressure should not exceed 66 per cent of the rated pressure of the disc. This percentage represents the minimum pressure differential that must exist between disc rated pressure and vessel operating pressure for the disc to give a normal service life. A few examples are in order.

Let's assume that the normal operating pressure is 50 psi, then we should use a disc rated at approximately 75 psi. If you are using a rupture disc rated at 150 psi, then your normal operating pressure should be 100 psi or less. When used in this method, a rupture disc is acceptable on coded unfired pressure vessels as a primary relief device. In addition, if discs are used in this recommended procedure you will receive good service life without frequent replacement and loss of material. Of course, if any wider margin or larger ratio can be allowed between bursting and operating pressures, then the diaphragm life will be considerably increased.

Paragraph UG-129 relative to marking, states: "Every rupture disc shall be plainly marked by the manufacturer in such a way that the marking will not be obliterated in service. The marking may be placed on the flange of the disc or on a metal tab permanently attached." The marking shall include manufacturers' trademark, design and lot number, size in inches, minimum and maximum bursting pressure, coincident disc temperature and capacity, i.e. pounds of steam per hour or cubic feet of air per minute.

How about your plant? Do you buy rupture discs as per code specifications or do you make your own? I know of one large size chemical plant and have heard of others that make their own rupture discs. What they do is this: they buy a sheet of thin gage aluminum or stainless steel—dependent upon relative temperature and pressure requirements and cut their discs upon these sheets. One disc will be tested in a holder of the same relative form and pressure area dimensions as that in which the disc will be used. If the disc will burst at 100 psi, then it is assumed that every disc cut from that sheet of metal will burst at 100 psi. If they need a 300 psi rupture disc, they simply cut out three discs and all three are inserted in the flange or safety head—therefore a 300 psi rupture disc.

These plants conveniently "forget" about the recommendation, i.e. rupture pressure should be at least 50 per cent greater than the normal operating pressure of the vessel, and the effect of temperature on rupturing pressure, etc. The code is very specific on the testing of discs; paragraph UG-127 states: "Every rupture disc shall have a specified bursting pressure at a specified temperature, shall be marked with a lot number, and shall be guaranteed by its manufacturer to burst within 5 per cent (plus or minus) of its specified bursting pressure."

Regardless of what some plants do, I hope that all of you buy your rupture discs from reputable concerns. No, I'm not a stockholder in plants that manufacture rupture discs.

So far, I've made no mention of what size rupture disc we should use, how we determine relieving capacities for pressure vessels and the scope of such calculations. The reason is this: we wouldn't have time this afternoon to discuss this important phase of relieving devices. However, it would make an interesting program for next year's chemical section program.

A cut-away section of a "pop" valve or safety valve—a valve that pops full-open at a preset pressure—would show that this popping action is caused by the huddling chamber. The huddling chamber consists of a disc with two areas, closing on a single seat, and the lower area of the disc protrudes through the seat. Assume the upper part of the disc or huddling chamber is $1\frac{1}{4}$ square inches in area and the lower part or protruding part is 1 square inch in area. Force extended on the disc by the spring is 100 pounds. Assume the vessel is under 90 pounds pressure. We then have 90 pounds per square inch pushing up on the 1 square inch of area and 100 pounds dead weight pushing down.

Now let's raise the pressure to a little over 100 pounds. Then the 100 pound disc will start to rise until the lip clears the edge. When this clears, we have 100 pounds pressure operating on $1\frac{1}{4}$ square inches and the upward thrust is now increased to 125 pounds. The downward thrust is only 100 pounds dead weight, so the valve pops wide open.

Now with the valve wide open, let's drop

the pressure to a little less than 80 pounds. We then have a little less than 100 pounds pushing up, but a full 100 pounds pushing down. The valve starts to close until the lip passes the edge. Then we have 80 pounds per square inch pushing up and 100 pounds pushing down and the valve shuts off with no throttling action.

A "pop" safety valve is recommended only for use on gases, steam, air—not liquids.

A cut-away view of a relief valve shows no huddling chamber and, as a result, the valve will not "pop" open, but only relieve the pressure.

To give a simple explanation of a relief valve, it consists of a flat disc closing an opening in a pressure-containing vessel. This disc is held to its seat by means of a spring. Assume for this discussion that the spring is pressing down with a total load of 100 pounds. Assume the vessel is completely full of water or gasoline at 90 pounds pressure. Then over an area of 1 square inch we have 90 pounds pushing up and 100 pounds pushing down.

When pressure is raised to 100 pounds, everything is in balance. When we raise the pressure to 110 pounds, the spring will compress, permitting the excess liquid to pass through the seat opening in a certain volume. When we raised the pressure to 120 pounds, the valve is discharging its maximum capacity. As the pressure is lowered to 100 pounds the valve closes to the seat and closes.

A relief valve is only designed to be used on liquids. When used for gases, steam, or air, it functions as a relief valve with no popping action.

A few examples of pop and relief valves would show their similarity. It would be rather easy to intermix, especially if the nameplate was missing. Speaking of nameplates or marking, paragraph UG-129 of the ASME code states: "Each safety and relief valve $\frac{1}{2}$ inch pipe size and larger shall be plainly marked by the manufacturer with the required data in such a way that the marking will not be obliterated in service."

Last of the basic relieving devices is a safety-relief valve—this is a type of valve that can be adjusted to give either "pop" or "non-pop" operation and can be used on steam, gas, vapor, and liquid service (with

modifications). The modifications: if used as a safety valve, the huddling chamber must be used; if used as a relief valve, it must be dismantled and the huddling chamber removed.

Let us consider four examples that illustrate diversified usage of rupture discs and safety valves in primary and secondary relieving capacities.

1. A rupture disc, used as a primary relief, installed under a safety valve. It is an accepted practice, when a safety valve is subject to excessive corrosion, jamming, stoppages from material in the system, to install a rupture disc in the pipe ahead of the valve. Avoid loss of valuable material by leakage. Also the rupture disc prevents deleterious materials from entering the valve until relief is necessary.

2. An excess flow valve (actually a ball-check valve). This vents the chamber between the rupture disc and the valve seat, preventing pressure which may leak through a corroded or leaking disc from building up on the top side of the disc and consequently increasing the rupture pressure.

3. A reverse of the last example. The rupture disc is installed downstream from the safety valve. This arrangement is adopted at times when it is necessary to prevent leakage of valuable, noxious or otherwise hazardous materials. In the words of the ASME code on unfired pressure vessels, "Users are warned that an ordinary spring loaded safety or relief valve will not open at its set pressure if back pressure builds up in the space between the valve and the rupture disc." To prevent this a specially designed safety or relief valve is required, such as a diaphragm valve or a valve equipped with a bellows above the disc. A safety valve may also be equipped with bellows.

4. A rupture disc installed in parallel with a safety valve. When equipment is to be operated at more than 66 per cent of its allowable working pressure it is best to place the rupture diaphragm in parallel with a relief valve, the relief valve being used for primary relief and the rupture disc as secondary relief. In this fashion the diaphragm supplements the valve providing emergency relief. Installed in this fashion, the bursting pressure can be at practically any value desired, from 50 per cent above

actual operating pressure up the test pressure for the equipment.

Poor installation of a rupture diaphragm may result in rupture that might endanger personnel in adjacent areas. An exhaust stack higher than the heads of any employees should be installed downstream from such a disc.

A few examples of poorly designed installations that are found in some chemical plants follow, showing rupture disc installation, but the principle is also applicable to safety and relief valves. Naturally, these examples are not indicative of installation practices at your plant.

A valve cannot be installed in a rupture disc or relief valve line unless it is locked open; in the event of a shutdown for repair or replacement, this valve would actually be useless if a rupture disc or valve had to be replaced, and conceivably it might be left closed. The rupture disc or relief valve coming off the end of the tank might vent directly into the path of personnel walking by. It should be vented to the outside or baffled.

While generally not recommended, a valve may be installed in a rupture disc or relief valve line as long as it is locked open, and shut only while supervision is present for replacement of a rupture disc, and then locked open again. By locking, I mean a physical method, such as a seal wire, seal tape, lock and chain, etc.

The relief valve or rupture disc having a vent line with two elbows can lead to disastrous results since every elbow reduces the available capacity of the vent line; if straight, the line might have ample capacity, but with avoidable elbows, the relief capacity can be restricted to the points where after the rupture disc has broken and functioned quite satisfactorily, the flange itself could be torn from the vessel.

In the last example we assume that one rupture disc or relief valve is set at design pressure and the other at test pressure. Actually, this venting of two relief devices into one line is normally expected on two adjacent vessels; in the event that one relief device was called upon to function, it could possibly impose sufficient back pressure on the other to reverse it, even under pressure in the adjacent vessel.

A monograph can be used for the sizing

of safety and relief valves, and is very useful. It not only saves time but insures that all corrections for absolute pressure, temperature and over-pressure have been considered. I'm sorry time does not permit an explanation of the monograph.

How do you treat your pressure-relieving devices? Rupture discs, safety and relief valves should be treated as precision instruments, for basically speaking that's what they are—they are self-actuated and depend on critical dimensions, surface finish, corrosion resistance and adjustments for good performance. Yet on many occasions I've seen them treated as casual pipe fittings and scrap metal, thrown in bins and boxes, mixed with other pipe fittings and left to gather grime and dust.

Inspection, testing and maintenance is an integral phase of a sound pressure-relief device program. Each plant should establish a regular schedule for inspection and testing of relief devices.

Relative to inspections, no general rules can be formulated because of the wide range of conditions and materials encountered. It is suggested that pressure-relief devices be tested quarterly under average conditions, but this should be tempered by consideration of local conditions and service.

Speaking of inspection and testing reminds me of the time I asked the general maintenance foreman of a large size industrial plant how often he inspected and tested the relief devices in his plant. He replied, "I've worked here for 23 years and we have never inspected or tested our safety and relief devices."

After I completed my inspection of the plant, I was forced to agree with him. I saw relief valves with bird's nests in them, wasp nests, metal plugs in the exhaust openings, corroded springs, chews of tobacco in the openings, broken level pins, missing bonnets, lead seals gone and levers blocked open with pieces of wood.

One bad practice I've noticed in plants is the use of safety and relief valves as control valves, i.e., if you want to maintain pressure in a vessel at 100 psi, it is very convenient to adjust a relief valve for 100 psi and let it do the controlling. Another is the installation of safety and relief valves in a horizontal position—they should always be installed in a vertical position.

SPECIFIC AND UNUSUAL APPLICATIONS OF PRESSURE RELIEF DEVICES

By R. L. PORTER

Sales Mgr., Autoclave Engineers, Inc., Erie, Pa.

In the chemical process industry, the proper selection and use of relief devices is well established. Many excellent papers have outlined the fundamentals of relief devices for commercially operated equipment.

The selection and use of safety devices in equipment to be operated under extreme conditions is a great deal more empirical. The term "extreme conditions," as defined by Gaseche and Stjepcevic, covers the range of pressures beyond 2000 psi, or temperatures above 1000°F, and various modifications of these conditions. Presently, only a few commercial processes fall within this category—the manufacture of polyethylene by the high pressure process, the manufacture of ammonia, production of alcohol by the oxo process, and a few others. The greater proportion of work is done in the research laboratory. Therefore, I wish to define the frame of reference of this paper to encompass the work performed in the high pressure research laboratory.

There are many difficulties found in the selection of proper protective devices for this type of activity:

1. Since the work is in the realm of research, conditions to be met are not well defined and may change rapidly.
2. The equipment is usually quite small and normal commercial devices may not fit.
3. Conditions are frequently beyond the

scope of normally available commercial devices.

4. Design protection is extremely difficult because code design practices frequently do not cover the conditions to be met, and sometimes safety factors must, of necessity, be very low.

Therefore, in addition to the relief devices to be discussed, it is felt that additional protection is required, such as extremely well qualified, trained personnel, and well engineered barricade systems.

For just a moment, I should like to discuss the two qualifications mentioned above. By far, the most important is highly qualified operating personnel.

The chemical process industry has recognized the need for barricading systems and has gone to great length and expense to provide them for their research personnel. The high pressure laboratory at Hercules Powder Co. in Wilmington, Del., is an example. From a view of this same laboratory, you could see that other precautions, in addition to relief devices were necessary.

With the thought in mind that the rupture disk is not the only protection given the high pressure research worker, let us examine some of the ways relief devices are used in this work.

With high pressure equipment, it is usually quite important that rupture disks be placed

as close as possible to the interior of the pressure vessels to allow little opportunity for build up of solids, and to ensure that the pressure drop ahead of the rupture disk be as low as possible.

An exploded view of the most common relief device for this type of operation shows that it consists essentially of the rupture disk body, the disk itself, a method of sealing the disk against leakage, and a means for carrying the exhausted products away from the equipment.

Rupture disks have become indispensable to the chemical process industry. There are some cases, however, where the range of work being carried out in research is beyond that covered by commercially available rupture disks. For instance, at extremely high pressures—in the range of 100,000 psi. or above—it is impossible to purchase rupture disks which are reliable.

As a means of solving this problem, the reverse intensifier has been developed. This common piece of equipment is used to raise pressures to high values by means of a differential area piston. In this instance, on a piston, the area on the low pressure side is approximately ten times the area on the other side.

This means that if a low pressure—say 10,000 psi.—is applied to the low pressure area, it is possible to generate 100,000 psi. on the other side. This apparatus is called an intensifier. For extremely high pressure work, it has been found satisfactory to reverse this process and place a rupture disk on the low pressure side of the piston and expose the high pressure side to the process under study.

The intensifier is used as a relief device. As an example, a 100,000 psi. system can receive the protection of a rupture disk normally rated at 10,000 psi. by use of a 10:1 reverse intensifier.

Frequently, high pressure research operations are carried out in the explosive range of certain chemicals. Sometimes, reactions take place which go through the explosive range during the course of reaction. In cases of this type, it is necessary to protect against extremely rapid rises in pressure.

Next consider an autoclave with a rupture disk built as the bottom of the autoclave. With this type of device, the objective is to have a rupture disk with as large an area

as possible. You will note in this figure that since the rupture disk is in the bottom of the autoclave, the possibility exists that the autoclave will become a rocket in the case of explosion. It is necessary, therefore, to mount this equipment with heavy duty reaction springs so that after relief, it will not end up through the roof.

No doubt you have been reading about the chemical "farmers" with their successful method of growing quartz chemically. This synthetic method of growing crystals is a major achievement, and will be of great significance in the field of communication. However, there is one ticklish problem associated with this operation. In a pressure vessel where the object is to grow a solid material, how does one protect the equipment and personnel with a rupture disk which does not become covered by this material. The problem was solved as follows:

In a view of quartz growing equipment you would notice the safety head equipment in the cover. An enlarged section of this portion of the vessel, shows at the upper cover the rupture disk which is made much the same as that discussed earlier.

At the lower section, however, is a small metal disk which is drilled with a single hole of .003-inch diameter. This diameter has been found to be sufficiently small to hold water, due to the surface tension of the water itself. This disk is then placed in the position shown, and the column between the disk and the rupture assembly is filled with pure distilled water. This means, then, that the small perforated disk is exposed on one side to the crystal growing liquor and on the other side to pure water.

This combination assures that the small hole will not become plugged with the crystals, since it is continuously being dissolved at the same rate at which it is formed. The passage below the rupture disk is, therefore, open in the event of failure of the disk.

Another method of attack on a problem of a similar nature is found in polymer chemistry. In this type of reaction, chemicals are allowed to polymerize in a continuous flow reactor. In order to allow for protection of the equipment, it was necessary to introduce the rupture disk into the interior of the reactor. In this way, even

though polymers may form over the rupture disk, protection is still provided. This type of protection has been found useful in such operations as the polyethylene reaction.

In chemical research work, one type of reactor which has frequently been used in the past, and still finds some occasional uses, is the rocking reactor. In this operation, a rocking mechanism is provided to give agitation to the contents of a high pressure reactor. Since the equipment is generally small and is continuously moving, the position of the rupture disk is something of a problem. Such a device has, on the left, the rocking reactor and, on the right, a valve which provides a means of shutting off the flow of gases to the reactor; a pressure gauge to indicate the pressure in the reactor; and a rupture disk to provide relief for the vessel.

Quite frequently, in high pressure research, very expensive or very toxic chemicals are used. It is, therefore, felt that a rupture disk, which is the final safety device, should be supplemented with a primary device which will relieve excess pressure temporarily, but will not empty the contents of a vessel.

In such a device, there is an air-operated valve, which is actuated by air on the valve diaphragm. The air is controlled by a solenoid valve and the solenoid valve is actuated by an electric contact gauge. In this manner, the electric contact gauge can be set to operate at a pressure just slightly above normal operating pressure.

Chemical Section

If pressure reaches this point for any temporary operational reason, the solenoid valve is actuated. This opens the air-operated valve and relieves the pressure. As soon as the pointer falls below the set point, the valve closes and the operation continues. In this manner, relief of a temporary nature only is effected. It is suggested that the exhaust from the valve be carried to a safe area.

We have mentioned many cases of difficult problems in the high pressure field, but have not discussed the other extreme of high temperature conditions. To date, only two methods have been used to solve the problem of relief devices on high temperature equipment:

1. To provide a cooled relief device. Quite often, water circulation around the rupture disk is used.
2. To provide a rupture disk made of a high temperature metal. To date, this is the preferred solution.

One of the most frequently used materials is Inconel. Inconel has a very high strength at high temperature. But perhaps even more important is the fact that the reduction of strength with increase in temperature is very low. A graph of temperature versus pressure on Inconel shows that the strength of the Inconel does not decrease significantly from room temperature to about 1200°F.

As more and more work is done in the high temperature field, other solutions to the safety problem will be forthcoming.

SAFETY IN STORAGE, TRANSPORTATION AND HANDLING OF GUIDED MISSILES AND ROCKETS

By RAY L. MYERS
Deputy Chief, Inspection Division
U. S. Army Ordnance Field Safety Office
Charlestown, Ind.

The safety of a plant must be a constant consideration of those in charge of it from the conception of the original idea around which it is designed, and throughout the entire period of its construction and operation. Safety must begin on the drawing board, as otherwise its necessary consideration later becomes a matter of increasing difficulty and cost, and the latter all too often becomes prohibitive.

Safety in the storage, transportation and handling of guided missiles involves several important factors: i.e., (a) the determination of the hazards inherent in the operations, equipment, buildings and areas; (b) the development and adoption of a proper protective procedure to eliminate these hazards, if possible; (c) to reduce their effect in the event of an accident, if they cannot be eliminated; and, (d) the establishment and continued application of methods of inspection to insure the maintenance of these protective measures.

The safety engineering approach to the general problems of guided missile and rocket safety has been a large factor in the remarkable record of the U. S. Army Ordnance Corps establishments that store, transport and handle guided missiles and rockets.

As an example, during World War I, 240 persons were killed for every billion pounds of propellant and explosives processed; whereas in World War II, this figure was reduced to five persons.

These statistics interpreted simply mean that the lives of more than 10,000 persons engaged in these operations during World War II were saved by safety measures that were put into effect.

Without these safety precautions, a billion dollars' worth of plant facilities might have been lost and, what is more important, our combat troops would not have received the

kind and amount of ammunition that they needed when they needed it!

The storage, shipment and handling of packaged missiles, rockets or their components, at present, poses no serious problem. However, the advent of ever-larger missiles and heavy rockets will create correspondingly greater challenges in storing, packaging, transporting and handling.

The type of storage facility provided guided missiles and heavy rockets or their components, is controlled by the hazard, or potential hazard, of the component itself. Explosive components, such as war heads, rocket motors, igniters, etc., require igloo storage. Liquid propellants, including both fuels and oxidizers, may be stored, properly segregated, in liquid propellant storage areas, in properly designed and constructed buildings.

The storage of present and future missiles containing solid propellant rocket motors, however, takes us into an additional problem area—that of explosive safety. The presence of these explosives—loaded rocket motors—demands that the safety of personnel handling, storing and shipping this material, the protection of government property and the safety and protection of the lives and property of surrounding communities will have been carefully pre-planned and is rigidly enforced.

How is this done?

First, safe distances must be provided between locations containing explosive materials. This includes operating buildings, storage magazines, loading docks and any other explosive facility. Inhabited building distance must be maintained between explosives locations and inhabited buildings. Intraline distance is the minimum distance permitted between any two buildings within an operating line. Magazine distance is the mini-

mum distance permitted between any two storage magazines.

Guided missiles and rockets are classified according to the expected damage if they explode or ignite. The maximum amount of explosives permitted in any location is specified in the quantity-distance tables, Section 17, ORL M 7-224. It is mandatory that local limits be established in amounts no greater than those consistent with safe, efficient operations.

Keep in mind that the cardinal principle to be observed in any location or operation involving guided missiles and rockets is to limit the exposure of a minimum number of people, for a minimum time to a minimum amount of hazardous material consistent with safe and efficient operations. All operations should be scrutinized to devise ways and means of reducing the number of people exposed, the time of exposure or the quantity of material subject to a single accident.

Guided missiles, rockets and their components are stored in accordance with applicable Ordnance Corps storage drawings. War heads, motors, igniters and other explosive components require igloo storage. An igloo magazine means an arch-type, earth-covered magazine which may be constructed of concrete, metal or wood. A "standard igloo magazine" means an earth-covered, reinforced concrete, arch-type magazine, with or without a separate door barricade, constructed according to approved standard service drawings.

Liquid propellants (fuels and oxidizers) must be stored in an area separate from all other activities. The facilities must comply with the requirements and standards for various propellants. All buildings, tools and equipment must be compatible with the various chemicals. The propellants will probably either be stored in approved shipping containers or bulk storage tanks meeting all the safety requirements. Among some of the liquid propellants used today are hydrazine, hydrogen peroxide, unsymmetrical dimethylhydrazine, nitrogen tetroxide, liquid oxygen and nitric acid.

At present, the shipment of large guided missiles and rockets, regardless of their hazard classification, is offering no particular problem. Future missiles may reach 15 to 20 feet in diameter and 75 to 100 feet in

length and weigh as much as 100 tons or more. Such dimensions offer not only problems in packaging and handling but also in shipment irrespective of the mode of transportation. The size and weight of these future components will necessitate further revision of the loading and blocking concepts.

The advent of these ever-larger explosives-loaded items will probably cause revision of the ICC Regulations to permit their movement by common carrier. The ICC Regulations are published in the 1949 edition of the Code of Federal Regulations, Title 49, parts 71-90, Transportation. Those regulations are also published in various freight tariffs.

Our present public highways have a maximum height clearance of 13 feet, six inches; yet, as has been pointed out, components of the new large missiles may be as large as 15 to 20 feet in diameter. Not only are our highways as presently constructed inadequate for the transportation of items of this size but the railroads will also have difficulty in handling any item whose loading height, plus the car height, exceed 15 feet, one inch. Such items usually require special handling and special routing.

Present guided missiles, heavy rockets and their associated components are loaded, blocked and braced in accordance with Department of the Army Ordnance Corps drawings. Truck and rail loading drawings have been developed after many tests to insure the best possible protection during shipment of the guided missiles and rockets. All of the Ordnance Corps drawings are approved by the Bureau of Explosives, Association of American Railroads, and are binding upon all shippers of guided missiles and rockets by, for and to the Ordnance Corps.

Shipments of guided missiles, rockets and liquid propellants must comply with the following regulations:

1. Interstate Commerce Commission Tariff Books;
2. Army Regulation 55-355;
3. U. S. Coast Guard Regulations and Instructions;
4. State and Municipal Laws and;
5. Ordnance Safety Manual, ORL M 7-224.

The handling of guided missiles, rockets and liquid propellants involves much more than the mere off-loading and out-loading of these items as packaged. In many cases, special handling equipment must be designed and fabricated for these operations. The handling of any item depends on the hazards involved. The handling of the unpackaged guided missile body, rocket motors and other associated components and/or hazardous material present special problems. In this connection, the size and weight of the component of the new missile, which the future may bring us may exceed the safety limits of the material handling equipment now being used.

It is of utmost importance that the nature and characteristics of the various items be fully understood by all who are required to handle them. Established rules have been developed as needed to fit actual cases. In general, all operating personnel must be taught the nature of the hazards involved in the handling of the guided missiles, rockets and liquid propellants.

The three basic hazards to be dealt with in operations involving the items are:

1. Fire;
2. Explosion and;
3. Toxicity poisoning or chemical burns. Any or a combination of these hazards may be present in a given situation.

Fire protection and prevention are a must at all times. Areas must be kept free of combustible materials. *Fuels and oxidizers must be kept separated.* Fire fighting equipment and extinguishing agents must be suitable to the type of fire which may occur with a particular fuel and oxidizer. Where flammable vapors are present, electrical equipment must be of the approved explosion-proof type, and equipment and containers must be grounded. Non-sparking tools, shoes, and non-static generating apparel should be provided where required.

The principles guiding the elimination and control of fire hazards are generally applicable to explosion hazards as well. Shock-sensitive materials must be handled carefully and protected from vibration, friction and impact.

The protection of personnel from poisoning and chemical burns involves:

1. Engineering prevention to minimize spills and leaks and insure adequate ventilation;
2. Use of appropriate personal protective clothing and equipment and;
3. Conducting of periodical health surveys;
4. Periodic physical examinations;
5. Constant education of supervisors and employees regarding safe procedures and practices.

In summation, the storage, transportation and handling of guided missiles and rockets involves, in general, highly hazardous materials. Consequently, in order to do the job safely the hazardous properties of each item must be fully known, recognized and understood. Specific and detailed safety standards to be followed in all operations involving these materials have been established. These safety standards are outlined in various publications in a manner adapted to the needs of the safety engineer, plant superintendent and operations supervisor.

Supervisors must devise and enforce a system of inspection to ascertain that all operations are being conducted in accordance with the prescribed safety requirements. Unless successful control for the hazards involved in the operations is maintained, sooner or later a fire, explosion, poisoning or chemical burn will occur at the plant. Therefore, during the storage, transportation and handling of guided missiles and rockets close adherence to all safety requirements is a must, and demand constant alertness to every new indication of a need for a change in the safety standards through actual experience.

SAFETY IN ROCKET PROPELLANT MANUFACTURE

By ROBERT J. SHIROCK
Deputy Chief, Evaluation & Investigation Division
U. S. Army Ordnance Field Safety Office
Charlestown, Ind.

The cardinal principle of hazardous operations; i.e., "In any location or operation involving explosives, ammunition, severe fire hazards or toxic materials, exposure must be limited to the minimum number of people for a minimum time to a minimum amount of hazardous material consistent with safe and efficient operations," must be the basic premise for all propellant manufacturing operations.

The introduction of rockets and guided missiles into the nation's weapons system for defense of our country has raised a question—what changes have resulted in the safety requirements for manufacture, handling, storage, and use. The assumption that the term rocket propellant connotes the unusual; therefore, the hazards must also be unusual, is wrong in most cases. Most often, careful and objective study of the materials discloses the hazardous properties. Thus, there have been few major changes to the basic safety requirements. Specific changes due to chemicals and/or components have resulted. Each of these require individual research in order to formulate the necessary safety requirements.

Rocket propellants are, in general, highly reactive materials designed to deliver large amounts of energy in short periods of time. Fuels and oxidizers, and their reaction products possess hazardous properties which must be fully understood by all who handle them in any manner.

Missile propellants are grouped according to the physical state in which they exist. At present, only two types are in general use—liquid and solid.

The hazards of liquid propellants are fire, explosion and toxicity. In the case of fire and explosion, the principles guiding the elimination and control of each are generally the same. As to toxicity, prevention of poisoning and chemical burns of tissues of the body require (1) proper engineering design of operations, (2) personal protective equipment, periodic health surveillance procedures and (3) trained supervision.

The hazardous properties of liquid fuels, oxidizers and starting mixtures can be easily determined.

The manufacture of solid propellant motors for guided missiles and rockets has introduced many potential hazards. The safety requirements for the manufacture of single, double, triple bases and cast and composite propellant have been developed over many years. Now, however, the ingredients of each are being combined. This has created new safety requirements.

Safety in manufacturing operations must start during the research and development stages of a particular item.

Many of the explosions which have occurred in the manufacture of rocket propellants are a direct result of the lack of complete and adequate research and development.

Solid propellants are basically high-energy mixtures of a fuel and oxidizer which, after certain process steps, are a solid mass possessing properties consistent with the manner in which they will be used. Because of their composition, combustion progresses in the absence of air or other externally supplied oxidizers. The fuel and oxidizer are either chemically bound or in solution as in single and double base propellants, or are chemically separate entities consisting of a generally elastomeric fuel and crystalline inorganic salts. Other ingredients are normally added to impart and control desired physical and ballistic characteristics to the propellant.

The particular chemical and physical differences of the propellants being developed and manufactured require a wide variety of process methods. These methods can be catalogued into major functional processes; i.e., raw material preparation, mixing, casting, curing and motor finishing.

The physical conditions such as increased size, sensitivity of ingredients and ability to detonate are important.

This has meant redesign of present equipment and development of new, unique types of equipment.

No single factor exerts more effect upon a solid propellant operation than the safety procedures under which the work is performed. The objectives of safety are well understood, but the impact of safety measures themselves tends to be underestimated by persons unfamiliar with explosives and industrial operations.

The Ordnance safety manuals are the regulatory explosives safety publications used at Ordnance Corps plants and private plants operating under Ordnance Corps contracts. The rapidly changing nature of solid propellant formulations results in areas for which the safety requirements have not been developed.

The safety manuals in the explosives and chemical field have been written in 'blood.' This was after the fact safety. Now we must, of necessity, build safety into our propellant operations before the fact.

The custom of designing and installing equipment and facilities and then examining it for hazards is obsolete. Consideration of safety after development becomes a matter of increasing difficulty and cost. The cost factor all too often becomes prohibitive.

The mechanization and automation of processing and loading techniques have gone

forward. Many things have been accomplished in the field, but the most important insofar as safety is concerned is the reduction in the amount of explosive materials which might be subjected to a single accident.

Advances in the art have been so rapid in the propellant and explosives field that there are many instances of equipment and processes becoming obsolete before they are actually put into production.

The explosions which have occurred during mixing, curing, finishing and testing of solid propellant motors have been the result of make-shift equipment and lack of complete knowledge. Technical advances have increased the efficiency of our propellants; however, this increase can result in disastrous results because of improper procedures.

Safety involves the determination of the hazards inherent in the processes, equipment, buildings and areas—the development and adoption of proper protective procedures, either to eliminate these hazards or, if they cannot be eliminated to reduce their effect in the event of accidents and to minimize the frequency of such accidents, and last—the establishment and continued application of methods of inspection to insure the maintenance of these protective measures.

SAFETY IN THE ROVER PROJECT

By ROY REIDER

Safety Director, Los Alamos Scientific Laboratory
Los Alamos, N. M.

The Rover Project began in 1955 under the auspices of the United States Atomic Energy Commission to investigate and demonstrate the feasibility of nuclear rocket propulsion. The Los Alamos Scientific Laboratory in Los Alamos, New Mexico, operated by the University of California, does the preliminary research on propulsion reactors and the development and testing of such reactors.

A correlated study of complete nuclear rocket propulsion systems now going on is administered jointly by the National Aeronautics and Space Administration and the AEC through the Space Nuclear Propulsion Office. In recent months engine contractors have been selected and their work will proceed toward the development of a working model of a flight system.

Test reactors designed and constructed at Los Alamos are tested at the Nevada Test Site. To date four models have been statically tested at varying degrees of power and propellant flow rates; about six other models are scheduled for test in the next calendar year. The Nevada Test Site provides a remote area large enough to give the necessary public isolation for this radical development work.

The simplest way to get a nuclear rocket propulsion system is by substituting a fission reactor for the combustion chamber of the chemical rocket engine. All the reactors thus far tested in Nevada and all those scheduled for testing in the Rover program are solid-fuel heat-exchanger reactors using uranium-235. The reactor-coolant and rocket-propellant gas used is hydrogen. We have reached the point where high pressure gas feed systems will not provide sufficient flow rates and so cryogenic systems are being employed.

1. High Pressure Systems.

The first storage system, for Test Cell A, consisted of banks of buried (below grade) high pressure bottles. The original capacity was 2,000,000 standard cubic feet of gas in 140 forged steel bottles. These bottles are two feet in diameter and of

random lengths, approximately 20 feet. Storage pressure is 3400 psi. Storage capacity has recently been increased to 3,300,000 standard cubic feet by the addition of four laminated steel bottles, each five feet in diameter, 96 feet long; these new bottles are above ground. They also are pressurized to 3400 psi. Underground installation proved unsatisfactory at the beginning as leaks developed after the system was pressurized with hydrogen although it had checked out at test overpressures with nitrogen.

In the new Test Cell, Test Cell C, storage capacity is about 5,000,000 standard cubic feet in 12 of the large bottles similar to those added to Test Cell A. Storage is mainly hydrogen although about 10 per cent of the capacity is in helium which is used for purging and 10 per cent in nitrogen which is used for blowdown, purging and inerting requirements which will be discussed later.

The design of the bottles follows generally the standards of the American Society of Mechanical Engineers, Section VIII, Unfired Pressure Vessels. The significant departure from the code was in using a lower factor of safety in yield strength. The usual factor of safety of four was reduced to 2½ for the following reasons:

1. Storage and operating temperatures are substantially below the upper limit of the ASME allowable upper range.
2. The location of the facility is isolated from the public and access is restricted.
3. Only non-corrosive materials will be stored.
4. An automatic deluge system protects the large above-ground bottles.
5. Shell openings are limited to a small drain and a small vent, neither of which is greater than an inch in diameter.

However, fabrication and inspection techniques will follow the usual ASME code requirements. Shop test procedures will follow ASME code standards with hydrostatic testing at 1½ times working pressure; field testing of assembled components is carried

not pneumatically at $1\frac{1}{2}$ times working pressure.

Two years after its installation the compressor station and the manifolds of the Test Cell A tank farm were pressure checked at $1\frac{1}{2}$ times the working pressure using ethyl alcohol as the hydrostatic medium. This testing technique, even with a combustible fluid, was quite satisfactory. The work was controlled remotely; the fire department was on standby at a safe distance.

Gas out-flow rates in the past have been several pounds a second; in the future these out-flow rates will be increased tenfold.

II. Liquefied Hydrogen Systems.

Test Cell A has a storage capacity of liquefied hydrogen totaling 55,000 gallons. This is contained in two 28,000 cylindrical dewars; these dewars are pressurized to 100 pounds. Daily loss of hydrogen is specified as 0.7 per cent of the net contents. The capacity of these dewars almost triples the gas storage capability of Test Cell A facilities.

Test Cell C has a storage capacity of 100,000 gallons of liquefied hydrogen in two 50,000-gallon spherical dewar tanks. These tanks are also pressurized to 100 psi; daily loss is specified at 0.3 per cent of net contents. Liquefied hydrogen storage is protected by deluge sprinkler systems which may be activated automatically or manually; the deluge system can be controlled remotely.

Hydrogen storage spacing is based on configuration and low pressure detonation risk only. Quantities of oxidants are not credibly expected to be in contact with liquefied hydrogen and so high explosive quantity-distance tables are not employed.^{1,2}

III. Safety Standards.

A. Operating Procedures.

Detailed experimental plans, including check lists, are prepared for all reactor runs. Independent of these runs, the filling and flow checks of the gas systems are also carried out with specific plans. Periodic pressure checks are governed by special procedures.

A general safety manual has been prepared for the Rover test work. This manual has been supplemented by the more detailed requirements and standards of specific groups.

B. Safety Administration.

A site safety committee headed by the test director meets monthly. Membership on this committee includes a representative from each technical group and the safety advisor. A safety engineer, responsible to the test director, is in residence during peak program activity.

Technical safety counseling is provided by the home laboratory in such specialized matters as criticality risk and cryogenics.

C. Electrical Safety Standards.

The National Electrical Code³ is the basic reference document in electrical design. In general, Division II conditions prevail so a vigorous application of the code with respect to Class I, Group B fixtures has not been necessary.

Light fixtures are of a sealed type, rather than explosion proof, with switches located in non-hazardous areas or outdoors. Other electrical equipment is specified with one or more of the following conditions:

1. Non-sparking or intrinsically safe.
2. Sealed against gaseous penetration.
3. Continuously purged (this is rather rare).
4. Located close to the floor.
5. Ordinary equipment might be present in a potentially hazardous area with its use precluded during hydrogen flow conditions.

D. Combustible Gas Alarms.

Continuous monitoring is carried out indoors with local alarms. There is also remote read-out during actual flow operations.

E. Inerting Techniques.

In Rover test work hydrogen is present indoors no more than 1 per cent of the time other than in small specialized facilities such as a flow testing laboratory. Nevertheless, during reactor testing operations the hydrogen flow volumes are indeed enormous, many pounds a second. Our test cell building design appears to compromise good combustible gas safety practice by being closed structures. But radiation shielding requirements are such that open-sided rooms cannot be used.

Some explosion venting has been provided in flow rooms but even a modest goal of two square feet vent area per 100 cubic feet of room volume cannot always be met.

Personnel are not normally present during these large flow conditions but protection of facilities is of concern. Design, construction, preparation and checking of facilities are so time-consuming and expensive that the schedule of Rover test work depends on just a couple of test buildings.

It is this overwhelming reliance on a few structures that prompted the capability of inerting some rather large volumes. Rooms with volumes in excess of 100,000 cubic feet will be inerted with nitrogen; a nitrogen capacity for a double purge will be available. Residual oxygen can be monitored with a remote read-out. The return to normal air can be accomplished in about 15 minutes with the ventilation system.

Provision is also made for personnel re-entry for minor adjustments. Self contained breathing equipment and portable oxygen monitors will be available for this purpose.

F. Ignition Control.

Hazardous areas are delineated by fencing and signs; in some cases these areas may be temporary. Permitted smoking areas have been assigned and designated.

Maintenance work and the use of spark producing devices is controlled by requiring specific permission of the responsible group.

No requirements exist for the use of non-ferrous tools.^{1,4,5}

II'. Radiation and Criticality Control.

As the reactor is operated remotely, radiation exposures may be minimized by delayed reentry. A radio-controlled railroad engine moves the test car away from the test cell and into a well shielded disassembly building two miles away. Here disassembly and post-mortem examination is carried out by remote manipulations. On-site radiological safety problems have been readily managed without significant exposures; there have been no off-site problems although backgrounds are surveyed.

Criticality safety problems are localized in the assembly of the reactor and the reactor in the test cart itself. Outside the reactor it would take an unfavorable three dimensional array, fully flooded to cause a critical excursion. In the assembly steps the presence of cadmium absorbing foils in the reactor inhibit the criticality risk. Upon the removal of the foils at the test cell stringent

access and activity controls are instituted. Locked control rod positions and control rod manipulation limitations further enhance the critical safety measures. Continuous neutron monitors with audible signals accompany the test cart when the reactor is present.

1'. Accident Experience.

Only one serious incident has marred our accident experience for two and a half years of Rover field testing. This was the failure of a compression fitting joining a copper tube to a quick disconnect.

A check-out team was in the process of connecting a reserve supply of helium to an inlet manifold at the compressor station to supplement a bank in the tank farm.

The reserve supply consisted of 6 tube trailers containing helium at 3400 psi. The trailers were connected to the closed manifold valve by flexible copper tubing having quick disconnect fittings with the tube ends held to the quick disconnects by compression fittings. The copper tubing was 19 feet long.

The procedure being followed was for the operators to open the tube trailer valves in sequence. A team had opened the valves of trailer #2 and were proceeding to trailer #4. Another person opened valve J2 on trailer #3 when a leak was noticed at the transfer tube connection on this trailer so the valve was shut off. Valve J2 was then opened on trailer #3 and the leak stopped. Just at this time a loud report was heard as the copper tubing had torn loose from its fitting at the quick disconnect and the flailing line struck two men. One received serious head injuries requiring extensive plastic repair and the loss of vision in one eye.

In reviewing the accident, it was obvious that the tube pulled out of the connector while under pressure. The tubing, 0.840" OD, 0.543-0.550 ID, with wall thickness averaging 0.145, was adequate to carry the load. The tubing was held in place with a compression fitting which consists of an assembly body, ferrule, and retaining nut. The assembly body received the tubing in a square shouldered well. At the upper $\frac{1}{4}$ " of the body is a taper. The nut is slipped over the tubing, then the ferrule. As the nut is tightened it forces the ferrule to conform to the taper of the body resulting in the ferrule actually biting into the tubing, thereby making a strong, leak-proof assembly.

bly. Through use and handling, small gas leaks had developed in these connections. It had been standard practice for an operator to tighten the retaining nut approximately $\frac{1}{2}$ turn or whatever was necessary to make a leak-proof fitting. Normally the ferrule "hites" in at about $\frac{1}{2}$ inch from the end of the tube. The end of the tube involved showed that the retaining nut had been tightened as far as it could be and that the ferrule was within $\frac{1}{16}$ " of the end of the tube. Insufficient metal was held by the ferrule to withstand 3400 psi pressure.

In discussing the incident with maintenance people it was brought to light that the plumbers always bulged the ends of the tubes to make them tighter in the fitting. Further investigation demonstrated that the tubing used was too small (in OD) for the compression fitting. Since the tubing was too small for the fitting, this meant that the tubing was not in full contact with the ferrule and retaining nut. This condition makes it highly probable that a tube could be worked loose by continual flexing, such as bending to mate the opposing fitting, whether or not it contained pressure. The only gas involved was that which was compressed in the 19 foot length transfer tube.

The quick lash of the tube can be likened to a bourdon tube—curved tubes under pressure tend to straighten out. If the tube does not rupture and vent, it will whip or uncoil with a straightening tendency when vented at either free end in order to relieve the strain of the metal when the pressure is suddenly released.

The investigation showed the following:

1. The "tubing" supplied was high pressure pipe, $\frac{1}{2}$ nominal (0.840" OD); however, the fittings were designed for tubing, size $\frac{3}{8}$ " (0.875 OD).
2. Originally the make-up of the fittings for the plumbers was supervised by scientific staff employees. The practice was discontinued after hundreds had been prepared and the work was then considered routine.
3. The 0.035 difference in pipe and tube size explains why the plumbers bulged the end of the connectors in order for them to approximate a fit.
4. The assemblies had been used a year.

These compression-type fittings had been used at the site since August, 1958. These

fittings were selected after various other connections, that were recommended by leading high pressure users, failed for one or more causes. Normal tube trailer pressures seldom exceed 240 psi, whereas our specially made trailers handle pressures to 3500 psi. The original coupling was a flex tube, having an accordion-type inner section, woven stainless steel mesh as an outer covering, and having screw fittings welded to the hose. These connections seldom lasted for more than two tube trailer transfers. Gas from the trailer in its initial flow through metal connectors heats the tubing to about 200°F; then as the gas expands the temperature will drop to about 0°F. These temperature fluctuations took place in about 15 seconds. The thermal shock resulted in leaks at the weld. In connecting this type tubing, quite often the tubing was ruptured at the juncture of the weld and hose when the tubing became twisted during a hook-up.

The second flexible connection consisted of stainless steel tubing in four sections connected by fittings. All fittings were loosened, the end sections were connected to the manifolds and then the center fittings were tightened making the assembly rigid. This system failed because of leaks and because of failure of the stainless steel threads.

It is quite apparent that: 1) the fittings should never be tightened, to prevent leaks, without disassembling the fitting and observing where the ferrule is grasping the tubing; 2) it is not good practice to distort high pressure pipe in order to approximate a fit that proper size tubing would make.

In order to prevent a recurrence of an accident previously described, the following changes were made at tube trailer inlet manifold locations.

1. A barricade was erected between the rear of the trailers and the inlet manifold. This barricade was about four feet high and extended the distance necessary to serve the number of trailers to be connected.
2. On the inlet manifold side of the wall was installed a work platform of steel grating about three feet wide and two feet high, extending the length of the wall.
3. Rigid high pressure piping was buried under the work platform extending from the inlet manifold and piercing the barricade to serve the trailers.
4. Short lengths of metallic flex hose (30

inches) connect from the rigid piping to the trailers.

5. Trailer manifold outlets were modified so that an additional connection to the rigid piping is made under the trailer.

For those uses of tube trailers or compressed gas banks at reduced pressures the above modifications were not applied. In some cases, of limited use, where barncoades were not practical, the ends of the flexible hose were chained and long lengths were anchored with sand bags.

VII. Future Test Problems.

To begin an early examination of safety problems in future testing the Los Alamos Scientific Laboratory has recently established a Rover Flight Safety Office; this independent office will be responsible to the laboratory director. Rover Flight Safety will examine the type and extent of all factors concerning the public safety which can arise from the testing or operational use of nuclear rockets.

The ultimate usefulness of nuclear energy for space flight will depend not only on satisfactory performance but of equal importance will be the demonstration that all public safety requirements are met. It is realized that unsolved safety problems can seriously affect the ultimate use of nuclear rockets.

The potential gains from the use of nuclear energy in space must be evaluated in comparison to the risks. While it is the responsibility of government authorities to evaluate and regulate hazards to the public, it must be the responsibility of the technical staff of research organizations to supply the necessary technical data for the proper evaluation of the safety problems in the nuclear rocket program. Now that progress has been demonstrated in the technical feasibility of nuclear rockets, effort must be directed to see that there are no unsolved safety problems for the flight testing inevitably to follow.

While some theoretical and experimental work dealing with Rover flight safety has been done prior to the establishment of the Rover Flight Safety Office, the work was done more on an individual interest basis rather than as part of the over-all necessary responsibility.

The principal flight safety criteria to be

met will require public safety during all launch and flight operations. This will require a reliable safe nuclear rocket disposal plan to be available for all abnormal and reentry conditions. One specific requirement will be the condition that no large fragments reenter or impact on any of the earth's land masses; perhaps this condition can be met for early testing, from coastal launch pads, by the use of a ballistic trajectory where the impact point is known. Nevertheless, such a test requires public safety near the launch area which means that any abort of a booster system or a reactor incident should not produce any safety problems serious enough to be other than those restricted to approximately the launch pad area.

The principal launch pad hazards appear to be first, the release of hazardous particles due to a launch pad fire which might consume the reactor or any part of it, and secondly, the possible oscillating critical excursion from the reactor after immersion in water.

The first look at Rover flight safety problems will involve the determination of some of the basic properties of the reactor core materials under normal conditions. Examples of some of the questions which have already arisen (and are only partially answered so far) are the following:

1. How will a fuel element behave when subject to very high temperature? Of interest here is a gradual temperature rise such as produced by a fast reactor.
2. Are the reactor core materials disposable by post-operational additives? This might employ the use of chemical fuels to burn up the remaining material or the addition of reactive chemicals that might effectively disintegrate the core materials.
3. What will the effect be of water immersion on fuel elements? How will fuel loading and temperature variation affect any water reaction? Will the reactor suffer an oscillating criticality excursion in water and thus produce a much higher fission product inventory than from a single power excursion? Will fission products leach out in ocean-water?
4. What is the nature of the radioactive source produced by the normal and abnormal operation of a nuclear rocket reactor? What is the rate of release of the different fission

products as a function of time, their particle size distribution and fallout pattern—with particular emphasis on those isotopes of higher toxicity such as iodine and strontium?

5. Can the reactor be broken into small enough pieces by chemical or nuclear explosives to assure burn-up on reentry? How small must the pieces be to avoid a criticality incident on a launch pad in case of an abort?

6. Are there any design changes which can enhance launch pad and operational safety?

Thus far a look at future testing safety problems has resulted in generating more questions than answers. Experiments will be done at the Nevada Test Site if needed in order to obtain the information required for sophisticated evaluation of test risks.

COMMUNICATION AFFECTS SAFETY PERFORMANCE

By L. K. JONAS

Chief, Supervisory Development Division, Engineering Extension Service
Texas A. and M. College System, College Station, Texas

Communication consists of more than just talking or writing. Others are constantly interpreting our actions (or lack of actions) into thoughts that suit their purposes. It might be well for safety and supervisory personnel to remember that someone has said, "What you do speak so loudly, I can't hear what you say."

For the purpose of this paper, I would like to define "communication" my own way: "Getting proper information to the right individual at the correct time in such manner that there will be common understanding and/or desired action."

Communication which affects one's attitude toward safe job performance begins during the interview for employment and continues as long as the person remains on the job.

A thorough check into the applicant's injury or accident experience could indicate the need for further safety training. The minimum would be an orientation session on the company policies related to safe job performance. On the other hand, failure to emphasize the importance of safe work practices could be confusing to the new employee in his effort to acclimate himself to the assigned job. This could lead up to an accident since the new employee must make many judgments regarding production vs. safety.

Before considering additional factors that can influence the safe behavior of people, it may be well to take a closer look at some of the weaknesses of oral and written communications or instructions—the communications tools that too often fail to accomplish the results we expect. Too often we erroneously take communication for granted.

At this point, I like to use some sort of demonstration to prove the fallacy of some ideas about "communication" we frequently over-

look. In this situation we will relate some things we have proved with the "Communicometer," a device we developed specifically for demonstrating problems inherent in communicating our ideas to others.

In this demonstration we will ask that one person instruct (communicate with) another on how to set five rotating dials according to a pre-determined pattern. These dials must be described and the desired positions identified. If he does this effectively the green light will turn on, but if done ineffectively the red light will flash and a bell will ring.

To make this part of the program more interesting we will assume that one person is communicating with another to turn valves thereby shutting down a boiler that is about to explode.

(At this point in the program the "Communicometer" experiment was attempted but failed miserably.)

It is not surprising that this communication experiment failed, but it is amazing there were so many communication problems which were obvious. Many of these problems we do not recognize in the work-a-day situation, but they are there just the same. Also keep in mind that any misinterpretation of instruction can cause a hazardous situation.

Here are some of the facts that can be clearly demonstrated with the Communicometer:

1. Few people read instructions and safety manuals as carefully as they should. This means that they have "two strikes" on them before instruction begins.

2. Words or statements have different meanings for different people. No two people have the same culture, background, or experience. For example, the same geometric

is not and should not be considered primarily an occupational disease. There are causes other than injury that bring about back disability.

It is a well-known fact that severe, even disabling back pain, can occur in the course of a simple motion.¹ Cases are frequently seen in which disabling pain occurs while the employee is engaged in motions to which he is accustomed, which are within normal range, and which lack excessive or unusual action. Such a disability obviously does not result from a strain or sprain. The simple act of motion should not be held responsible for the pain. There is usually some other less obvious factor (or factors) which is the real cause of the disability, and which has to be searched for. The simple motion during which the pain arose should be thought of as coincidental rather than as a precipitating factor. The search for the causative factors should be made by both the physician and management. This search begins with a thorough, detailed history, followed by a complete physical examination, including x-rays of the spine taken from more than one view.

A detailed history should be taken of the events which occurred in the precipitating injury. What type of force was involved and how was it applied? Was it a fall, twist, lift, pull, or push? The size and the weight of the object being lifted should be noted. When the pain occurred is important. Did it begin as the person was getting into position, or only after he had exerted some force? What was his position? Was it his normal working position? Was it awkward or in a cramped space? Did he slip?

It is important to know whether the pain and disability occurred immediately or whether there was a latent pain-free period following the injury. If leg pain is present, it should be determined whether it was immediate or delayed. Its exact location should also be determined.

An important source of information as to the severity of the injury and the patient's reaction to pain is what he did immediately following the injury. Did he finish his shift or quit immediately? How long was it before he reported it to his foreman or requested treatment?

If the patient is first seen sometime after the alleged injury, it is important to know

what progress has been made in the interim. Disability from most back injuries either improves or gets worse, and one which remains unchanged for a long period of time is cause for suspicion.

In history-taking it is well to keep in mind that back pain is a common complaint among neurotics. Pain as a subjective complaint is difficult, if not impossible, to disprove, and so back pain is frequently found in malingerers.

The type of work involved has a definite relationship to the incidence of back pain. Prolonged heavy work predisposes to back disability even in those physically fit. Degenerative changes in the spine occur more frequently and earlier in the laborer doing heavy work. New employees unaccustomed to heavy work are prone to develop back pain. Everyone doing heavy work sooner or later reaches the age when he is no longer able to do it. Such a situation may result in a prolonged disability not otherwise explained.

Since many diseases may simulate the picture of low back injury, a systematic review should be made to rule out causative factors other than simple trauma.

The typical acute low back injury occurs most often as a lifting strain. However twisting motions are also frequently responsible for back disability. The pain is usually in the lower lumbar region and is aggravated by any motion of the lower spine and relieved by rest. The physical findings are usually few and include muscle spasm, limitation of motion, tenderness and sometimes a list. X-ray and neurological examinations are negative as a rule. Under conservative treatment, recovery is usually complete (in three to four weeks).²

Clinical Screening of Applicants and Transferees—It becomes obvious then that normal function of the spine is essential for any job assignment which involves heavy labor.

We know very little about the intricate mechanics that cause sudden stress or strain on the structures of the back during the performance of routine work. We cannot determine to what limits each individual can use muscles, ligaments, and joints of his body. All the knowledge concerning the effect of heavy work upon the spine that is shared by medical and non-medical men is

based on experience. Decisions, therefore, greatly depend upon empiricism, common sense and some degree of intuition rather than upon scientific data. Working conditions and working standards for jobs requiring great stress and strain have been established on the basis of time studies, without giving due consideration to the physical capabilities of the individual.

In his studies on the mechanics of the spinal column and the effect of the movements of the spine upon the intervertebral disks with and without carrying weight, Hans-Henning Mattiass³ found that in a 30-year-old man 6 feet tall and weighing 200 pounds the pressure exerted upon the intervertebral disk of the lumbosacral joint in an upright position, not carrying any extra weight at all, is approximately 134 pounds. The pressure is caused by the weight of the trunk, the head, the upper extremities and the tension of the muscles of the back and abdomen. When the same person bends forward 10 degrees without carrying any weight the pressure at the lumbosacral joint increases about 123 per cent the tension of the back muscles being 21 times greater than in the upright position. There is an increase in pressure to 928 pounds during forward bending to an angle of 90 degrees without carrying weight. When lifting 65 pounds, this pressure increases to 1600 pounds.

Therefore it is very important to teach employees proper lifting methods, and at this time I would like to present a few rules for safe lifting.

1. Never try to lift beyond your strength.
2. Get a firm footing.
3. Always crouch down to what you are going to lift.
4. Keep your arms straight and keep your back in as near a straight up-and-down position as possible.
5. Get a firm grip.
6. Lift gradually.
7. Avoid twisting motions.
8. Lift by standing up or by pushing up with the strong leg muscles.
9. Put things down generally reversing the above methods.
10. Learn the trick or knack.

The above illustrates that it is of utmost importance to adopt the most economical

motion for job performance as well as to select, prior to their assignment to a heavy job, employees whose physical conditions signify optimum function of the spine.⁴

What then must industry do to prevent or reduce the frequency and severity of these injuries?

First—The company should hire only those applicants whose medical history and examination indicate that they are competent for heavy labor.

The examination given an employee whose work necessitates heavy lifting begins with his previous history of illnesses, operations, and injuries, especially back ailments. Letters should be posted to former employers for the individual's previous record in safety, absenteeism and back difficulties. A general inspection reveals his body type—normal, slender or stocky. Individuals of different body types show different susceptibility to various injuries. Persons who are very tall or very heavy are poor candidates for heavy work. Anatomical defects and deformities like asymmetry of face, wry neck, deformity of chest, asymmetry of extremities, and poor condition of arches are of great importance. Individuals with definite physical defects or general muscular weakness should not be placed on a job which requires expending great quantities of physical energy.

Age and previous occupation are important factors in this evaluation of the employee's ability to perform his particular assignment. A history of frequent backaches of longer duration excludes an employee from heavy work. Circulatory and genito-urinary disorders which call for restricted work render him unfit for more strenuous work. Subnormal muscular or skeletal development, limited back motion, advanced varicosities are other reasons to declare him physically unfit to do heavy lifting. Individuals with high myopia, persons who are wearing thick concave lenses are not qualified for strenuous labor.⁵

Serious consideration should be given to the inclusion of back x-rays in this program. Certain changes in the anatomical structure of the spine are incompatible with heavy labor. Therefore, x-ray findings are of great importance and may often be the deciding factor in determining the employee's physical ability to perform a given job.

The purpose of this physical examination program is not to deny employment to those with physical impairment. The purpose of this examination is to fit the worker to the job.

The examination is followed by a critical evaluation of all the findings. Such an evaluation must be individualized. Each case may represent a separate problem which has to be studied and judged on its own merits.

Second—A safety program must be developed that stresses the proper methods of material handling.

This requires constant training and education at the foreman level. These men should be trained to recognize faulty work habits especially as regards lifting and to see that corrective action is taken. To succeed, the foreman must be made to recognize the economic implications of back injury to the employee and employer alike, and to take immediate steps to correct faulty work habits. To be successful this training program must be on a continuing basis.

Third—Consideration should be given to new employees and a break in work period be permitted. Also it might be well to consider a warm-up period for all employees prior to heavy physical exertion.

Fourth—The company must develop a treatment program that is decisive and does not give the employee the feeling that he is a "goldbrick" and motivated only by avarice. In the past the company and the doctor both developed an attitude of resistance and distrust since they felt the only cure for these problems was the "greenback poultice." The employee reaction to this attitude was naturally one of resentment and vengeance and interfered with his normal rate of recovery.

The psychological response of the employee to injury must also be considered by the doctor and employer.¹⁴ This response is conditioned by many factors. For example, fear and anxiety for the future, financial problems associated with decrease in income, etc. Therefore, we must assume that the patient's history and findings are credible and proceed with therapy with the idea that the employee wants to get well and is not seeking a settlement.¹⁵

Many patients with back pain, both acute and chronic, will improve and recover even

though they continue working. However, this does not apply to all cases. As long as muscle spasm and limitation of motion of the spine are present, work involving lifting, climbing, pulling, etc., should not be considered. If special work can be provided, which does not require the use of the sore back muscles, the exercise incident to the lighter work will serve to preserve muscle tone and hasten rehabilitation. Such a regimen will have good psychological effect upon the patient and will prevent a prolonged convalescence so common in back cases. The physician must ascertain that the work available is well within the limits of the patient's physical abilities. It is the doctor's responsibility to see that the patient is returned to his usual work as soon as possible, and that the other therapeutic measures are discontinued as the patient improves. (There is no sense in continuing diathermy treatments on a worker who is able to do his regular work.)¹⁶

In summary, I have presented for your consideration a program that is designed to reduce the frequency and severity of back strain and hernia. I want to emphasize that the medical examination alone will not solve the problem. To be effective, the program must be multiphasic and include:

1. A competent pre-placement medical examination.
2. An active campaign of instruction in the techniques of proper lifting.
3. Immediate on the job correction by trained supervisors of poor work habits.
4. Improvement of working methods.
5. Utilization of mechanical equipment where feasible.

When adopted, these factors give us control of the materials used, the machines, the working methods and the man.

The control of accidents falls within the province of industrial medicine because of the role played by the man. An attempt must be made to control the above items on the basis of advanced analysis and continuing inspection. This requires the combined efforts of the personnel department, the safety engineer, the industrial hygienist, the plant nurse, and the industrial physician. Significant results can be obtained only by the integration of these specialists into an effective accident prevention team.

WHY YOU SHOULD HAVE AN OFF-THE-JOB SAFETY PROGRAM

By J. S. QUEENER

Safety & Fire Protection Div., Employee Relations Dept.
E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

In your business is it hard to make a profit? Is the sales-earnings squeeze affecting you? Then you would like to contribute to higher earnings in your company for competition is getting tougher. Don't misunderstand me. I have no secret formula.

I immediately come to the point that you should have an effective off-the-job safety program in your company if you want to help lower costs. I should also say that what I have to suggest is with the presumption that your company is already sold on the value of on-the-job safety and is doing something about it. I will discuss primarily the need for taking action rather than what action to take. There is a big problem nationally to motivate industry to accept the challenge of preventive action to reduce the accident toll daily occurring throughout the country on the highway, at play and at home.

Unless you know, and I presume you don't, off-the-job injuries are costing your company in many different ways. Here are several of the costs which accrue when an employee is hurt off-the-job:

1. Relief personnel is necessary.
2. Training of substitute employees is necessary.

3. Equipment is damaged and product spoiled by replacement personnel.

4. Additional work loads are placed on supervision.

5. Injured employees on return to work are not fully effective for some time.

6. Accident and health insurance payments are increased.

7. Disability wage costs rise.

8. Group life insurance payments may be increased.

9. Medical and hospital insurance payments are increased.

Indirectly, there may be other costs. Community services and facilities are generally taxed to capacity. Hospitals, rehabilitation centers, orphanages, welfare and numerous other agencies are called upon to render aid. Since they are supported by tax dollars or community funds, business becomes involved again.

The du Pont Company is completely sold that promotion of off-the-job safety is good business. Here is the way one of our vice-presidents expressed it to employees:

There are many things which require serious consideration if a business is to be successfully operated. Cost and quality are the matters we most frequently hear about as

every process or action which may in some way be contributory to the end point desired—in the case of our discussion here today—in the accomplishment of an effective, workable accident prevention program.

To the degree that any individual or any group fails to maintain this awareness and interest in his portion or phase of the operation, the accomplishment of that desired end point will fail in direct proportion.

No individual involved in a business operation, be he a top management man, middle management man, supervisor or worker can afford to allow any thought or action to take place which will in any manner result in failure to execute a safe, effective accident prevention program. The stakes are indeed high! Too often we find it necessary to "go for broke" when we fail in our accident prevention program.

At this point, I hope to have established the fact that accident prevention ranks in importance with any and all other phases of a business operation and that it most certainly is one of the areas of responsibility and accountability of management—top management as well as middle management.

If it is agreed at this point that top management has a responsibility, it would appear that agreement could also be reached in the concept that the initiative for recognition of the need for and the establishing of an accident prevention program, with or without the services of a safety department, rests with top management.

This is not to say that the possibility for suggestion or initiative on the part of the line worker or supervisor or plant manager should be prohibited. In fact, it should be encouraged—the line worker is the one who knows best the hazards that exist and steps needed to remove them.

What we mean to say is, in essence, that for a program to be effective, it must be established firmly by management policy and continuously promoted, aided and nurtured by management. Responsibility and authority must be established by those with the power to do so, and assigned to the individual or individuals who are to plan, develop and execute an effective accident prevention program.

It is essential that management provide ample evidence, to those involved in every

phase of the operation, of its policies, its awareness and vital interest in an effective program and its expectation of the whole-hearted cooperation of every group or every individual in the business operation. This evidence must be of a continuous nature—an announcement at the beginning of a program and then silence from management is not enough. Instead, management must take steps necessary frequently to evidence interest in the program, its effectiveness, its shortcomings and the need for everyone, every day, to think positively about the program.

Perhaps at this point we might well consider clarification of the term management. Just who do we mean by management?

My remarks so far have tended to include all people in an organization who have been assigned supervisory positions and who have any voice whatsoever in the planning, development and execution of programs of this nature.

Therefore, while we most definitely feel that top management—from the chairman of the board on down through the ranks—must be keenly aware of the needs of accident prevention, and vitally interested continuously in its effective execution, we must also conclude that you—regardless of whether you are vice president in charge of safety, director of the safety department, a supervisor of a production department with assigned safety responsibilities—you are also included in this terminology of management.

You have been selected by your organization as the one person to eat, sleep, and live accident prevention programs. You are the safety specialist. You may also serve in other areas of responsibility, but, in essence, you are included in the area of responsible management. You must accept your role. You must feel, and give evidence of your feeling that accident prevention is of prime importance and see to it that it is given day-to-day attention.

You must accept the responsibility to spot hazards and remove them when and where possible and practical and also to plan, develop and execute effective programs to create an awareness and a consciousness, on the part of all people involved, of the hazards involved, of the hazards which cannot be removed, and the

best methods of living and working safely while these hazards exist.

You must be able to convince individuals who have been on the job for years and years and who refuse to accept suggestions or safety precautions. You will find it necessary to convince the ones who feel that programs are not for them—that they are accident immune. Ironically, it seems to be characteristic of humans to feel that safety measures, accident prevention programs are designed especially for "the other guy—not for me." To achieve cooperation from individuals such as this requires the utmost in selling skill.

In my estimation this means that management, you, if you please, must be a professional salesman as well as a professional safety man. This also means the ultimate in clear, concise communications to all concerned as to how the program is to work. One technique frequently used by management in this regard is to involve some of these so-called "difficult individuals" in the areas of planning and execution of the program.

Let them feel they are a part of the program. Incorporate their ideas when possible.

In addition to selling the program "down" to the line employee, you will also find it necessary to continuously sell "top management" on the value and accomplishment of your program and secure their vocal blessing of it. The attitude of the chairman of the board or president and vice president seem to be "telegraphed" immediately to all levels of employees throughout the business family.

Selling men in these positions is sometimes difficult—for they spend great portions of their time in areas of product lines, capital requirements, new facilities, plant expansions and similar fields, which all too frequently are considered more important than safety.

Yet, these men must be constantly kept aware of and interested in our accident prevention program. They must be kept informed of the effectiveness of the program—the savings in insurance premiums due to lower accident ratios, the stepped-up production of products due to fewer accidents, the improved quality of products and the many other benefits.

In our company, for example, we operated for a time under the concept that safety was "not for us"—we didn't need it. The situation developed that due to excessive accident and injury losses, we were unable to secure insurance at the standard rates.

This shocked us into action. Our first move was to appoint one of our men as a part-time safety supervisor—in addition to his other previously assigned responsibilities. Our experience was one of almost immediate improvement in our accident and loss record. As a result, the decision was made to establish a safety department and assign full-time responsibilities to a safety director.

This past year our record was one of which we can be proud. Our premium costs were 13 per cent below the national average. Our objective is to be at 50 per cent below the national average by the end of the next fiscal year.

Now, what is your role in accident prevention? What are you doing? What plans do you have? You know by now that you are included in this term, management.

We all want to succeed. We all desire recognition, prestige, and that satisfied feeling that accompanies success.

If we are to succeed, we need to give constant attention to several important areas. Number one—ourselves.

We must give serious, constant attention to ourselves. We need to be certain that we have definite, clear-cut goals established—well-defined, attainable goals. Too many of us want to succeed, but we are unwilling to take the steps necessary, one at a time, to achieve success. Too many of us look at a successful friend or co-worker and immediately rationalize wherein he has succeeded—an easier job, more God-given ability, or some other unrealistic reason as to why he has succeeded.

If we are to succeed, we must recognize that all of us, successful and unsuccessful alike, have the same ability and the same equipment, but the successful people make more and better use of the ability and equipment which they possess.

Too many of us strive to develop a successful personality so that we may be a success. In this situation, it appears to me, we have the cart before the horse.

The first goal, the first objective, should be to succeed and, as a result of succeeding, a successful personality will have been developed.

Through the achievement of success one gains poise and confidence. Confidence comes from competence, and competence comes from knowledge gained through study and applied practices. We need to recognize in our struggle for success that the spectacular comes from many unspectacular attempts. We need to be willing to carry the papers before making the headlines.

As we move forward in trying to convince top management, as well as each and every individual in our business, it is most important that we are always positive and optimistic in our attitudes. In our dealings with our fellow man, we must strive to keep in mind that all of us have the same problems. The only difference between us is the attitude towards the problem that we face. This little poem seems to express the spirit which I have been trying to develop here:

One ship sails west, another east,
By the self-same breeze that blows,
It isn't the gale, 'tis the set of the sail,
That determines the way it goes.

Area number two: We must also give constant attention to our job.

Your job is the vehicle for "going places" in this country. The amazing thing is that most people do not seem to recognize and understand that fact. Everyone, everywhere gives the indication that he would like to "go places," that he would like to succeed, that he would like all the comforts, privileges and prestige which accompanies "going places."

A sad commentary, evident in too many places across this great land of ours, is that in spite of our desire to "go places," the majority of people today discharge their responsibilities in such a manner as to give the impression that this is the "land of the great goof-off." We seem to have lost the desire to do the best we know how and the best we can on the job we have to do. This is a serious—most serious—situation which far surpasses the area of safety, but which also encompasses those of us in the safety area of activity.

Today, our civilization is being challenged. Whether or not it will stand the test will be determined in large measure by whether or not we, the people of this civilization, care enough to do those things required of us to continue to enjoy the benefits we now have. Toynbee, the noted contemporary historian, in analyzing the rise and fall of the many civilizations of the past, tells us that 19 of the last 21 civilizations crumbled because the people just didn't care.

We need ambition. We need a desire to be different. We need the courage to rise above the level of the common man to that of an uncommon man. We need to be willing to sacrifice to learn to improve on our jobs. We need to study and become as knowledgeable in our profession as possible. This requires constant study and open-mindedness to new information, new techniques and procedures.

Yes, you will succeed because you know. It has been stated many times, that knowledge is power. It is indeed a sad sight to see men attempt to live in a profession "camel-like—on the hump of their accumulated knowledge." We must understand that it is impossible to be an effective leader in any field when we are willing to "rest on our laurels." We should be willing continuously to study and learn. For from the accumulation of new knowledge comes a new birth of enthusiasm, a new condition of alertness of mind, a new inspiration to the approach and solution of problems at hand. Yes, to discharge our jobs effectively, we must desire to succeed.

Area number three: We must give constant attention to "the wisdom of the ages."

As safety people, the only product we have to sell is an intangible—one which, if effectively sold, will allow ourselves and our workers to say more frequently, "There, but for the grace of God, go I." It is satisfying to feel that because of our programs, lives are spared, injuries, some which could maim for life, are prevented.

It has been said many times that history repeats itself because man refuses to listen the first time around. It is imperative in safety work, as in any other line of professional activity, that we learn from the experiences of others, not from trial and error.

As we work with people, we must constantly keep in mind that strong fiber which is evident in each and every individual concerning moral responsibilities. We must understand that immorality and success are incompatible. We must obey the Ten Commandments in our dealings with mankind wherever and whenever we meet.

To summarize what I've been trying to say, we could list specifically the following as management's role—your role—in accident prevention:

1. To initiate—motivate—act as catalyst.
2. Plan, develop program.
3. Explain how program is to work.
4. Assist in guiding execution.
5. Follow up.
6. Provide needs for continuity of program.

As we go home from this conference, we are faced with two very definite, very clear alternatives. First, we can go home with the thought that this was a good conference, get up and go back to work following the same old groove—the same old pattern of carrying out our responsibilities. Or, we can follow the other alternative available to us and pick out one idea of the many ideas which were put out at the conference. We can commit ourselves to re-dedication to our jobs, to strive continuously for an open mind, a positive outlook, continuous study and an aggressive approach. We must try to convince top management people of the importance of safety and the vital importance of their support to the success of accident prevention programs throughout the organization.

Remember—you are a part of management.

ELIMINATING THE RISK OF OVERHANGS IN FERTILIZER PILES

By T. A. BAYLEY

The American Agricultural Chemical Co., Cleveland, O.

In modern fertilizer manufacturing, the changes in methods of operations which have taken place, have created new and complex safety problems. The problems of armored meters for liquid measurement, pipe lines for corrosive materials, and high temperature reactions, have replaced the problem of the Georgia buggies and the three-wheeled dump trucks. However, all the old problems have not been replaced, and many are with us every day.

Foremost among the carry-overs is the problem of eliminating the risk of overhangs in fertilizer piles. This problem has not been ignored. To the contrary, so many fine analyses have been made, that it raised a question of whether or not there were really any new methods in use. It also raised the question of how diligent have been our efforts in applying the knowledge we already have.

When we speak of the risk of overhangs, we refer to the danger of material falling

or sliding from the height of a bulk storage pile. Everyone is well aware, by experience and by demonstration, of the devastating damages and fatal injuries caused by the falling of overhangs.

A recent fatality, involving a plant superintendent, should serve notice that pile overhangs have no respect for the position held by an individual. Can you picture yourself buried under the massive weight of tons of fertilizer in a desperate, painful struggle for air if not already crushed into unconsciousness? Or envision the tragic vigil and cautious haste of a team, seeking to recover a friend and fellow employee from the tumbled slope of a fallen pile? Certainly these are scenes which we all prefer to avoid.

The goal then is the elimination of risks by overhangs. An understanding of the causes of overhangs is vital in order to affect their removal. The common causes of overhangs can be listed as follows:—

1. Ineffective blasting of piles leaving overhangs at top.
2. Cracks or fractures in piles as loose materials gradually break loose.
3. Large lumps on face of pile often occurring after blasting.
4. Undercutting face of piles by mechanical devices.
5. Building posts holding material from falling.
6. High front bulkheads in entrance to bin, causing material to bridge at a point higher than digging device can reach.

There are variations of the foregoing list which can be made, but the basic causes cited are those which will be subsequently treated.

Although the ultimate goal is elimination of the overhangs by study of the causes, knowledge should be gained in the corrective action necessary, should the presence of an overhang be detected. It is the same old story of struggling for the best—while prepared to handle the worst.

Overhangs caused by ineffective blasting are most often best corrected by blasting the peak of the pile from the top. This avoids working under the overhang which should never be done. The top shot made by the dynamiter working at a safe distance from the brink of the pile is fast and only requires a small quantity of dynamite.

Cracks or fractures in a pile happen frequently after blasting, and are difficult to remove. Latent action of the explosion keeps the pile working for some time. Blasting is still the best way to remove the risk of severe cracks. However, the difficulty of forming a loading hole is greater in the soft material from the previous shot. Inspection of the pile for the best location as to size and drillability should be carefully made. The use of a bar to lever the fertilizer out of its hazardous position should be carefully surveyed.

Many times the brink of a pile is an extremely unsafe area for manually barring down material. Cracks, which appear easily movable with a bar when viewed from the ground, are often very difficult to move. Many a stout bar has been bent in an effort to dislodge material. Another blast in the best possible location is the choice method. Large lumps on the face of a pile present

the risk of potential missiles rolling down on equipment, operators or passersby. Eliminating these large lumps is a matter of reducing them to safe size. A small dynamite charge can shatter a lump effectively. Manual pounding with a maul can break up more modest size lumps.

At times a bar can be used to lever a lump down to ground level where the digging device can cut it down to carrying size. Lumps have been known to roll down the pile and up the bucket and arms of a front end loader, pinning the operator in his seat. Prompt removal of lumps from pile slope will avoid such tragedy.

Overhangs created by undercutting the pile face can be handled in a manner similar to overhangs created by other methods. With pulverized fertilizer in a narrow bin, the use of a top shot with dynamite represents the safe method of restoring a safe pile slope. The warning should be repeated that the loading hole can be drilled from a safe distance from the brink of the pile.

Fall of the overhang could be started by walking on the brink of the pile and result in a quick trip to the ground and the hospital for the dynamiter. In cases where the pile face is in a wide bin, it may be possible to shoot down the overhang by angling a load hole from the side. This would probably call for more explosive and might result in a deeper cavitation of pile face.

Overhangs in granular fertilizer have the same risk but the corrective action can possibly be varied. In areas where clearances will allow, a specially constructed boom may be placed in the bucket of a front-end loader. Then the point of the boom can be thrust upward at an angle to the rear of the pile. The piercing action will loosen the top sufficiently to remove an overhang and start movement of top material. The set in granular materials allows the boom to poke through quite readily.

These booms of 16-foot lengths constructed of 8-inch channel and suitably braced have proven quick and efficient. It is a tool available to the operators and doesn't require a special classification for its use. It is important that the boom be anchored four ways to prevent it from toppling out of control and falling upon the operator or people standing in the vicinity.

Granular material can be blasted from the top if done carefully and with patience. Since it is difficult to form loading holes due to inflow of granules when the drill is withdrawn, it is a slower job. If water is poured down the drill bit and allowed to wet enough material to provide a bonding action, a loading hole can be formed. A small charge will do the task in a well placed location.

Material that hangs up behind posts or in knee braces must be handled to avoid damage to the building. A long bar used from overhead walkways works best on knee braces and sometimes will successfully dislodge material held by posts.

In conditions where ex-drenned superphosphate is dumped across beams, an inverted cone will develop on the beam and should be knocked down before it falls uncontrolled.

There is a peculiar condition which has recently arisen in the storage of granular mixed goods. The front entrance to the storage bin has, in some cases, been bulkheaded to gain maximum storage utilization. These bulkheads usually are constructed so that the lower 10-foot section has removable boards set in at an angle. Above the 10-foot section, bulkhead boards are permanently fixed.

In order to dig material from the bin, as many boards are removed from the bottom as are needed to allow the flow of granules until the entire 10 feet is free of boards. The desired result is for material in the bin to feed downward to a point accessible to the front-end loader, but frequently the material resting against the permanent part of the bulkhead in the upper area does not slide and forms a bridge instead. The front-end loader can not reach this material and a treacherously roofed cavern develops. This overhead roof of fertilizer must be removed before safe entrance to the bin can be made.

Two methods have been used to break the bridge. One method is to use the bucket boom mentioned earlier to poke through the material and break its arch from underneath. Although the major part of the loader is outside the bin, the bridge can break and fall with enough force to cause a downward action on the bucket and

cause an unwary operator an awkward moment.

The second method is to poke the bridged material from the top with a suitable bar. The man using the bar should be provided with a safe platform on which to stand so that a sudden cave-in of the bridged materials would not cause him to fall due to a sudden loss of balance.

The corrective actions described have been used successfully in granular and pulverized fertilizer piles to cope with hazardous situations. The tools required are simple and available to anyone desiring to employ them. There is nothing really new in the methods described. They have been mentioned in other literature and are used throughout the industry.

The successful corrective action would then seem to reduce itself to a matter of execution. Successful execution is in proportion to the practice exercised, whether it be a fundamental play in football or a basic job in a fertilizer plant. Although "practice makes perfect" may be a tired cliché, it has lost none of its truth.

Up to this point, the main points covered were methods of corrective action to handle existing risky overhangs. An examination of the causes of overhangs might reveal some means for preventing the development of overhangs. It is noted that three of the six causes result from ineffective blasting and that one of the six causes is created by equipment operation.

This would indicate that part of the causes are under our control and that there is an opportunity to do something about them.

Blasting results have been vastly improved with the use of long delay caps. I do not intend to represent myself as an expert in this field, but I have seen improvement occur. Explosive suppliers are a good source of advice as is the National Safety Council. A good deal of progress can be made by reviewing blasting methods.

Overhangs caused by building design represent a local problem, which must be reviewed to find the best way to handle materials under the existing conditions.

However, the control of equipment operation is readily observed and corrected. If the cause of overhangs from undercutting

figure calculated from the previous three-year period is shown, as a solid horizontal line on the chart. Control limits also are calculated, using standard statistical formulae. These are shown on the chart as horizontal dotted or dashed lines above and below the mean. The distance between the control limits is the estimated amount of random variation which can be expected to occur without any change in the kind, intensity, or effectiveness of injury prevention activities.

As with any quality control chart, when our serious injury index stays within these control limits, it is considered to be under control.

Or, another way of looking at these variations of the index within the control limits is that the effectiveness of what we are doing in the way of injury prevention is about the same as long as the index is within the control limits. If the index, however, goes above the upper control limit, something has probably gone wrong in our prevention activities, and we should begin to try to find out what did take place so corrective measures can be instituted.

Likewise, if the index goes below the lower control limit something special probably has taken place to give us such a good performance and we should try to find out what it was to continue and expand its use.

Through these control charts then, we should be able to detect when effective or ineffective accident prevention activities are in use or certainly when they remain in use for a short period. This is something we could not detect by the use of disabling injury frequency rate alone. When plants such as ours operate with but one or two disabling injuries in a year, and sometimes without any such injuries, the statistics are just too meager to interpret.

We've been using these charts to keep our manufacturing department management informed month by month of program effectiveness.

We think it has been a useful and effective tool in spurring injury prevention activities.

Looking at a number of different classes of injuries we can see the reductions which have taken place:

	First Aid Cases Per Year	Doctor Cases Per Year	Serious Injuries Per Year	Disabling Cases Per Year
1951-52	7,000	500	275	13
1953-54	6,000	450	240	12
1955-56	4,500	325	200	11.5
1957-58	2,900	270	135	8
1959-60	2,600	240	120	8.5

But aside from control chart techniques, let me urge you to look beyond just disabling injuries. Let's not be satisfied just because many of our injuries don't involve loss of time.

Think of the many times men have fallen at work only to get up, limp a little for a few steps, or rub their arms or hands or shoulders for a few minutes and then go about their work. Or how many times such falls have resulted in strains of the shoulder, or leg or arm muscles which have kept them from doing their full jobs for a few days or even longer. They are the same kinds of falls which sometimes result in broken arms or legs, cracked ribs, fractured skulls—so why not look into them more deeply and intensify your efforts to prevent falls.

Or how about the number of times men have bumped into things or have had parts of their bodies caught between two objects and have sustained lacerations which had to be stitched up (sutured—say the doctors) instead of badly fracturing bones or amputating fingers or hands or toes or otherwise seriously injuring themselves. I can assure you it is very nearly impossible to tell how serious an injury will result once the accident cause has started on its way.

And how much time and effort goes into explaining why a man lost time from work, or even why he doesn't have to lose time because there is work he can do without aggravating his injury. And how much more productive that same time and energy could be when used in preventing more and more accidents and thus preventing more and more injuries of varying degrees of seriousness.

This basically is what is behind our own efforts in promoting the concept of serious injuries, both disabling and non-disabling. We make no claims that our system is the last word but I think we are preventing more injuries than we ever did. Perhaps you don't have the same types of injuries

that we have, but I feel sure that if you looked long and hard at all your injuries you would see a number of recurring types which could be the basis of your own serious injury index.

Of course, your own objectives will determine which way you will go. If you are satisfied with the disabling injury fre-

quency rate as your measuring stick—fine. If you are not, then here is a suggested system.

For ourselves, we think it has helped us to reset our sights on the goal of preventing injuries, rather than largely on the prevention of loss of time from work, as important as that is.

OFFICERS OF THE

CHEMICAL SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—H. H. FAWCETT, Consulting Engr., Research Laboratory, General Electric Co., Schenectady, N. Y.

Vice Chairman in Charge of Program—E. R. WALLACE, Sr. Safety Engr., Industrial Safety Dept., Accident Prevention Section, Eastman Kodak Co., Kodak Park Works, Rochester, N. Y.

Secretary—G. R. CUMMINGS, Head, Safety and Industrial Hygiene Dept., Eli Lilly & Co., Indianapolis, Ind.

Laboratory and Pilot Plant Sub-Section—J. B. BLACK (*Chairman*), Safety Officer, National Institutes of Health, Bethesda, Md.; E. L. STOUT (*Secretary*), Safety Engr., Los Alamos Scientific Laboratory, Los Alamos, N. Mex.

Rocket and Missiles Sub-Section—G. S. LEISK (*Chairman*), Safety Dept., Head, Solid Rocket Plant, Aerojet General Corp., Sacramento, Calif.; A. L. HEISEMAN (*Secretary*), Chief Safety Engr., Grand Central Rocket Co., Redlands, Calif.

Newsletter Committee—J. J. PRABULOS (*Chairman*), Suprv. Safety Dir., National Distillers and Chemical Corp., New York, N. Y.; J. N. ROWNE, Safety Dir., Research & Development Dept., Phillips Petroleum Co., Bartlesville, Okla.; W. S. WOOD, Safety Engr., Research & Development Div., Sun Oil Co., Marcus Hook, Pa.

Engineering Committee—G. M. ELLSWORTH (*Chairman*), Maintenance Supt., Monsanto Chemical Co., Plastics Div., Springfield, Mass.; A. L. CORA, Dir. of Industrial Safety, Kodak Park Works, Eastman Kodak Co., Rochester, N. Y.; H. A. VOIZ, Safety Dir., Calvert Chemical Co., Muskogee, Okla.

Public Relations Committee—A. P. OSTI (*Chairman*), Safety Engr., Charles Pfizer & Co., Inc., Brooklyn, N. Y.; P. C. LAHR, Safety Adm., Lever Bros. Co., New York, N. Y.; S. F. SPENCE, Dir., Safety & Loss Prevention, American Cyanamid Co., New York, N. Y.

Technical Publication Committee—A. H. CHRISTIAN (*Chairman*), Corporate Safety Engr., American Viscose Corp., Philadelphia, Pa.; P. J. McDONOUGH, Mgr. of Loss Prevention, Chemicals Div., Olin Mathieson Chemical Corp., New York, N. Y.; F. G. STEPHENSON, Sec. Gen. Safety Committee, Manufacturing Chemists' Assn., Inc., Washington, D. C.

Health Committee—H. W. RAPP, JR. (*Chairman*), Asst. Suprv. Engr., Engineering & Loss Control Div., The Travelers Insurance Co., Hartford, Conn.; E. L. ALPAUGH, Ind. Hygienist, International Harvester Co., Chicago, Ill.; J. V. HOUGHTON, Supv., Industrial Chemical Service, Liberty Mutual Insurance Co., Boston, Mass.; D. J. KILIAN, M. D., Medical Dir., Texas Div., The Dow Chemical Co., Freeport, Tex.

Training Aids Committee—G. L. FEAZELL (*Chairman*), Dir. for Safety, U. S. Army Chemical Corps., Washington, D. C.; C. D. ARTAWAY, Chief Safety Engr., Thiokol Chemical Corp., Marshall, Tex.; H. K. LAMMIE, Safety Mgr., Kaiser Aluminum & Chemical Corp., Oakland, Calif.; E. J. MEYERS, Asst. Mgr., Safety & Fire Protection Div., E. I. du Pont de Nemours & Co., Inc., Wilmington, Del.

Membership Committee—F. C. GAUGUISH (*Chairman*), Dir. of Safety, Sherwin-Williams Co., Chicago, Ill.; C. A. HENRY, Supr., Safety & Plant Protection, Ethyl Corp., Baton Rouge, La.; R. M. NIXON, Safety Codes Dept., Union Carbide Corp., New York, N. Y.

Safety Awards Committee—T. J. LANIGAN (Chairman), Safety Specialist, Defense Systems Dept., General Electric Co., Syracuse, N. Y.; C. M. OLSON, Supv. Health & Safety, Eastern Chemical Div., Hooker Chemical Corp., Niagara Falls, N. Y.

Statistics Analysis Committee—E. L. ALPAUGH (Chairman), Industrial Hygienist, International Harvester Co., Chicago, Ill.; F. E. MACAULAY, Safety Supv., Wyandotte Chemical Corp., Wyandotte, Mich.; M. A. SMITH, Supv. of Technical Services, Hartford Accident & Indemnity Co., Hartford, Conn.

Off-the-Job Committee—G. G. FLEMING (Chairman), Dir. of Safety, Celanese Corp. of America, Charlotte, N. C.; M. KRICKORIAN, Area Safety Dir., Reynolds Metals Co., Richmond, Va.; W. L. TISDALE, Dir. of Safety, Midland Div., Dow Chemical Co., Midland, Mich.

Nominating Committee—E. G. MEYER, Ph.D. (Chairman), Dir., Industrial Hygiene Div., Employers Mutuals of Wausau, Milwaukee, Wis.; *A. B. RITTER, Safety Engr., Research Center, Hercules Powder Co., Wilmington, Del.; *J. J. WHALEN, Safety Coord., Allied Chemical Corp., Solvay Process Div., Syracuse, N. Y.

Research and Planning Committee—*S. F. SPENCE (Chairman), Dir., Safety and Loss Prevention, American Cyanamid Co., New York, N. Y.; *R. H. ALBISER, Safety Mgr., Merck and Co., Inc., Rahway, N. J.; A. H. CHRISTIAN, Corporate Safety Engr., American Viscose Corp., Philadelphia, Pa.

Advisory Committee—G. L. CORRELL, Mgr., Safety & Fire Protection, Monsanto Chemical Co., St. Louis, Mo.; J. E. NICHOLS, Dir. of Safety, Reynolds Metals Co., Richmond, Va.

Non-Voting Officers of Sub-Sections—Laboratory and Pilot Plant—W. S. WOOD (Chairman Elect), Safety Engr., Research & Development Div., Sun Oil Co., Marcus Hook, Pa.; L. E. ROMILLY (Assistant Secretary), Safety Supv., E. I. du Pont de Nemours & Co., Inc., Experimental Station, Wilmington, Del.; *Rockets and Missiles*—B. D. BRENNAN (Vice Chairman), Safety Engr., Rocketdyne Div., North American Aviation, Inc., McGregor, Tex.; W. G. HAYDEN (Vice Chairman), Mgr., Safety & Security, Thiokol Chemical Corp., Wasatch Div., Brigham City, Utah.

Staff Representative—J. T. SIEDLECKI, National Safety Council, Chicago, Ill.

*Members of Advisory Committee

OFFICERS OF THE FERTILIZER SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—GASTHER T. NEWNAM, Dir. of Industrial Relations Insurance and Safety, Smith-Douglass Co., Inc., Norfolk, Va.

Vice-Chairman and Program Chairman—JOHN S. MARK, Mgr., Fertilizer Manufacturing Div., Farm Bureau Coop. Assn., Inc., Columbus, Ohio

Secretary—C. S. GRIFFITH, Supt., Virginia Carolina Chemical Corp., Cincinnati, Ohio

Newsletter Editor—*GEORGE F. DIETZ, Safety Dir., Fertilizer Manufacturing Cooperative, Baltimore, Md.

Assistant Newsletter Editors—*ELMER C. PERRINE, Dir. of Technical Service, Nitrogen Div., Allied Chemical Corp., New York, N. Y.; GENE HARLAN, Personnel Dept., Indiana Farm Bureau Cooperative Assn., Inc., Indianapolis, Ind.

National Plant Food Institute Liaison—WILLIAM S. RITNOUR, Treas., National Plant Food Institute, Washington, D. C.

Engineering Committee—E. M. JONES (Chairman), Midwest Product Mgr., Nitrogen Div., Allied Chemical Corp., Indianapolis, Ind.; R. D. CHAMBERLIN, Safety Supv., Cooperative Farm Chemicals Assn., Lawrence, Kansas; RAY ENGEL, Schrock Bros. Co., Connersville, Ill.

Public Relations Committee Chairman—WILLIAM S. RITNOUR, Treas., National Plant Food Institute, Washington, D. C.

Membership Committee—*A. I. RANEY (Chairman), Safety Dir., Phillips Chemical Co., Bartlesville, Okla.; R. S. BROWN, Safety Dir., J. R. Simplot Co., Minerals & Chemical Div., Pocatello, Idaho; R. L. FREEMAN, Supv., Safety and Maintenance, Hooker Chemical Corp., Phosphorus Div., Houston, Texas; CHARLES FRANKLIN, Technical Representative, International Minerals and Chemicals, Indianapolis, Ind.

Statistics & Contest Committee Chairman—W. A. STONE, Plant Mgr., Wilson & Tomey Fertilizer Co., Jacksonville, Fla.

Insurance and Legislative Committee Chairman—*E. O. BURROUGHS, JR., Mgr., Insurance Dept., F. S. Royster Guano Co., Norfolk, Va.

Research Committee Chairman—*JOHN E. SMITH, Safety Dir., Spencer Chemical Co., Pittsburgh, Kansas

Nominating Committee Chairman—*A. I. RANEY, Safety Dir., Phillips Chemical Co., Bartlesville, Okla.

Supervisory Training Committee Chairman—W. C. CZEEL, Safety Dir., State of North Carolina, Dept. of Labor, Raleigh, N. C.

Off-The-Job Safety Chairman—JAMES W. SMITH, Production Supt., Western Phosphates, Inc., Salt Lake City, Utah

Members-At-Large—QUINTEN S. LEE, Dir., Plant Food Production, The Cotton Producers Assn., Atlanta, Ga.; F. A. GERARD, Mgr. of Safety, Olin Mathieson Chemical Corp., New York, N. Y.; C. E. ALKIRE, Supt., W. R. Grace & Co., Davison Chemical Div., New Albany, Ind.; M. C. ELLISON, Protection Supv., Mississippi Chemical Corp.,

Yazoo City, Miss.; E. J. LARGANT, Industrial Hygienist, Reynolds Metals Co., Va.; G. B. MORRIS, Mgr., Production & Construction, Cooperative Fertilizer Service, Inc., Richmond, Va.; J. L. SHOPEN, Safety Dir., Consumers Cooperative Assn., Kansas City, Mo.; F. C. RINEFORT, JR., Supv. Safety & Claims, Finance Div., International Minerals and Chemical Corp., Skokie, Ill.; D. W. FLAOLE, Supt. of Maintenance, Florida Phosphate Div., W. R. Grace and Co., Bartow, Fla.; *A. B. PETTIT, William R. Bradley and Associates, Newark, N. J.; LARRY RILEY, Safety Dir., O. M. Scott & Sons, Marysville, Ohio; G. M. DOUGLAS, Industrial Relations, Swift & Co., Phosphate Center, Bartow, Fla.; J. C. REEVES, Production Mgr., Robertson Chemical Corp., Wainwright Bldg., Norfolk, Va.; A. C. PALMER, Plant Supt., Planters Fertilizer & Phosphate Co., Charleston Heights, S. C.; J. C. INK, Supv., The Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, B. C., Canada

Staff Representative—MARSHALL F. PETERSEN, National Safety Council, Chicago, Ill.

*Past General Chairman

PLAN NOW --

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

CONTENTS

CIVIC LEADERSHIP SESSIONS

The Safety Organization and Civic Leadership	(Symposium)	4
Representing Civic Organization Viewpoint	Mrs. Carrie Noelling	5
Representing the Volunteer	Mrs. Henry S. Pierson	8

CIVIC LEADERSHIP SESSIONS

CIVIC LEADERSHIP—THE SAFETY ORGANIZATION AND CIVIC LEADERSHIP (A SYMPOSIUM)

Presiding: DOROTHY DOWNS, Asst. to Dir. of Engineering, Firemen's Mutual Insurance Co., Providence, R. I.; Women's National Safety Conference, N. S. C.
Moderator: MRS. JOHN E. KRUEGER, Milwaukee, Wis.; Member, Board of Directors, Executive Committee of Women's Conference, N. S. C.
 (Mrs. Krueger pitched in for Mrs. Lucille Blakesley, who was unable to attend.)

(A) THE STATE

Mr. James K. Williams, executive dir., Connecticut Safety Commission, gave the purpose of the CSC as being to co-ordinate the activities of groups engaged in traffic safety work with the official program. He mentioned that such so-called do-gooder organizations may be found at all levels of the citizenry: local, city and state.

Mrs. Harry L. Nair, chairman, Advisory Committee of Women's Activities, CSC, discussed the woman's role in traffic safety, and said that women in Connecticut have the opportunity to participate in a program beyond their particular affiliation when, under the aegis of the CSC, they engage in traffic safety work under the official program. She says that the last thirteen years have seen women emerge as the dominant force in traffic safety work. Women's organizations have been persuaded to include a speaker on traffic safety in their programs. She says it took a year to accomplish the objective of introducing instructors in driver education into the schools. Now 77 per cent of Connecticut schools have a full driver education course.

Mrs. Nair then listed several ways that women's organizations can turn to the CSC for safety information: staff assistance in education is available to community organizations, resolutions of the Women's Workshop of the CSC Conference represent the interests of all community clubs (the permanent women's advisory committee having thus been established) and thus serve as a coordinative outlet for official safety policy.

(B) THE CITY — A CHAPTER OF NSC LOOKS AT CIVIC LEADERSHIP

Mr. Ivan A. Martin, mgr., Safety Council, Chamber of Commerce, Fort Wayne,

Ind., said that accomplishment in traffic safety work depended on active interest and constructive work in public safety. He said that the Ft. Wayne chapter of the National Safety Council was mandated to go to work on a safety program under the sponsorship of the Chamber of Commerce. Committees were set up to cover the various regions of safety. He then mentioned the part played by Ft. Wayne as a pilot city for seat belt study.

Mrs. Homer A. Ellison, State Safety Chairman, Indiana Federation of Women's Clubs, spoke of the 35 clubs in Allen County, Ind., each with a safety program. She mentioned the frequent talks given by members of the police and sheriff's departments, and their excellent cooperation in a voluntary safety vehicle check, of which the paper work was done by the women's clubs. In 1956 a well-attended parking clinic was held, with instructors from the police department, and another in the following year that was a great success.

Mrs. Ellison continued that in February, 1960, a steering committee of eight persons set up the present safety organization, which advocated that hardware for seat belt installation be included in 1962 cars.

(C) THE SMALLER COMMUNITY — A VOLUNTEER COUNCIL SPREADS THE SAFETY GOSPEL

Mr. and Mrs. Ralph Eisenschiml represented the volunteer Citizen's Safety Council of Highland Park, Ill., of which Mr. Eisenschiml is president. They mentioned the nine committees into which the safety council is divided: elementary school (the focal point of their program of safety education) and high school (the most people at work here in driver education), police (representative of the council sits

with the chief of police, listens to problems, and uses the material obtained for public relations purposes, making statistics vital), fire, parks and beaches, home, municipal court (the treatment of teenagers of greatest interest here, the seal of the council being the establishment of a student traffic court in the high school), special events, liaison (especially with the activity of civic clubs), and civil defense (the big issue being school versus home in civil defense activities).

Mr. and Mrs. Eisenschiml showed publications sponsored by the council which are designed to get safety across to children who can't read, explained Highland Park's monthly courteous driver award program, and reported that Highland Park had been the winner of the Community Safety Award for 1959.

QUESTIONS AND ANSWERS

Question. In Connecticut, does one women's organization work on a safety project, or do all of them have the opportunity?

Mrs. Nair. Safety projects are limited to the field of traffic safety. On any specifically defined problem, all pertinent traffic legislation and the official program of the CSC is made available at a conference of all women's organizations.

Question. Is Bar Association talent used in safety measures?

Civic Leadership Sessions

Mrs. Nair. The chairman of the CSC is a lawyer, and he works closely with the legislature in the formation of bills, with local and state Bar Association support.

Question. How sensitive are legislators and judges to the press, particularly to news from the traffic courts?

Mrs. Nair. They are sensitive enough so that the court system has recently been reorganized, and the chief justice is a member of the safety commission.

Question. In Connecticut, is there any legislation on reporting deaths and injuries in the home?

Mrs. Nair. There is no statute; it is handled by the vital statistics department. (Mrs. Ellison noted that in Indiana there was the same situation, the board of health supplying a monthly report.)

Question. Is there any NSC pressure for smog control?

Mrs. Ellison. There is in Indiana, especially for the control of back-yard fires.

Mrs. Nair. There is no program in Connecticut.

Question. Do you charge a fee for participation in safety meetings?

Mrs. Nair. The safety program in Connecticut is state-supported.

Mrs. Ellison. In Fort Wayne, the safety program receives budgetary support from the Chamber of Commerce.

REPRESENTING CIVIC ORGANIZATION VIEWPOINT

By MRS. CARRIE NOELLING

Vice President, Kansas City Safety Council, Kansas City, Mo.

Several years ago it was publicly stated by Paul Jones, then director of public information for the National Safety Council, that more women were brought into the safety movement in Kansas City, Mo., than in any other community. I quote from a talk he made the latter part of last year:

"If the whole country could get the leadership and support of safety by women that Kansas City is getting in ever-increasing volume, the accident problem would be nearer a solution."

It is a real pleasure and a special privilege

to tell you briefly what civic groups in the Greater Kansas City area are doing in the field of safety. Following the pattern of the Women's Conference of the National Safety Council, the Women's Activities Division of the Greater Kansas City Area Safety Council is sponsoring a group who, themselves, chose as their name "Safety Conference of Women's Organizations."

This group is made up of approximately 70 representatives of business, professional, religious, civic, school, literary, cultural and service clubs and auxiliaries. "Coffee" meet-

ings are held once a month on Saturday mornings at the home of the vice president of the Council, and qualified speakers present a different phase of safety each time. Literature pertaining to the particular subject is distributed.

At the time this group was being formed, at least one member of each club was given a personal or telephone invitation, explaining the reason for the organization and asking her to realize her civic and personal duty to the cause of safety and, if she attended, always to make a report back to her organization. The response was most gratifying, and at no meeting have we had less than 80,000 individual club members represented. The programs presented stimulate open discussions which usually continue long after the meetings adjourn. This same enthusiastic sharing of ideas and responsibilities has resulted in outstanding safety programs which no one individual or organization could have developed alone.

Realizing the tremendous power that can be created when enthusiastic women join together for any purpose, a speaker said recently, "Every man should get down on his knees every night and thank the good Lord that women don't know the power they really have." Maybe individually they do know, but sometimes we fail to realize all they can do or accomplish when organized for a worthy cause, working together.

The Women's Chamber of Commerce developed a mobile unit to carry their driver testing program to the people, appearing at high schools, colleges, community centers, fairs, shopping centers, national conventions, churches, commercial truck and bus drivers' conferences, in fact, anywhere where there were drivers or an interest in driving, there seemed to be a demand for this program. This project brought to the Women's Chamber the highest 1959 Carol Lane Award for Traffic Safety. Within a 2-year period, more than 167,355 man-hours were spent by volunteer workers in testing alone representing 346 eight-hour days. It was impossible to keep a detailed record of the number of volunteer workers or their organizations. However, it is estimated that over 1,100 three-hour shifts were staffed to carry out this program.

Our Parent-Teacher Association of the public schools has been recognized as conducting the most effective bicycle safety

program in the United States. They have had requests from over 60 major cities, such as New York, Los Angeles and Chicago for copies of their booklet of 20 typewritten pages covering every detail of their important program.

Home safety workshops and baby sitting clinics are conducted every year through our safety council.

Another annual program, the national "Operation Edith," was originated in Kansas City. This means "Exit Drills In The Home," which are featured each year during Fire Prevention Week. In cooperation with the fire department, women's groups have supplied Christmas tree dealers with more than 50,000 combination price tags and holiday safety reminders.

The Railway Business Women in Kansas City carry on a strong safety program, featuring speakers on various safety subjects at their regular meetings several times a year and distributing safety information. Reports of their activities are made at their national meetings.

Through the Women's Conference, information regarding a revised traffic code in our city was passed directly to other organizations by officials of the municipal courts, police department and City Engineer's office.

When in 1960, Kansas City's traffic toll rose at an alarming rate, at the mayor's request we participated in an all-out traffic safety program, and a marked decrease in the number of fatal accidents is shown in this year's record. From January through September last year, there were 50 fatalities; but for the same period this year there were only 29.

In conjunction with the American Red Cross, a water safety carnival was held at one of the nearby lakes, where marine operating regulations were explained and boat safety demonstrations were conducted.

A series of 39 original safety cartoons were published locally and through inquiries, went into every state in the Union and several foreign countries.

After working with one of our women's groups on a "Safety Fair," the Association of Community Councils has established a Traffic Safety Committee, comprised of representatives from each of the more than 13 community councils.

Three thousand of the familiar yellow and green school safety patrol flags were made by members of women's organizations this year at a saving of over \$1,700 to our area safety council. Also the local chapter of the National Secretaries Association has given many hours of secretarial work in the safety council office.

A leading member of our group was appointed by Governor Faillon of Missouri to serve in this area to carry out an educational campaign regarding needed traffic safety legislation. This campaign was aimed particularly at civic, church and women's organizations. She spoke at countless meetings explaining the pending traffic legislation, and handed the voters explanatory leaflets and maps showing the legislative districts and mailing addresses of their legislators. The flood of correspondence from their constituents caused Missouri legislators to bring about the greatest strides in traffic safety laws in the state's history.

At the time of the Central States Safety Congress which meets in Kansas City bi-annually, the women have always helped with the plans and have always had a women's session. This year, we are told, the women's session had the best attendance of any at the Congress, regardless of a deluge of rain that day.

On January 1st of this year, our safety council added a new division known as Religious and Church Activities, which will stress the moral aspect of safety. They had an interesting session at the Central States Congress, where a talk was given by Harold Holmes, director of this division for the National Safety Council. They participated in an area "Safety Sunday" in May, by furnishing material for sermons, house organs and bulletins. Churches of all denominations cooperated in this program. The council and church leaders are now working on a Christmas safety program for the coming holiday season.

We know that women have proven their leadership in spiritual guidance as well as alleviating suffering.

One of the leaders in our women's group

Time Leadership Sessions

was instrumental in getting Kansas City, St. Joseph Diocesan Council of Catholic Women, representing 30,000 women in our area, to set up a safety committee and for the past 3 years a report of their activities has been read at their monthly board meetings. At their annual conventions safety displays have been prepared and literature of all phases of safety are made available.

A Sunday School teacher of a large religious organization with headquarters near Kansas City contained a Ten-Point Creed for Teen-Age Drivers. It was later printed on cards and our women's organizations distributed them to teen-age drivers throughout the area, and they have become a part of the driver education kits used in our public schools. The first National Student Traffic Safety Conference was held in Kansas City in 1959, and again in 1960. Delegates from all the states and Alaska came, and these creeds were distributed at that time. Since then, requests came from all over the United States for supplies of these cards to be used in other driver education programs.

If I were not, as the Egyptian mummy said, "pressed for time," there are many other worthwhile safety projects I would just love to tell you about. But now, I must close, and I would like to share with you the safety prayer that we use to close every meeting of the Safety Conference of Women's Organizations:

"Father-God, we thank you for this safe place in which we dwell and work: For the life-saving bond that unites us; for the hope of greater accomplishments with which we expect the tomorrow; for the health, soundness of limb and general well-being that makes life worth living, and for our friends and co-workers in all parts of the earth. Give us and them courage to continue the life-saving and accident-prevention efforts that must be so pleasing to You. Bless us in all our safety endeavors. Give us the strength to meet the day-to-day problems of discouragement, antipathy and apathy. Give Your own special blessings to all who in the spirit of good will, take up that most humane cause: Safety."

REPRESENTING THE VOLUNTEER

By MRS. HENRY S. PIERSON

Chairman, Greater Chicago Women's Safety Conference, Des Plaines, Ill.

The role of a volunteer is the most exciting and rewarding experience in a lifetime—especially in the field of safety. All the hurry, worry, tears, and sweat make sense for you are doing something for some one else.

My experiences have been thrilling and varied with one thing leading to another. One experience that was different was a blood typing program which started in Evanston, Ill. The object was to record all persons having type O blood for use in case of disaster.

The remaining experiences have taken place and are taking place in Des Plaines, Ill., where I have lived for the last five years. To move into a strange area makes it easy to break ties so I thought I was out of safety forever—my children grown and away and I thought that at last I would have time to learn to cook and darn the socks. For two years this is what I did.

Then I read in the local newspaper that the Des Plaines Safety Council would welcome anyone interested in safety. That did it—I sent in my name and have been hooked ever since. I attended the general meetings but came away disappointed. People brought in their neighborhood problems and gripes but we got no safety education. There seemed to be a need for good safety information.

So I offered to organize a Home and School Safety Committee, such as Evanston has had for thirty-five years. The Safety Council, as well as the public and parochial schools, the police and fire departments all agreed it was an excellent idea and there was a need but they didn't think it could be done. However, they were all willing to help if I got the thing organized.

Letters were written to P.T.A. and parent groups of all schools asking that they send a woman representative to the newly organized Home and School Safety Committee of the Des Plaines Safety Council which would meet one morning a month. The letters included accident facts on the national level as well as on the local. The

object of the committee stated to be that of safety education at the adult level as the schools already had an excellent program.

We divided the school year into a different type of safety each month, covering back-to-school safety and the "Safest Route to School;" fire prevention and Halloween; pedestrian and firearms; holiday and Drink, Don't Drive; winter driving hazards; poisons; Spring clean-up; civil defense; bike safety; vacation etc.

The police and fire departments sent a representative who reported on all local accidents and fires. The fire department issued a special bulletin on fire prevention each month. At each meeting we recorded these reports on special sheets so a continuous record was kept and at the end of the year we had a true picture of our own community.

The Home and School Safety Committee is in its fourth year and now includes representatives from the Woman's Club and neighborhood civic groups.

Next was a baby sitting course open to the public. The Interdenominational Church Youth Group were looking for a civic project and at the time the city officials had nothing to offer. However, the *Home Safety Review* published a splendid baby sitting program and we presented it to the group. They became most enthusiastic and decided to undertake it. With the cooperation of the Des Plaines Safety Council a seven week course was outlined with meeting on Saturday mornings. A different speaker and subject for each meeting. We had a pediatrician, a nurse, fireman, policeman and meeting on home safety, child safety and first aid. Teen-age boys and girls as well as adults regularly attended. Each was required to pass a written examination in order to graduate and receive a card showing them as qualified sitters.

The course was successful and was repeated the following year.

This Fall we offered the "Safest Route To School" on a city-wide basis. We just made use of all the information available

the Safety Council, Board of Education, the parochial schools and the Police Department all cooperated. We obtained a list from each principal of the intersections guarded by patrols and adult guards with the hours they are on duty. The newspapers printed this information and included a map of city blocks on which the parents were to mark the school and guarded intersections—then to draw a line from school to home following the safest route for their child to follow. This was accompanied by an "Open Letter to Parents" by the safety council making a plea to all parents to establish with their child the safest route and to walk with his child over this route until he knew it by heart and then to insist that his child use only this route to and from school each day.

This is the first time a city-wide effort has been made to show how the schools and the police department work together to provide the school children with the greatest protection possible.

The latest project is in the final planning stage. We are planning a clinic on winter driving hazards which will take place early

Civic Leadership Sessions

in January through the cooperation of the safety council, the Driver Education department at Maine Township High School West and the Park District.

The clinic will be held in a field house on a Saturday morning where drivers young and old can see a movie, hear a chalk talk by the driver education teacher and an explanation of charts showing the stopping distances under various road conditions. This will be followed by a demonstration outside on the ice skating rink of the right and wrong way to handle your car on ice and snow.

We have found that there is a tragic lack of actual knowledge as to how to handle your car under adverse conditions so we are offering to the driving citizens of Des Plaines the opportunity to learn what to do and when to do it as an experienced teacher.

You can see that there is no limit to the opportunities awaiting an enthusiastic volunteer. I hope you will join the ranks and experience this exciting and rewarding service.

PUBLIC SAFETY SESSIONS

LOCAL COOPERATION FOR SAFE OUTDOOR RECREATION

By AL MCGEE

Dir., Home and Public Safety, Seattle-King County Safety Council, Seattle 4, Wash.

The Federal Charter of the National Safety Council provides that one of the Council's objectives is "cooperation with all existing agencies and individuals concerned with Safety." I suppose this wording implies that there are some agencies and individuals who are not concerned with safety, but I must confess that I have never yet encountered one. There are many individuals and agencies which think they are not concerned with safety, because they have not yet discovered how safety affects their interests.

When we set out to organize local cooperation for safe outdoor recreation, we have a primary duty to show those who are oblivious to the impact of accidents, just how they are personally affected. Let me give you a couple of concrete illustrations.

Out in the Pacific Northwest, some 200 boat builders, boat sellers and marine supply firms have organized a trade association called Northwest Marine Industries, Inc. The principal purpose of this association is to encourage the sale of marine products and services. This it does in admirable fashion by sponsoring each year the Seattle National Boat Show. But Northwest Marine Industries has no direct humanitarian responsibilities, it is not a "Safety" organization.

However, this "non-safety" organization puts more money into the annual operating budget of the Seattle-King County Chapter of the National Safety Council than any of the rest of nearly 500 firms, agencies and individuals who hold annual memberships. Why? Because someone pointed out that each serious boating accident is followed by a wave of cancelled orders.

Junior high schools are not "safety organizations" either. Their principal purpose, since the Russians fired the first Sputnik into orbit in 1957, has been to turn out

junior grade scientists. Yet, despite the pressures put on school curriculums by the international missile race, South Mercer Island Junior High School in King County Washington recently installed a required course in boating safety which all eighth graders must take. Why? Because someone reminded the members of the school board that youngsters who drown now won't be around to sh. rockets later. And in a school district where some of the larger families own as many as a dozen boats, this is a pretty potent argument.

Let me go back now and tie these two examples together. South Mercer Island School District had no teachers who were boat safety experts, but the Seattle-King County Safety Council had access to the best brains in the business through Northwest Marine Industries. South Mercer had few text materials; we were able to offer them such a wide variety, all furnished by the boating industry, that they had trouble choosing between them. Four untrained instructors put 270 students through the first course last year and told us afterward that the help we gave them enabled them to do a good job despite the lack of previous experience.

The same "help" — including guest lecturers, the loan of films and wide variety of printed text materials—are now available to all 25 King County High Schools and Junior High Schools without charge. This "without charge" feature is important. School budgets always seem to be overstrained.

The point I want to make here is that every one of us in this room lives in a community where there are organizations which have not yet discovered just how they are "concerned with safety." We often can aid them to full awareness and enlist their aid in solving community problems. Let me give you some more examples:

The primary concern of newspapers is news rather than safety education, and for weekly newspapers this means *neighborhood* news. Yet when we staged our Free Family Boating Festival this year, 30 newspapers and a couple of magazines gave us free advertising that would have cost nearly \$2,000 if paid for at their regular rates. Why? We gave it to them as hard news. There were 34 weeklies involved and in almost every case we were able to find a volunteer who lived practically next door to the editor. These volunteers carried our handouts to the editor personally and said:

"Mr. Editor, I live in your circulation area and I'm serving on a countywide committee which is putting on the Free Family Boating Festival. We are giving the people of our county five hours of free life saving demonstrations and marine entertainment. I hope you will find room for our copy." More often than not he did, because now he had a perfectly legitimate reason for doing so. "Mr. John Smith, prominent district business man, is serving on a countywide committee which will put on the 1961 Free Family Boating Festival." And having said that much, the editor could hardly stop without saying a lot more.

Radio stations have a present concern with safety education either. They are permitted to fulfill their public service obligations by giving you weather reports, the time of day, religious programs, or "great debates." Your spot announcements on safety compete with the March of Dimes, The United Fund, Heart Fund, Milk Fund, Muscular Dystrophy and Cystic Fibrosis. But despite this hectic competition for a limited amount of public service time, the Seattle-King County Safety Council has done very well in its efforts to use radio for safety education.

The biggest single attraction of our Free Family Boating Festival this year was a rowboat race for disc jockies — for a "Blistered Palm Trophy." Nine jockies from eight stations competed, and our "race announcer" was a prominent local television star. For a week before the festival, these fellows talked it up on the air, giving us publicity that we were completely unable to measure, but which was certainly welcome. Why were all of these stations so good to us? Because we do something practically no other public service organization seems to

do — we write letters to the Federal Communications Commission praising the licensees whenever they help us! Our letters go directly into the official files, and when the license renewal date rolls around, the station has our written endorsement in the field of public service.

Television stations don't really owe us anything either, but they are usually willing to give us a bit of time for safety projects. The trick here is to avoid accepting an expensive gift that really isn't worth anything. Television time sells for \$100 a minute and isn't worth taking unless properly used.

If we get our safety message on the air at 8:00 a.m. on Sunday morning who's watching? Usually, nobody. Anyone up at that time is either getting ready for church or too sick to care whether he's safe or not.

How about those local versions of *Today*? Those nine a.m. week-day shows with news, interviews and exercises? Well, they are fine for the light, bright type of message or interview. But what housewife wants disaster with her second cup of coffee? And disaster is usually what we are peddling.

How about the cookbook shows? Usually very good, if your safety message is directed at young mothers. We ran the GEMS baby-sitter training course on one of these mixmaster marathons in ten-minute sections, one each week for six weeks. It turned out great for both us and the station. Poison-control doctors, pediatricians and orthopedists work fine on these, but traffic safety experts get nowhere.

Documentary or panel discussion programs can sometimes be "put in the can" for future use, now that most stations have video tape machines. You "tape" a half-hour documentary on some controversial subject like driver training in public schools, and the station will slip it into the schedule when the ball game ends early or a can of film fails to arrive on schedule. These programs are tricky to put together, but they work hard for you when you get them right.

The most desirable spot on the daily telecast schedule is the evening newscast, but you can't get on this with platitudes and poetry. You need the news-connected interview with the victim—the kid with the eye just blinded by the firecracker, the pretty

girl who had 184 stitches after running through a glass door. We ask insurance adjusters and firemen to tip us to unusual accidents which might not otherwise be reported. One TV station gives us half-a-dozen two to three minute newscast interviews a month. Each of these is worth as much as an hour of "dog time."

If you're any good at scouting talent at all, you'll have to work hard to avoid becoming a talent scout instead of a safety peddler. Some of the most charming people in the world work in TV and if you're not careful, they'll charm you right out of your mission. I've carried boxes of pickles up and down stairs, helped build sets and carried messages for the producers while shows were going on. Sometimes my little buddies forget to toss in the safety plug which was my sole reason for being at the station. Sometimes my boss is watching and notices it, too.

So much for television, and I will return to it only briefly in connection with my next example of agencies who suddenly discover out of a clear blue sky that they are, indeed, concerned with safety.

Early in 1960, we were contacted by the sales manager of a firm which manufactures power lawn mowers. He said his product, which has many built-in safety features, had been taking an awful beating, sales-wise, from cut-price, inferior, unsafe mowers. We checked the reputation of his firm and his product and discovered that here indeed was a company whose product reflected the company's sincere desire to perform a public service. It was a company which had budgeted funds for safety education. We said we would try to help. But if anyone had told us then that we would be able to help as much as we finally did, we would certainly not have believed it.

This sales manager had the friendless, wistful look of a cocker spaniel about to be spanked. So we persuaded television interviewers at all four stations to give him a rough time—a real Mike Wallace treatment. And the sales manager had his audience nearly in tears. They were so sorry for him, as he gave his little pitch on power lawn mower safety. He didn't once mention the name of his company, but four of its shiniest products were on camera with him most of the time. The commercial

value of the free time on the four stations was \$3,000.00. Viewers began to call up and ask where they could buy this "safe" mower. And we were able to book the sales manager into high schools for demonstrations and distribute thousands of Power Mower Safety Leaflets to students.

When safety supervisors and engineers begin to feel their way cautiously into an off-the-job safety program for employees, they would do well to re-evaluate the firms from whom they buy supplies for their on-the-job safety programs. You will find that some firms deal on the basis of price alone, with little thought to quality and none at all to public service. You will also find firms like Johnson & Johnson who not only sell high quality first aid supplies at a fair price but who have as a public service conducted a nation-wide "Emergencies Don't Wait Week" each year for the past 13 years.

The Resuscitube, an aid to artificial respiration which has saved hundreds of lives in industrial accidents, is a Johnson & Johnson development. It is now included in marine first aid kits, and available separately for use in plants and factories.

A working arrangement with one good firm like Johnson & Johnson can help your off-the-job safety program immensely. You can pick the best brains of a national organization which has been making mistakes and then correcting them for many years. Their advice on off-the-job safety has now reached a high degree of refinement. You can tie new efforts to their established ones and get the benefit of nationwide publicity. And it often turns out that this sort of cooperation is more valuable than saving a few cents on a case of inferior adhesive bandages.

In summary, let me say that I have been talking to you as public safety director for a chapter of the National Safety Council and I have assumed that most of you are safety supervisors for industrial firms. I have attempted to show you how one safety council has worked to organize local cooperation for safe outdoor recreation in the Pacific Northwest. Of course I have only scratched the surface of this important subject. You can get other ideas by writing to managers of safety councils anywhere, or by studying carefully the summaries prepared by NSC.

SURGEONS AND SAFETY—THE JOINT ACTION PROGRAM

By DR. PRESTON A. WADE

American Association for the Surgery of Trauma and American College of Surgeons
New York City

Surgeons are interested primarily in treating the sick and injured. The prevention of injury and safety problems have traditionally been left to other agencies. However, in the last few years, the physician has made prevention one of his major interests.

The American Association for the Surgery of Trauma and the American College of Surgeons have joined with the National Safety Council to develop a joint action program in which an effort is being made to improve the prevention of injuries and also help in the treatment of the injured. The history of the Joint Action Program began in 1956 when Dr. Charles G. Johnston, president of the American Association for the Surgery of Trauma, wrote a letter to the National Safety Council pointing out the necessity for those concerned with the prevention of accidents to work with those concerned with the treatment of the accident victims. The first formal meeting of the top level representatives of the three co-operative organizations was held in October, 1957.

This group decided upon a joint action program and formed itself into the policy committee and directed Dr. Paul R. Hawley, the director of the American College of Surgeons, and General G. C. Stewart, executive vice-president of the National Safety Council, to have prepared a basic document outlining the program. This document was prepared by Dr. James B. Mason and Mr. Ralph Kuhl and was published jointly in May, 1958 entitled, "The Joint Action Program." The objective of the program was the approach on a solid front to prevent accidents and minimize the serious effects of trauma.

The National Safety Council is concerned with the prevention of accidents and the two other agencies are primarily concerned with salvage after accidents occurred but, actually, the two aspects of the trauma problem cannot be separated and the pre-

vention of accidents and restoration are interlocking.

As a result of this effort, all of the safety council managers and the local trauma committees of various states and localities were asked to co-operate and to serve as co-ordinators and to promote the program.

There were several projects in which all of the interested groups could co-operate. One of these was concerned with the transportation of the injured in which ambulance attendants would be properly trained and qualified. Secondly, the communitywide promotion of attendance at courses of instruction in accident prevention and first aid and, thirdly, an effective, vigorous support at the state and local levels of the objectives of the President's Committee for Traffic Safety. Later, in July of 1959, planning memorandum No. 2 added new projects for the promotion of seat belts and for safety in sports.

The policy committee for the combined program plans and allocates projects and programs. The chairman is Dr. George M. Wheatley, a member of the executive committee of the board of directors of the National Safety Council. I am the vice-chairman and other members are the top representatives of the three sponsoring organizations.

We, the surgeons of America, are extremely interested in the prevention of accidents and have entered into this association with great enthusiasm. We have found in our efforts to help the injured, that, on many occasions, proper preventive measures might have obviated the serious injuries which we encounter.

Automobile Crash Injuries—One of the most important efforts in which we have been involved has to do with the prevention of injuries in automobile crashes. We have not, of course, had a great part in the prevention of accidents except insofar as we have supported the governmental and

local agencies in proper screening of applicants for driving licenses and helping in the usual traffic control discipline. We have, however, taken a great interest in the prevention of injuries in inevitable automobile crashes. Speed has become so vital in our national economy that we must accept the inevitable price of injury and death.

The Cornell University Medical College was a pioneer in the effort to investigate the cause of death and injury in automobile accidents. Hugh DeHaven, in 1940, first became interested in the factors involved in *break survivals* of free-falls and suicide attempts. He applied these factors to the designing of cockpits of fighter planes during World War II and as a result of his recommendations, the cockpits of fighter planes were constructed so as to package the pilot in the plane. The improvement in mortality and injury rate was so effectual as to cause the armed services to ask him to continue his investigation. It was only natural that his discoveries would be applied to automobile crash injuries after the war.

The American College of Surgeons became very much interested in the results of preliminary studies in which he found certain major causes of death in automobile accidents. The first was the finding that passengers ejected from an automobile, at the time of the crash, were apt to sustain severe to fatal injuries five times more often than the passengers confined within the vehicle. This led him to suggest the possibility of a confining seat belt.

The other findings of the Cornell Automobile Auto-Crash Injury Program showed that there were certain areas within the interior of the automobile that caused serious injury. Usually these were the protruberant areas on the dashboard as well as the conventional steering wheel. He made several suggestions, five of which were: 1. improving the design of the steering wheel so as to catch the driver when the crash occurred, cradling him in the steering wheel so as to protect him from the force of the driving rod; 2. padding the dashboard and removing the protruberant objects from it; 3. improving the design of the car door so as to prevent it from opening at the time of the crash; 4. adding seat belts; 5. fixing the seat to the chassis of the car so as to prevent the extra weight of the seat with

the passenger's body from being propelled against the front part of the car.

These suggestions were considered by the American College of Surgeons Trauma Committee and transmitted by resolutions through the Regents of the College of Surgeons to the five major automobile manufacturers in 1955. It is to their credit that they took cognizance of these suggestions and all complied in one way or another. One automobile manufacturer included all of these five improvements in the 1956 model and centered its advertising campaign on safety during that year. Unfortunately, there was a severe drop in that company's sales for that year and this was thought to be due entirely to the accent on safety. Apparently, safety is not popular to the automobile buyer so this had to be dropped in their future advertising campaigns. Nevertheless, all of the automobile manufacturers have continued to add these safety features in their automobiles.

The Cornell Auto-Crash Injury Research Department made a study of the results of these improvements. It was quite interesting to note that the study of the 1956 cars indicated that there was considerable less danger in injury and death in those cars which had been fitted with the new design car door. The incidence of ejection from the car was considerably less as was the injury and fatality rate as the result of being ejected from the car. A further investigation of the use of seat belts indicated that there was a remarkable decrease in the incidence of death and injury as the result of the use of seat belts.

There is no question about it that the seat belts do not prevent death or injury when automobiles hit, head-on, in crashes at high speed. But for the usual accident the seat belt has proved to be a life saving device.

The surgeon has also interested himself in the pedestrian problem and, recently, the Cornell University Trauma Research Department has made a study of 200 consecutive pedestrian deaths, the study being undertaken with the co-operation of the police department and the medical examiner of the City of New York. This study will show that there are a few improvements that can be made in the design of the automobile to prevent death but, most certainly,

the pedestrian's disregard of the law of traffic lights is probably the most consistent cause of death.

Surgeons are also interested in the injuries sustained on the farm and as a result of their studies of the injuries treated have made certain suggestions as to improvement in farm machinery.

The medical profession has also interested itself in such things as the serious injuries resulting from rotary lawn mowers and gas and oil heaters and has made suggestions that may be helpful in the manufacture and sale of these products.

For many years, physicians have taken the lead in the effort to control the injuries that result from sports, particularly in football injuries. The advice and counsel of those surgeons interested in the sport have helped to prevent serious injuries and death. Particularly in the treatment of the injured football player on the field, the proper transportation and care of the patient has helped a great deal in the prevention of the worsening of his injury. It has been as the result of the physician's insistence that the practice of sending a player back into the game after he has been injured has been abolished. Many of the serious knee injuries which are often the result of a secondary injury on what might have been a simple knee strain have been prevented by proper investigation and control. Also, the surgeon has helped in great measure to help design the helmets and face guards which, in the past, have been more harmful than helpful.

Ambulances and Speed—One of the most important contributions a surgeon can make to safety is the control of the speeding ambulance. The excitement and hysteria engendered by an accident usually stimulates all concerned to use great speed in everything they do. As a result, ambulances are usually driven at an unnecessary rapid rate. It is very unusual for one to see an ambulance traveling the streets of any city at a reasonable rate, obeying traffic laws. Yet, we in the medical profession, know that there is rarely a need for speed in an ambulance call.

Furthermore, Curry and Lytle have shown in a study of 2500 cases at Flint, Mich., that in only one case was speed necessary to prevent serious difficulties in the treatment of the patient while, in some nine cases, a rough and rapid ride might very well have caused an aggravation of the injuries and even a fatality. We, therefore, feel that we have sufficient evidence to indicate that speed is unnecessary in the transportation of the injured and that careful transportation and obeying speed laws is not only helpful to the patient being transported but also will prevent injury and death to the unwary pedestrian and motorist. In my opinion, the speeding ambulance causes death to more people than it saves. I believe there should come a time when all ambulances should be made to travel at normal speeds and obey all traffic regulations. This concept of ambulance control is resented by ambulance companies and volunteer ambulance units and many will give examples of how speed of the ambulances saved a life but these claims are all speculative and depend upon the opinion of an interested bystander. However, the death caused by the speeding ambulance is not a speculation but is a true statistic. It was found that in one large American city ambulances were used to transport radio stars from one studio to another so that they would not have to be delayed by usual traffic regulations. Ambulances should be required to obey all traffic laws and the surgeons of this country will, some day, give evidence that speed is not necessary in ambulances and strongly support their control.

Civilian Defense—There is one further effort in which the surgeons of this country are interested and this has to do with civilian defense. With international difficulties being such as they are, it is our solemn duty to take cognizance of the danger and prepare for our national survival. This means that the medical profession must take steps to assist the government in teaching the public as well as the medical profession and paramedical personnel to treat and take care of those who are injured in a mass catastrophe.

SHOOTING SAFETY IN OUTDOOR EDUCATION

By JULIAN W. SMITH

Dir., Outdoor Education Project, American Association for Health, Physical Education, Recreation, Michigan State University, East Lansing, Mich.

One of the significant developments in education during the past several decades is the concern for the wise use of man's leisure time—that increasingly large portion of waking hours when he can participate in activities of his own choice. Due to the influence of industrialization and the expanding role of the school, the curriculum now includes a wide variety of offerings which help equip children and youth with the skills, attitudes, and appreciations which contribute to good living. In a volume entitled *Leisure and the Schools*, the following statement is made:

The entire school curriculum must be conceived as a tool for developing attitudes, understandings, knowledges and skills required for leisure literacy.

The most recent announcement from the Educational Policies Commission of the National Education Association has this to say about education for leisure:

The worthy use of leisure is related to the individual's knowledge, understanding, and capacity to choose, from among all the activities to which his time can be devoted, those which contribute to the achievement of his purposes and to the satisfaction of his needs. On these bases, the individual can become aware of the external pressures which compete for his attention, moderate the influence of these pressures, and make wise choice for himself. His recreation, ranging from hobbies to sports to intellectual activity pursued for its own sake, can conform to his own concepts of constructive use of time.

An examination of the current scene indicates that the outdoors is occupying an increasingly important place in man's life as he seeks to find good and wholesome adventure and relaxation in this complex urban society. This is reflected in the emphasis in education known as outdoor education which helps develop concepts and insights about the natural environment and man's relationship to it; provides laboratory experiences for more effective learning in

some of the essential subject matter areas; enables one to acquire skills with which to enjoy a lifetime of creative living; and gets us back in touch with those aspects of living where our roots were once firmly established.

Learning in the outdoors applies to the educational activities that take place in outdoor settings; while education for the outdoors encompasses the skills and knowledge necessary for satisfying participation in outdoor pursuits.

Learning through the use of the outdoors as a laboratory contributes to the phase of outdoor education which might be termed the appreciation arts. Education for the outdoors consists of the development of the manipulative and creative skills which are expressed in the more active types of outdoor recreation activities such as shooting and hunting.

Historically, shooting and hunting have been favorite activities for generations. But only in recent years have schools and other educational agencies recognized the need for teaching the basic skills for these significant activities which have lifelong values and in which so many people can participate. Shooting and hunting are among the important activities in the phase of outdoor education which may be called the manipulative skills or education for the outdoors. While shooting has been regarded as a desirable activity in a broad program of physical education and recreation in schools, colleges, and agencies for some time, it was not until the National Rifle Association initiated its excellent program of hunter safety that the need for systematic teaching of safe shooting and hunting came to the attention of the public.

In the mid 1940's, the National Rifle Association enlisted the cooperation of the National Education Association in setting up a broader hunter safety course which could be conducted in cooperation with the school and community. Hundreds of thousands of youth have participated through community sponsored hunter safety courses

under the leadership of N.R.A. instructors. It became increasingly evident that the basic skills for a wide variety of sports and activities in which large numbers of children, youth and adults can participate should be a part of the curriculum of schools and colleges and that broad opportunities for participation in these activities should be provided by community agencies and organizations. Ideally, the home should provide early instruction in the care and use of sporting arms, but as in many other activities, the conditions of modern living have deprived many children from the opportunity for participation with their parents in shooting and hunting.

Prompted by the need for leadership in schools, colleges, and community agencies for teaching the skills, appreciations and attitudes through outdoor education, the American Association for Health, Physical Education and Recreation initiated the Outdoor Education Project in 1953. Following the effective pattern in a cooperative program by business, industry, and education, the Project was developed with the financial support of the American Fishing Tackle Manufacturers Association, the Sporting Arms and Ammunition Manufacturers' Institute, and the Daisy Manufacturing Company, and in cooperation with the National Rifle Association, departments of the National Education Association, and the American Casting Association. The Project, now in its seventh year of operation, has given impetus to the initiation of many new programs of shooting and firearms safety.

Over 50 state and regional workshops involving school and college administrators and teachers, recreation and conservation personnel, and outdoor education leaders have been conducted. In each of these, shooting clinics were provided, with the leadership of nationally known instructors from the N.R.A., S.A.A.M.I., the Daisy Manufacturing Company, departments of conservation, and industry. Shooting clinics have also been included in many other state and national workshops, conferences and conventions. Two publications of the A.A.H.P.E.R., entitled *Shooting and Hunting and Marksmanship for Young Shooters*, have wide distribution. Thousands of other publications from the N.R.A., S.A.A.M.I., and Daisy have been distributed.

An important phase of shooting safety in the Outdoor Education Project is the program involving the use of the air rifle as an instructional tool. Many elementary and secondary schools now include marksmanship and gun safety activities for young shooters. A survey conducted by the A.A.H.P.E.R., after the Project had been under way for three years, indicated that the number of shooting programs in schools and colleges had increased from 12 per cent to 28 per cent.

Safety is recognized as an important phase of hunter training. Operating on the basis that a good sport is a safe activity, safety techniques and procedures are included in the instruction about guns, in the demonstrations of the use of guns, and in the actual participation. It should be pointed out that shooting in an educational program is considered a sport and is taught according to the same principles that are used in other sports and games that are part of the school and college curricula.

Shooting and Hunting Instruction — In schools and colleges, shooting and hunting fit logically into physical education and recreation. They are included with other activities in the regular physical education class period or through school clubs, intramural sports, after-school programs, and in special activity periods. Rifle shooting, especially, has often been administered as a club activity, but in order to provide more basic instruction for all who need it, the physical education class is more inclusive.

Clubs provide excellent outlets for field experiences and competitive events. Many schools offer concentrated instruction in hunting and correct gun handling in activity periods and after school hours. This kind of instruction often is conducted prior to the opening of the hunting season. In elementary schools, shooting through the use of the air rifle is often included in physical education classes, clubs, after-school programs, and in school recreation departments and school camping. In colleges and universities shooting may be offered as a service course or as a part of the professional classes in physical education. A portion of a report on the Outdoor Education Project prepared in June 1961 will illustrate the development of shooting programs.

Program developments in shooting: Students learn casting and angling, shooting and hunting education, boating and water safety, archery, winter sports and other outdoor activities in school, college, and agency programs.

Percentage increase in shooting and casting programs:

In 1955—12 per cent + of the schools surveyed reported programs

Now—28 per cent + have programs (reported in survey of 1958)

Programs listed in schools and colleges that were surveyed, most of which were represented in the Outdoor Education Workshops:

1958 survey—Casting: 358

Shooting: 528

1961 projection—Casting: 1000+

Shooting: 1056

Note: More than a million youth are enrolled in the schools reporting these programs.

Hundreds of other programs are under way in schools and colleges which were not surveyed.

In colleges and universities—

3,000 prospective physical education teachers and recreation leaders receive instruction in shooting and casting in physical education and recreation courses and activities each year

Total for five-year period: over 15,000—approximately 5,000 of this number are certified American Casting Association and National Rifle Association instructors

Examples: Pennsylvania State University—900 students receive shooting instruction each year

Michigan State University—150 students receive shooting instruction each year

"Outdoor schools": Entire classrooms of students and teachers spend one week periods in camps, on school time and as part of the school program.

In 1956—300 school districts in the United States

In 1961—750 school districts in the United States

250,000 children in elementary and secondary schools learn science and outdoor skills (including casting, shooting, archery, and woods survival) in these outdoor schools as part of the school program.

Resources—There are many resources for teaching shooting in the curriculum of schools and colleges and in the programs of community agencies. The National Rifle Association with its certified hunter safety instructors reaches into nearly every community to assist in the initiation and development of the instructional programs. Many physical education and recreation leaders now have had instruction in college or through in-service education and are competent to teach shooting. In most instances, conservation departments have personnel available to assist in the preparation of local instructors and in some instances work directly with schools and colleges. The Sportsmen's Service Bureau of the Sporting Arms and Ammunition Manufacturers' Institute has excellent publications and provides some field service. The Daisy Manufacturing Company, through its Training Services Division, offers leadership and materials in the use of the air rifle. Other leaders are often available from sportsmen's clubs and industry.

Because of the extensive participation in shooting and hunting in the United States and since there are firearms in upwards of 25 million homes, shooting safety should be a part of the basic instruction in the public schools and opportunities for participation for those interested should be provided by the community. Like other community activities, this can be a cooperative venture between the school and other education and recreation agencies. Local safety councils, sportsmen's clubs, parent-teacher associations, and other civic organizations can do much to make shooting a safe and satisfying sport. It should be pointed out that the sport of shooting, through participation in shooting games, constitutes an activity which has great appeal and extensive participation for a wide range of age groups. The number of hunters each year constitutes another large group of citizens who seek wholesome outdoor recreation, many of whom need more instruction in shooting safety.

Since shooting is a legitimate and recog-

nized sport, and because of its opportunities for lifelong participation, shooting safety is finding its place in outdoor education. It is estimated by Marion Clawson that as the year 2000 approaches, ten times as many people will be participating in outdoor activities. Many millions of these outdoorsmen will use sporting arms for recreation. It is a challenge to the nation's educational system to develop outdoor minded citizens

who will find wholesome recreation and devote their efforts to the care and preservation of our natural resources which make outdoor recreation possible. Shooting, like many other activities, is an avenue to the out-of-door and outdoor education needs to provide the appreciation arts along with the skills in order that those who seek the open spaces may find maximum satisfactions in their endeavors.

SHOOTING SAFETY IN ORGANIZED YOUTH GROUPS

By FRANK L. WYMAN

Dir., Program Div., National Rifle Association of America, Washington, D. C.

Shooting safety in organized youth groups doesn't just happen—it's safety ever day. It is planned for and is the end product of continuous and constant effort. Some of this planning and effort is shown in the Outdoor Education Workshop project. It is through this type of educational work that we can reach the largest number of people at an impressionable age.

Undoubtedly, there were youth shooting groups many years prior to the 1920's, but it was at that time that the first major safety effort was made in such groups on a national scale. It was at that time that the well known Winchester Repeating Arms Co. organized the Winchester Junior Rifle Corps. As can well be imagined the response from young people was immediate, as it always is when the words "gun" or "shoot" are voiced around youngsters. In fact, the response was so great and in a field rather far removed from the actual manufacture of rifles and ammunition that the originator of the idea offered to turn the entire project over to the National Rifle Association, at that time a small organization.

The NRA accepted enthusiastically and set to work to teach both firearms marksmanship and safety to boys and girls. The Association's records were not too complete in those days, but reports indicate that it was not until 1931 that these youth shooting groups totaled over 200. Today there are 5,000 Junior NRA Rifle Clubs actively

engaged in a safety training and competition program.

These clubs have a membership of approximately 250,000 young men and women under 19 years of age. During the average 12 month period they will earn about 100,000 pieces of shooting qualification insignia, such as medals and brassards which are offered as an incentive to develop and to maintain the young person's interest through the program, as well as to attest to the winners shooting prowess.

This program has become popularly known as the NRA Junior Shooting Program and is conducted by volunteer leaders, and instructors in local communities. Frankly, the National Rifle Association is not financially able to furnish paid employees for a project with 250,000 eager participants and 53,000 trained instructors. This program to be successful relies on municipalities, schools, churches, business firms, luncheon clubs and adult shooting clubs to become group sponsors. Dedicated men and women are required to become the trained instructors. Without these sponsors and instructors this safety project could not carry on in the successful manner in which it is operating.

Many firms and individuals who are members of the National Safety Council are already actively engaged in shooting safety work. Every member can take part in some helpful manner. The town or city where

you live can assist with facilities through its park or recreation Department. Your business or employer can do likewise and hundreds have done so already, either because someone in management had a personal interest in shooting or because an employee or business associate called attention to the need. Your schools, churches and clubs all should have this good work called to their attention, not only from the safety training aspect, but also as a recreation which appeals to all boys and to many girls.

Shooting occupies an enviable position in the safety training field because it is an enjoyable sport which can be, and is, participated in on an equal level by both sexes and most age groups. Furthermore, it can be enjoyed as a family recreation feature to a degree seldom found in an active outdoor sport. The family recreation feature has been attractive to many industrial recreation departments as an assist to them in their personnel relations. The National Industrial Recreation Association membership is active in support of a marksmanship and safety training program.

I have spoken previously of the need for range facilities which many municipalities, business firms and clubs are helping to solve. Shooting to many of us brings up visions of large areas being required for one sole purpose—to be closed for everything except use as a shooting area. True, some types of shooting do require extensive real estate, but I am happy to say that the types we are concerned with today do not.

The youth shooting program concerns itself with nothing larger than 22 caliber and usually the firing is indoors, or on outdoor ranges confined to comparable distances to those used indoors which is 50 feet from shooter to target. Sometimes even this short distance may not be available in a convenient, comfortable location and when that occurs there are parallel programs at 25 feet with low-power CO₂ gas rifles and at 15 feet with spring type air guns. The same safety training can be accomplished at 25 and 15 feet with the appropriate guns as is accomplished at 50 feet with the more familiar and commonly known 22s.

More about range locations. Many ranges for the types of firing we have mentioned are so located that they use an area for

shooting which at other times is actively used for an entirely different purpose. For instance, a school gym is a desirable spot. A club auditorium can quickly be made into a satisfactory, safe range, and as quickly returned to its status as an auditorium. This comes about through using the available space for 25 or 15 foot shooting or by building the backstop for 22 caliber firing on a platform, which is equipped with catters. Thus, the backstop is pushed into position for range use and easily moved into its storage space when the area is not being devoted to shooting. Many such ranges are in daily use and more are being built.

Outdoor ranges are frequently equipped with a low shelf under which the rifles remain at all times, even while being fired. Due to the low shelf the rare bullet which would not hit the backstop will be contained in the wood from which the shelf is made. A range such as this is well adapted to park areas and has been used during the last two Boy Scout National Jamborees, which by the way presented the opportunity to give firearms safety instruction to 53,000 Scouts who chose rifle instruction as one of the elective sports they wished to take part in.

As you have no doubt gathered rifle shooting as a sport and safety training project is very much of a group activity. This is most desirable for our purpose of safety training. An instructor can supervise several young people while they shoot with little more work than required to supervise a single boy or girl. Competitive shooting is an ideal sport where those taking part learn much beside how to shoot safely and well. Through observing others a youngster learns many correct shooting habits. They learn cooperation with their teammates, how to observe the habits of others and correct faults quickly and efficiently. They learn that careful and precise handling of equipment is necessary for good work to result—and all the while they learn more about "Safety."

In order to spread safety instruction among organized youth groups to the greatest extent close work is carried on with many other national associations. A natural bond exists between the NRA and the Boy Scouts of America. One of their merit badges is for rifle shooting and here

the safe handling of firearms is a very large and important part of the work each Scout completes to earn this award.

A series of annual postal type competitions is conducted in cooperation with several national associations, including the Boy Scouts, the Veterans of Foreign Wars, the American Legion, the YMCA, and the DeMolay. Several of these names may come as a surprise, but through them shooting safety instruction reaches a new audience, one of youngsters who might not otherwise have been exposed to firearms safety training.

Each Fall season is heralded by both the beautiful autumn leaves and a rash of newspaper stories on accidents to hunters. Close scrutiny of these articles may disclose that the unfortunate victim died from a cause far removed from a firearm, but the fact does remain that there are too many unsafe hunters going into the fields and woods.

A little more than ten years ago the State of New York, through its conservation department, came to the NRA for help in connection with its problem of too many hunting accidents. That state had already used its splendid corps of game wardens in an effort to give safe hunting instruction to young people who were applying for their first hunting license. Their game wardens were literally swamped with applicants for instruction and many more trained, qualified instructors were needed, and the instruction material for this special work was also needed. NRA contacted its affiliated clubs in New York who furnished hundreds of instructors the first year and thousands later. In cooperation with our good friends in the National Education Association the needed material was prepared, both to teach proper instruction techniques to instructors and to teach the hunters themselves. From a small beginning with only one state in the program, the now nationally known and accepted NRA Hunter Safety Training Program has expanded until at present 31 states are using it, plus one Canadian

province, and more are being added each year. There is not a state in the nation where hunter safety instruction is not available, either as a state project or by individuals dedicated to the work. Millions of pieces of literature, such as manuals, examinations, safe hunter identification cards and insignia, and safety posters have been distributed in this campaign for safety. The effectiveness of the campaign, in face of a major increase each year in the number of hunters going into the field, is shown by the many words of praise received from conservation departments. For example, the Washington State Fish and Game Department recently stated "In Washington it is very apparent that the activities in the field of hunting safety have accomplished their primary purpose . . . there has been a definite reduction of fatal accidents . . ." Other states have made similar statements in their official reports.

Many times this afternoon you must have noticed that I mention marksmanship training either with or closely akin to safety training. I assure you this was not a mistake. When either a young person or adult is instructed in rifle marksmanship a large part of that instruction deals directly with safety. An expert marksman is usually a safe person with a firearm for he, or she, has handled firearms sufficiently to almost subconsciously take safety precautions which have been learned through hours spent in instruction, practice and competition. Therefore, it is not a mistake to mix marksmanship and safety instruction—they go together naturally. An expert driver usually is a safe car handler and an expert swimmer usually is super safety conscious for both himself and others.

As said before, each of you, each of your business firms, your churches, lodges, luncheon clubs and kindred groups, as individuals and as organizations can take an active part in the program to offer even more education on shooting safety through organized youth groups—the National Rifle Association of America will be glad to tell you how.

CAMPING AND SURVIVAL

By FRANK MENTZER

Editor & Publisher, Family Camping Magazine, Philadelphia, Pa.

For a good many years, our family has enjoyed living during our vacations under what many people might consider to be hardship conditions. We have enjoyed living under canvas, without all the niceties of home. We find it a pleasure to be without television. There is a relief to be away from the jangling of the telephone. And there are many compensations for the inconvenience of a pit toilet, for the trouble of having to tote your water from a central supply.

Over the years we have discovered that no matter where we go we always arrange our gear in just about the same way. Thus, everywhere we go our camp has a feeling of sameness, of being at home.

The gear that has given us so many pleasant vacation trips and happy weekends, receives loving care. We have developed the habit of maintaining and storing it so that it is always ready for an unexpected opportunity to go camping.

Packing the family station wagon has fallen into a routine; each item has its place, predetermined by experience.

Now, suppose war does come again into our lives. Suppose the order is given to evacuate that section of Pennsylvania in which we live. As a typical camping family, just how are we better trained and equipped for survival?

First, because we have been training to operate under "adverse conditions", we could pack our gear into our wagon and be on our way in 30 minutes. Upon arrival at the evacuation zone, we could set-up in less than an hour—completely prepared, equipped and trained to live under these conditions for an indefinite period of time.

In contrast, can you imagine the pandemonium that would reign in the homes of my neighbors, none of whom are campers? For that matter, how long would it take your family to evacuate? When you arrived at the safety zone, what would you do?

One of the many conditions that are mentioned in every discussion of civil defense is the probability that the family will be

separated at the time an unexpected attack occurs.

Here again, the camping family is better equipped and trained for survival. Because of the teamwork involved in setting-up and breaking camp, every member of the family knows not only what he or she is expected to do, but could also take over for a missing or disabled member.

We are hearing and reading a great deal about fallout shelters these anxious days. Concrete shelters, steel shelters, indoor shelters, outdoor shelters. What to put in them; what to leave out.

But have you read one word about how to live together in such a confined space?

Last August we camped with three days of continuous rain. We learned that two adults and two active children can live together in confined quarters and under adverse conditions. It is possible, we admit, that we did not learn this lesson as well as we could have, for by the end of the third day we were all a little edgy.

If we are ever forced to seek refuge in a fallout shelter, we will be better prepared to survive because we know what many of the pitfalls are and, I hope, how to avoid them.

What I have just said about the ability of the camping family to survive is based on my own family. I know our own situation best. But what I have said is just as true of most every other camping family. We will all differ in degrees—but we are all trained and equipped for survival as family groups.

None of us kid ourselves into thinking that life under emergency conditions will be anything like vacation camping. But the transition will be easier for us than for our non-camping neighbors.

I am not "some kind of a nut, or something." I do not preach the gospel of doom and gloom. On the contrary, I am the eternal optimist. I honestly do not believe that I will ever load my camping gear into my

station wagon for any reason other than a pleasure trip.

But if I am wrong, our family will move out with the efficiency and confidence learned through camping for the fun of it.

And we will be able to lend help and guidance to a mass of people who will be floundering in a sea of confusion.

Today, survival is mentioned primarily in connection with nuclear blasts. But there are other catastrophes—that families, communities and a nation—must be prepared to survive. In all of these, I believe, the family that camps together has the best chance for survival, and makes the greater contribution to the future of our nation.

SAFEGUARDS FOR BIG CROWDS AT AMUSEMENT PARKS AND FAIRS

By AULTON D. MULLENDORE

Asst. Supt., Engineering Div. The American Insurance Group, Newark, N. J.

The subject of public safety, as it relates to crowds at amusement parks and fairs, is something I am sure many of you have not thought much about. This lack of interest may be explained by the fact few of you are directly responsible for safety of persons gathered at amusement parks and fairs.

How long has it been since you attended an amusement park or a fair? I am sure it has not been very long; most of us have either had a personal urge or have been urged to attend such events by members of our families. If you have not attended such an event, it probably will not be long until you will have had the opportunity to do so.

If you have attended such an event, you should have been concerned with this aspect of public safety. I believe that any person, in any crowd, should be alert to any conditions which might conceivably produce an emergency and a resulting panic.

Think with me for just a moment about this problem in order that we may put it into proper perspective. I have tried to estimate the number of persons annually exposed in crowds, at amusement parks, beaches and fairs throughout this country. The only conclusion I can reach is that the total annual attendance far exceeds the total population of the United States. This is certainly an astounding figure and it is a foregone conclusion that, if this be the case, such crowds pose one of the greatest public safety problems we have in these United

States. We must be alert to the fact that crowds in amusement centers are becoming larger. As more leisure time is developed, more of it will be spent at amusement centers. People will seek out such places of amusement as a means of relaxation and escape from the routines of work and normal living.

To help get this problem into perspective, let me elaborate. There are approximately 300 cities with a population of more than 100,000, and there are over 3,000 counties in the 50 states, all of which are constantly promoting, arranging and causing crowds to gather at public places.

All of the major, and many of the minor, cities in the United States boast of having one or more amusement centers, either privately or publicly owned. Each year the season usually begins with Memorial Day and runs for at least three months, ending with Labor Day, so you can see most of these places of amusement operate at least one quarter of the year on a seven day per week basis. Many of them, in areas of moderate climate, are open on a longer schedule. Places like Disneyland, and the state fair grounds in Dallas are open for longer operating seasons. Furthermore, keep in mind that practically all of our states hold some kind of state fair, and a large majority of the counties within these states conduct fairs.

You may be saying that these are not crowd exposures because people are not grouped in confined areas, but let me re-

mind you that at all of these amusement parks and fairs, there are special events which are repeated, sometimes nightly. I refer to events such as rodeos, horse races, stock car races, fireworks exhibitions, prize fights, ice shows, horse shows, ball games, political rallies, dance halls, roller skating rinks, restaurants, boat races and excursions, musical concerts and drama programs. Also, there are many amusement devices which carry dozens, and sometimes hundreds, such as roller coasters, miniature trains, ferris wheels, and the like. Readily, we see that the problem of group exposure at such events in the United States is something for us to be concerned about. So let us become aware of this exposure and properly control such crowds in order to prevent catastrophes.

Many companies annually plan group picnics and excursions which crowd employees into places of amusement in numbers sometimes in excess of the building or area capacity. They crowd into amusement devices to the point of overloading. A few years ago, at a mid-western park, a miniature train was upset when a rowdy group of picnickers over-loaded and began swaying and rocking the ride excessively. Dozens of riders were injured. Let us be aware of this type of exposure, and continue to set up controls in accordance with the purpose of our profession as safety engineers, police, security officials, etc.

Let me pause here to pay tribute to the individual owners and operators of amusement parks, pools and beaches. This group of responsible businessmen and women have long been concerned with the safety of their patrons, and with few exceptions, have provided adequately for the public's safety. The National Association of Amusement Parks, Pools and Beaches, with headquarters here in Chicago, is doing an outstanding job of promoting safety among its many hundreds of members throughout the United States. In spite of the fact that each year, millions upon millions of persons assemble in groups at amusement parks and fairs on an almost daily schedule, none of our country's major catastrophes or holocausts have occurred at such places. This segment of American amusement industry is indeed to be commended for this accomplishment.

You may ask then, why should crowds

at amusement parks and fairs be considered a special problem? Why separate these from crowds at professional football and basketball games? Isn't the hazard the same? The difference is that crowds at major ball games are generally larger and of necessity require and get special handling. Millions of dollars have been spent, in a well planned program of permanent buildings designed and constructed to provide safety for these groups.

Crowds at amusement parks and fairs often gather in buildings which were not originally designed for public occupancy. Sometimes these buildings are conversions and do not possess the same safety standard which would be required today for new construction. Building and electrical codes were not in existence or were not enforced when these structures were built. The original design and construction might not have contemplated their use as a place for public assembly. Some of these buildings may have inadequate exits, sub-standard lighting, and in many cases no emergency ventilation, may be built of combustible materials, and may have weak foundation structures susceptible to collapse under heavy loads.

I might add that all too often these combustible materials are made more hazardous because of the addition of non-flameproofed drapes, bunting, billboards, and other decorative or advertising materials. Oftentimes, the addition of such materials cuts down and reduces the number of exit units. The famous Coconut Grove Night Club fire in Boston in 1942, where 492 persons were burned to death is an example which illustrates this point.

In speaking of collapse, I am sure that you have seen a parade, a political rally, or a sports event, which called for the erection of temporary stands or bleachers. All too often, these stands or bleachers, because they are temporary, are not properly constructed. Footings are not secure, bracing may be inadequate and the quality of materials used is not commensurate with load requirements. There have been repeated instances of catastrophes where grandstands have collapsed, seriously injuring dozens of people. The best example of this was the collapse of stands at Baltimore Regiment Army in March, 1952, in

which 29 persons were injured while watching an ice show. A more recent incident was the collapse of a viewer's stand at the Indianapolis auto races in May of last year. Two died and scores were injured.

A few moments ago I mentioned non-flameproofed materials. This brings to mind one of the greatest catastrophes in the country's history. It did not involve an amusement park or fair, but it was a place of amusement. I refer to the circus fire which occurred in Hartford, Conn., in 1944 in which 168 persons were burned to death when a big-top tent was completely destroyed by fire.

Tents are a continuing problem at places of amusement, especially fairs, because smaller tents are often used as a temporary structure to house crowds. Occasionally, we find them at amusement parks. Tents are always a fire hazard unless they have been properly flameproofed, and occasionally, they pose a problem from the standpoint of collapse due to sudden wind gusts.

I also referred, a few minutes ago, to buildings not having proper ventilation. I am sure you are wondering why this should be a concern of ours when thinking about the public's safety. Over-crowded, poorly ventilated buildings, or areas can conceivably cause panic, and panic as you know, often causes injury. Let me cite you a couple of instances; one back in 1936, and another one within the last year or so.

In 1936 when Texas was celebrating its centennial, thousands of public school children were transported and gathered at the Cotton Bowl to witness and participate in the celebration. They were gathered to sing patriotic songs commemorating this great event. It was a hot, still, sunny day when these thousands of children were gathered on the playing field and in the stands. The stated objective was to crowd as many persons as possible into this place because great numbers would be impressive. You know, they like to do things big in Texas.

Suddenly, without any forwarning, dozens and dozens of these children began to faint, collapse, and fall because of extreme heat, excitement, and the crowded condition. The shape of the Cotton Bowl, together with the existing weather conditions and the immense crowd brought about a situa-

tion which caused the children to lose consciousness and you can well imagine how serious such an emergency could become, as panic ensued.

One would think that such a place, would have natural ventilation at all times, because it is open. Here was an emergency created because of the lack of proper ventilation, even in an outdoor area. Properly ventilating the Cotton Bowl, under similar conditions, would have been almost an impossibility. The control of such situations obviously is in proper planning and supervision for such large crowds. Potential emergencies must be anticipated and planned for; in so doing, they are prevented.

I should like to bring another incident to your attention. It occurred a couple of years ago in a mid-western state and received a considerable amount of national publicity. At a basketball game, in a public school gymnasium, the school buses were parked near the building air intake vent; during the course of the game, the engines of the buses were permitted to run in order to keep the buses warm. The exhaust from the buses was drawn inside the ventilating system. Many people inside the Gymnasium were overcome by carbon monoxide. Naturally, confusion and near panic ensued. I cite these instances to show you how remote the cause of a catastrophe or panic can be. I cite them also to emphasize the point that any time you have a crowd of people together, you have a problem with reference to public safety.

We usually think in terms of Public Safety as it relates to fires. As we all know, it is certainly one of the primary factors to be considered when crowds of people are assembled; but, as you can see, these are not the only factors to be considered. Any conceivable emergency which might cause panic, should be anticipated and procedures put in force to deal with it, just in case it develops. Panic, which develops within a crowd of people, is a horrible and often a catastrophic experience. Therefore, panic control is fundamental and basic in handling crowds.

Whether the location is owned by an individual, a municipality, county or state, it is always important to see that one person, or better still, a committee of persons is assigned and given the responsibility

for public safety. All too often, events are planned, publicity arranged, and large crowds are expected to gather without anyone in particular giving thought, or being concerned about the safety of the people. You may say, well, that is everybody's business. I agree with you, and I am one who believes that everyone should be concerned, not only with his own safety, but the safety of all the members of the public.

However, being concerned is not like being responsible. There must be someone, or some committee, assigned and held responsible for the public's safety. Even though we'd like for everyone to be concerned, we cannot escape the fact that the nation, "that which is everybody's business, is nobody's business," still applies. Someone must be in charge of safety and be held responsible.

Your local police and firemen are always available to consult with you and help you plan such events. Building inspectors, employed by municipalities, can advise you concerning exit codes, building floor load requirements, wiring, and ventilating requirements. Your fire marshal or chief can give you advice on flame-proofing materials, and setting up permanent as well as emergency fire fighting equipment.

He will assist you in training your employees in handling emergency situations. For most events, local and state police are available for on duty assistance if they are called upon. Stand-by firemen are likewise available and often render valuable service. If public police and firemen are unavailable in your area, you can designate and train your own employees to carry out certain functions in the event of an emergency.

Advanced safety planning is absolutely essential where crowds gather. Days before the crowd assembles, those responsible should inspect the area, checking exits, using the national building exits code as a guide, because this is generally the accepted standard throughout the country. Any de-

fective wiring should be removed and any new wiring needed for the performance should conform with the local and national electric codes. It is important to see that emergency lighting is installed to take care of any kind of temporary disablement of the regular system.

This inspection should involve all of the seating arrangements, making certain there is no collapse hazard and that there will be no overcrowding in the event it becomes necessary to evacuate the place. Competent technicians should check out the heating and ventilating systems for defects and adequacy. Adequate fire extinguishers should be available and those responsible should be familiar with their location and method of use.

Finally, management should review what has been done by the safety committee, making sure that there is nothing in existence which is likely to cause an emergency. These plans should involve details of what each usher, watchman or other employee will do in the event an emergency develops.

So, in summary, I might point out that there are several major causes for catastrophes and panic when you have crowds gathered. They are fire, collapse of structures, poor ventilation, and overcrowding of places of assembly and amusement devices. The three points I want to give you for control of these hazards are:

1. Place the responsibility for public safety upon an individual or a committee.
2. Secure the help of all public agencies such as police and firemen; appoint or hire additional help to handle the crowd if needed.
3. Days before the crowd assembles, management should make a complete inspection of the premises, checking lighting, structure of buildings, heating, ventilating, and fire hazards; make sure there are adequate controls established to take care of any emergency; check also to see that all known hazards have been removed.

I conclude with this admonition, plan *not* to have an emergency, but also plan to have one.

WHEN INDUSTRY HAS A SERIOUS EMERGENCY, WHAT IS THE PUBLIC'S JOB?

By HENRY E. WEBB, JR.

Safety Dir., Nitro Plant, Monsanto Chemical Corp., Nitro, W. Va.

The public's job is to assist in the containment of an emergency and in an orderly return to normal operations. To understand this job, we must have the answers to several questions.

1. Who is industry?
2. Who is the public?
3. What is a serious emergency?
4. How does industry plan for the containment of an emergency?
5. How is the public included in such plans?
6. Who is responsible for coordinating the public's effort?

Who is industry? Industry is a plant or a group of plants. Within the term "plant" we have first of all the people that are engaged in the operation of the plant, whether they are on the actual property or away from the plant, so long as they owe their livelihood to the proper operation of the specific plant. The real estate enclosed by a fence is a part of the plant. The buildings and the equipment therein are parts of the plant. A particular plant may be a portion of a totally industrial community or it may be a part of an industrial-business community or it may be a part of an industrial, business, or residential community.

Who is the public? The public is composed of people, property and equipment within a given area. There may be an overlapping as in the first instance where the public may comprise a community which has a plant or business or residential area, any one of which may be an exclusive member of a public community. In addition, we will certainly find other elements of community life such as organizations whose purpose is to protect the common good, the fire department and the police department. Educational institutions, churches, hospitals, libraries and other plants whose purpose is to assure community members of a well-rounded life, generally, complete the total community.

There is considerable overlap in the terms industry and public. If we consider our people, we find that they are of one industrial community and may be a member of still another "public" community. A person's allegiance and interest most certainly are governed by his own residence. His reactions to a situation which will involve his family will be more acute than to a situation that is remote to the well being of his own family.

For the family of the individual in the plant, their concern about the safety of other individuals in a plant where their breadwinner is not a member is of a lesser degree than the plant where he spends his working day. The whole of a specific community whether it be totally industrial, residential, business, or if it be any combination of these, must be examined very closely to determine where one ends and the other one begins.

Now let us examine question three. What is a serious emergency? In our industrial environment almost routine plans for the handling of an emergency are developed. In the chemical industry for example, one must assume that certain things may go wrong with an operation. Therefore, means are provided to care for an unusual occurrence. A sudden pressure rise in a reaction may be compensated for by an over-pressure device on the reactor or by cooling or by a combination of the two.

One step further, if a reactor's contents exceeds these control measures and a material is released which is flammable and which catches fire, an emergency beyond the initial scope of the safeguard is encountered. This emergency may be countered by sprinkler systems or by other methods to extinguish the fire.

Suppose a fire which exceeds the ability of the extinguishing agents occurs, then there are measures such as diking and hold-up ponds as another line of defense. If the entire reaction occurred in such a rapid fashion as to spread large amounts

of flammable materials over a wide area completely beyond the scope of sprinklers and ponds, there is the plant fire organization which becomes effective, and we border on a serious emergency.

This emergency may or may not be within the ability of the plant to contain. It may endanger adjacent operations which in turn can create even more serious problems. If the material which is burning and which has threatened the surrounding plant area also gives off toxic vapors, the entire plant is then threatened and if the plant is adjacent to a residential or business community we have a threat to the "public." Since there is a threat to the "public" and it has been recognized, most plants have plans for the containment of serious emergencies.

In one area it may involve only the operation of adjacent industrial organizations. In another it may involve a total industrial-business-residential area. The Kanawha Valley may be considered as an example of such a heterogeneous community and an example of how industry plans for the containment of an emergency. So, question four is best answered by a description of the Kanawha Valley Industrial Emergency Planning Council.

The KVIEPC includes the area along the Kanawha River from Gaudy Bridge to Nitro, a distance of about 60 miles, and from Charleston north along the Elk River to Clay, a distance of about 43 miles. High hills border these rivers and limit the size and number of ways in and out of the greater Kanawha Valley. These limiting factors were emphasized during a serious plant emergency when aid to the stricken plant was delayed because of heavy traffic that included many sightseers.

Following this incident members of industry met and developed the Kanawha Valley Industrial Emergency Plan which was approved on May 21, 1952. Refinements of the Traffic Diversion Plan and expansion of the Emergency Plan's scope followed. The name of the mutual aid group was changed to the present one but the objectives remained as they are today. The valley is particularly heavily industrialized from Belle to Nitro. In the KVIEPC we have 34 members and 31 associate members, 100 per cent of the eligible groups.

The objectives of the KVIEPC are eight-fold:

(1) To establish a well-coordinated and practical long range plan for handling industrial emergencies in the Kanawha Valley.

(2) To build public confidence in and understanding of how to cooperate with established industrial and utility emergency procedures.

(3) To insure cooperation with municipal, county and state agencies to the same extent that the public may be involved or affected by industrial emergencies.

(4) To encourage self-sufficiency in each industrial plant and utility installation with material assistance from others within set limits.

(5) To establish an organization of Kanawha Valley industries and utilities in order to facilitate cooperative action to any degree in event of an all-out emergency (conflagration, sabotage or enemy action).

(6) To set the stage for appropriate evaluation of potential industrial emergencies and appraisal of the adequacy of available materials and manpower to cope with foreseeable emergencies.

(7) To improve techniques and facilities for emergency control through:

a. Application of available manpower and facilities more effectively, and

b. Supplementing protection within practical limitations.

(8) To cooperate fully with national efforts to safeguard industrial plants and their utilities in order to insure continuity of production in peace and war.

Each organization sends to the council at least one official representative and one alternate. The council is responsible to the managements of the participating industries and utilities. The council elects a president, vice-president, and board-of-directors all of whom serve for one year. The president and vice-president serve as chairman and vice-chairman, respectively, of the board of directors. All past chairmen of the board will serve as ex-officio members to the board.

Board-of-director members serve as chairmen of the standing committees of KVIEPC. These committees are: communications, fire protection, materials assistance, medical and welfare, membership and by-laws, program,

public relations, risk evaluation, security and traffic.

Other officers of the council are secretary and treasurer.

The "grits" of KVIEPC is our traffic diversion plan. Zones have been established and all police agencies in each zone have cooperated to work out methods of diverting traffic from the disaster scene and at the same time pass through roadblocks the aid needed at the stricken area. This plan is tested continually by dry runs and revised as the need is observed.

Frequently one or more plants in a given zone will simulate a serious emergency in order to test other facets of the mutual aid plan.

It is well to emphasize that there is no magic number that activates KVIEPC. KVIEPC is a method of operation, a way of cooperation, a simple policy of good neighborliness. When a plant has an emergency that threatens to become serious, an authorized representative of management will call that state police nearest their plant. He will state that an emergency exists and request that the traffic diversion plan for his area be activated.

If assistance in the form of material, manpower or a combination of these is required, it is requested by the involved plant who calls direct to a member organization for the aid needed. (Our KVIEPC has been alerted and has rendered assistance in the "natural" disasters that have afflicted the communities within the scope of our operations since the inception of the plan.)

Question five. Within the KVIEPC the total public is included. The plan as outlined has as members all of the individuals who either manufacture or handle dangerous materials or who find themselves giving service to such industry or who are themselves concerned with the preservation of life and property.

Civil defense plays an increasing part in the containment of emergencies whether they be natural, industrial or caused by enemy action. Civil defense in a well-organized sense is largely accomplished by existing officers of a community who simply swap hats when the need arises. Possibly the largest segment of the non-industrial public finds its place in industry's plans for the containment of an emergency in or-

ganizations such as the Red Cross, Salvation Army, civil defense auxiliaries, and fire and police auxiliaries.

The responsibility for coordinating the public's effort, in answer to question six, is the responsibility of the duly elected public servants, whether the public consists totally of a residential community, or of a residential, business community, or even if industry is included within the boundaries of such community. It is his job to make certain that through all avenues of communication, people are advised of the emergency that exists and are instructed as to how they might best aid in returning the situation to normal.

It is his responsibility through his department of public safety to see that committees and sub-committees in whatever degree necessary are formed and that the work of traffic control, of the control of people in and out of the area in private and other vehicles is determined; that evacuation routes for the general public have been established; that emergency supplies in the kind and amount needed as dictated by the community's character have been established; and that his plans have been tested through dry runs to a point where he can expect that the general reaction, when the emergency alarm is given, will be carried out along pre-determined lines.

Since industrial emergencies can involve a total community and because such events may be caused by natural forces and considering that the total community may have developed after the industrial start, we must concern ourselves with moral rather than legalistic values.

In an area where a mutual aid plan exists, is tested and working, the public job is largely one of considered cooperation. Where no plan exists the previously outlined one can be made to work.

First, a traffic plan must be developed. It must be tested to detect and eliminate the bugs in it. The best plan in the world is no good if shelved after its conception. Some communities have developed wonderfully comprehensive plans but have done nothing to implement them and when disaster has hit a tremendous loss of life and property has occurred.

Second, a risk evaluation group must be organized to assess the needs of a particu-

lar area. From this group will be developed lines of communication and other functions necessary for the preservation of life and property.

Third, the plan must be widely publicized. Everyone in the community must know that a plan exists. Everyone must know the responsibility that he has to the community in which he resides. Everyone must cooperate in the plans and tests to the degree that he is involved, be it to stay at home and listen to the radio or for a phone call, or to follow a diverted traffic, or to come to an assembly area for assignment.

The "five knows" of emergency planning that have been developed by KVIEPC apply to any mutual aid effort. They indicate again, public's part in planning and aiding to restore normal operations after an emergency has been dealt with.

(1) Know Your Hazards

To prevent an accident, to avoid an emergency, requires that one must recognize a hazard. Whether we are part of an industrial plant or a "communal plant" we must be able to pinpoint the type of emergency that we might encounter. The range of emergencies is wide. It might be something as personal as a heart attack, insulin shock, heat stroke and the like. It may be something as unexpected as the flash flood that claimed twelve lives this past July in our Kanawha Valley.

It might be fire, explosion, mechanical failure, inadvertent release of air or water contaminants, even toxic gas or radiological exposure.

Hurricane, tornado, earthquake or war-time are but a few more of the problems that confront one who is "hazard hunting."

It is a tribute to man that he can handle hazardous materials safely; that he can perform hazardous tasks safely. We seldom hear of an electrician being electrocuted, or a trained deep-sea diver drowning, or a "powder man" blowing himself up. The outstanding record of the Atomic Energy Commission and the various space age agencies is example enough that knowing your hazards will minimize the potential for accidents and the development of emergencies.

(2) Know Your Facilities

As a member of the chemical industry, I can vouch for the need for good plant layout, proper arrangement and specifica-

tions for equipment and machinery, prescription of adequate protective equipment with full recognition of hazards inherent in the process. We must know the limitation of our facilities if we are to combat accidents. We must be aware of the consequences of the loss of our protection devices and instrumentation, loss of control and loss of manpower who are in position to take emergency action.

(3) Know Your People

Risk evaluation such as those made by insurance engineers involve pinpointing of hazards and their potential to inflict harm to people and damage to facilities. The estimates of these hazards and their effect determines premium rates. This illustrates that no matter what we do, how we do it or where we do it, the common denominator in all of our thoughts and calculations is people. The insurance engineer's evaluation; the research engineer's project; the chemical engineer's pilot plant.

We depend upon the manufacturer of railway tank cars, of pressure vessels, or an atomic reactor to make these items with "built-in" safety factors. We have to depend upon the pilot of an airplane, the driver of a car or a chemical plant operator to take the prompt, proper action when danger appears.

We can develop, communicate and completely understand information concerning potential hazards and limitations of facilities, but if we have no plan of action, very little will be accomplished. Knowing our people means knowledge of ability to apply the emergency plan. People must have a willingness to cooperate and be motivated by opportunities to drill and test themselves.

We possess five senses: seeing, smelling, tasting, hearing and feeling. Every one is essential to accident prevention and disaster control. Even these will not produce the results we want and need if attitude is wrong. If mutual aid is to work, then the attitude of the managements concerned must exemplify the willingness to cooperate as a good neighbor. The plant or community that seeks help through mutual aid must be willing to give help in return. The principle of self-sufficiency must prevail to the maximum.

Government agencies and authorities and private agencies concerned with the protection of life and property must eliminate

political bias and genuinely cooperate to seek a common plan for emergency action.

(4) Know Your Community

In an industrial sense community relations are affected by an industrial emergency. In a "communal" sense industry is affected by a "public" emergency. For instance, an auto smashes a power line and shuts down the community including industrial operations. A train derailed and spills flammable, toxic material into a tank farm. A large supermarket is closed, a leak in a gas main occurs, an explosion throws flaming debris throughout the "communal" and industrial community.

From past experience we can predict what an uninformed "public" will do in each specific emergency situation. If you don't believe me, read Donald Robinson's *The Face of Disaster*. He has compiled an excellent bibliography of re-search in "disaster behavior."

An informed "public," a "public" with a tested mutual aid plan that carries assurance for those who might panic and discipline for the curiosity seekers is the sort of "public" that we are discussing today and working toward achieving tomorrow.

Knowing your community means fulfilling a moral responsibility to do one's part in a community concept of emergency planning and disaster control. The introduction of the fire chief to the plant emergency on the evening of a fire makes no sense. The change in a traffic pattern that might affect emergency mutual aid to a plant will not be recognized as a hazard unless police authorities are aware of their part in the overall plan. The Salvation Army, Red Cross, members of the press cannot be expected to perform their services without guidance of those who know conditions and potential dangers. The director of civil defense should not have to dictate emergency orders involving hazardous conditions beyond his technical abilities to recognize and control.

(5) Know Your Plan

Howard Minckler, director of manufacturing of the Organic Chemicals Div., Monsanto Chemical Co., speaking at the Fourth Annual Industrial Mutual Aid and Disaster Control Conference at Cincinnati, May, 1960, said while discussing mutual aid, "The point I want to make is that the road to

preparedness begins at home. We have to make the effort to stand on our own two feet before we can expect others to join us. . . . We must make detailed plans to avoid the risk of being unprepared to meet these responsibilities."

Your plan has to be designed to meet the specific and unique needs of your industry, your community, your topography, your people. A single point of authority is desirable for planning and must be strived towards in serious emergency though the pitfalls to such an achievement are many.

In the Kanawha Valley, we speak of a cooperative authority and a procedure that brings together the leadership necessary to cope with a given set of conditions.

You have heard of the title "Emergency Director." It has been used many times. I tell you there ain't no such animal. We do not direct emergencies or disasters. The chaos resulting from an emergency dictates the requirements for control.

If your house is on fire, you have called the fire department and you direct the chief to the scene of the fire and give him information about what's burning, location, etc. The fire chief determines what sort of equipment is necessary to extinguish the fire and to protect adjacent structures from exposure. Prompt-arriving police determine who comes into the fire area and is available to obtain aid such as medical or additional fire equipment. The need dictates and directs the action.

A traffic diversion and control plan is of the utmost importance. We must be assured that emergency aid in any form can be called for and can get to a stricken plant, quickly. Also, the problem of evacuation, clearance of the injured to hospitals is of equal importance. A master plan for cooperative action between fire departments in a specific area is fundamental.

At one plant in the Kanawha Valley eight fire companies from six municipalities worked successfully in a team operation to provide water for fire fighting at a chemical plant which lost its own protection because of an explosion. Now the fire services are in the best position to solve their own problems but it is up to those depending on the fire service to let them know what these potential problems might be.

A good basic medical plan including rescue and first aid at the scene in cooperation with fire and police services and planned usage of local hospitals are practical parts of any plan for disaster control.

Material assistance is a well-understood term in mutual aid circles. But unless there is a registry and procedure to ask for specific assistance in an emergency there will be no guarantee that the mutual aid will be efficient or effective.

Your plan should start with your personal

I. Who is industry?

II. Who is the public?

III. What is a serious emergency?

IV. How does industry plan for the containment of an emergency?

V. How is the public included in such plans?

VI. Who is responsible for coordinating the public?

Appendix

Emergency exercises are practiced in earnest. Our folks know that an incident could occur which would call upon all their skills. That might sorely tax their ability to act reflexively—to do the right thing at the proper time. There is a minimum of joking and kidding during these tests. Occasionally, someone is doused by a water hose or showered with foam as the simulated fire fighting activities are carried out. Such things are accepted with good grace. Once in a while a really hefty "victim" is chosen and then we have many comments from the litter bearers.

In 1957, the National Association of Manufacturers visited Charleston, West Virginia, and made a film about the Kanawha Valley Industrial Emergency Planning Council. A copy of this film may be borrowed from the NVEPC, or from the West Virginia Safety Council, 808 Nelson Building, Charleston, W. Va.

Last year Monsanto was the scene of one of the many drills that are conducted to test in-plant plans as well as several facets of the mutual aid plan.

Community Mutual Aid

The Five "Knows"

- I. Hazards—Fire, Explosion, Electric Shock, Toxic gas
 1. Gas lines (other buried pipelines)
 2. Electric service (transmission lines, distribution systems)
 3. Transportation through city (Train, truck, pipe lines, air lines, boat)
 4. Flammables stored in area (Gasoline in service stations, autos, trucks, HOMES, stores)
 5. Adjacent industry (its threat potential)
- II. Facilities
 1. Homes and materials stored therein
 2. Business's such as Grocery, General Mer-

knowledge of "What you would do in case of fire." What is your building plan, area plan, plant-wide plan, the plan to seek outside aid? What are your ties with Civil Defense and the Red Cross?

In closing may I stress that people cause disasters and people restore conditions to normal. We can each do our part insofar as each of us knows his job and participates fully. To sum up, let's look once again at the original six questions and their answers as to what part the public plays when industry has a serious emergency.

People Property Equipment	Industrial Plant	Total Community	Industrial Residential Business Plant
People Property Equipment	Communal Plant		
One that threatens to involve a total industrial or communal plant.			
Plant emergency plans and mutual aid organization.			

Thru mutual aid, CD and/or other emergency service organizations.
Duly elected public officers with aid from business and industry management. A cooperative authority.

chandise, Dry, Exterminators, Hardware, etc.
other public buildings

III. People

Housewives, children at home, infirm and ill at home
School children
Business people
Professional persons
Artisans and craftsmen, etc.

IV. Community

Street layout: dead-end streets, width of streets, surface.
Business and residential distribution throughout community.
Building's size, type, construction, heating, ventilation access.
Schools, churches and other public building.

How protected when empty.

Police and Fire Protection

Mutual Aid

Civil Defense

V. Emergency Plan

Fire Drills—Evacuation Drills—RESCUE

DRILLS

Home

Schools, churches

Hospitals

Business buildings

Other public buildings

Methods of inspection—checking for flammable or toxic vapors—gas leaks (natural gas—oxygen—CO—CO—cleaning fluids, etc.)

Power failure—who affected, how.

Fuel supply failure—Protection, how.

WEATHER FORECASTING FOR BOATING SAFETY

By PAUL H. KUTSCHENREUTER

Asst. Chief, U. S. Dept. of Commerce, Weather Bureau, Washington 25, D. C.

THREE DROWN IN SUDDEN SQUALL—HEAVY SEAS CAPTIVE PLEASURE BOAT—COAST GUARD RESCUES SIX

How often have you seen similar headlines? What can be done—or could have been done—to prevent, or at least to lessen the number of such accidents? Know the weather!

The June 1961 issue of the *Ensign* includes a summary of the Coast Guard's tabulation of 3,790 recreational boating accidents reported in 1960. Of the 739 deaths resulting from accidents in pleasure craft, seven and one-half per cent were attributed directly to either weather or sea conditions. Of the 926 injuries, four per cent were attributed to weather and sea conditions.

Inadequate weather safety precautions, presumably by less experienced boatmen, during the calendar year 1960, then, resulted in nearly twice as many deaths as it did in injuries. It is extremely likely, also, that weather and sea conditions were contributing factors in an important percentage of the other causes such as excessive speed, unsafe loading, over-powering of the hull, inexperience, inattention, forgetfulness, and poor judgment.

Recognition of the importance of weather forecasting for safety of life at sea dates back to the very beginning of the United States Weather Bureau. A joint Congressional Resolution, HR 143, signed on February 9, 1870, created the first U. S. Government weather service. By this Resolution the Secretary of War was required to provide for taking meteorological observations and to provide information on the approach of storms on the northern lakes. These functions were assigned to the Signal Service of the U. S. Army, predecessor to the present U. S. Department of Commerce Weather Bureau.

Although the intent of this initial Resolution was to provide weather information for the safety of shipping on the Great Lakes, recreational boating has developed and grown to such an extent that the provision of information and warnings for

light pleasure boating is an important aspect of the Weather Bureau's service.

According to estimates made by the Outboard Boating Club of America and the National Association of Engine and Boat Manufacturers, in 1960 there were over eight million pleasure boats, including cabin cruisers, in operation throughout the U. S. seacoasts, Great Lakes and inland waterways. This is an increase of over a million pleasure boats since 1957. These organizations estimate that the number of individuals making at least two or more boating pleasure trips during 1960 is approximately 40,125,000. This large increase in the popularity of pleasure boating has created a problem of familiarizing the large number of new skippers with weather safety rules.

Weather Hazards

Of the weather factors affecting boating safety, the most important are: wind and waves, fog, lightning and heavy rain. Of these, wind and waves are by far of major importance. Fog and heavy rain are important primarily from the standpoint of reduced visibility which, in turn, makes navigation difficult. Except for fog, these weather hazards result mainly from thunderstorms, squalls, strong cold fronts, tornadoes over inland areas, deep mid-latitude storms, and tropical storms and hurricanes. In addition, there are the relatively infrequent but none the less very damaging seiches on the Great Lakes.

From the standpoint of weather-caused fatalities among pleasure boat enthusiasts, the sudden squall or thunderstorm tops the list. These frequently develop and move quite rapidly in otherwise fair weather conditions; their exact path and time of occurrence usually cannot be forecast very far in advance. The unwary skipper can thus easily be caught off guard and away from safe mooring.

Dollar-wise, the pleasure boat owner sustains the greatest loss from major mid-latitude storms, tropical storms and hurricanes. These are usually well-developed before

reaching our coastal sections, however, and it is generally possible for the Weather Bureau to issue warnings at least 16 to 24 hours in advance of their approach. Advisories in connection with such storms invariably include advice to small boat skippers not to venture too far from shore during the early stages of the storm; later, to seek shelter and safe mooring as the storm approaches.

For example, the advice issued in connection with Hurricane Carla, whose center passed over Port O'Connor on the Texas Coast on the late afternoon and evening of September 11, 1961, are an excellent example. As Carla moved through the Yucatan Channel on September 7, the Weather Bureau advisory broadcast shortly after 1:00 p.m. stated that Carla was a dangerous hurricane and that its force would soon be felt over most of the Gulf of Mexico. The same advisory also cautioned small craft from Sabine Pass, Texas, to the Florida Keys not to venture too far from port. This cautionary advice was later extended to include all Texas ports. As Carla approached the coast, boatmen were advised to seek shelter and safe mooring.

In many cases there isn't a really safe mooring in low lying coastal sections to the immediate right of the path of the hurricane center. Wind, tides and waves combine to tear boats loose from their moorings and convert them into veritable battering rams to destroy any structures in their path. The weather-wary skipper is well advised to complete precautionary mooring for maximum security well in advance of the onset of hurricane waves and tides and not to attempt to change moorings once hurricane waves and winds have set in.

While the experienced pleasure boat skipper generally recognizes and usually appreciates the importance of winds, waves and reduced visibility, the hazards of lightning are frequently overlooked. Actually, danger from lightning at sea has been recognized ever since the days of Ulysses. The English Navy lost many ships because lightning ran down the masts, caused fires aboard and sometimes punched holes in the hull. The use of a chain as a grounding device dates back to Captain Cook's Pacific expedition in 1768.

During a thunderstorm the operator of an outboard motor boat alone in open waters

is almost as inviting a target as a sailboat with its masts. This is equally true also for larger power boats with non-metallic hulls and especially for those with inadequately grounded electronic equipment. Especially vulnerable is the radio antenna; unless it is grounded directly to the water, this is a particularly lethal instrument in an electric storm. Without adequate grounding, the antenna should be lowered whenever a thunderstorm is encountered.

An equally good target for lightning is the fisherman who keeps right on fishing in spite of a thundersquall. A wet, metal-tipped pole is as dangerous as an ungrounded antenna.

What the Pleasure Boat Skipper Needs to Know

How can the pleasure boat skipper keep from becoming another statistic in the log of weather-caused boating casualties? The first requirement is to observe three weather safety rules:

Weather Safety Rule No. 1: Check weather and sea conditions before setting out.

Weather Safety Rule No. 2: Keep your weather eye "peeled" while out.

Weather Safety Rule No. 3: Keep checking on weather forecasts and warnings until you return to your mooring.

These three rules could readily be combined into one simple statement: Keep up to date on the weather.

What the Weather Bureau is Doing to Meet the Need

The vast majority of pleasure boat cruises cover periods of from two to twelve hours. All of the weather information needed in order to observe these safety rules is readily obtainable from the United States Weather Bureau. Forecasts especially prepared for the purpose are readily available in frequent radio broadcasts. A corollary safety rule therefore is: *Keep a good radio receiver aboard.* The forecasts are also available by telephone from your local Weather Bureau office—if you can get through his usually busy telephone.

The Weather Bureau issues annually a series of coastal warning facilities charts covering all areas of the U. S. seacoasts, including the Great Lakes and Puerto Rico.

These charts contain explanations of warning displays made by the Weather Bureau at over 500 seacoast points in the U. S., voice weather broadcast schedules of commercial and government radio stations operating on standard bands, as well as those on the 2.3 mc. frequencies. These charts are available from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., for ten cents each. Those for your own area are usually available also at yacht clubs, power squadrons and elsewhere in the area.

Marine forecasts and warnings covering the following 36 to 48 hours are issued every six hours. These now cover much smaller areas than they did a few years ago. As a result, the forecasts contain much more detail and are of greater use in planning boating operations. For example, years ago only a single forecast was issued for the stretch of coastal waters from Eastport, Maine, to Block Island, Rhode Island. Separate special forecasts for boating interests are now issued four times daily covering the area 15 miles seaward and extending from Eastport, Maine, to Portsmouth, N. H.; Portsmouth to Chatham, Mass. and Chatham to Block Island, R. I., as well as separate advices from Boston Harbor, Buzzards Bay and Narragansett Bay. Special boating forecasts are also issued for comparable small areas along the rest of the U. S. seacoasts and for a number of inland lakes, dams and reservoirs.

Weather observing stations have been established at a number of seacoast and inlet points to furnish reports which include not only wind, weather and visibility but wave heights as well. Bulletins containing forecasts, advices and reports of current weather to boatmen are broadcast by AM and FM radio and TV stations and also by marine radiotelephone stations on regular daily schedules.

To increase the small boat skipper's appreciation of weather safety factors, the Weather Bureau arranges weather exhibits at a number of the larger motor boat shows which are usually held throughout the country in the late winter and early spring months each year. The theme of these exhibits has been "Boating Safety through Weather Knowledge." Valuable assistance has been received from the U. S. Power Squadrons and numerous other organiza-

tions as well as boating enthusiasts. All of these have been very helpful to us in making improvements in weather service to promote the safety of navigation among small craft operators.

To improve the short range forecast accuracy of hurricanes and severe local storms, the Weather Bureau has installed modern weather observing radars at a network of stations. Our eventual goal is to have every square mile of the U. S. and immediately adjacent waters under constant weather radar surveillance. Information from these radars is included in regular and special forecasts on AM radio stations, in the special short range forecasts broadcast especially for boating interests in some areas and in the automatic telephone forecast service in many areas. By keeping in touch with any of these, pleasure boat skippers are less likely than ever to encounter sudden or unexpected local squalls and thunderstorms.

An amazing recent addition to the forecasters' weather observing tools is the weather satellite Tiros III is still in orbit and has been instrumental in pin-pointing several hurricanes and typhoons. It gave the first indication of the formation of Hurricane Esther. Tiros I showed a unique square cloud formation at 2:00 p.m. on May 19, 1960, approximately 50 miles west northwest of Wichita Falls, Texas. This cloud formation moved northeastward and later spawned tornadoes and hail.

Future satellites are planned to help maintain a constant broad-scale weather surveillance of the entire globe. Radar, then, will give a "close-up" picture of important segments of the broad-scale weather patterns detected by the satellites. Study and correlation of these will further improve the forecaster's knowledge and understanding of the various physical factors at work in the atmosphere and hence his ability to further improve his forecasts.

How to Get Boating Weather Information

Insuring that weather information and advice are readily accessible to the ever-increasing number of small boat skippers still poses a problem. This becomes particularly acute during summer weekends and holidays and especially in many of our large metropolitan areas. In earlier years, one could easily telephone the Weather Bureau and talk to the forecaster. As with boat-

ing, however, requirements in other areas for up-to-date weather reports and forecasts have also expanded. The busy-telephone has become a serious problem. There have been instances where people have tried in vain for as much as two to three hours to telephone a Weather Bureau office.

More telephones and more people to answer them is not the solution. The Weather Bureau began looking around for automatic devices capable of bringing especially tailored forecasts to large segments of the population. In eleven of our larger cities the telephone company has cooperated by installing automatic telephone forecast service. A twelfth installation will be added early next year. Information available by this facility includes local weather and forecast information which the small boat skipper can use to good advantage in planning his outing. More important: since local forecast demands of most of the public are satisfied by this means, it improves the odds that the pleasure boat skipper will not encounter a busy telephone when he seeks specific boating weather information directly from the Weather Bureau.

To provide special boating weather and forecasting information in areas where this demand is particularly heavy, the Weather Bureau has been experimenting with the installation of special broadcast equipment. Continuous FM marine weather broadcasts for harbor and boating operations are now made in the New York and Chicago areas. Both transmitters (KWO-35 in New York City and KWO-39 in Chicago) operate on a frequency of 162.55 MC, each year from May through October. A number of surplus receivers have been made available to yacht clubs and other marine interests in these areas in order to help evaluate the programs.

In Washington, D. C., special boating forecasts for the Chesapeake Bay area are transcribed by the Weather Bureau forecasters and are available by dialing NATIONAL 8-4100. In Baltimore, upper Chesapeake Bay area forecasts are similarly available by dialing SO 6-3382; in Los Angeles, ORchard 0-0234 is the marine weather forecast number.

In Providence, still another pilot project in rapid dissemination of forecasts directly to the public is underway. FM multiplex

is used for continuous broadcasts which currently cover the hours from 6:30 a.m. to 2:30 p.m. on Mondays, 6:30 a.m. to 7:30 p.m. Tuesday through Saturday, and 7:30 a.m. to 2:30 p.m. on Sundays. These broadcasts include boating forecasts as well as spot weather reports from Coast Guard stations and other short points. Here, too, in order to evaluate the service, receivers have been installed at several yacht clubs, docks, and other places where the recipients have agreed to give us the benefits of their comments and suggestions.

Scheduled marine weather forecasts and warnings are broadcast on regular schedules by marine radiotelephone stations; special warnings are broadcast on receipt. Hourly and special aviation weather reports and aviation advice are broadcast by air navigation radio stations at 15 and 45 minutes past each hour; some, such as at Andrews Air Force Base in Maryland, have continuous broadcasts. These broadcasts include wind, weather and temperature and are of use to the small boat skipper. Schedules and frequencies for these as well as other weather broadcasts of interest or use to the pleasure boat enthusiast are listed on the Coastal Warning Facilities Chart mentioned earlier.

Finally, what aids are available to help "keep your weather eye peeled" while out? The careful skipper is well advised to take advantage of available weather courses such as those offered in many localities by the U. S. Power Squadrons. In most instances he will find that his local Weather Bureau forecasters conduct these courses during their off-duty hours and that they provide much in the way of specific information on how to obtain and to make the most of the weather and the forecasts available in the local area and vicinity.

In summary: Helping to promote boating safety is an important function of the U. S. Weather Bureau. In effect, it is a part of our organic legislation. The Weather Bureau makes special weather observations, prepares forecasts and warnings for increased boating comfort and safety. In cooperation with the Coast Guard, Coast Guard auxiliaries, power squadrons, yacht clubs, government and commercial radio stations and any other means available, it does its utmost to see that this information

reaches all marine interests. Intelligent and effective application of available weather information in promoting boating safety is,

in the final analysis, up to the skipper. Even here, the Weather Bureau helps provide guidance and suggestions.

ENGINEERING SMALL BOATS FOR SAFETY

By GORDON H. MILLAR

Chief Eng., McCulloch Corp., Scott Div., Minneapolis, Minn.

Over the past ten years an increasing number of people have adopted boating as a means of recreation and a hobby. This trend, and the ability to participate in this wonderful sport, has been made possible primarily through the availability of outboard motors and boats. It is possible for almost anyone to buy a boat and an outboard motor, and with little or no training and completely unaware of whether or not the boat and engine combination is a safe marine vehicle, take his family out for a weekend or an afternoon on the water.

In the past two or three years it has become more and more understood that safety problems involving boats and motors are related to several primary factors. First, boats must be made sufficiently safe so that even in the hands of the inexperienced the boat does not become dangerous. Secondly, the combination of the boat and engine must be rated in a way and sold under circumstances which make a satisfactory boat-engine combination.

Most people have had the opportunity, I am sure, to observe, in populated boating areas, boats which are both underpowered and overpowered and which are dangerous in the hands of the inexperienced boat operator.

With rare exception, engines and automobiles are not sold separately. It is allowable that boats and motors are a completely different breed than land transportation vehicles; however, the combination of a boat and motor still represents the marine vehicle and there is no reason to expect the average uninitiated consumer to possess the knowledge necessary for making the best selection.

A partial step in the direction of boat and motor combination selection exists in the ratings which are provided by the O.B.C.

Although there is no law governing the size of an engine a person can put on a given hull, boats rated by the Outboard Boating Club state specifically on the boat name plate the size of engine for which the boat is rated and the number of people the boat can carry.

From a corporate point of view, however, we at McCulloch Corp. feel that the responsibility of a manufacturer goes much further than a rather loose attempt at wedding the boats and motors. It is our basic philosophy that boats, motors, and the marine vehicle, should be designed to be completely compatible with each other; individually designed to be safe in the hands of the inexperienced and that these combinations should not allow optional selections of engine power and boat performance which would produce an unsafe marine vehicle.

From the engine point of view, safety consists primarily of operating reliability and freedom from failure of rotating parts which may cause human injury due to fragmentation. In this regard, engines today are the most reliable, the safest, and best performing power plants ever made available to the consumer.

The boat problem is not as clear cut. It is impossible in the short time available to cover all the problems which the average boat builder and manufacturer must face. In the design of a small boat, however, consideration must be given to stability, performance, construction, ability to install accepted auxiliary safety equipment, load carrying ability, and safety with and without power under all conditions of weather the boat will encounter.

With the introduction a number of years ago of the fiberglass method of construction, tremendous latitude was made avail-

able to the small boat designer with regard to hull shape, structure and appearance. I believe it is adequate to state that from the standpoint of performance, the lines of the bottom of small boats must be laid out in the manner which will produce smooth performance in turns, level riding capability, and freedom from abrupt boat reactions which can occur with the inexperienced operator. Part of the solution to the boat handling problem is a knowledge of the hydrodynamics of boat bottoms and the positioning of the keel and planing surfaces in a way which will produce an accepted performance standard.

In order to do this with some reasonable assurance that a workable combination will result, the small boat designer must know from the very beginning the weight and performance of the power plant. When boats are designed to accept any and all engines, compromises in performance result which detract from the safety of the boat combination. The manufacturing solution to the problem of small boat performance is in our judgment the integration of the boat and motor package so that the small boat designer eliminates the need for compromise and produces a small boat and maximum performance for the power plant available and with the maximum degree of safety which can be built in a given hull design.

Figure 1

To illustrate this point, I would like to refer to Figure 1. This figure is a diagram of a cross section of a small boat where consideration has been given to a hull structure rigidity, flotation, sheer line configuration for splash control, boat configuration for ride control, and designed with the basic thought that the passenger compartment will hold people. This can be seen in the cross section; tremendous rigidity in the beam strength is achieved through the use of controlled bottom sections which are channelled to give a very high section modulus.

lus. The sides of the hull are formed in a manner which provides both longitudinal and lateral rigidity and provides space for permanent flotation.

Figure 2

The next series of figures show a model of this hull cross section in various conditions of flotation. Figure 2 shows the condition when both the side tanks and the bottom tanks formed by the hull structure are used for flotation and the passenger compartment is punctured in a manner which would simulate a free flow of water into this part of the boat. The center of gravity has been adjusted in the model to the same height as produced by the outboard motor and hull combination. As can be seen in

Figure 3

Figure 3 this condition is a safe condition and although the boat is lowered in the water it remains upright and does not capsize.

Figure 4 shows the same model in a condition of submersion which punctures both the passenger compartment and the double bottom flotation tank. Once again, in this condition the boat will float in an upright

Figure 4

fashion although it will be lower in the water. Again, this is considered a reasonably safe method of flotation as the passengers will remain contained in the hull and stand a more reasonable chance of rescue.

Figure 5

Figure 5 shows a situation where the bottom flotation tank remains unpunctured and the side flotation tanks are punctured as well as the passenger compartment. Figure 6

Figure 6

ure 6 shows what happens under these circumstances as the relationship of the center of gravity of the hull with regard to positioning of the flotation in the hull structure produces an unsafe condition and the hull no longer remains upright but turns upside down.

The distribution of flotation is tremendously important in any small boat design. It is not adequate to provide only vacant space for flotation as flotation tanks themselves can be eventually punctured and as was shown, under certain conditions, can result in a dangerous flotation system. It is also not necessary to fill all compartments with foam as certain conditions of tank flotation are completely adequate for both flotation and stability. It is, however, tremendously important to fill the key flotation compartments with foam material which will remain buoyant even though the compartment is punctured.

In the hull used for the model from which the film was made, and referring again to Figure 1, it is technically obvious, that foam must be used to completely fill the side tanks so that the dangerous condition of upsetting the craft during a swamping condition is effectively avoided through proper design of the hull structure.

To reiterate again, the possibility of utilizing to the maximum the fundamentals of boat design can only occur when the engine, boat and passenger carrying ability is designed as an integrated package. When a hull is designed for a wide selection of engines, large compromises must be made in the location of the center of gravity both vertically and longitudinally as well as dimensional compromises which will alter boat performance and the ability of the boat to resist swamping.

There are, of course, many other factors affecting the safety of small boats. The ability of the boat to resist fire and the proper location of fire fighting equipment is of great importance. It is further of importance to provide proper venting of fuel tanks, proper venting of confined areas in the bilges and to minimize during the design and manufacture the chance that fuel vapors will be trapped and a fire result from a spark or open flame.

All problems related to safety, however, are more susceptible to solution when the engine and boat combination is manufactured as a marine vehicle rather than separate add-on packages. Above and beyond the manufacturing responsibility, however, continues to loom the necessity for the exercise of judgment on the part of the user. No matter how thoroughly a small boat is designed and no matter how skilled an

operator is employed, in the last analysis, certain boating accidents result exclusively from the lack of judgment with regard to weather, loading capabilities, availability of fuel, knowledge of safety devices, and the exercise of simple precautions if in trouble. It is our job as a manufacturer of marine vehicles to minimize the exposure of the user to danger when trouble does

occur and this has been done to a great degree through boat and engine integration. The ultimate responsibility for safety in performance must still rest with the user and this judgment can only be altered or improved through education. In the long run, it is education which will minimize that small portion of boating accidents which cannot be solved by intelligent boat design.

UNIFORM MARKERS FOR RECREATIONAL WATERWAYS

By KEITH WILSON

Dir., Michigan State Waterways Commission, Detroit

I have been invited to address you today to outline the recommendations that a committee of state officials on uniform markers is making to the Council of State Governments relative to the national adoption of a system of uniform navigational and regulatory markers. These recommendations are to be submitted to the advisory panel of the Merchant Marine Council, U. S. Coast Guard, at a meeting scheduled for October 31, in San Francisco, Calif. Representatives from all 50 states have been invited and, if these recommendations are adopted by that body, they will be submitted to the Council of State Governments for submission to the individual states.

To give you a brief background on this matter, and to acquaint you with some of the governmental organizations active in this field, I would like to outline to you the manner in which this study was initiated. A group called the North Central States Boating Law Administrators, which consists of officials charged with administration and/or enforcement of the boat registration and boat safety laws of the states of Kentucky, Indiana, Ohio, Michigan, Illinois, Iowa, Wisconsin, and Minnesota, first determined the need for a uniform marker system and created a special committee to investigate this matter.

This Committee came up with recommendations which were accepted by the parent organization and were then referred

to the advisory panel of the Merchant Marine Council, U. S. Coast Guard. This group recognized the desirability of action in this area and appointed its own committee which included two members from the north-central states organization and it is this committee which is making the recommendations that I am here repeating upon.

The general problem was to develop a system of uniform navigational aids suitable for all water areas and types of watercraft to supplement the Coast Guard system, and still be compatible with it. Specifically, there existed a need for water signs or markers which would convey to the small-craft operator information which under the Coast Guard system is normally found on navigational charts or in published regulations. Small-craft operators, often without experience and without navigational charts, need markers on the water itself or on the adjacent land to indicate presence of natural hazards, zoned areas, and directions and distances.

The committee divided the problem into two general areas, the first being to develop a system of regulatory markers to indicate to the watercraft operator the existence of regulatory areas, speed zones, restricted areas, etc., and the second being to develop a system of navigational aids to supplement the U. S. Coast Guard system.

In attempting to evolve a satisfactory buoy, careful consideration had to be given

to the colors of the buoy and its markings, since the Coast Guard has almost completely pre-empted this field and, unless our regulatory marker was in a design acceptable to the Coast Guard, it could not be used on federal waters. Therefore, the colors international orange and white were selected, since these colors have been designated by the Coast Guard for use on special purpose buoys. To avoid confusion with other special purpose buoys, it was agreed that the buoy would be painted white with an orange band at the top and an orange band at the bottom of the buoy. The white area between the bands would be used to place any special symbols or lettering to indicate the purpose of the buoy.

The committee, after further deliberation, decided that it was desirable to standardize the markings which would be used on the white portion of the buoy, and, after experimenting with a multitude of markings, settled upon the use of three distinct designators for this purpose. The first designator consists of a diamond shape which is to represent danger outside the diamond, in letters of black, will appear an explanation of the specific danger involved. In cases where boats are to be absolutely prohibited, a diamond shape with a cross will be used and any explanation given will be given outside of the diamond itself.

The diamond alone would be used when you wished to warn the boatman of some danger ahead, especially to himself, such as a submerged obstacle or a dam or something similar. The diamond with a cross would be used when you wished to absolutely prohibit boat operation within an area and would be used to mark swimming beaches, wildfowl preserves, waterfalls, and similar areas.

Where a regulation has been established, the same buoy with a round designator would be used, with the nature of the regulation indicated in black letters within the designator itself. This designator indicates prohibited or controlled activities and would be used to warn of speed limits, no wake areas, and similar prohibitions.

For informational purposes only, a rectangular shape is provided and the purpose of this designator is to inform boatmen of distances, directions, and the availability of services. It is considered likely that this

type of information will generally be provided on shore signs because of the limited surface of a buoy, but a buoy can be used if desired.

For navigational buoys to supplement the Coast Guard system, the committee attempted to follow the federal system to the greatest extent possible. However, certain problems are faced on inland lakes that do not exist on navigable waters of the United States to any great degree. This required the adoption of a special system of markers for this purpose.

The Coast Guard system is called a "lateral" system of markers and depends upon a given body of water having a definite inlet or outlet or, where such does not exist, presumes the inlet to be to the north and the outlet to the south of the given water area. However, many inland lakes have a multitude of inlets and outlets and also have sufficient obstructions and islands to preclude the use of the lateral system of buoys.

On these waters, a "cardinal" system of buoys is more effective and this system depends upon the use of buoys which permit travel to the south or west or to the north or east of a specific type of buoy. The committee found it necessary to adopt both systems in order to adequately deal with the varying conditions found on interior waters of the various states.

The committee therefore recommends that the lateral system be used on well-defined channels, including rivers, which would require the use of the all red and all black buoys used by the Coast Guard. In these situations, a red and a black buoy will be installed at both ends of the channel so that there shall be no question as to the fact that boats should pass between solid red and solid black buoys. Any staggering of the black and red buoys should be limited to instances where they are close enough together to eliminate any possible confusion, and they should then be installed in conformity with the buoys at the beginning of the channel. The use of numbers on these buoys is discretionary, but if used, the numbers should be colored white and may be reflectorized. Odd numbers should be used on black buoys and even numbers on red buoys.

In those instances where there is no well

defined channel, or the obstruction is of such nature or in such a location that it can be approached from more than one direction, a cardinal system will be used, by using a white colored buoy with a red top or a white buoy with a black top, the width of the top color to be approximately one-third of the portion of the buoy showing above the water level. Navigation will be to the south or west of the red-topped buoys and to the north or east of the black-topped buoys. The use of numbers on these buoys is also discretionary, but, if used, the numbers should be colored white and may be reflectorized, and shall be placed on the top portion of the buoy. Odd numbers should be used on black-topped buoys and even numbers on red-topped buoys.

In cases where the obstruction is of such a nature that boats should go outside, that is away from the shore around the end of a reef, a buoy striped vertically with red and white stripes, the white stripe to be twice the width of the red stripe, shall be used. The significance of this buoy is that boats should not pass between it and the nearest shore.

Use of this system will require only that a boatman have a reasonable idea of the direction of north and, thereafter, he can proceed throughout any body of water marked under this system without reference to charts or other material. Of course, this assumes a working knowledge of the buoyage system, and each of the states is expected to give wide publicity to this system when putting it into operation.

The committee has also adopted a standardized color for use on a mooring buoy, the buoy to be white with a blue band through the center. The Committee adopted the color white for use on all other water structures, such as ski jumps, diving rafts, etc., as the principal designating color.

Because many of these aids will be used at night, the committee has also made recommendations relative to the use of reflectorized materials or lights. If reflectors are used, a red reflector will be used on a solid red buoy, a green reflector on a solid

black buoy, while all other buoys will have a silver or white reflector.

Whenever navigational lights are used, they shall be flashing and the color of the light lens will be as outlined for reflectors. That is, all red buoys will have red colored lenses, black buoys will have green colored lenses, and all other lights will be white. Whenever lights are desired on bridges, they shall be fixed red lights marking the edges of the safe channel with a single fixed green light to be placed over the center of the safe channel so as to indicate the maximum vertical clearance at that point.

The Committee made one final recommendation, and that is that the flag prescribed by the Underwater Society of America for use during diving purposes be adopted and recognized by the individual states. This flag is red with a white diagonal stripe running from the upper left hand corner to the lower right hand corner.

The committee has spent a good deal of time and research in arriving at these recommendations and we believe that we instituted this study at a propitious time in that most states are just now beginning to recognize the need for such a system. We feel that this system will provide for every reasonable need of any body of water and that through use of a standardized system on a nation-wide basis, confusion and the likelihood of misinterpretation of the meaning of these buoys will be greatly reduced. However, to be effective, it will be necessary to secure the affirmative action of each of the individual states and it is in this area that individual boatmen, boating organizations, and boating groups can be of great assistance both to themselves and to the Council of State Governments.

I urge each of you to encourage boating officials in your state to adopt this system when the day arrives that such markers are required on waters of your state. If we can begin on a uniform basis before various states have an opportunity to institute their own special programs, the problem should be greatly reduced and it should be much easier to maintain uniformity in future years.

THE MOBILE BOARDING UNIT IN LAW ENFORCEMENT AND BOATING SAFETY

By CAPT. J. J. HUTSON, JR.

Chief, Port Security and Law Enforcement Div. United States Coast Guard
Washington, D. C.

It often comes as a surprise to many of our citizens to find that the Coast Guard functions as a water-borne law enforcement body, since most people, when recalling this service to mind, think only of the search and rescue functions which our forces perform. However, the law which states that Coast Guard "may make inquiries, examinations, inspections, searches, seizures, and arrests upon the high seas and waters over which the United States has jurisdiction, for the prevention, detection, and suppression of violations of laws of the United States" is not really new.

When originally established in 1790, the Coast Guard, then called the Revenue Marine, was primarily concerned with law enforcement, in particular the apprehension of smugglers who were evading the payment of custom's duties. The young nation could no more countenance the loss of this revenue than the federal government can allow evasion of income taxes today. A small fleet of sailing cutters effectively reduced smuggling to a tolerable degree and thereby began our now traditional responsibility for law enforcement on the federal waters.

Over the years there have been continuing changes in this responsibility until today the Coast Guard's enforcement job has taken a very different aspect. Rather than pursuing the smuggler intent on violating revenue laws, our forces are now busy enforcing the laws and regulations concerning safety of life and property on the navigable waters of the United States. These laws and regulations are numerous.

There is the Federal Boating Act of 1938, with which most of you are conversant, which requires the numbering of boats and the reporting of boating accidents. The Motorboat Act of 1940 specifies certain lifesaving equipment requirements and provides for the assessment of monetary penalties for reckless and negligent operation. There are others covering water pollution

by oil or refuse and of course, those which concern merchant vessels. For today, I shall confine myself to those laws which concern the smaller watercraft, in particular the pleasure boats, and to their enforcement.

New advances in boat building technology, safe modern propulsion equipment and the advent of the mass-produced popular outboard motorboat, have made their contributions to the explosive expansion of recreational boating. In 1947 there were approximately two and one-half million boats used for recreation; today there are over eight million boats.

The mobility of the average boatman who owns an outboard motorboat transported on a trailer creates many problems, such as what is his state of principal use required for numbering his boat, overcrowding of popular water areas from time to time, and last but not least the overtaking of the capabilities of law enforcement officials to give proper coverage to given areas for the safety of the boating public. Our Coast Guard law enforcement capabilities have not kept pace with the increase in the boating population.

Perhaps here would be an appropriate spot to explain how the Coast Guard law enforcement program operates in the recreational boating field and what it attempts to accomplish. The two primary Federal boating laws, which I mentioned earlier, were established as aids in the promotion of boating safety. The Federal Boating Act of 1938 provides for numbering boats for identification (perhaps to identify a reckless operator) and to provide a system for reporting of boating accidents, while the Motorboat Act of 1940 requires that boats carry such lifesaving devices as life jackets, fire extinguishers and carburetor flame arrestors and provides, under a 1958 amendment, certain administrative monetary penalties which a proved reckless or negligent operator may be required to pay.

The enforcement of these laws is accomplished basically by boarding motorboats on the navigable waters of the United States and examining their equipment to insure compliance with legal requirements. Additionally, Coast Guard craft frequently patrol federal water areas, apprehending the overtly reckless or negligent operator. These two types of operation are the basics of the Coast Guard program. As you can see, it is a program slanted towards assistance to the average pleasure boatman, towards making his water-borne recreation safe and sane. The boarding operations are conducted in a courteous way and in a very short period of time—usually less than 15 minutes per boat. Our boarding officers have always been considered as "friends of the boatman" and we wish to have this thought continued.

Until very recently all boarding and water safety patrols were conducted by regular Coast Guard facilities such as our major cutters, patrol craft and small craft attached to shore stations. These facilities include 140 shore stations operating 300 small boats and 300 patrol craft and larger cutters. The primary mission of these units is not law enforcement patrols or boarding but rather includes such duties as search and rescue, ocean station patrols or servicing aids to navigation. Boarding and safety patrols can only be accomplished by these units when they are not engaged in their primary duties.

Also, these units are, in nearly every instance, located only along the sea-coasts, the Great Lakes or in a few instances on the major river systems. The great number of recreational water areas which are of a lesser degree of importance commercially, but which are navigable waters of the United States and therefore subject to Coast Guard jurisdiction, are not covered by these existing forces.

The vastly increased number of boats and the increased use of these more remote inland waters subject to federal jurisdiction and the increases in these areas through flood control and irrigation projects require additional Coast Guard facilities. Because of seasonal use of many of these inland areas and because of the great expense in building and maintaining permanent stations, new methods had to be investigated, looking toward an effective solution at reasonable cost to the taxpayer.

From this new thinking was developed the mobile boarding unit concept. This new type unit was to consist of a small number of fully qualified boarding petty officers, equipped with a small outboard motorboat and trailer and towed by a truck. Being completely mobile, it could travel from place to place without any difficulty whatsoever, spending as much time as needed in an area boarding boats, instructing fledgling boaters in the rudiments of boating safety and carrying out water safety patrols.

The first mobile boarding units were placed in operation for a few months during 1957 but due to a budgetary crisis, had to be suspended. Because other Coast Guard programs of national importance took precedence, the mobile boarding units remained out of commission until last year when, on July 1, Congress authorized the Coast Guard to re-establish twenty units. This fiscal year we have been authorized an additional 15 units so that, by the beginning of the boating season next spring, the Coast Guard will have 35 operational mobile boarding units, with more planned.

Geographically the units are located from Maine to Hawaii and from Washington state to the Florida Everglades. Most often the mobile boarding unit is based at a large Coast Guard installation and operates on the inland waters remote from regular service facilities.

As now organized, the mobile boarding unit consists of four petty officers: a chief boatswain mate, first class boatswain mate, second class engineman and a third class boatswain mate. The equipment consists of a 16-foot modern design, rugged, fiberglass boat built by the Coast Guard, a 40 H.P. outboard motor, a heavy-duty boat trailer and either a carryall or panel truck. A complete set of equipment is provided including such items as samples of approved life-saving equipment and safety handout pamphlets. Both the boat and vehicle are equipped with two-way transistorized radios which enhance both their law enforcement and rescue capabilities.

I hesitate to quote dry statistics, but in the case of the mobile boarding unit program, they may help me to show their effectiveness.

During fiscal year 1961, that is, from 1 July 1960 to 30 June 1961, mobile boarding

units boarded and examined 41,169 motorboats and issued 12,377 reports of violation on these boats. It should be noted that although the units were authorized on 1 July 1960, it took some time to detail personnel and collect the required equipment. Most of the units were operational by late July; a few did not begin operating until the start of the boating season, around 1 April 1961. Therefore, the statistics quoted earlier are not entirely representative of their potential.

However, when you consider that the total motorboat boardings for fiscal year 1961 by all Coast Guard units were 152,441 and violations totaled 25,125, it can be clearly seen that the mobile boarding units were performing their mission very well, despite the organizing difficulties encountered.

I would like to pursue these statistical records just a bit more, citing the operations of one mobile boarding unit which operates in this area. Mobile boarding unit 09-1, under the operational control of Commander, Ninth Coast Guard District, Cleveland, Ohio, was assigned to the Fox Chain of Lakes, located in Illinois near the Illinois-Wisconsin boundary. Being a large water area located near Chicago and other metropolitan areas, it receives tremendous usage during the boating season. During the period of 1 April to 30 June 1961 this four-man unit boarded 2,647 boats and issued 363 reports of violation.

This unit thus boarded and examined in excess of 29 boats every single day during this three-month period and cited approximately one in seven of these boat's operators for some violation of the boating safety laws. I had not as yet received a report for the three-month summer period when I left Washington yesterday, but it can be assumed that the statistics for that period will be even more impressive.

The record of all the mobile boarding units closely parallels that of the unit at Fox Lakes, although certain of them are more affected by seasonal closings than others.

It had been considered that because of the seasonal nature of some areas, the personnel attached to the mobile boarding units would be idle during the inclement fall and winter months. However, we have

found that because of the experience gained by these men, they make excellent instructors for our regular established unit personnel in boating law enforcement duties.

Therefore, regular training programs have been instituted in every Coast Guard district covering the very complicated duties of a boarding officer. These courses cover such subjects as "Boating Laws and Regulations," "Reckless and Negligent Operation Cases," "Numbering Boats Under the Federal Boating Act of 1958," "Lifesaving Devices," "Documents, Papers and Inspection Requirements," "State Boating Laws," and many more.

Men of the mobile boarding unit travel from one Coast Guard unit to another during the late fall and winter months, conducting classes for periods of three to five days duration. Whenever the weather permits, actual boarding duties are performed under the watchful eye of the instructor, and when the weather is such that actual boardings cannot be made, they are simulated in the classroom. By such training our regular forces become more competent boarding officers and our mobile boarding unit personnel keep from becoming rusty in their regular work through forced inactivity.

It is well worth noting that persons other than regular Coast Guard personnel are also instructed at these training classes. In the last year and a half, forty states have adopted approved motorboat numbering systems, and thereby accepted the responsibility for enforcement of their boating laws on their own state waters. The Coast Guard accepts that the states also have concurrent jurisdiction with this service on the navigable waters of the United States within the state.

Now, only a very few of these 40 states had any conception of the problems involved in maritime law enforcement nor did they have trained boating law enforcement officers. In many states the responsibility devolved upon the county sheriffs, in others on state game wardens. The Coast Guard volunteered to include a limited number of these state and local enforcement officers in our regular training sessions conducted by the mobile boarding unit personnel.

During one three-month period early this year, 138 civilian enforcement officials were

recipients of Coast Guard training. In every case, these officers have expressed their sincere thanks to our personnel for the training received. A side effect of such training is that the federal and state or local enforcement officers better understand each other's problems, which has resulted in increased cooperation between the two forces.

Another important aspect of the mobile boarding unit program is the public education work carried out by the personnel at each area that they visit. The men call on the local civic organizations and boat or yacht clubs, show water safety movies and give lectures on boating safety and the Coast Guard function in this field. During the period of 1 April to 30 June of this year, mobile boarding unit personnel were engaged in such endeavors 3,771 hours. No similar program of public education at the more remote water areas had been possible prior to the inception of this new type program.

Before closing, I would like to comment that these mobile boarding units are en-

thusiastically received at each place they call. State enforcement authorities, local residents, and the visiting boatmen have all indicated their appreciation for the services rendered by the units and more often than not have requested that they make more frequent visits to an area. Insofar as possible, these requests are met. Schedules for their operations are planned well in advance and are often submitted to state boating law officials for their comments and recommendations. Such scheduling permits more efficient utilization of both our Coast Guard mobile boarding units and of state and local enforcement forces.

The Coast Guard has ample reason, through long and trying experience, to know that the traffic slogan "where traffic laws are enforced, deaths go down," is equally true on the water. Through our mobile boarding unit concept, as well as by optimum use of our regular forces, we believe that enforcement of the various boat safety laws and regulations will result in lower accident statistics and more real pleasure to the boating public.

HUMAN FACTORS IN LIGHT PLANE SAFETY

By B. DIXON HOLLAND, "D."

Dir., Dept. of Occupational Health, American Medical Association, Chicago

There is a total of about 114 thousand planes aloft, of which fewer than 2 thousand are commercial airliners, 42 thousand are military planes and over 70 thousand are private and business aircraft (general aviation).

In 1959, certified air carriers flew 1.15 billion plane miles, general aviation planes almost 1.65 billion plane miles.

In 1959 the number of private pilots and commercial pilots (most of whom are involved in private aviation) exceeded the number of airline pilots by a vast majority, these numbers being respectively around 464 thousand, 255 thousand and 19 thousand.

Marring this picture that looks so pretty for general aviation, however, are the following stark statistics (those for 1957 are cited):

There occurred in general aviation over 420 accidents, one for every 16 active aircraft. About a tenth, that is 42 of these accidents, were fatal accidents, costing a total of 560 lives. There was one fatal accident for every 187 active aircraft, contrasted with the occurrence of one fatal accident for every 2,000 motor vehicles.

Investigations have shown the pilots to have been at fault in most of these accidents. This fact accounts for the interest and intercession of physicians in this situation. Physicians are rightfully concerned not only that flying be safe but that it be pleasurable, its pleasure not marred by the discomfort and pain that could accompany a disregard of certain health rules.

There are certain inherent limitations, physiological and psychological, built into the human machine that have to be reckoned with, disregard of which can lead to an accident. These limitations are found in so-

called normal, healthy, able-bodied persons—and this is the type of person we are talking about, one medically certified to fly a plane.

Some have despaired of insuring proper regard for these built-in human limitations except through legislation. For instance, the need for oxygen at a certain altitude is one of these built-in limitations of the human machine. Some have advocated strict governmental regulations to require that planes lacking oxygen equipment be prohibited from flying even momentarily at such an altitude.

Our program is planned to revolve around two subjects. Since there has been recent publicity suggesting the possibility of Federal legislation relative to oxygen use, we thought this would be a topic of interest. As weather is the major cause of death in private aviation, it was felt that a medical explanation for pilots as to why the following two statements are factual was appropriate.

I. You cannot always avoid clouds at your option (because of the visual limitations of the human eyes).

II. You cannot maintain control of an aircraft under instrument conditions without training because of the limitations of the positional and motion senses of humans.

Though the minimal instrument requirement for new private pilots has been in effect for the past year or so the vast majority of general aviation pilots flying today have little or no instrument training. Based on letters to the editors and other articles in some of our national flying magazines, it appears that many pilots are not conscious of the above two facts. Explanation and repetition of explanation of why adequate instrument training is a must, cannot be overdone if the vast majority of fatal general aviation aircraft accidents are to be avoided.

HUMAN FACTORS IN LIGHT PLANE SAFETY

By HAROLD N. BROWN, M.D.

Chairman, Safety Committee, and President-elect
Flying Physicians Association, Lombard, Ill.

The following is extracted from the presentation on "Human Factors in Light Plane Safety" given to the National Safety Council, General Aviation Safety Meeting.

This paper is limited to a discussion of what the writer is convinced is a major cause of death in general aviation. It refutes the concept that cautiousness alone will always permit a pilot to avoid clouds. Pilots frequently enter clouds inadvertently. This is because of the limitations of their eyes in determining distance when familiar ground objects are absent. This writer, whose concept is supported by the Flying Physicians Association through their teaching and self imposed instrument requirements (in effect since 1958), is anxious to promote instrument training for all pilots, at least, sufficient in amount to permit them to extricate themselves calmly and with full control from instrument conditions inadvertently entered.

The Federal Aviation Agency has devised an excellent stimulus by placing a blue seal on licenses of those pilots demonstrating adequate proficiency. Since June 1960, the Federal Aviation Agency has required such proficiency prior to issuing a new pilot's license. The Aircraft Owners and Pilots Association is effectively promoting its "360" rating which incidentally qualifies any pilot so rated for the Federal Aviation Agency's Blue Seal. The publicity associated with the Aircraft Owners and Pilots Association's rating is extremely effective in promoting consciousness of the necessity for adequate instrument training. It is generally conceded that 5 to 10 hours of proper instrument training with occasional refreshing serves the purpose.

In spite of these efforts, many pilots not inclined to avail themselves of this training, state that sufficient knowledge of weather together with caution, would prevent a large

number of fatal accidents caused by lack of instrument training. Others state that this minimal knowledge may tempt pilots to enter clouds when they are not fully qualified for the entire instrument system. It is our contention that until a pilot has some instrument training, he has inadequate basis for judging the dangers. These pilots have a right to know the facts so that the basis for their judgment is through knowledge rather than supposition.

We should no longer accept the concept that clouds can always be avoided at the pilot's option for the medical reasons discussing vision which follow.

Once inadvertent cloud entry occurs, the untrained pilot can expect a "graveyard spiral" for the reasons outlined following the discussion of inadvertent cloud entry.

This is a typical story of what happens to the uninitiated.

This pilot is flying along anxious to get to his destination, knowing there is some haziness or clouds about, but feeling that he can stay out of the clouds if he is careful. He does not realize how limited his depth perception is and does not have the benefit of experience which helps the trained pilot use whatever few clues there are to best advantage.

Unintentionally, and suddenly, he enters the clouds. The aircraft starts to roll slowly but the pilot's semi-circular canals do not perceive this slow roll. Because the nose drops in a turn, speed is built up. This, the pilot detects either by noise or his air speed indicator. He assumes he is descending straight ahead, as the buttocks pressures are equal. He pulls back on the wheel. Though he is tightening the turn and probably losing altitude, the increased pressure on his buttocks tells him he is climbing.

He knows something is wrong because his airspeed is still high. Eventually he catches a glimpse of a toppled artificial horizon or a markedly offset needle. He will then suspect he is banked, but because of the lack of training and resultant panic he will not know in what direction. He will also not know to what extent. He may get another try at it if his guess is correct. In this instance, a newspaper account by a non-pilot observer will read "Airplane must have had engine trouble as I heard it zoom twice before it came out of the clouds in pieces."

If the pilot guesses wrong as to the direction of bank, the newspaper article will be identical except for one word instead of two. If the airplane disintegrates before striking the ground, it usually occurs when the ground is first seen in a dive. Extreme sudden back pressure on the wheel, at this time, pulls the airplane apart. In this instance newspaper articles will be similar except that included in the comments will be something to the effect that the airplane must have exploded.

Let us discuss the human mechanisms which permit the above to occur:

Depth Perception Mechanisms

Binocular Vision—Convergence—Within 20 feet of the viewer, the closer an object is, the more the eyes turn toward each other. The brain interprets this change of the muscles which control eyeball movement, in terms of distance. It is upon this single principle that a photographic range finder is based. Using mirrors, two images of the same object are superimposed by varying the angle of the mirrors. The distance is evaluated from this angle. Between about 20 feet and infinity this angle is almost constant as the rays from the object approach parallel in both instances.

The range finder is more sensitive than the eyes (can differentiate up to as high as even one hundred feet and infinity) because it amplifies the angular change by internal projection of one image. Without transplanting the eyes farther apart, the same limitations apply to convergence depth perception in humans.

Stereopsis—This is another depth perception mechanism requiring both eyes. It also applies within 20 feet, having almost no value beyond that. It can be thought of in two ways. Within 20 feet, each eye sees a different view of the same object. The brain interprets these different views in terms of distance. Stereopsis is also used for comparing the relative distance of objects. If we look at an object 20 feet away, with a pencil at arm's length along the line of sight of the left eye, both images will fall on the same spot of the left retina (the film of the eye), but the image from the pencil will be displaced toward the outside of the right retina. This difference informs you of the relative distance of the pencil and distance object. Use a pencil and try it, closing one

eye at a time. Remember that the lens of the eye inverts and reverses the image.

These above mechanisms, which are not usable beyond about 20 feet, can not help us avoid clouds. It can be said then, that aside from a larger field of vision which two eyes provide, depth perception beyond 20 feet is achieved as well with one eye as with two.

Monocular Mechanisms

The following mechanisms can be thought of as monocular (one eye). They give depth perception information at all distances. However, you will see that for the most part they use ground objects for interpretation and thus are frequently useless in determining distances to clouds.

Known Size—A man, whom we assume is five or six feet tall, is at an unknown distance. If the image he creates on our retina (the recording film of the eye) is small, we assume he is at a great distance. If a cat's image is the same size, that is, takes up the same space on our retina, we would conclude he is much closer than the man, because we know a cat is less than one fifth the height of a man. Approaching a cloud in the air, we frequently can not tell if it is small and close or large and far. This is because clouds can have the same shape and appearance, and be vastly different in size. Thus, the known size mechanism frequently does not help us.

Geometric Perspective—If we look along a railroad track upon which is lying a steel rod, we know the distance to this rod because the rails appear to converge proportionate to the distance from the viewer. In flight, this type of perspective is frequently unavailable because of no markings for reference. This would apply in the following circumstances; over water, especially if the surface is smooth; over dense forests which have an even appearance; above a solid cloud blanket or fog; at night when there are no ground lights, as over unpopulated areas.

Overlapping Contours—When one object is seen to overlap another, the overlapped object is most distant. If a DC-6 is seen to move within the line of sight of a cloud and remains visible, we know the cloud is farther away than the airplane. If the airplane disappears, we know it is farther away than the cloud. Without the airplane as

reference, clouds may be separate and at different distances and yet appear to be one cloud. Thus in flight, with no distinct object for comparison, availability of this mechanism can not be relied on.

Light and Shadow—The way in which shadows separate objects gives us clues as to their relative closeness. If a lamp casts the shadow of a man toward us, we know the lamp is farther away than the man. Because clouds are frequently illuminated through other clouds, as with a high overcast, the light is often diffuse and gives us no shadow clues. Also, since the sun is at relative infinity, all primary shadows are cast in the same direction. We get no clue as we would if we were observing our changing shadow while walking under a street lamp. This mechanism then, is also frequently unusable.

Terrestrial Association—We see an isolated thunderhead while flying above an overcast, and radio reports this thunder-shower over "X" city. If we know our present position we know the distance to the cloud; if we do not know our present position, as is usually the case without instrument training, this mechanism is lost.

Aerial Perspective—We have learned that the more distant objects are, the more they appear indistinct. If a cloud is seen through haze, the thicker the haze, the farther away we tend to assume the cloud to be. It can be seen then, that "aerial perspective" is more apt to lure us into clouds than to help us avoid them.

Motion Parallax—Looking at a distant mountain while riding on a train, nearby telephone poles appear to be moving behind, while the mountain appears to be moving in the same direction as the train. As we gaze at the mountain, any object closer will appear to be falling behind at a rate depending upon its distance. In flight, we get similar information from distinctly outlined clouds; but if we are near large clouds, or if their outline is indistinct as in haze, they appear to melt together, frequently giving us no clues of motion parallax.

In concluding this summary of depth perception mechanism, it should be said that when one or more of these mechanisms are available, they are available not so much in proportion to our visual acuity as in proportion to our accumulated experience of

cloud forms from previous flying. As an example, an experienced pilot on the ground can determine the height of cloud bases with extreme accuracy; a beginning pilot with no accuracy. Both can have perfect vision. Frequently, circumstances are such that none of these mechanisms are available to help us avoid entry into clouds. Without instrument training we can expect a graveyard spiral for the reasons we will consider next.

An untrained pilot has thus entered clouds and not illogically assumed that he will know the earth's whereabouts without vision. Can he not tell the earth's whereabouts when standing on the ground and his eyes closed? This conclusion is dead wrong for the following reasons.

Positional Mechanisms

Position and direction of motion are relayed to the brain in three ways: the eyes, the proprioceptive senses, and the vestibular apparatus of the inner ears. Ignore the eyes for now, as we assume we have entered the clouds. We will discuss the remaining two positional mechanisms.

Proprioceptive Sense — This deals with those sensations sent to the brain as a result of forces which arise from pressure on, or from movement of, a joint or muscle. Because of this a man on the ground with his eyes closed can sit, walk or point. He can do this because the earth's gravitational forces are perpendicular to the earth's surface, and therefore tell him where the earth is. In the air, G forces happen to be perpendicular to the earth's surface only in straight and level flight, and in constant climbs and descents. Only in these attitudes, by coincidence, is the pilot's proprioceptive sense (buttocks) a guide to his position relative to the earth's surface.

In other coordinated flight maneuvers, the aircraft's G forces, rarely and then only momentarily, coincide in direction with gravitational pull, such as the bottom of a loop, thus our usual guide towards the earth's center is gone. Pressure on the buttocks increases during entry into a climb, and thus any other maneuver which also produces pressure against the buttocks, as a coordinated turn, will be interpreted wrongly as climbing. In entry to a descent the seat is pressed less firmly and any maneuver causing a similar sensation, such

as leveling out after a turn, will be interpreted wrongly as a descent.

The student instrument pilot tends to climb when rolling out of a turn and tends to lose altitude when he has rolled into a turn. He believes that if his buttocks pressure is constant his altitude will remain constant. Because of this he wrongly holds the amount of elevator necessary to maintain this buttocks pressure. Greater lift is necessary to hold altitude in a turn than in level flight. As the lift increases, more buttocks pressure must be accepted proportionate to the rate of turn.

The student VFR pilot does not grasp the necessary pressure changes until he learns to use the horizon as reference. The student IFR pilot has to reaccept this changing sensation. In a slip or skid the pilot is forced sideways on his buttocks and because of this he will have the impression that he is tilting. This feeling of tilt will be in the direction opposite from the slip or skid. It can be said then that while flying, the proprioceptive senses do not substitute for our eyes. They give us no usable indication of the earth's whereabouts. In fact, because of our ground experiences, they tend to mislead us.

A vestibular apparatus is located in each inner ear. It has two basic parts: the semicircular canals and the utricle.

Semicircular Canals can be thought of as three small doughnut shaped tubes lying in three different planes; horizontally, vertically side to side, and vertically front to back. These canals are joined together at one point and contain fluid that circulates freely within and between them. Where the three joint, hairlike cells project into the fluid, and as this fluid moves these cells are bent toward the direction of flow. Nerves from the cells' base relay the direction of flow to the brain.

These semicircular canals are affected only by rotation of the head in any plane. They work in this manner. Let us visualize a glass doughnut containing fluid with floating particles as the horizontal semicircular canal. This tube is placed on a table, and suddenly rotated counterclockwise. Initially, because of inertia, the water stands still relative to the table. As the tube is continually rotated at a constant speed, the water catches up to

the tube because of friction, and there is no relative motion.

If we suddenly stop the motion of this tube the water continues to move until stopped by friction, and the relative motion is then in the opposite direction. If a sensory antenna were projecting into the canal of the tube, it wouldn't know if the tube or the water were moving, unless there were a connection to the table beneath.

Similarly, but in all three planes, the semicircular canals tell a pilot in the air only that he is rotating in a certain direction. They do not tell him from what position he starts or stops. In fact, as the rotation of his head stops he believes he is starting to rotate in the opposite direction unless his eyes give him information to the contrary. This conflict between the eyes and semicircular canals is the main cause of vertigo during instrument maneuvers.

Vertigo can also occur if the head is suddenly tilted or turned during a turn of the aircraft. This activates a different plane of the semicircular canals and deactivates or even reverses the flow of fluid in the plane that was originally active. Turning your head sideways to look at a map while in a turn can do this. Vertigo under these circumstances is normal. Thus, during instrument flight one should not turn his head more than a few degrees except in level flight or in constant climbs or descents.

If the rotation of the head is accelerating at less than three degrees per second, there is no sensation of rotation. Less than this does not overcome friction between the fluid and canals. This adds to the problem of knowing when rotation has started or

stopped. For this we need our eyes. In the air, as a demonstration of this friction problem, have a friend in the right seat close his eyes. Ask him to tell you whether you have turned left or right, after the following maneuver. Roll the aircraft very slowly to the left (at a rate of roll less than three degrees per second) until the bank is quite steep; then quickly rotate to level flight. He will say he is turning to the right at this moment and will be surprised, when opening his eyes, to find himself level. The untal roll did not overcome the friction of the semicircular canals but the second roll did. It should be evident then, that the semicircular canals give no indication of the earth's whereabouts.

The Utricle—The other part of the vestibular apparatus, the utricle, is adjacent to the semicircular canals. It is, in essence, a small sac containing erect hair cells, upon which rest tiny particles similar to grains of sand. These hairs are displaced by gravitational pull or G forces, and nerves signal the brain of this change. If the head is tilted towards the left, the weighted cells are bent towards the left, signaling the brain that the head is tilted left relative to the earth. In an airplane it would tell the position of the head relative to G forces. In a level skid to the left, these hair cells bend to the right, causing a wrong sensation of tilting to the right. This organ then, has approximately the same limitations as does the proprioceptive sense, and thus gives us no usable guide to the aircraft's altitude.

Adequate instrument training must be continuously promoted to decrease the major cause of death in general aviation.

LESSONS LEARNED FROM AVIATION CRASH INJURY RESEARCH

By VICTOR E. ROTHE

Mgr., Flight Safety Foundation, Inc., New York City

Each year, more and more people are traveling by air. More commercial aircraft are being used, and private and business flying has increased beyond all expectations. New aircraft types are being continually

developed with emphasis on speed, range and all-weather capability. Better environmental facilities are being provided, new flying aids are being introduced and operational limits are being strictly defined in

the requirements for airworthiness certification.

With all of the steps being taken to prevent the occurrence of accidents, the present accident rate will undoubtedly be improved. Really striking reductions cannot be achieved, however, without disproportionate increases in the cost of aircraft and aircraft components. Further, there is the unpredictable human error, which is the chief causation factor in some accidents. Based upon the foregoing, it is reasonable to assume that we can expect occasional accidents and, since some of the newer aircraft types are carrying greater numbers of people, we can also expect more casualties per accident.

Accepting the inevitability of an occasional accident, it then becomes the joint responsibility of certain medical, engineering and research groups to strive to minimize the consequent injury to the occupants by drawing attention to measures which may reduce unnecessary death and injuries in aircraft accidents. The aim must be to provide the safest possible design within the limits imposed by operational and economic considerations.

There is a reason for every injury, and if all the facts are known, each injury can be related to forces with or without contact between the site of the injury and some part of the accident. A knowledge of the relations between injury, force and aircraft structure will serve as a source of ideas concerning prevention, diagnosis and treatment of certain injuries—all of which will improve the rate of survival.

This brief introduction suggests that crashworthiness, or crash safety, is a subject as worthy of comprehensive study as is airworthiness.

The work presently being done by the Aviation Crash Injury Research Division of the Flight Safety Foundation is to conduct research involving the relationships between injury, force and aircraft structure for the purpose of increasing our knowledge in this area with the hope of improving the survival rate in aircraft accidents. The research conducted by AvCIR involves aircraft of all types—fixed wing as well as rotary wing, civilian as well as military, transport as well as lightplane. Many of the research findings are of such a broad nature that they are applicable to

most different aircraft types. For example, most Army aircraft have their civilian counterparts. The findings under the research conducted for the Army are, therefore, applicable to light or business type aircraft. The reverse also holds true. Likewise, knowledge gained from investigation and study of survivability in transport accidents is translated into both military and private plane applications. Consequently, the collective research of the entire project has broad direct value to all interested agencies. The research conducted by AvCIR is performed by the following branches:

Accident Investigation Branch—This branch conducts on-the-scene accident investigations on military and civilian, fixed wing and rotary wing accidents. The military accidents investigated are limited to Army aircraft which fall into both the lightplane and helicopter categories. Civilian accidents investigated include both transport and private aircraft. When investigating civilian accidents, the investigators of this branch serve as members of the CAB or FAA investigation teams.

In addition to on-the-scene investigations, this branch also conducts evaluations of preliminary designs, mockups, prototypes and operational aircraft from a crash safety point of view. This work is done for the military under the terms of our military contract and for civilian companies on a request basis.

As a result of the investigations and evaluations conducted, appropriate reports are prepared on the findings for distribution to interested agencies. These reports include recommendations which form the basis for new, improved designs and modifications to existing designs from a crash safety standpoint. The information compiled by this branch also becomes a part of the mass data compiled by the organization for statistical studies.

Statistical Analysis Branch—The function of this branch involves collection, coding, and analysis of accident data. The data are forwarded to the organization on AvCIR accident and medical report forms by the FAA, CAB, Army, state aviation groups, and state police forces.

The data are analyzed for the purpose of determining injury causal factors out of the complex and otherwise indeterminate

events. The branch also observes and measures trends of a general nature in, for example, accident rates, injury severity rates, installation and utilization of safety equipment and structural and design features relating to injuries. Special studies are also conducted which deal with the frequency and pattern of injuries experienced in specific areas of the body.

Training Branch—This branch maintains and operates the crash injury investigator's school. It conducts five two-week training courses annually for military and civilian design engineers, flight surgeons, aviators, safety officers, etc. The operation of this branch permits direct dissemination and interchange of the data and findings of AvCIR and other agencies as a result of research and investigation.

Human Factors Branch—The basic activity of this branch is the study of the correlation of injuries to causative agents in aircraft accidents with emphasis on occupant restraint, occupant environment, protective equipment and emergency evacuation.

Experimental Research Branch—This branch is responsible for the design and execution of experiments which will provide increased knowledge of the dynamic behavior of aircraft and their components under actual crash conditions. The experiments include testing of full-scale aircraft under fully-instrumented controlled conditions and the dynamic testing of aircraft components. The design of each experiment is built upon the problems brought into focus by the other elements of the organization, wherein the indications are that answers to certain key questions can be found only by simulating certain crash situations under dynamic conditions.

Before discussing some of the detailed findings resulting from research conducted by AvCIR, it might be well to dwell on two points which we feel require some clarification.

The first point for clarification is the question: "What is a survivable accident?" Almost everyone involved in aviation safety today has at one time or another used the expression "a survivable accident." Numerous attempts have been made to define a survivable accident without success. The difficulty in attempting such a definition stems from the fact that there are no present

or foreseeable means to accurately determine the crash force factors such as: peak magnitude, duration, rate of onset, direction, and frequency through post-crash calculation. This, in combination with the lack of reliable data on tolerance levels and survivable limits of the human body when supported by standard restraint systems makes it doubtful whether such a definition is feasible.

If it is assumed, however, that the crash resistance of modern pressurized fuselage structures are within the survivable limits of human G tolerance, a more practical criterion can be based upon the post impact condition of the fuselage structures. In that case, a relatively intact fuselage structure or portions thereof would imply survivable conditions, which in turn would justify survival expectancy for the occupants of those areas.

The second of these points is the definition of the term "crash safety," as we see it. A number of terms have been used by various agencies and individuals involved in aviation safety to express the overall degree of safety built into an aircraft. A term which has been used by many people is "crashworthiness." We don't feel this term is as meaningful, nor can it be as well defined as the term "crash safety." We therefore, have adopted the expression "crash safety" as an all-encompassing expression which lends itself to definition. "Crash safety," as we see it, is the result of the following factors:

A. **Crashworthiness.** We see crashworthiness as the ability of the basic aircraft structure to resist deformation, disintegration, or collapse into areas normally occupied by vital body areas during an impact in which survivable crash force conditions existed. This feature in itself, however, does not assure survival.

B. **Adequate Tie-Down.** Assuming crashworthiness of an aircraft design, our next problem is to keep the occupants and loose equipment anchored in their respective positions during a crash. This requires that the floor structure does not disintegrate, the seat anchors not fail, the seat structure remain intact, and that the restraint system for both occupants and loose equipment be adequate to retain the occupants and loose equipment in their respective positions under survivable crash force conditions.

C. *Elimination of Injurious Environment.* If we now have a crashworthy aircraft structure which incorporates adequate tie-down features, the next problem is to eliminate items within the immediate environment of the occupants which are potentially injurious such as non-yielding seat backs, food trays, arm rests, etc.

D. *Crash Force/Energy Absorption.* If an aircraft is provided with the desirable features set forth above, there is then the possibility that the structure of the aircraft has become rigid at the point where the crash force energy is transmitted directly to the occupant and in some instances, may even be magnified during the crash deceleration. Crash safety design should include provisions for absorbing energy either in the basic aircraft structure or through the use of suitable energy absorbing materials or devices without compromising crashworthiness or any of the other features cited above.

E. *Elimination of Post-Crash Hazards.*

If the above factors are properly incorporated in the design of an aircraft, then the survival rate in aircraft accidents should be substantially increased. There are, however, still the post crash hazards to contend with such as post crash fire and drowning in ditching accidents. Crash safety design should include proper emergency placarding, proper emergency lighting, adequate emergency exits, and methods for reducing the possibility of post crash fire.

In summary: crashworthiness, adequate tie-down, elimination of injurious environment, crash force/energy absorption, elimination of post-crash hazards equals crash safety.

In conclusion, we feel that the following deficiencies represent the most significant findings resulting from aviation crash injury research:

(1) The lack of sufficient medical data, particularly autopsy data from fatalities associated with aircraft accidents. More information of this type would permit better correlation between injuries and their causes, particularly internal injuries. Such information would also be extremely valuable in determining the causes of accidents in some cases, especially where alcohol or drugs are involved. It is hoped that someday a way may be found whereby complete autopsies could be performed on all fatalities experienced in aircraft accidents.

(2) The present load factors governing the tie-down chain are inadequate. These load factors were developed at a time when very little was known about the actual loads experienced in aircraft accidents and they have been improved very little during the intervening years. During the past decade, however, through experimental research in improving the crash testing of full scale aircraft, considerable knowledge has been gained with regard to the loads experienced in actual aircraft accidents for both fixed and rotary wing aircraft types.

The information gained through this research has indicated that deficiencies exist in the present standards with regard to magnitude of the loads, direction of application, duration, and frequency. It also indicates that there are significant differences between the loads experienced in fixed wing and rotary wing aircraft which leads us to believe that the same standards are not applicable to both types. Further, deficiencies exist in the present requirements for meeting the standards and specifications now in existence. The present requirements are for static testing of the various components involved whereas the environment in which these components function is dynamic and the testing procedures used should closely simulate the conditions in which these components function; that is, they should be dynamically tested.

ORGANIZING FOR SAFE WATER SKIING

By JAMES R. LAUZON

Midwest Regional Vice Pres., American Water Ski Assn., Chicago

Picture, if you will, a high powered water ski tow boat. The boat is streaking toward a water ski jump at 35 miles per hour. The boat is pulling a highly trained, extremely competent skier. The skier angles toward the jumping ramp at a speed in excess of 48 miles per hour. He miscalculates his timing. At the last fraction of a second he futilely attempts to swerve away from the jumping ramp. There is a resounding thud, then silence.

The time and place of this actual incident was August 20, 1961 in Austin, Tex. The occasion was the National Water Ski Championships and the skier was Chuck Stearns, former national and world champion.

You are probably asking yourselves, will this boy ever ski again? He skied again ten minutes after this hair-raising incident. Had it not been for safety precautions conceived and insisted upon by organized water ski groups, this skier might have been severely or even fatally injured.

Statistics—There are an estimated 12 million water skiers. However, water skiing has an exceptional safety record in comparison with other water sports. This statement is backed by the fact that of all the boating fatalities studied by the Outboard Boating Club of America in 1959, only 3.9 per cent of those fatalities occurred while the victims were engaged in the sport of water skiing. These figures represent a drop of 0.6 per cent from the 1958 study which had a 4.5 per cent fatality ratio.

The 1960 report by OBC is even more encouraging. Of all the boating fatalities studied, water skiing fatalities comprised only 1.8 per cent of the total. This is a drop over 1959 of 2.1 per cent. This safety record is not only amazing but certainly gratifying to both OBC and AWSA. Both organizations have carried on extensive campaigns to educate the boating and water skiing public in matters of safety and common sense.

Safety Precautions—Several safety devices have become commonplace in organized water skiing. Some states now have laws making the use of some of these devices mandatory. In water skiing, life belts are the most commonly used flotation device. Through the efforts of many manufacturers, life belts have become less bulky and less obtrusive. In some cases they are even attractive.

The second item is a life vest or jacket. These jackets are manufactured in different sizes ranging from large all the way to extra small. Some jackets are designed to be more than just flotation devices. In tournament competition skiers attain speeds in excess of 45 miles per hour and a fall at these speeds could certainly injure a skier internally. These jackets cover the chest and back protecting the skier's rib cage, chest cavity and such vital organs as the heart and lungs.

In all AWSA sanctioned tournaments, it is mandatory for all skiers to wear a life jacket during jumping events. Just as a football player wears a helmet and a hockey player wears shin guards for protection, so should water ski jumpers wear a life jacket for protection.

The third item is a wet suit. These suits are made of rubber comparable to those worn by skin and scuba divers. In many cases, the skier uses a wet suit to keep warm while skiing. A wet suit is considered a flotation device, but the suit must meet the same requirements as any other flotation device. It must float the skier. The wet suit, however, cannot be used as a flotation device in jumping because it does not afford the skier the protection from injury that the jacket does.

When it comes to a flotation device, I am a believer! I never ski without a belt, jacket or wet suit. It's just good common sense. Not too long ago, those of us who considered ourselves "hot shot" skiers thought that anyone wearing a life belt was a "sissy." Now we realize how wrong we were. As a matter of fact, the Illinois Water Ski Association, of which I am a member, has a standing rule that no one

skis without a flotation device. This also applies to our ski shows. Not a single act leaves the dock without a flotation device.

Some local ski clubs have adopted the slogan: "If you see anyone skiing in our area without a flotation device, he is not a member of our ski club." This type of thinking and action can only help to promote safety on the water.

This next item of ski equipment is a ski hitch. This ski hitch is manufactured by the Futurity Company of Joliet, Ill. The ski hitch is designed to attach to the transom of an outboard motor boat. It holds the ski line high above the water so that the line will not become entangled in the propeller. This hitch also tilts forward so that the observer, or line handler, does not have to reach down behind the motor near the propeller to retrieve the line.

The increasing use of these safety devices will certainly make the sport of water skiing an even safer water sport.

Rather than reading a long list of "do's" and "don't's," I refer you to the "Signals to Boat Drivers" and "Guideposts to Safe Skiing." All of these "do's" and "don't's" are certainly important and we encourage their observance by skiers and boat drivers. I would like to comment on just a few of these rules.

One of the most important signals used in water skiing is the one signifying "I'm O.K." This signal consists of clasping both hands overhead after a fall. This signal should be automatic to water skiers. Its use is not only encouraged but insisted upon in all American Water Ski Association sanctioned tournaments.

Another extremely important rule concerns a skier's landing. Never, but never attempt to land directly toward shore.

The American Water Ski Association Official Tournament Rule Book specifies the rules to be followed at all sanctioned tournaments. Safety is strongly emphasized in this rule book. There are eight sections in different parts of the rule book devoted to safety.

One section in particular specifies that a safety director be appointed for all sanctioned tournaments.

Section 6.09 states: "At least two weeks before a tournament, the sponsoring affiliated

club, with the approval of the chief judge, shall appoint a safety director, who will appoint such assistants as appear necessary. The safety director shall be responsible for the safe condition of all equipment, facilities, and operation of the tournament. He shall have the authority to take whatever action is necessary, including stopping the tournament whenever he observes a condition he believes unsafe."

We, of the American Water Ski Association, feel that the safety director of a tournament is a very responsible position. We, therefore, feel that this position should be assigned to a competent, responsible individual. The safety director must see that safety boats are in position before a skier leaves the starting dock. Two safety boats are required for jumping and slalom. This means for both practice and competitive sessions of a tournament.

The requirements for safety boats are as follows:

1. The boat must have sufficient length and be powered by appropriate horsepower motor, or motors, which will enable the boat to quickly reach a fallen skier.
2. There must be a driver and a rider. The rider should be a good swimmer and must wear a flotation device.
3. Ring buoy and line.
4. Boarding ladder.
5. Water stretcher (can be an inflatable air mattress).

The safety director must also check the safety sides on the jumping ramp to see that they are in a safe condition. The safety sides just mentioned are plywood enclosures which cover the sides of the ramp. They are attached to the ramp surface and jut outward at an angle to below the water line. If a skier strikes this slanted safety side, it is not like running into the proverbial brick wall. The skier is merely deflected away with little or no injury.

Had it not been for these previously mentioned safety precautions, Chuck Stevens, whom I mentioned earlier, might have been seriously injured.

It is interesting to note that in 22 years of water ski tournaments with 65 tournaments sanctioned by the American Water Ski Association this year, there has never been a fatality in a sanctioned tournament.

American Water Ski Association—The American Water Ski Association (AWSA) is comprised not only of single memberships but also of affiliated clubs. Local clubs find it advantageous to be affiliated with AWSA. Information not readily available to others is available to them. Publications such as the "Water Ski Club Manual" and the "Tournament Manual" are sent upon request. These publications contain specific sections on safety.

People often ask me, "Why should I join a club?" One of the basic reasons for joining a club is the availability of equipment which of course includes safety equipment. Many ski clubs have safety rules formulated by their own committees to suit the needs of their specific area. For example, a certain area might require a definite pattern for boat traffic. Our local club has a safety director and a safety committee. They have drafted rules for our ski area which, incidentally, include all of the local laws as well as existing state laws pertaining to water skiing and boating. By joining a club a skier may enjoy the protection of regulated, safe organized water ski activity. The new club member will also benefit from the background and knowledge of safe skiing procedures acquired by the older members of the club.

In a great many instances, local ski clubs have worked hand in hand with marine manufacturers in the development of their products. The manufacturer gains the much needed testing his product requires and the ski club gains the use of the equipment. The recommendations of seasoned skiers is invaluable and the final product is always a safer, more durable product.

The Mid-West Region of AWSA is deeply indebted to many marine manufacturers for the consignment of their products to the region for use in tournaments and ski shows. The Jones and Yandell Company and Billy Boy Products have donated life belts and jackets. The Kaar Engineering Corporation consigned two-way radios to be used in tow and safety boats. The major motor manufacturers, Scott McCulloch, Johnson, and Evinrude have made boats and motors available. The use of this equipment by the region certainly helps to make our tournaments and water ski activities more proficient and thereby, safer.

These manufacturers have also co-operated with AWSA, by including membership applications and safety literature and safety pamphlets with their products. Scott McCulloch co-operated again with AWSA to prepare and produce a booklet called "Trick Riding Made Easy." This booklet, incidentally, also includes a section on safety. Evinrude Motors has produced and distributed a booklet on water skiing stressing safety. Johnson Motors has produced a complete library of water skiing films and has made them available to clubs throughout the country. Kiekhaefer Corporation has also produced films in water skiing.

These manufacturers have done much to foster and further the cause of safety and certainly deserve a commendation for their efforts.

Cowboys—As in any way of life, or in any sport, there are always a few bad apples who can spoil the barrel. We of the water ski world are also plagued with this problem. The cowboy, or renegade, as we often call them, are the guys who buy or borrow their first boat, borrow a pair of skis and a tow line, grab a friend by the neck and hit the waves. They have had no previous instruction or indoctrination. They do not know, nor do they care to know the local or state regulations on boating or water skiing. They run their boats and ski with little or no common sense, and very little regard for other water enthusiasts. The comments made by fishermen and land owners alike naturally are, "there goes another blankety, blank water skier." These comments are justified, but certainly place a stigma on water skiing in general.

We feel that the most practical method in which to corral these cowboys is to encourage them to join an organized ski club. There are well over 800 water ski clubs throughout the country, which should provide plenty of corral space. Recently, there has been the development of statewide water ski associations, or federations, who are organizing the water ski clubs in their states. Much is being done through these state water ski federations to promote safety and common sense.

The primary lesson taught by organized water ski groups is as follows: "When water skiing, give a wide berth to all other boats, swimming areas, and objects on the

water. Give particular regard to fishermen, canoes and sailboats so that a healthy situation will prevail on the water. Water skiers and other boaters, who use our waterways, will then be able to live together and enjoy their respective water sports in harmony."

Legislation—Many states throughout the country have enacted or have attempted to enact legislation which we feel is restrictive to water skiing. Some examples of this type of legislation are as follows: "Restricting water skiing to only certain hours of the day. (This would certainly impose a hardship on a person who has unusual working hours.) Restricting horsepower or even eliminating boats from lakes of certain acreage. (This can cause a hardship on a person who has purchased property on these lakes.) No double skiing. (This could put show skiing out of business.)"

Organized water skiing groups not only warrant favorable legislation, they unequivocally endorse it. Organized groups, by example, have shown that they are not

afraid of legislation that requires flotation devices, or requires an observer, or a wide-angle rear view mirror. Our local ski club has had these regulations for years. If, by example, we can show others that this is what an organized group does, perhaps they will emulate us, or even join us.

Summary—Safety devices and safety rules are useless unless the skiing and boating public are educated as to their existence and usefulness.

The American Water Ski Association, in co-operation with the Outboard Boating Club of America and marine manufacturers, is actively engaged in furthering safety in water skiing. The AWSA is constantly in contact with affiliated ski clubs, working with them and sending them safety and technical information. The AWSA has been represented at boat and sport shows throughout the country. The message being relayed is 'ski safely, join a local ski club and the AWSA.' Then enjoy the fastest growing all family and competitive sport, but enjoy it safely.

HOW TO USE LOCAL PUBLICITY IN PROMOTING WATER SAFETY

By PHILIP LESLY
Pres., The Philip Lesly Co., Chicago

Educating people for safety is an anomaly. It is an axiom that "Self preservation is the first law of nature," and yet everyone associated with safety education knows how difficult and frustrating it is to get people to heed messages that can save their lives. This is not unique in America, because in this country, admired all over the world for creating the highest standards of living based on selling products and services, we are strangely inept at getting across ideas.

We have the best economic system ever devised by mankind, yet we have done such a poor job of getting it understood and appreciated that we must constantly be beating off efforts to destroy it. We have the best social system for the total of the people in the history of mankind—yet most

of the time in most parts of the world Russian communism is much more effectively projected than American freedom.

Behind these difficulties is one key rule of communication that too few people understand: You can't *sell* ideas the way you sell products. You can't *sell* safety by driving messages at people, trying to impose what you have to say on people's minds. Ideas are accepted by people who come to feel they are their own ideas as a result of exposures that are meaningful to them.

So, to educate people for safety—on the highway or on the water—safety must be made meaningful to them, at the local level, and in their individual lives.

We have seen that safety programs do not succeed on slogans only, on emotional

appeals, or on vague calls for safe action. They must be as specific in concept as possible, and identified as closely as possible with the individual *personally*. People must absorb the safety message out of exposures and activities that they voluntarily encounter because of benefits they themselves seek.

Safety education programs should be simple, easy to understand, and easy—even enjoyable—for people to engage in.

Here is another important principle: Convey the message of safety in terms of the wife, the children and other loved ones, rather than the person himself. It's a basic psychological fact that many people consider it a sign of weakness to admit, even to themselves, a concern for their safety; but it is a sign of strength and admirable to be concerned about one's family.

Tell a man how he can help protect the life and health of his wife and children and you will be educating him in safety without his acknowledging the fact.

Now let's look at how we might go about organizing and conducting a local publicity program for water safety.

First of all, let's recognize that as in all fields where ideas are the primary ingredient, the best publicity cannot be done by committee. No matter how many people may be involved or delegated to carry out assignments, the program will be successful in direct relation to the availability of some one dedicated person with imagination, creative ability and energy.

The media for reaching the public include all of the mass outlets—newspapers, magazines, radio, television and public meetings. These can be utilized in a variety of ways: interviews in newspapers or magazines with local safety council members or Coast Guard personnel; an insurance man who points up the dollar losses incurred in boating mishaps; soliciting the services of boating editors to comment editorially on how water activities can be best carried out with safety and security for one's loved ones. Radio and television interviews can be arranged with local marine dealers, Red Cross, safety council or Coast Guard personnel, newspaper or magazine boating editors or outdoor editors, or with police officials.

Wherever possible, the information about safety should be couched in material about

water sports in general—boating, swimming, water skiing—and treated as proper procedure, rather than as lectures on avoiding accidents.

People who can speak authoritatively on water safety almost always are glad to cooperate in a program that holds real promise for making the public more alert to proper practices on the water. These include local safety council members, Coast Guard or power squadron personnel, police officials, local Red Cross representatives, or personnel from the Outboard Industry Association, formerly the Outboard Boating Club of America.

Materials to help get across the message of proper procedures on the water are readily available. Pamphlets, booklets, photographs and films can be obtained usually by written request to the National Safety Council, commandant of the Coast Guard District in which you live, your area Red Cross director or the Outboard Industry Association or the National Association of Engine and Boat Manufacturers.

Now, here are a few specific suggested activities in which a local organization might engage to foster safety on the water:

1. Stage a public on-the-water demonstration of proper and improper practices. Urge that wives and children be brought as observers so that they will learn. Cooperation can be solicited from the Red Cross, local dealers, the Coast Guard, Sea Scouts and similar groups. Ski clubs can provide attractive entertainment, at the same time pointing out the proper ways to water ski. Free rides can be offered at another inducement to get people to come out and to absorb proper procedures. So can free engine checkups be offered by dealers.

2. A talk before a civic club or service organization by an authority on water activities or a safety expert can provide an immediate outlet for information on proper procedures and techniques. It also provides very important means for reaching thousands of people in addition to those who attend the talk. It is always important to remember that any meeting represents only a portion of the impact that can be derived if it is properly planned and handled; the publicity that appears as a result of the meeting in various kinds of media can frequently be much more effective in total results.

3. Marine dealers can be interested in holding on-the-water demonstrations at which experts would be local Red Cross and/or Coast Guard personnel. The demonstrations could include illustrations of good boating techniques, engine care, rescue practices, etc.

4. Arrangements can be made for police, Red Cross or Coast Guard personnel to talk before school assemblies on water activities, proper procedures, and getting the most out of fun on the water. Films can be shown that illustrate these points. Such appearances also provide an opportunity for publicity in local newspapers, radio or television.

5. A newspaper interview can be set up between a local insurance man who specializes in marine coverage on the dollar losses in water mishaps, caused by improper practices, and the savings that can be effected by good boating habits. In many cases the fear of financial loss can be made more graphic to people than the always-unreal likelihood of their being killed or injured.

6. An interview can be arranged between a boat racer or water ski champion and a newspaper boating editor on techniques to be used at high speeds, under trying conditions, etc.

7. A local marine dealer can be urged to sponsor one-minute suggestions on proper boating techniques, over radio or television.

8. Other interviews can be arranged for local Red Cross or Coast Guard personnel; the president of the local outboard boating club; a marine dealer or a local garage man on how to hitch and pull a boat trailer with a car.

9. Films available from the various outboard motor manufacturers, the Outboard Industry Association, the Red Cross and other sources can be shown to many organizations such as women's clubs that are not directly interested now in boating. The big problem in water safety is not the veteran so much as the beginner who ventures too soon, with too little information. The new boaters and water skiers and swimmers each year are most in need of education. The future water sportsmen—those not already aware that they will be interested in water sports—need to be reached before they venture out onto the water.

Reducing the accident toll on the water is a challenge worthy of the best abilities and the most humane instincts of the American people. It is not an easy assignment, but one that can be most gratifying in its results if imaginative and energetic efforts are applied.

WATER SURVIVAL COURSES

By ROBERT W. BUCKLEY

Dept. of Physical Education, University of Washington, Seattle

Few water safety instructors have understood the value of teaching their students safe methods of swimming while clothed. It can be shown that more than 80 per cent of all people who lose their lives in the water are fully dressed at the time of the accident. It is common knowledge that most people believe that clothing will drag them down with its weight and therefore, must be discarded before they can swim to safety.

Swimming instructors have attempted to cover this important subject matter by teaching their students to disrobe while swimming in deep water. In most cases,

the swimmer does not have sufficient clothing to give him a true test of his ability to disrobe. He does not have, for example, shoes that lace above the ankles; he does not have the multiple layers of clothing a sportsman is likely to wear when on or around the water, such as a T-shirt, a wool shirt, a sweater and a windbreak, a parka or a rain jacket. Each of these must be systematically removed one at a time; or there is great danger in becoming entangled, thus making swimming almost impossible.

Swimming instructors should quickly recognize this fact: only the smallest percent-

age of their pupils will ever be able to swim well enough to disrobe properly.

Under actual conditions, people around the water participating in boating, sailing, hunting and fishing are usually heavily dressed for protection against the cold. The water is often rough or choppy, and sometimes distances to safety are great.

There is a definite need for standardizing instruction in "clothing swimming." Most text books teach clothing inflation, outlining only procedures for disrobing and inflating garments that have been removed from the body. It has been proven that students can be taught to inflate the clothing that they wear while on the body. Without removing a single object, students very low in swimming proficiency can be taught to splash air into their shirt or jacket while being worn. They can be taught to keep air in their trouser legs by falling or jumping into the deep water, bending their knees slightly and coming up, and rising their knees to the surface about the same time their head breaks the surface. This should be done face up, hips low, and feet remaining underwater.

Let us look at some of the advantages of keeping the clothes on the body instead of disrobing.

1. Clothing protects the body from the initial shock of hitting cold water and allows the swimmer to adjust to the cold a little more gradually in order to get his breath.
2. It offers support for the first few critical moments when panic is likely to strike the swimmer. He may be able to calm down and more rationally plan his course to safety.
3. Clothing protects the body from prolonged exposure. Sometimes rescue is many minutes, if not hours away. In many places cold is a cruel enemy and causes loss of life to even the strongest swimmer. Water, trapped within successive layers of clothing acts as an insulator against the outside cold. Water coming in contact with the skin warms up, thus cutting down exposure to cold. Alert instructors in the military service taught men for survival in South Pacific waters the advantages of keeping their clothing

on for protection against the sun, predatory marine life, and rocks and reefs when swimming to safety.

1. Remaining dressed eliminates dangers of becoming entangled in the clothes. Clothing is not damaged as a result of inflating it on the body. Clothing can be inflated in much less time than it takes to disrobe.
5. It takes less time to teach inflation than to teach disrobing.

Inflation of Upper Garments—By holding a shirt tail or the lower front of a jacket or any other upper garment out and away from the belt, air can be pulled into the water by the free hand. This is accomplished by cupping the hand and delivering a striking blow downward, thus splashing the air into the front of the jacket. By assuming a semi-vertical position in the water, belly slightly downward, back arched, face out of the water, as in the head high breast stroke, the air splashed into the jacket inflates the area over the upper back and shoulders. This support is vital for keeping a person afloat in a desirable position for swimming breaststroke, side stroke or dog paddle. Air can be replaced when needed with little difficulty.

Inflation of Trousers—By turning up on the back, flexing one knee and holding the cuff away from the shin at the ankle, air can be splashed down and under the holding hand. This air becomes locked in the trouser leg over the knee. Each trouser leg should be inflated a little at a time. The position maintained on the back should allow the belt and trouser fly or feet to remain lower than the rest of the inflated trousers. Of the two methods of inflation, the one most useful under most conditions is the inflation of the upper garments. Usually support from the upper garment is lost when attempts are made to inflate the trousers. The position on the back allows air to escape through the open front of a jacket or shirt.

Suggested Inflation Test—Simplicity should be stressed in testing. Keep in mind that poor swimmers need inflation techniques requiring little skill. The good swimmers can usually survive their mistakes. *Test No. 1.* Students dressed in cotton shirt and trousers. Completely button shirt, including collar button; roll down sleeves and button. Jump

1961 National Safety Congress

into water, feet first, pull out front shirt tail, splash air into shirt. Time limit 10 seconds. Remain air-borne, re-inflating from time to time when necessary for support. Test No. 2. Students jump into water feet first, bringing knees to surface just a little ahead of their feet and head. Air is trapped

in trousers above the knees. Students are to remain motionless and air-borne within ten seconds after hitting the water.

FARM SAFETY SESSIONS

OUR STAKE IN A HEALTHY AGRICULTURE

By PAUL C. JOHNSON
Editor, *Prairie Farmer*, Chicago

American agriculture has been at some kind of a crossroads for as long as I can remember. Nevertheless the situation today has many aspects which cry for understanding and articulation. We are here primarily to talk about a specific farm problem, namely that of safety in farm operations, but I think it would be well first to do some broad thinking about the place of the farmer in our society. This thinking might well explore his state of mind and his relations to the rest of society.

They say a disturbed man is accident prone. It makes sense then that leaders in the safety field should make a real project of understanding the mental and occupational climate in which the farmer works. This is an important step toward achieving our goal of inducing farm people to analyze their safety problems and attack them systematically.

There's an old saying that you should learn to love and understand your neighbor before you set out to improve him. So that is my task in opening this conference.

Those of us directly involved in farming and agribusiness have been worrying a good deal lately about the public relations of agriculture, that is the image of farmers and farm business that is being impressed on the minds of American people. The public distaste and "bad press" that have grown up around a succession of government farm programs are largely responsible. Friends of agriculture who have been deeply concerned about this governmental involvement have sometimes worsened the situation by dwelling on the evils of dependence to the extent that the success stories of agriculture are overshadowed or overlooked.

We all suspect that a bad public image may have serious consequences in misdirecting public attitudes on such things as cost of living, or indeed safety, and may encourage anti-farm legislation that will not serve the national welfare.

I am even more concerned about the effect of the deteriorating public relations climate on the farmer and his family. I have detected a growing tendency on the part of farmers to be apologetic about their work. There has been loss of pride in their vocation, evidenced by dropping enrollments in agricultural colleges and lack of enthusiasm about the future of farming.

This adds up to a situation which might best be described as "unnatural." City people want to think well of farmers and will do so if given half a chance. They may be far behind in their understanding of modern farm practices, but they like to think farmers are the salt of the earth. Many non-farm people have a background of farm experience. There is deeply rooted in man a desire to own land and a feeling that in land there is both romance and security.

I believe this relations problem can be attacked by working diligently at developing four lines of public understanding: (1) tell the truth about present-day farming; (2) explore the future of farming with optimism; (3) bring the needs and priorities of land use into perspective; and (4) set up national goals for farming and farm people.

The nature and extent of the revolution in agriculture is not well understood, even by farm experts and farmers themselves. It is not surprising that non-farm people fail to grasp what has been going on. Yet the magnitude of the change explains why we have many tensions, plus farm programs to treat the problems of adjustment. The consumer has fared very well indeed and it is not necessary to point the finger of blame at anyone. Just tell the truth.

The fact is that modern farming methods have made the farmer a bigger man. With his new tools and his new knowledge, he can do three to ten times more than his grandfather, depending on the type of farming.

I do not believe, as some do, that the farmer was pushed into technological and business farming. He chose the new methods eagerly, even though the rapidity of the change has at times caused much economic anxiety. He chose the tractor in preference to the horse, then bigger and better tractors and auxiliary machines. He hired the electric motor because the motor can duplicate the muscle work of a man for a tenth the cost. He took readily to the new chemicals that transformed agronomy, and the new science of breeding and feeding his animals for higher production. Incidentally, you safety experts know these improvements have also spawned a whole new set of working hazards.

The speed with which this transformation has taken place is a tribute to the farmer's own ingenuity and enterprise, and to the vast forces of institutional and commercial invention which were unleashed by this enterprise.

Changes in farming have been complicated by changes in patterns of supplying farmers and processing the products of the farm. Farm suppliers must produce in quantity to survive, so they advertise diligently and put forced draft behind educational and research programs, their own as well as those of the colleges.

Processors have found their business changed radically by the advent of the supermarket. This institution has brought low-cost merchandising, standardization, and convenience packaging. The processor had to look to his sources of raw material to meet this new demand and was forced to change his buying habits to suit the somewhat cumbersome organization of the large food chains.

The tremendous productivity of farmers has made food steadily cheaper. City folks may find this hard to believe when they check out a grocery order. They need to be reminded that the higher costs they pay are the costs of the packaging and processing that have been added to the food since it left the farm.

Less than a tenth of the people in this country are now farmers. As a matter of fact, more than 90 per cent of all our food is grown by approximately one-twentieth of our people. A hundred years ago it was the other way around. This change

has given us the highest standard of living in the world, but it also has given us some persistent headaches, because many people have to leave the farm to find other work and it is necessary to reduce the amount of land which is being farmed.

It is this adjustment that has brought the long succession of experiments we call government farm programs. These programs have not all been successful, but it is only fair to say that they have been mostly honest attempts to save us from depression, and to save a lot of people on small farms and on poor land from becoming a burden on the nation.

The cost of farm programs has been relatively small when you keep in mind the magnitude of this judgment. The experiments will continue until we get more nearly the right number of people living decently on more nearly the right amount of land.

It's up to us to call forth the kind of citizenship that will direct the adjustment wisely, and to have wisdom we must have understanding.

A lot of people, both on and off the farm, carry in their hearts a deep concern for the future of farming. After all, haven't we drawn from our farms, generation after generation, young people of good work habits, stable outlook, and honest ambition? Hasn't the family farm stood us in good stead throughout our history? Do we want to trade it in for some kind of agricultural factory system which might grow out of present trends toward big business farming? Can our traditional family-farm system meet the new demands and continue to survive?

I believe the answer to this last question is yes. There have been many experiments in vertical integration as well as industrialized farming. There will be more as we probe the future, but as of now farming still belongs solidly to the individual operating his own business. Except in a few fields, the industrial type corporation seems to be out of its element in farming. I do not believe that processors or grocery chains want to farm. They will go into it only if they must, to procure the kind of raw material they need, when they need it. Its investment cost is too high by industrial standards. There are too many variables, too much grief.

I believe the independent farmer is in business to stay, *provided he recognizes the importance of keeping himself fully employed and the necessity of turning out a good product at a cost in keeping with his tools and his capacity.*

This calls for a farm of considerable size, a \$100,000 investment in land and capital, perhaps more. It means outside financing of one kind or another, probably some separation between ownership of the land and the ownership of the other means of production, because the investment load is likely to be too big for one family.

There's a lot to be said for the two-family farm, giving full employment to two able-bodied men, father and son, two brothers, or an operator and an able hired man. The two-family farm makes better use of land and machinery, and it makes farming much more compatible with modern standards of living. Can this size economic unit compete successfully with the really big ones? It will depend, of course, on the type of farming and on the organizational aids farmers can muster. By the standards we now recognize in the midwest, I would say that this bigger family farm can still run corporation farming off its legs. This means that in safety and other programs of betterment we can still address ourselves to the farm family as an independent operating unit.

The larger family farm has an economic resiliency hard to match. This accrues from such things as personal interest in the business, willingness to put in overtime at half rather than double pay, willingness to build up capital rapidly in a good year and to live on it when the going is hard.

I believe the farm as an independent economic unit of moderate size can hold its own as the prevailing pattern of American agriculture if we can give some help in bringing the amount of land and resources in farming into better balance with the needs. It is hard to understand that we now need less land to feed more people.

This points to another line of understanding that we must diligently pursue if the public image of agriculture is to be an honest one. It is really a wonderful thing that at a time when the population is growing we still have surplus land for highways, industrial expansion, airfields, parks, and other very important non-farm uses.

Somehow we as a nation have gotten ourselves into a predicament where we are farming some 70 or 80 million acres of land which should be shifted to other uses. One time-honored method of adjustment, letting the price drop so far that this land will go back to the county for taxes, is no longer socially acceptable. We just don't believe in putting anybody through this kind of a wringer any more if we can possibly help it.

Modern farming demands optimum use of the best land, so the acres to be shifted should be the acres least suited to farming. This is hard for the individual farmer to do. Goaled by fixed overhead costs and fired by ambition to succeed, using the land he happens to have, he produces for whatever market there is. If the market is phony and the price bears little relation to honest need or true demand, farming is thrown even more out of kilter.

Use of public funds to develop new agricultural land or subsidize the improvement of unsuitable land aggravates the problem further. Our government does have a responsibility in dealing with this overexpansion in agriculture. Present programs for idling acres tend to treat symptoms rather than causes. They are unacceptable as long-term solutions.

I've been plugging for some time for something I call a Federal Land Reserve Board which might be given the responsibility of planning and implementing long-time adjustment in the use of land. We need a sounder approach than that we have been using. *Over and beyond his own ability, nothing will do more to assure the farmer of success than bringing the total capacity of the nation's agricultural plant into reasonable line with the total need. This is the way to make the free market effective.*

There is a fourth area of concern which I recommend to the attention of all leaders in farming and agribusiness. If we are to entrust our food-growing function and our best land to one-twentieth of our people, they should be among our finest citizens—strong, competent, well-educated, proud of their work. This means more than just earning a living. It means taking a responsibility for conservation of the soil and the countryside, dealing intelligently and confidently with the economic and sociological

problems of the changing rural community, building their own safety and improvement programs, and impressing the viewpoint of the grower on our national and international leadership.

A good many farmers I know are living up pretty well to this ideal, but it certainly is not the usage being held before the American public today.

The entire nation should re-examine the new role of the farmer in the light of the public welfare and America's future, divest it of some of the romantic and nostalgic notions that have come down out of the past, take a hard look at the facts of adjustment, and in general put the food industry into more realistic focus.

It is tragic that the American housewife, whose family has been emancipated from the historic fear of famine, should wheel her cart down the wondrous aisles of the supermarket, utterly oblivious to how this great treasure was assembled, often contemptuous of the farmer and his carping problems.

Fifty years ago an American Country Life Commission, headed by Liberty Hyde Bailey and utilizing many of the best brains of the time, presented to President Theodore Roosevelt a commission report in which they evaluated the needs of the country at the turn of the century, when we were much younger. They wrote a credo for American agriculture that is well worth

reading today, and they drew in surprising detail the blueprint that has made possible the success story of American agriculture unfolded in the past half century.

I think this job should be done again. As an editor I have confidence in the written word. If it is well considered and carries the force of insight and sincerity, it can go far to elevate our purposes and unite our efforts.

What do we want from the American farmer in the future? Continued abundance, yes, but this is only a part. The nation should speak out on this subject.

Is the farmer merely a cog in an economic machine? Is he a cow to be kept happy and well-fed so he will give much milk? Or is he a free man doing important work and having an important part in the great decisions of his time? What we really want him to be may affect the way we tackle the host of perplexing problems that have grown up around today's agriculture.

I have sketched this background of modern farming because it needs to be understood by all who work in farm programs. If we are to be effective leaders, we have to believe in farming as a vocation and farmers as good and useful citizens. I urge you to familiarize yourself further with the truths about farming and enlist in a crusade to make them widely known. If you do this your work in farm safety is sure to be blessed with success.

THE ACCIDENT SYNDROME

By MORRIS S. SCHULZINGER, M.D.
Cincinnati, Ohio

Practical considerations as well as the complexity and enormity of the accident problem have made it advisable to attack the accident problem piece-meal. Hence, the division of accidents into home accidents, automobile, aviation, recreation, farm accidents, etc.

Basically, however, all accidents, no matter where they occur, have more things in common than what sets them apart. I would know of no group who could ap-

preciate this truism better than the farm group.

For many years a dissertation on accidents frequently began with a statistical recitation of the horrible annual accident toll. The figures seldom varied:—accidents are the first cause of death under the age of 35 and the fourth cause of death for all ages. One hundred thousand deaths are caused by accidents annually, 400,000 are injured with permanent disabilities, 10,000-

000 are injured with one or more days of disability and the cost of accidents is \$10,000,000,000 annually. In recent years, the cost has risen to some \$15,000,000,000 and by means of some statistical magic, the annual casualty figures were raised to 50,000,000 injured, with one or more days of disability.

When the impact of these figures began to wane, the astonishing fact was brought out that in terms of productive years lost, automobile casualties alone are responsible for one and a half million years lost annually. While counting all accident fatalities, nearly 5,000,000 productive years are lost annually in the U.S., and these figures do not include the losses due to partial-and-permanent-disability accidents.

If a disease was to threaten continually with incapacity or extinction any large or small segment of the population, particularly among the young, the medical profession, the public health services and an aroused public would promptly shoulder the responsibility of studying its cause and checking its havoc. The seeming public indifference to the annual accident holocaust and the innumerable personal tragedies that follow suggests that accidents may serve some deep inner needs of the individual, or that the overwhelming nature of the problem evokes a measure of fatalism and resignation in face of the inevitable, reminiscent of parts of the Orient, where every new calamity denotes little more than a break in the monotony of suffering. Yet progress in accident prevention has and is being made as is evidenced by the proceedings of the current National Safety Congress, and the increasing number of reports from research laboratories throughout the country.

Some 30 years ago when the author entered the practice of medicine, there was no accident literature to speak of, accidents were considered fortuitous experiences or an act of God, and accident prevention was largely unknown outside of major industry. Soon after World War II, accident prevention bloomed forth as a new and exciting field due to the introduction of the magic concept of "Accident Proneness." You will recall the erstwhile chorus of many loud and booming voices pronouncing, that 85 per cent of all accidents were caused by 15 per cent of the people and that all we

needed to do to solve the accident problem was to find, train, isolate or remove the 15 per cent of the culprits who caused most of the accidents.

By 1947 this author had treated some 35,000 accidents in his private practice and on the basis of experience the new concept of accident proneness, as the cause of most accidents, did not ring true. The challenge was great and thus the author began an intensive study of his case records, which among other things showed: that when the period of observation was sufficiently long, i.e. one or more years, the 15 per cent of the population who suffered 85 per cent of the accidents were not the same people, but were in reality a changing or shifting group, with new persons constantly entering and leaving the group.

It is now generally agreed that the vast majority of all accidents are preceded by personal acts which, in a manner, pave the way for the accident and in fact, make its occurrence almost inevitable. The personal acts described as precursors of accidents are usually in the nature of physiological, psychological, or physical aberrations, subject to detection by clinical means. Yet, accident prevention is still largely directed at manipulating the environment while clinical efforts aimed at manipulating the individual are relatively rare.

In the past, major gains in accident prevention were truly achieved by all of those measures commonly known as "safety." Our hope in stressing a change of emphasis, from the environmental to the personal and clinical aspects of the problem is to engender the overall conclusion, that future major gains in accident prevention devolve upon a comprehensive clinical approach of which "safety" is an integral part.

Various studies suggest that an accident in itself is merely a culmination, and often times an inevitable culmination, of single or multiple factors which temporarily or more or less permanently are in the background of life. Given a set of circumstances of unfavorable nature, with fair fidelity, it is possible to predict the coming of an accident, but the background is more important than the culminating final event. The accident itself chiefly serves as a trigger mechanism for the impending disaster.

Clinically speaking, there are three factors underlying most accidents: an environmental hazard; a temporary or a prolonged personal impairment, or maladjustment; and faulty behavior under stress. It can also be shown that preceding most accidents, there is a combination of signs, symptoms, and circumstances which together determine or influence its occurrence. These signs, symptoms and circumstances, though numerous, follow a pattern and lend themselves to the formulation of a syndrome—the accident syndrome.

The Accident Syndrome is thus a combination of signs, symptoms and circumstances which together determine or influence the occurrence of an accident.

Susceptibility or proneness to accidents is largely a passing phenomenon, shifting from group to group; with age, with experience, with the degree of hazard, the intake of alcohol or drugs and a host of other transitory or more or less permanent situational, personality and health factors. In the course of a lifetime nearly everyone can and does become temporarily accident prone. Most persons, consciously or sub-consciously, rapidly adjust to their unsafe or accident prone state and an accident is avoided. It is when the individual fails to recognize his accident prone state, or when he is unable to adjust to it, that an accident is liable to occur.

Susceptibility to accidents varies in degree and duration, and fluctuates with personal and situational factors. Susceptibility to accidents may be divided into personal and situational proneness, and these may be subdivided into mild, moderate, and severe, and again, into temporary, long-term and permanent accident-proneness.

Freedom from accidents depends on physical and mental health, on an integrated harmonious functioning of the sensory-motor and psychomotor systems, and on conditioned safe behavior, or the ability to react in a safe manner under stress. The adequacy of adjustment of the individual to himself and to his environment, and his ability to adapt to sudden change, is a measure of his non-susceptibility to accidents at any given time. An individual's accident potential may thus be said to vary with current stresses and strains, superimposed on basic or long-term personality trends.

For maximum effectiveness, accident prevention should begin in early childhood with a careful indoctrination in safety habits and the art of safe living. The home is the place where susceptibility to accidents and immunity to accidents are born and bred. The family and the home are the ideal units for favorably affecting accident susceptibility and accident experience. The schools, industry, and the community also may admirably serve these aims.

Essential to the success of the clinical method in accident prevention is a working familiarity with the accident syndrome and with the physical, physiological, and psychological factors which determine accident causation. Another pre-requisite is a systematic effort to check out predisposition to accidents, and the pre-accident state, in all routine medical examinations and screening procedures. More intensive examinations and appropriate therapy may be necessary in individuals with a high accident potential, in accident repeaters, in persons under severe emotional strain, and in those engaged in hazardous pursuits. Careful clinical examination and treatment are especially indicated in the three main accident-producing groups: the young, the male and the maladjusted; as well as in the permanently or acutely accident-prone.

Viewed as a clinical entity it becomes incumbent upon physicians, in their examinations of patients, to determine the possible presence of accident-producing abnormalities, or factors and to forewarn their patients accordingly. Of special concern in the clinical prevention of accidents are the patient's current illness or state of health, their past medical history, their current life situations, emotional stability, motivation, developmental and family backgrounds; history of adjustments on the various levels; current and long-term stresses, behavior under stress, physical and mental disabilities, smoking and drinking habits, the use of drugs, the frequency of accidents, occupational and situational hazards, etc.

To diagnose the accident syndrome or the pre-accident state, the properly trained physician would begin with a careful history and physical examination of the patient. Psychological and physiological tests may provide additional aid. The accumulated information then has to be evaluated on the basis of clinical experience, and the study

of the patient. In diagnosing the accident syndrome, as in other complex clinical entities, diagnostic acumen is sharpened by a state of alertness, diagnostic receptiveness, and a heightened index of suspicion.

Suppose the physician does diagnose a pre-accident or accident-bound state in one of his patients, what could he do about it? The physician's first task is to protect the patient against the impending accident. With this in view, pre-accident patients should be divided into three groups, those who are safe for exposure to hazards; those who are unsafe; and those who are safe for limited exposure.

Where treatment is indicated, pre-accident clinical therapy should attempt to prevent an accident thru the control or cure of the known accident-producing personal impairments and maladjustments, discovered in the examination of the patient. Of lesser importance, but never to be neglected, are the situational or environmental hazards of the individual which are to be controlled with the aid of safety specialists. Every physician's office thus can and should become a source of accident prevention information and treatment.

In clear-cut cases, treatment of the accident syndrome should begin as soon as a working diagnosis has been established and the treatment should be as all-inclusive as possible. In border-line cases, the need for appropriate treatment arises whenever pertinent accident-producing physical, physiological or psychological abnormalities are discovered, and whenever the loss of emotional, psychological, or physiological equilibrium is threatened. The aim of treatment should always be to eliminate, modify, or neutralize the accident-producing factors discovered in the examination of the patients.

What about the vast majority of accident casualties who do not happen to see a doctor before the accident? Here undoubtedly preventive therapy would meet its greatest challenge. To prevent most accidents, emphasis should be placed on: educating the entire population to recognize common, recurring and other important accident-producing factors. Emphasis should also be placed on the importance of adequate and speedy adjustment to impairments; and on developing a conditioned pattern of safe

behavior and safety awareness. Highly susceptible or "unsafe" individuals and those exposed to hazardous pursuits should receive more intensive preventive treatment.

In order to reach every segment of the population and still remain within realistic bounds, prophylactic therapy should attempt to make use of seminars, workshops, and educational literature, as well as visits to the home and periodic re-examinations. Preventive therapy should stress accident prevention in personal health education, with emphasis on the role of the individual's deficiencies, abnormalities, capacities and skills in accident causation and prevention.

Guidance should be provided on: vocational placement and training; on general and specific situational hazards; on the role of the home and the family; on the need for adjustments on the various levels; the importance of youth, inexperience, alcohol, speed, fatigue, and stress; on the role of such factors as aggressiveness, frustration, lust and guilt and the role of extremes of temperature, humidity, seasons, weather, time of day, drugs, smoking, CO, noise, vibration, high altitude, transient factors, etc.

From the above listing it can be readily seen that the clinical and "safety" approaches to accident prevention overlap in many respects. The need for cooperative effort and teamwork by many disciplines cannot be stressed too often.

Important therapeutic goals in treating pre-accident patients are to help them achieve and maintain emotional equilibrium, to help them diffuse their uncontrolled aggressiveness with appropriate action, to help them develop a proper sense of respect for minor temporary impairments, and to help them adjust to their permanent impairments. In their unique position of trusted advisers in matters of health, physicians have the opportunity and the responsibility to educate their predisposed patients in the clinical principles of accident prevention. Such an effort should be no more difficult nor less rewarding than the education of pre-cancerous, pre-cardiac, pre-hypertensive, diabetic, and other patients whose continued well-being depends on an acquired ability to recognize pertinent signs and symptoms and to adjust to their impairments.

In the final analysis, true accident prevention rests with each individual citizen, and education in the basic principles of the accident syndrome as part of an individual's personal hygiene education, could go a long way to prevent accidents by way of a safer pattern of behavior and living.

Will the clinical approach to the prevention of accidents place an undue burden on the medical profession? Probably not. In the vast majority of instances simple non-medical measures will suffice. Where a physician's attention is called for, a considerable number of the patients are likely to derive therapeutic benefits from the mere evaluation of their accident potential by the physician, and the insight gained therefrom. Some may require superficial psychotherapy, correction of specific physical or physiological impairments and maladjustments, a course of training in safe practices, or a change of employment. Relatively few patients will require prolonged medical treatment or deep psychotherapy. The relatively small percentage of accidents which are due to specific psychological conflicts, or to a compulsive need for self-punishment through injury, may require specialized psychiatric help. The treatment of physical and physiological impairments and superficial psychological abnormalities is, in the main, along straight medical lines.

By the very nature of the accident syndrome, preventive and therapeutic efforts must deal not only with the individual but also with his family, the community, and with the patient's social, economic and physical environment. In modern urban society, this calls for a community-wide multidisciplinary approach with the personal physician in a position of leadership. The clinical opportunity to prevent an accident before it occurs, through the identification

and treatment of the pre-accident patient, should provide the necessary diagnostic and therapeutic challenge, which has hitherto kept physicians from playing their proper role in accident prevention. Widespread public participation and approval would be of considerable help.

In major industry and in other controlled environments, the clinical method of accident prevention can be applied even now. In other areas of activity a successful application of the clinical method would be facilitated by an enlightened and aroused public participation, the development of a solid body of validated clinical facts, thru research and an active participation of the medical profession. The establishment of special departments by medical schools for the study and teaching of accident causation and prevention would be a welcome step in the right direction.

To advance and test the limits of usefulness of the clinical methods in accident prevention, the author proposed several years ago the establishment of community accident prevention and diagnostic clinics. Such clinics would be exceedingly useful in the practical daily task of diagnosing and treating pre-accident patients. They could also serve research goals by enabling a systematic study of the health, behavior and adjustment of pre-accident and post-accident patients. Well staffed and equipped accident prevention and diagnostic clinics would also serve the needs of undergraduate and graduate medical teaching and as centers for public education in the hygiene of accident prevention.

Unless vigorous application of the clinical approach be espoused, or others of equal or greater promise, if there be such, then the present appalling accident frequency will continue.

WORKMEN'S COMPENSATION IN AGRICULTURE

by E. W. FOSS
Pres. Cornell University, Ithaca, N. Y.

Since the 1930's, in many of the States, there has been a marked increase in the number of farm accidents. The most serious of these have

been able injured workers in getting adequate for injuries without the delays present under common law or employer's

liability laws. The damages include payment for lost time, medical and hospital bills, and reimbursement for permanent injuries.

Until recently, agriculture was not included in compulsory coverage. At present eight states; Alaska, California, Connecticut, Hawaii, Massachusetts, Ohio, Vermont, and Puerto Rico, cover agriculture the same as other workers. Ten other states have some types of compulsory agricultural workers coverages—most of them machine operations. These additional states are Arizona, Kentucky, Louisiana, Minnesota, New Jersey, New York, Oklahoma, South Dakota, Wisconsin, and Wyoming.

From an occupational hazard standpoint, agriculture has the highest death rate of all industry groups. It rates third from the top in total injuries and also third in deaths per 100,000 workers—exceeded only by the extractive industries and construction.

From a social standpoint, there is a need for workmen's compensation benefits by all workers including agricultural. With all other major industry groups covered, and with agriculture moving steadily toward almost complete mechanization, including more hazards, whatever major difference in "mode of life" of farming compared to other industry is fast disappearing.

Because workmen's compensation laws remove much of the risk of civil suit or injured employee against the employer, and workers prefer to be employed by farm operators extending such coverage, there is also a large amount of voluntary agricultural workmen's compensation insurance.

To summarize the workmen's compensation table, some 22½ thousand farm operators in 38 states paid over 10 million dollars of premium based upon some 300 million of payroll. Thirty-six deaths were recorded as part of the 28 thousand "large" claims, amounting to nearly 9 million dollars. This is big business as well as a tremendous waste!

Employer's liability for farm employees shows one and one-half millions of premium based on 66 millions of payroll paid by farm employers in 43 States. Approximately

three thousand medical claims came to over a quarter of a million dollars and 1500 liability claims came to a third of a million dollars—also big business and big waste!

From a safety standpoint, such records of work injuries in agriculture would be a powerful ally. In education we would have exact goals toward which we can aim our publications, our demonstrations, and all other efforts. In engineering we can likewise turn our energies toward improvement in machine guarding, safety interlocks, housing structures, electrical hazards, etc. Enforcement can likewise—through insurance inspection and state regulations—bring about many improvements, based upon facts. Unfortunately, these workmen's compensation records can be summarized only in dollars—no injury summary is available or even possible under the present system of workmen's compensation records! The employer's liability records are likewise useless from an injury summary standpoint.

Recommendation

1st. Recognize the potential value of both workmen's compensation and employer's liability records to aid in agricultural safety work—both research and education.

2nd. Develop a system of record keeping, in cooperation with and the sanction of the insurance industry, that will provide satisfactory information on injuries.

3. We need the assistance of the Farm Conference Board of the National Safety Council on a national level to expedite work with the National Bureau of Casualty Underwriters and with the National Council on Compensation Insurance.

4. We need every state's rural safety council to back this program—particularly to point out the needs to the respective state insurance organizations.

WHY A SUMMARY OF BASIC AND APPLIED RESEARCH IN THE FIELD OF FARM AND HOME SAFETY?

By L. W. KNAPP

Institute of Agricultural Medicine, State University of Iowa, Iowa City, Iowa

For years we have all been aware of the enormous numbers of farm and home accidents. Best efforts to date, although great, have not solved this problem. My premise is that one of the major elements missing in our efforts is the lack of general recognition of the usefulness of safety research and a definition of needed research.

One of the first principles in problem solving in any field of endeavor, including safety, is the identification of that which needs to be done. It is imperative that all the elements be correctly identified if any logical order is to be found for their assembly and the solution of the problem. Differentiation must be made between basic (underlying factors) and applied (problem solving) research and evaluation (surveys and studies). Programs and future research, if they are to be effective, must be developed upon fact and not hypothesis, personal opinion or speculation.

A logical step to a breakthrough in farm and home safety is the classification in summary form of all research, either safety or safety-related, listing that which has been done or is presently being undertaken. Any work under wraps or unintentionally left hidden will only delay the establishment of a sound basis for farm and home accident prevention. Too much time has already been lost in duplication of efforts or running down trails already proven unfruitful. Such detours frustrate the strong and discourage the weak, arousing a feeling that such work is useless and wasteful of men and money.

The summary will provide a number of needed links for a well thought out, organized effort toward developing an effective accident prevention program for the farm and home.

1. It will recognize work under way for improved communication between interested investigators.

2. It will provide a resource platform from which to launch new research efforts.

3. It will be a source of basic factors upon which educational programs can be developed.

4. It will provide a measuring stick for the progress made by those involved in safety research.

5. It will create enthusiasm in those doing such work and stimulate interest in those presently uninvolved but receptive to new ideas.

Each of us must in his own way stimulate those agriculturally oriented organizations, societies, manufacturers of machinery, land-grant institutions, and safety organizations to delay no longer. We must raise questions, suggest needs and show personal desires in such quantity that this summary of basic and applied research will be forthcoming immediately.

However, having shown such desire, the work is still not finished, for the compilation of this information again needs the same sort of support from you to assure its distribution and use as did its inception.

Lastly, I personally feel that this summary would provide you with a mirror, which, if we have the courage to look into with truth, would shock us with its emptiness. However, on the other hand, and far more important, is the possibility of setting in motion the creative thinking which will find a solution to the problem of reducing the number of farm and home accidents about which all of us are concerned.

There may be a wide difference between the mechanisms of a modern rocket and farm and home safety, but each needs an adequate launching platform if it is to perform successfully. There are visible signs of sputtering safety rockets all over the nation. The need has never been greater for this summary of basic and applied research than now. Let's set up an adequate launching platform for once and adjust the gyros for a true course.

WHAT DO WE NEED TO MAKE FALLS AN EFFECTIVE AREA OF EMPHASIS FOR AGRICULTURAL SAFETY?

By HERBERT T. BOGERT

Agricultural Safety Advisor, The Industrial Commission of Ohio
Div. of Safety and Hygiene, Batavia, O.

I will attempt to cover the findings and recommendations of the 1961 National Institute For Farm Safety, and other additional points for reducing the occurrence of falls in the agricultural industry.

Injuries and deaths from falls affect persons of all ages, and are usually caused by a "loss of control," in some way. To help to eliminate or reduce the injuries from falls:

We need to develop a greater understanding of the exact causes of falls.

We need to develop the ability to recognize the causes of falls, on the part of all persons with whom we work.

We need to develop an increased awareness of the various injurious effects of falls.

And finally as a result, we need to thus reduce the causes of falls.

Stateways and steps are recognized among the leading sources of falls — around the home, the farm, and around farm machinery. To help more effectively reduce the causes of falls from this source, we need:

More adequate lighting.
Better conditions of construction, repair, and maintenance.

Removal or elimination of the practice of storing items (of clutter) on steps.

More adequate handrailings and handholds.

More suitable and solid step coverings.

Ladders are another important source of serious falls. In this relation, we need:

A more adequate awareness of what really constitutes a "good ladder."

More understanding about how to correctly take care of a ladder, to preserve its quality.

Better awareness of how to correctly use a ladder.

Floors in themselves are the source of many other falls; as a result, we need:

To motivate people to eliminate the loss of rugs—scatter rugs, etc., by use of the various recommended methods.

To eliminate highly waxed slippery floors, and to popularize the use of non-slip floor waxes instead.

To improve housekeeping, to remove obstructions, etc., in passage ways.

Better maintenance of floors in barns, on porches, in attics, etc.

Permanent openings in floors of homes, of hay mows and other parts of farm buildings, etc., need to be more adequately protected with railings, etc.

Clothing is a cause of some falls. We need to develop a respect for the fact that bad shoes, high heels, loose and long shoe laces, cuffs on trousers, ragged trouser cuffs or bottoms, etc., must be eliminated to effectively reduce this cause of falls.

Farm machinery is involved as a source of many very serious falls. Many things have been done in recent years to eliminate the falling hazards connected with machinery. However, with the increasing size and height of much of our modern farm machinery, it is evident that we need further effort in eliminating fall causes.

We need more usage of non-skid platform and step materials, of the expanded metal grating types, carbonium surfaced metals, non-skid coatings, etc.

We need more adequate and solid hand rails and hand holds.

We need continued effort toward the designing of farm machines so that those parts which are now tripping and falling hazards, (such as levers, bars, rods, cables, etc.) will not obstruct the safe mounting, riding, or dis-mounting of farm machines.

We need a continual effort toward developing a respect for the hazard involved with extra riders on farm equipment.

If additional riders are needed in the operation from time to time, then we need to have provisions designed into the equipment, for the safety of such additional persons.

Recently, one possible cause for many falls, which has become recognized and has been discussed, is the problem of "inadequate vision" (the inability of the individual to see clearly and adequately).

We need an increased study and understanding of the inter-related factors involved in the subject of human "vision" as it applies to our personal safety.

Finally, in order for the overall emphasis on "fall safety" to become most effective, we

all need to give our co-operative assistance in developing a bibliography of presently available materials and information which could apply to the subject of fall safety, and which could in turn then be used by all safety promoters.

We need to compile a "catalogue" of all applicable program materials and information, films, slides, bulletins, demonstrations, visual aids, etc. The National Safety Council—Farm Division, in cooperation with appointed members of the National Institute For Farm Safety, has been suggested as the logical "clearing house" and compiling agency for this overall project, to help make fall safety an effective area of emphasis for agricultural safety.

RURAL YOUNG PEOPLE SAFETY PROGRAM PLANNING

Session number one was "Techniques of Initiating Safety into the Home," and was illustrated by a film on handling and controlling poisons in the home. Nadine Elder was speaker at this gathering. A very good film on poisonings is available for only five dollars. To promote safety at the local level, a poster contest on safety could be used.

At number two, Frank R. Burrows, Jr., presented a new approach to safety by the use of comical gimmicks and novelties. "Reaping the Harvest of Your Farm Safety Program," was his topic. If each person would carry a kernel of corn with his change, he would have a reminder of safety every time he saw his change.

In the third group session, Mr. Grice Sexton led the group discussion on "Setting up the Theme for Safety Programs." Traffic signs were discussed. Four things can be done to help with traffic safety. They are:

1. Correctional signs can be observed.
2. The law can be strictly enforced.
3. Roadsides can be kept free of weeds and obstructions.
4. Coffee stands can be set up along the road to help keep drivers alert and awake.

Number four, "The Importance and Value

of Accident Reporting," with Rollin Schneider as speaker was interesting. Portable flares, fire extinguishers and first aid kits are some safety ideas that would help on a car if there were an accident. Prizes for safety plays and exhibits could help create interest. The seven to thirteen age group could be given a small prize such as a ball point pen. In the fourteen year old and up age group, they can win the big prize—an expenses-paid trip to the National Safety Congress.

The meeting Wednesday morning was, "Tools in Home Accident Prevention." Jon F. Greenstein gave us ideas on using them effectively. Visual aids as well as communication can be used to promote safety. Some examples of this would be a flannel graph with cut-out pictures to incorporate safety. Slides can also be used to create an interest in safety as James T. Wadkins proved. Some of these were pictures which had been enlarged and were projected overhead. Drawings can be used as a basis for these slides. Robert E. Whalen explained and illustrated how low-cost exhibits can be made and used effectively. A "do-it-day," was an idea which could apply to any type of safety and would mean—"Do it today, not tomorrow"—when it may be too late.

REAPING THE HARVEST OF YOUR FARM SAFETY PROGRAM

By FRANK BURROWS
Field Service Dir., Citizens Traffic Safety Board, Chicago

I wish to create an enthusiasm within you so that you will reap a better harvest from your safety program. By using some of what I call "advertising gimmicks"—may I refer to them as enjoyable methods of "fertilizing" a program—your harvest should reap dividends in your community.

I hope to impart to you a variety of ideas

to advertise good safety tips. This collection of ideas first began to accumulate when I was asked to lecture at Northwestern University Traffic Institute. Since a large part of my work consists of lecturing before all kinds of groups, old and young, large and small, a need to do something other than just talk safety arose.

I discovered, as I am sure you have be-

cause it has happened to you, that part of the audience does not receive the safety message. So I began to incorporate little attention getters to hold interest. In other words, I improved upon my fertilizer. The audience seemed to receive the safety messages more strongly, especially if they were down wind, and in a sense I became a better harvester for safety.

To understand how an idea, or "gimmick," should be used, one must keep in mind three definitions which when used through all your safety planning will enable you to attain the maximum results. The three definitions are:

1. **Safety**—Doing the "job" the right way. Job is anything a person undertakes to do—standing, sitting in a chair, crossing the street, driving a car, running a machine, peeling potatoes, shucking corn, milking a cow, etc.

2. **Safety Education**—The art of making a man want to do what he ought to do.

3. **Safety Program**—To create an appetite in people who are not hungry.

Keep these definitions in mind. I am going to demonstrate how I sell safety. (Here the audience viewed a short part of a traffic safety lecture in which several visual aids, gimmicks, magic and humorous stories were used as an example of what adding a touch of glamour to a safety message means) . . . and that is the way I attempt to present the safety message to the people here in our area.

You know, sometimes those of us who have a safety message to sell overlook the obvious. Sometimes we create our own illusions. Our own most trying problems are often the result of self-deception. And too many people selling an intangible safety message are prone to assume that the doors are locked against them when the difficulty is actually a mental block. Remember Harry Houdini? He was an ingenious entertainer.

Behind Houdini's skill as an illusionist was a profoundly scientific mind and a keen grasp of the application of modern mechanics to intricate physical problems. He matched wits with locksmiths and prison wardens, and never failed to escape within the time limit. But he almost failed on one occasion by overlooking the obvious.

The warden who nearly outwitted Houdini

used a simple artifice. He placed Houdini in an "escape-proof" cell and closed the door. Houdini tried all his ingenuity on the lock but could get no action from the mechanism. A few minutes before the deadline, in desperation, he tried the knob of the ponderous door. Presto! It opened. It hadn't been locked in the first place.

I want you to use gimmicks, humor, or anything else you can think of to enrich the mixture of your fertilizer to reap a better safety message harvest. Let's stop overlooking the obvious. Let's use proven advertising principles. Let's encourage people to at least look at or want to hear what we have to offer.

Let me encourage you to use some of these ideas so that you will not only be doing a good deed, selling safety, but you will enjoy it more and you will be creating an appetite in people who are not hungry by making them want to do what they ought to do—that is, to do every job the right way.

Here are some of my ideas. You could build a whole routine around gimmick types of glasses. "Goo-goo" glasses—funny to look at, aren't they. Goggle glasses—make me look side. Open and shut glasses make me look as if I'm popeyed. When I'm wearing these I could tell you that I want to see what's actually causing accidents. While you're laughing at my glasses, you're listening to my message. This is what you have to do with your safety program. People will enjoy it more, and they will receive more from it.

Here are some other articles. I have a little police badge, a little boy's police cap, his gun, his whistle and his handcuffs. Any one of these items can be tied into a safety message. You can tell the audience while twirling the handcuffs that with their cooperation you can "handcuff" a certain cause of accidents. With the gun you could pretend that you are out "gunning" for crime and that it is the thing that causes accidents in a specific field. Blowing your whistle can be tied in with blowing the whistle to stop accidents, and so forth.

You could build a whole safety message around dollar bills that come in many shapes and forms—large comic bills, little dollar bills, rubber dollar bills. With a little bit of imagination you could tie in the cause

of accidents or stretching your money, stretching money through the prevention of accidents. See what I mean. Let's enrich the fertilizer and reap a better harvest!

I have developed a little **safety six pack** in order to help you plant a safety message in everyone's mind. This six pack contains six items which have retention value and are very inexpensive. The six items are:

1. A piece of string—"string along with our message of safety."

2. A kernel of corn—a pocket or change purse reminder of the need for cooperation of the individual in the safety program.

3. A safety pin—to be pinned on one's clothing as a reminder to keep one's guard up against accidents and be safe at all times.

4. A band-aid—to be placed on the back of the hand or dashboard of a car as a reminder that traffic laws or good safety rules practiced will hardly ever result in an injury serious enough to need more than a band-aid for repair.

5. A rubber band—"you must stretch your efforts for safety."

6. A lollipop—"don't let accidents make a 'sucker' out of you." "Work hard to 'lick' the problem of accidents."

Let me give you an idea of how to think about enriching your safety message. I have what's called a "Hypo-Pony." It looks like a regular doctor's syringe, and it looks as if I am drawing blood right out of the air. I saw this article in a drug store. It cost a buck and a half. I felt I could use it in a safety message, so I purchased it.

Shortly thereafter, I received a telephone call asking me what the title of my lecture to be presented before the Woman's Auxiliary to the American Medical Association would be. I looked at this toy on my desk

and told the caller that the title would be "You Can Get Blood Out of a Turnip." I made the turnip resemble their impossible task of selling safety. I then proceeded to tell them how to use good programming to sell safety, and I concluded my speech by saying that if you use the right tools, the right safety programs, etc., you can do the impossible.

Of course, the right tool for extracting blood is a doctor's syringe. I inject my syringe into this bloodless turnip and extract blood. This is the only time in my life that I ever received a standing ovation for a lecture, and it cost me a buck and a half.

If any of you are interested in enriching your mixture, if you want some additional ideas, please drop me a card or contact me by phone.

Use one or all of the ideas, enough so that the audience will receive your safety message. Remember, the purposes of these ideas are to add color, humor and enjoyment to your safety talk. So often selling safety is a thankless part of your program because the recipient knows it all and he mentally tunes you out.

The ideas expressed here and the ones I'd be happy to send you are audience tested. If used as suggested, or as you see fit, they will make your safety lecture a little unusual. This alone will create an interest in the audience. Some of these ideas, by nature, will bring a chuckle or smile to the faces of those who observe them. This tells you that they are listening. Please do not be mistaken by the laughter—it is not directed at you but at the "gimmick" which emphasizes your point.

Do enrich your fertilizer with these ideas and see how the audience's attention will improve. Remember, you can reap a better harvest from your farm safety program.

THE IMPORTANCE AND VALUE OF ACCIDENT REPORTING

By ROLLIN SCHNEIDER

Safety Specialist, University of Nebraska, Lincoln, Neb.

An accident is considered reportable when it requires professional medical attention, results in permanent disability, or when the accident victim is unable to return to his job or resume all normal activities on the succeeding day. Personal property when incident to an accident should also be reported.

What value do we receive from accident reports?

1. Gives an indication of the accidents that are taking the greatest toll in human suffering.
2. Gives an indication of what accidents are causing the greatest economic loss in an area.
3. Gives some indication of what accidents can be eliminated or controlled.
4. Shows up some of the danger areas.
5. Points up accident ratios.
6. Makes people more aware of their local problems.
7. Promotes safety on a National, State, or Local level.

What are the requirements of a good accident reporting program? It is essential that groups cooperate in acquiring accurate accident records. Careless work by any member of an accident reporting team can nullify the effectiveness of the project.

Perhaps the most important thing to consider in respect to an accident survey is its validity. The question we may ask is: "Does the survey test what it purports to test? (Or what it claims to be).

Another requirement is the reliability. The survey should be trustworthy or fit to be relied on.

Criteria for selecting a problem:

1. Try to avoid duplication of some other work.
2. Should be interesting. (There are no uninteresting subjects, only uninterested persons).

3. Should have practical value.
4. Data should be accessible.
5. Cost.
6. Time.

Characteristics that must be possessed by your accident survey.

1. Accuracy—The dissemination of correct information is very desirable, but the dissemination of erroneous information is unforgivable.

2. Objectivity—Survey should be based upon facts with verifiable evidence. If opinions must be used, use only those of qualified persons.

3. Impartiality—Only the truth is wanted. It should be impartially sought and recorded even though it be against your feelings.

4. Verification—The survey should be so reported that it may be readily duplicated and verified by some other person or persons.

5. Readability—If survey is to be read and used by other persons, it must be written in a readable and attractive style.

What methods may be used for collecting data for the survey?

1. Personal investigation method

- (a) Personal correspondence is used
- (b) More accurate data is usually procured
- (c) First hand information is received

2. Questionnaire method

- (a) This method is widely used and often abused
- (b) Questionnaire must be easily filled out
- (c) Questions must be clear
- (d) Questions must not be leading questions
- (e) Must be ample space for answers

What will you do when you get the information? Data may be put on a reporting

form. Prior to making the survey, you should set up a procedure for getting the information and analyzing it once you have it. To do this, the survey may be broken down into divisions. Such divisions might be:

1. Statement of survey (A study of all farm accidents in the State of Nebraska from January 1, 1960 through December 31, 1960).

2. Purpose of survey (To determine the agency most responsible for farm deaths for the period).

3. Limitations of the study (Time, who is concerned, what constitutes an accident, sex, etc.).

4. Procedure for collecting data (Questionnaire method or personal interview method may be used).

5. Analysis of data (Reporting form may be quite helpful).

6. Summary (Main points of survey).

7. Conclusions (Must be as a result of findings).

8. Recommendations (As a result of your survey, you may have ideas on how accidents can be reduced).

Accuracy & clarity of your survey. Any statement should be written so that it cannot be misunderstood. The basis for accuracy and clarity rests largely upon mutually understood definitions. It is impossible to make our write-up too clear.

Von Moltke, a general in the German army in the Franco-Prussian War told his officers, "Remember gentlemen, any order that can be misunderstood, will be misunderstood."

YOUTH SERVICE TO SAFETY

ATTITUDES ESSENTIAL TO THE SAFETY MOVEMENT

By WALTER A. CUTTER
Director, Center for Safety Education, Division of General Education
New York University

To someone approaching the "golden years," the youth picture is somewhat confusing. We are removed from youth—if not in space, then in time. There is a definite time lag even between the time most youth leaders have the youth and the time they reach the university.

Basically, the threats facing our generation today are not too different from those of previous generations, but how well are we measuring up as youth leaders? Do we ever tell exactly what is expected of young citizens by the state—by the community?

We hear of delinquencies. We read of Fort Lauderdale. We read of thrill crimes among middle and upper class youth. The "beat" generation.

Then we see, hear and read of unnumbered deencies, accomplishments, achievements, progress—in the ranks of youth!

We reach a preliminary conclusion: "... nothing is completely true about youth, yet there is an element of truth in all of it."

We hear much today of images. How do we, our organizations, our country look to others? What is our national image? Needless to say, it is a confused image.

To what heights, to what dimensions, to what levels of achievement do we want our young people to come? Who is the good citizen who exemplifies the best national traits?

Here again we run into an age-old problem. We find adults often want youth to do both more and better than the adults have done or are doing!

Spiritually, we have lost much. The gap between precept and practice becomes increasingly confusing to youth. This factor, added to the obvious confusions of our era, often puts us in a very weak position to issue appeals, mandates, challenges.

Before we can ask others to be better, we must be better. We must create and reflect a better image.

This difference between precept and practice is very important. A child—or a dog—can tell so easily whether a precept is from the heart, or if it is just words coming from the front of the mouth.

Urbanization has created a climate in which there is nothing for young people to do. Young people today do have chores, as was customary in the past. Many parents want to do more for their children than they had for themselves, but keep in mind that you can't give anyone more than he can take.

We are living in a soft age. This lack of sharing in responsibilities has caused many young people to develop a feeling of being "not needed" and "not wanted."

Any youth will respond to some motivation, so we must hold up higher standards. There must be a public and private morality to which people can be attracted.

One of the most powerful motivations in the world is to show our young people that they are needed.

Safety, we can agree, is not an electrifying concept for youth. Adventure, chance-taking, breaking new paths, and old prohibitions make much more appeal.

So, our approach to a philosophy of safety must play down the static connotations of safety, and place more emphasis on doing—doing whatever we do, better.

A good saying is: "What we want to do in safety is to teach people to do better what they are going to do anyhow!"

But, we must provide a basic, unarguable reason which will have oomph—and appeal—and compulsion!

All philosophies begin with basic premises and presuppositions. Are we interested in

such a basic and comprehensive premise? We have tried sportsmanship, maturity, as impulses. We have cajoled, criticized, praised, condemned. Perhaps we have not held up a high enough standard and held it up consistently.

Let us consider: *Your moral obligation for survival for service.*

Integrity. In today's world, we are quite literally "struggling for our lives," for our way of life, our freedom. We need the contribution of all to preserve our system. Have we made this clear and compulsive to youth?

Have we convinced them that they are needed for a big cause?

"What are you dying for—in an accident?" one might ask.

Look at the response to the announcement of the Peace Corps. Admitting the romance,

the adventurous challenge, the rampant idealism, and all, does this not suggest that *large goals breed large efforts?*

What you can do?

Illustrate in your own lives, and practice survival for service. Practice. Teach. Inspire.

Illustrate it to your own generation. Safe habits and attitudes spring from character. We need better men and women. Work to show youth that it is needed, and needed desperately.

Youth needs to be needed—by his family—by his community—by his state—by his country—by his world!

Survival for Service—a clarion call to youth!

Can we measure up to worthiness in issuing such a call—for such a philosophy?

Youth Service to Safety

YOUTH INVOLVEMENT IN ACCIDENT PREVENTION PROGRAMS TRAFFIC SAFETY — "SIGNS OF LIFE"

Illinois Assn., Future Farmers of America

Kenny Mc Millan, Pres., Illinois F. F. A.
Don Gillespie, Central of Clifton F. F. A.
Chapter

I. National level

- A. Chapter safety award program
- B. Each chapter applies; state winner selected from applicants; Central of Clifton selected state winner
- C. Winner selected on point system of different aspects of safety
- D. State winner submitted for national awards sponsored by National F. F. A. Foundation

II. State activities

- A. Through program of work
 1. State program of work—each chapter assigned to certain convention committees, one is program of work, another is a specially planned state committee on safety

2. Chapter program of work—definition: planned program of year's activities; the real accomplishments come through chapter programs; chapters have special safety committees, community service committees and other committees where safety is stressed; safety is a major project in most chapter's programs of work

- B. Through Illinois Foundation F. F. A.
 1. The Ill. Foundation F. F. A. was organized 14 years ago for the purpose of encouraging farm boys to develop characteristics essential for good citizenship and successful farming
 2. Safety is one of the Foundation's major award programs
 3. A special cumulative four-year record book is provided for students in safety activities

4. Awards—chapter winner's medal (provided by national foundation), sectional winner's plaques, district and state winners' plaques
5. Foundation brochure: published account of award winners, including safety
- C. Safe Corn Harvest
 1. Old stand-by looked forward to each year by farmers
 2. Sponsored by National Safety Council and Farm Equipment Institute
 3. Unique feature—safety six-pack
- D. Safe Farm Power (sponsored by Safe Corn Harvest)
 1. Kit in Corn Harvest
 2. Contains—newspaper mats, radio programs and releases, news releases, stickers, pamphlets and reminders
- E. Signs of Life program
 1. Sponsored jointly by N. S. C. and Illinois Agricultural Association
 2. Just in infancy with plans for increased usage
 3. Summary of statistics available
 4. Further Signs of Life discussion by Don Gillespie
- F. Additional programs and uses
 1. Safety used as topic for—public extemporaneous speaking contests, parliamentary procedure demonstrations and contests, school assemblies, radio programs, state and national convention exhibits
 2. State is sponsoring civil defense program later this year
 3. State officers stressing enlargement of safety programs
 4. "Gimmick" for state officer safety—picked up from last year's safety congress, kernels of corn, to remind one of safety, put in change pocket

FIRST AID AT THE ACCIDENT

Chicago Chapter, American Junior Red Cross, Chicago

The Chicago Chapter of the American National Junior Red Cross demonstrates first aid techniques used at the scene of an accident.

The members of the group are: Frances Losselyoung, Patricia Skora, James Cocomas, Robert Glenn, Claude Pickens, Sylvan Schwab, and George Reaves.

This summer at Lake Forest Academy, we participated in a Junior Red Cross Training Center. At the Center, we were trained in first aid and what to do at the scene of an accident. Of course, the primary purpose of first aid training is prevention of accidents. If, in our training we become aware of causes of accidents, we can prevent most of them and have less use for our first aid training. But no matter how careful we are—accidents do happen and we must be prepared to cope with them and take care of the injured party.

We are going to show some typical ac-

cident scenes—caused by carelessness, and follow this by the proper first aid techniques used in taking care of an accident victim.

Bob is tackling a very difficult problem—how to take this plain piece of wood and turn it into a decorative wall plaque. By the look of great concentration on his face, he is really struggling—but look out for that knife; it's very close to your hand.

Ooops! Well, it was bound to happen—that's a pretty nasty looking cut on your hand.

Now Jim comes to the rescue. With his first aid training, he is able to cope with the problem.

The objective in treating a wound is to protect it from contamination and control the bleeding.

First, Jim applies direct pressure on the cut, to stop the bleeding. If the bleeding is still severe he applies digital pressure.

He uses his finger to press the brachial artery against the bone to stop the blood supply. In extreme cases, such as a severed limb, a tourniquet is applied. Once applied, it is not loosened until the victim is in a physician's care. Once the bleeding has stopped, the wound is wrapped with a sterile dressing and bandage and the victim is told to see a doctor.

For minor wounds the steps are as follows:

1. The first aider washes his hands.
 2. He washes the wound with plain white soap and water.
 3. He applies a dry, sterile dressing and bandages it snugly in place.
 4. He tells the patient to see his doctor.
- The next accident is one that could happen to any of you girls in your own home. Frances is busy doing some ironing. Her friend Pat comes in to chat awhile and because the gossip seems so very interesting, Frances forgets about her work. Her hand is dangerously close to the hot iron.

Just as we expected—the hot iron topples over on her hand. It is a lucky thing that Pat is trained in first aid and will be able to treat the burn.

The objective in treating a burn is to relieve pain, prevent contamination, and treat for shock. The bandage used in treating the burn relieves pain because it excludes air, and prevents contamination. It is fitted snugly in place and tied securely. Always remember that a sterile dressing is placed next to the burn and any thick clean material such as a towel can be used to hold it in place.

The patient should see a physician.

To treat sunburn with which we are probably all familiar, sunburn lotion, cold cream, salad oil or shortening may relieve pain. Butter or oleomargarine should not be applied. A dressing should be used if blisters appear.

Our next accident can happen easily when you don't take the time to read labels. Sylvan has a severe headache. He knows that there is a good headache remedy in tablet form in one of those bottles on the medicine shelf.

That bottle looks right, so he takes a couple of the tablets. Too late, he realizes that the bottle contains a poison. Claude knows what to do, though. First he checks

the label on the bottle to see if the antidote is listed. If not, he remembers three words in treating poison cases: fill, draw, refill.

He quickly administers fluids in large amounts. Four or more glasses for adults. Water is most readily available. Milk protects the digestive tract and slows the absorption of poison. Baking Soda in water will induce vomiting. The Universal antidote will help in most poison cases. It consists of two parts burnt toast, which absorbs the poison, one part strong tea, which neutralizes alkali poisons, and one part milk of magnesia, an alkali that neutralizes acids.

In prepackaged form, it can be purchased at your drugstore and stored at home.

The next situation can be found where amateur electricians and "Mr. Fixits" are found. Claude has decided that he will fix some faulty wiring in his home. As you can see, he is an expert since, he's jamming the fuse box with a screwdriver.

Next we see what is inevitable—an electrical shock! Electrical shock paralyzes the body and the victim cannot breathe for himself.

But the rescuer, George, arrives.

George positions his victim for the most effective form of artificial respiration—mouth-to-mouth resuscitation. Notice how he extends the head back to get a clear passageway for the air. He can do this in several different ways. He can press down on the forehead and up on the back of the neck—or place an object under the shoulders and drop the head back—or he can hook his finger in the jaw and pull up. His action has another effect—it gets the tongue out of the way of the air passage. He can also do this by pushing on the jaw from the side.

George seals his mouth over the victim's, pinches off the victim's nose, and breathes into his mouth—then he turns his head to one side and watches to see if the chest is rising and falling. If it is not, it is obvious that the air passage is blocked. He turns the victim on his side and raps him sharply between the shoulder blades to dislodge any foreign matter. He then wipes out his mouth and proceeds with Mouth-to-Mouth resuscitation. He does this until

the victim is breathing comfortably to himself or until a physician pronounces the victim dead.

How many of you have ever ignored a "DON'T WALK" sign? These signs are put there for our convenience and safety but if you stand on one of our busy street corners for awhile, you will see many offenders.

Here is "non-reader" in action. She ignores the sign and pays no attention to the incoming automobile. As the driver rushes over to offer his assistance, she finds that her leg hurts badly from the collision. Many Red Cross Mobile Unit Operators have splints and equipment in their cars but this fellow must improvise with what he has.

He remembers that he has a blanket in his car and with a belt, a necktie and some cloth he can improvise a splint that will give support to the injured leg until help can be obtained. Notice how the thickness of the folded, over blanket is tied around the leg and foot to keep it immobile.

For our last accident, we see a tree

limber. He is waving to some friends and maybe cleaning a little. Well, there he goes!—and it's a long way down. Glowing is a major cause of accidents. A show-off forgets about his safety when he's trying to get attention.

He is on the ground and unconscious. His friends see that he has to be carried to safety since an ambulance can come into the woods. We show how to place a blanket under a victim without disturbing him too much and then how to lift him enough to slide a stretcher under him.

As Frances builds his head for support, a folded blanket is placed around his head. As two helpers lift his shoulders slightly, the other two pull the blanket under him as far as they can. Then they roll the blanket up to his body and grasp it firmly. They lean back to pull the blanket tight and lift his body. This enables George to slide the stretcher underneath. After this is completed we wrap the blanket around him and he is ready for transportation.

This completes the Junior Red Cross presentation on "First Aid at the Accident."

TEEN-AGE ACCIDENTS

By DONALD DUNCAN

De Kalb Agricultural Assn., De Kalb, Ill.

Bringing a greater realization of the principles of safety to the attention of the younger generation is surely a worthy enterprise. If you ask me, they need it.

The DeKalb Agricultural Association, Inc. is a formidable name, but in the town of DeKalb, Illinois, it is usually called the "Ag." Our company started as an outgrowth of one of the oldest Farm Bureaus in America—the DeKalb County Farm Bureau. After its incorporation in 1917 as an organization to conduct the financial affairs of the Farm Bureau, it first dealt in limestone, legume seed and open pollinated corn. As hybrid corn was developed, the Ag early became identified with its production and soon began to expand to nearby states. Later in the early 1940's, hybrid chickens were added and in the late 1940's hybrid sorghums were

developed with a large research center near Lubbock, Tex. Right now, we are engaged in producing a sort of hybrid cotton with research headquarters near Athens, Ga. We are the biggest producers of the hybrid type of seed crops in the world, but the various lines are quite competitive with half a dozen major producers in each. Our trade mark is the "Winged Ear" which you have surely seen in driving about the country.

Since most of the products from our seed stocks—corn, sorghum, and cotton—are now harvested mechanically, we feel that we have some obligation to help protect our customers against the mechanical monsters which can overcome them unless they are careful and your organization is doing much in such protective work.

I am not a safety expert—I can think

of no special qualifications, except that I have all of my fingers and toes intact, have never had a broken bone, never been in the hospital, and have driven a car a million miles with never an accident of any consequence. I am better qualified than the prospective speaker on safety of a recent FFA meeting I attended. He failed to appear because as the chairman announced with embarrassment he had gotten his toes in the power lawn mower.

The types of accidents change, but the general reasons behind them remain the same. When I was a boy on the farm, accidents were caused by bulls, runaways with horses, involvements with threshing machines, silo fillers and other stationary power equipment. There were no safety councils to point out precautions, or there would probably be more older farmers living or ones with a full quota of fingers or hands. It was not an uncommon occurrence not long ago when shaking hands with an older farmer to find missing fingers or a misshapen hand.

Now, accidents primarily involve automobiles and moving power machinery. This means accidents of much greater severity involving much loss of life and property damage.

When you are making a talk and are at a loss as to how to proceed, a standard device is to say, "I thought I'd consult Webster to see what he has to say." Noah Webster, of course, was always looking for exact meanings. Webster says an accident is "undesirable, unfortunate, unexpected and unintentional." I like his succinct definition of safety "Making harm unlikely." That sounds like a good slogan.

If I asked you who said, "We have met the enemy and they are ours" I have no doubt that you could immediately as loyal Americans who have been exposed to history identify the speaker as Oliver Hazard Perry.

A paraphrase on this statement was made recently by Pogo of the well known Walt Kelley comics, who said "We have met the enemy and they is us."

We certainly have to agree that most accidents are caused by our own carelessness. A recent advertisement for automobile insurance suggested protection against

the "If, only" driver. "If only I'd been driving slower." "If only I'd had the windshield wiper fixed." "If only I'd bought that new tire yesterday." After the accident is too late—forethought prevents the difficulties.

Knowing how accidents can happen, can prevent us from doing the things which cause them. Presumably this is the work of your organization.

As representatives of youth, you should have fewer accidents than anyone else. You can see better, hear better, think faster and have quicker reflexes. But what is the disgraceful record of the younger generation—more automobile accidents, more deaths, more property damage, more cars turned over, more trees hit, more of every kind of accident. When you look at a record of accidents in your local paper, most involve boys of from 17 to 22. Insurance companies recognize this fact by exorbitantly high rates to anyone who insures a car with a boy in that age bracket. This is certainly a tremendous field for safety improvement where the most progress should be made.

When Jack Kennedy was elected president, his success was ascribed to his greater effort in the metropolitan areas where most of the votes were. Safety success among a junior organization could similarly be aimed at the young driver menace who is responsible for a disproportionate share of accidents. These accidents go far toward developing an adult concept of teen age irresponsibility.

Why does youth have more accidents? Is it a natural recklessness? A desire to show off? A desire to impress friends with fast driving and shrieking turns? An inferiority complex? These reasons are a science in themselves and deserve much study.

Trying to impress others is a cause of much of our conduct and many of our problems and frustrations. Someone said, "You wouldn't worry so much about what other people think, if you know how seldom they do." A good illustration is in golf. A player works long and hard to improve his game to impress his friends. But they couldn't care less—they're thinking mostly about their own good shots. When you can get away from the necessity of

trying to impress somebody, you're growing up. Developing such an attitude might help prevent a lot of accidents.

What have I tried to say here—accidents are largely our own fault and as such are highly preventable. Greatest safety emphasis should be placed where accidents are worst

—teen age automobile accidents. A young group should be particularly able to fathom the psychology of this group with an opportunity to cutting down the accident rate. Your organization is performing a worthwhile service and certainly receives our commendation.

SENTINELS OF SAFETY

By FRANK E. LADERER

Dir. of Safety, Nationwide Insurance Co., Columbus, Ohio

We live in the finest country on earth. We have more things (material possessions) than any other people. It seems we should be a healthy, happy lot. Yet we live—it seems—in a crazy mixed-up world. But is it the world—or the people? When you fellows were little, you couldn't wait for your first pair of long pants. Now you men rush home from work, jump into your shorts and potter around the yard showing your shapely legs to the neighborhood.

Don't laugh, girls. Remember when your crowning ambition was to get into a pair of high heels, no matter how oversized the shoes were, and strut about. Now the high heels must be undersized and you can't wait to sit down at the table, slip them off—then hope you can get 'em back on again.

Yes, we have a mixed-up world. We, with all our many blessings, should be an alert, helpful people. But too many of us are worry warts:

Worry about the Russians, then get run over by a neighbor.

Worry about radioactive fallout, then get poisoned spraying flowers.

Worry about the kids getting in front of cars, then drag them across the street on a red light.

Worry about crashing in an airplane, then fall off a ladder painting a house.

Worry about getting enough exercise, then drive two blocks for cigarettes.

Worry about getting the car greased every thousand miles — then never get a medical checkup.

Worry about the kids getting proper

nourishment, then leave household poisons around for them to snack on.

Worry about retirement, then do everything we can to keep from lasting that long.

Worry about H-bombs, then blow our heads off lighting a stove.

Worry about polio, then get crippled by a power lawn-mower or a home-shop power tool.

Worry about tornadoes, then get liquidated in an auto collision.

But our subject is "Sentinels of Safety." We would challenge each of you here attending the National Safety Congress to become a "Sentinel of Safety." How—your ask.

First, let's consider "sentinel." *Sentire*—from Latin, to perceive by the senses. Webster says, "One who watches—guards; to watch over."

How about safety? There are many definitions. Sidney Williams, one of the founders of the safety movement has said:

- (1) Safety or accident prevention is in the main a problem of organization and education
Or
- (2) Safety is efficiency, but it is more than efficiency because it is human
Or
- (3) Safety is applied Christianity stated in terms any child can understand, any adult can practice
Or
- (4) Safety is a great social force worth the best any of us can give.

Webster defines safety as: "A keeping of oneself or others safe." So, "Sentinels of Safety" becomes, by definition, "One who watches over or guards against danger, keeping himself and others safe."

Briefly then, how can you and I translate into action and results the safety lessons we learn here at the Congress, in the days ahead as we return to home and loved ones?

We talk a lot about safety education. Too often our solution is to "pass a law." Harry Emerson Fosdick, New York Pastor, has said, "Religion is something we catch rather than learn." He says that "right attitudes"—so important to safety—may be quite similar. We learn by precept and example. Most safety is caught not taught. If we learn from the examples of others, then as sentinels of safety you and I must continually ask ourselves, "What kind of an example am I setting?"

For example, a grade school boy who was very good in mathematics was frequently asked by his teacher to work out problems on the blackboard. In doing this he made his figure 2's with a real flourish. Many of the class learned to make 2's just like his—but still couldn't work problems! So even as we attempt to set good examples let's be sure we do not mislead others.

I am reminded of the story of the driver who was caught out in a very dense fog. So dense that it was impossible for him to see the road ahead of him. He could, however, see the tail lights of a car ahead of him and decided to follow it. A sudden stop by the driver of the lead car resulted in a collision. As each of the drivers got out of their cars, the man who had been following demanded to know why the first driver had not signalled before stopping, and received the reply: "What—signal in my own garage?"

So, as Sentinels of Safety, let's be sure our examples are clear, that they are good, that they will be understood—and followed.

Spiritually we have lost much as a nation. The gap between precept and practice becomes increasingly confusing to youth. Parents, teachers and youth leaders too often say one thing but do another. Before we can ask others to be better—we must be better. We must be real sentinels of safety if we are to help reduce accidents. Let's not be excuse makers.

I'll go where you want me to go, dear Lord.

Real service is what I desire;
I'll sing a solo any time, dear Lord,
But don't ask me to sing in the choir.
I'll go where you want me to go, dear Lord.

I like to see things come to pass;
Don't ask me to teach boys and girls,
dear Lord,
I would rather just sit in a class.

I'll go where you want me to go, dear Lord.
I yearn for the Kingdom to thrive,
I'll give you my nickles and dimes, dear Lord.

But don't, please don't ask me to tithe
I'll go where you want me to go, dear Lord.

I'll say what you want me to say
But I'm pretty busy myself just now,
dear Lord.

So I'll help you some other day.

Many ask, "Why is youth so reckless?"
My answer is, "They are not, generally."

There are many reasons why some youth are frequently involved: Untold thousands do not have "good" homes, chores to do (no purpose in life), loving parents, a sense of belonging. Many feel they are not needed—not wanted.

Those of us who have good homes (not just houses), who have good understanding parents, who have close friends or buddies, who have a real feeling of purpose in life—should be eternally grateful. What if we were unwanted, shunned, made fun of?

That many young people have to live with these situations may be hard for us to realize, but we must try to understand the problem youth—or youths—in our community. Any youth will respond to some motivation, so we must hold up higher standards. There must be a public and private morality to which he can be attracted. You may be the beacon or lighthouse that keeps such a youth from going on the rocks. One of the most powerful motivations in the world is to show these youth that they are needed and wanted—not just shoved about or ignored. As sentinels of safety, you can help this youth become a part of the group.

Safety, we can agree, is not an electrifying concept for youth. Adventure, chance-taking, breaking new paths and old prohibitions, make much more appeal, have more glamour. Drag racing, chicken, and similar "games" are prime examples of chance taking. High diving, speed boating, dreaming of rocket ships, blast-off to the moon, all are thrilling prospects to many youths. So, our approach to a philosophy of safety

must play down the static connotations of safety, and place more emphasis on doing whatever we do—better.

What we want to do in safety is to teach people to do better what they are going to do anyhow. If we will drive a car—let's help 'em drive well and safely. If we swim or dive—let's do it skillfully, in a safe place and not alone. But we must provide a basic, unarguable reason which will have compulsion, appeal and compulsion! Make it extremely unpopular to be a speed demon—a slow-off—a big shot—a bully.

Sentinels for safety can be a major force for good, as we help control behavior of our own age group. Dr. Cutter of New York University Center for Safety has said: "We have cajoled, criticized, praised, condemned, perhaps we have not held up a high enough standard and held it up consistently." We let our halo slip frequently, and somehow people remember these slips but forget the many good things youth does.

Dr. Cutter proposes a new challenge, "Your moral obligation for survival for service." In today's world, we are quite literally "struggling for our lives"—for our way of life, our freedom. We need the contribution of all to preserve our system of government, of democracy, of freedom. I'm sure we have all known lads who seemed to be "me-er-do-well," but after a hitch in the Armed Services they found themselves and became outstanding citizens. What if we rule out some "bad actor" and he never finds himself? Or is killed or severely maimed? As sentinels of safety we have a Christian responsibility to be our brother's keeper. Let's help others to be someone that counts, who are part of the answer, not part of the problem.

Ambitions are many—we all have our ambitions—a goal for which we strive. What constitutes one person's failure may make another thrive. Some seek for higher learning—while others are content. Some seek to spend their lives by doing good—for those who know torment. The clown is happy when he makes a tear turn into laughter.

The poet gains a thrill when hearts are happy ever after. A doctor's job is greatest when he lessens someone's pain. A teacher is rewarded by the knowledge pupils gain. Men of God are joyful when their congregation prays. Mom and Dad live for their young—and dream of future days.

That's how it goes in this world—ambitions are so many. I don't believe you'll ever find a person without any! What is your ambition? To get ahead no matter what the cost, or who is pushed aside, or will you help others become sentinels of safety?

Why do some become real sentinels of safety while so many others do little or nothing? I'm sure we all think of qualities like dedication, vision, concern for others, unselfishness and perseverance.

Let's be sure, as sentinels of safety, that we take time to recognize and give credit to others "round about us. Don't just take people for granted. I'm reminded of the experience of Dr. Arthur Secord—who was the principal speaker at a large company's service awards banquet one night.

During the program "They brought two men up to the dais and presented them with lapel buttons and certificates signifying membership in the Wise Owl Club. Many of you know what that meant. It meant that during the past year each of these men had had the sight of one or both eyes saved because he was wearing eye protection. The safety glasses were on display—one with a completely shattered right lens, the other with both lenses shattered.

"After these men had been honored and returned to their tables, I heard a man at the head table turn to a neighbor of his; only the three of us, I believe, heard him. I quote: 'That's the silliest darn thing I ever heard of. Why honor a man for doing what he should do?' Now, think that one over. Why honor a man for doing what he should do? So they were supposed to wear eye protection, so they had it on, so they saved their eyes, so what?"

"That night I wondered how that fellow would like to live in a world where God operated on that basis. It seems to me there would be just one adjustment—there would be no heaven, no reward for doing what you should do. Just hell for the boys who didn't do what they should do. And I wonder in how many of our industrial establishments—our mines, and factories, and plants, and offices—and in our religious organizations, and schools, and homes we operate on that basis.

"We're awful quick to jump somebody when he's not doing it right. We're awful slow to pat someone on the back simply because he is doing what he should do."

So far we have touched upon: (1) state of mind (worry, etc.), (2) right attitudes, (3) setting good examples, (4) doing what we say, not making excuses, (5) understanding problem youth, (6) doing whatever we do better, and (7) the importance of recognition.

But there is more. Without a deep and abiding faith in God, good works will not prevail. And now in closing, let us look to God in prayer.

Forbid it, Lord, that our roots become too firmly attached to this earth, that we should fall in love with things.

Help us to understand that the pilgrimage of this life is but an introduction, a preface, a training school for what is to come.

Then shall we see all of life in its true perspective. Then shall we not fall in love with the things of time, but come to love

the things that endure. Then shall we be saved from the tyranny of possessions which we have no leisure to enjoy, of property whose care becomes a burden. Give us, we pray, the courage to simplify our lives.

So may we be mature in our faith, childlike but never childish, humble but never cringing, understanding but never conceited. For what profits a man who gains the whole world but looses his life?

So help us, O God, to live and not merely to exist, that we may have joy in our work—becoming true sentinels of safety. Amen.

YOUTH IN COMMUNITY SAFETY PROGRAMS

Presiding: CALVIN SCOTT, Pres., National Junior Achievers Conference, Ypsilanti, Mich.

Moderator: ALEX MALESKI, Boys Clubs of America, New York City

Panel: CATHERINE A. CARTER, State Advisor, F.H.A., Springfield, Ill.; GEORGE E. TEWKSBARY, Supervisor of Youth Programs, Nationwide Insurance Co., Ohio; MIKE RAPP, Key Club International; ROBERT McALLISTER, Key Club International

A panel consisting of three youths and two adults discussed the role of youth in community safety programs. To do this, the following areas of concern were considered:

1. Does youth have a place in community safety programs?

2. If so, what is its role?

3. If roles are identifiable, how do we as youths work with adults in order to make our communities a safer place in which to live?

4. What are some of the stumbling blocks our youths and adults working together on community safety programs?

5. How may we work around these stumbling blocks?

It would seem logical that the adults working with the panel of youth would want to find out what youth thinks; the adults would be the catalyst so that the ideas of youth would be foremost. Such a panel discussion clearly points out that youth has a place and can contribute to community safety programs.

The moderator and the two adults serv-

ing on the panel were named ahead of time; the three youths were picked from the delegates after they arrived in Chicago.

Notes taken from this panel discussion.

Adults and youth—work closer for better safety. They should work as one cooperative group for a common goal.

Youth—its effect on other youth. Youth most definitely has effect on other youth, they look to each other for leadership, inspiration and as models.

Example of adults and youth working together for safety (effectively). An insurance club in Ohio high school is most productive today. Safety posters, programs in school safety worked out with teachers and students, high school auto driving courses, with results in reduced auto insurance for the graduate.

Illinois has community groups that meet regularly with their youth on local community projects that are of interest or concern to youth.

Youth rejects the fact that adults will take over a youth project when it is not satisfactory to adults, thus completion of

the project is by adults and youth is left out.

Youth needs encouragement in projects in local communities. Youth feels adults lack confidence in them. Adults want the credit for themselves, rather than wanting to just help youth with their projects.

Youth speaks on panels. Adults with titles or specialists in youth fields cause youth to be shy and reserved in talking and discussing their problems, because youth gets the feeling that the experts know all there is to know in their particular field, thus they are not interested in listening to youth's ideas and problems. Youth prefers to talk with an average adult, who will inform the expert on youth's problems. This gives youth an easier feeling for expression of their thoughts.

Youth wants adults to act as council for their activities. Titled adults can help carry

out youth's projects, where youth would not have the connections.

Summary

Youth in safety.

Youth is active in community and school safety projects.

Youth's thoughts on working projects with adults.

Adults should guide youth, not try to run activities for youth.

Adults feel youth is not capable on their own, youth wish more confidence in them from adults.

Youth on panels.

Youth is shy when on panels with professionals on youth—rather discuss with an average adult panel. Must not be outnumbered by adults on panel, wish equal number in audience also.

HOME SAFETY SESSIONS THE IMPACT OF HOME ACCIDENTS

(a) ON THE FAMILY

By LEONA BAUMGARTNER, M.D.
Commissioner of Health, New York City

I was asked to speak today and set the stage for this session. This is the second time in a few months I've been asked to set the stage for a meeting and I'm not sure it isn't a sign of approaching something or other, like middle-aged spread. The person who sets the stage is essentially a harmless and amiable type who utters fuzzy generalities while late-comers creek into their chairs . . . who is considered serviceable for holding the floor pending the appearance of more important participants, and who, under no conditions, is to be used for ringing down the curtain.

Well, I set a messy stage, and I hope you will let me wander a little as we open this meeting on the subject of Home. Sister Home.

I suppose the problem we are dealing with began tens of thousands of years ago when some early and primitive man stubbed a toe on a stalagmite in his cave. And then, later, I suppose he tripped on an adze or a stone knife, marking the beginning of his experience with man-made hazards.

The toll of accidents has grown since then and homes have changed, and we are now dealing with a problem so serious that if it were considered a disease the clamor for correction and control would be deafening.

In the 1 to 14-year age group, accidents kill more than 11,000 children a year. They are the leading cause of death in this age group and kill more than the next four causes (cancer, congenital malformations, pneumonia and heart disease) put together. While I am talking to you, if the average holds, two youngsters in this age group will die somewhere in this nation due to accidents. By the time we finish lunch, almost a dozen will have been wiped out.

This is only in this one age group. If

you count everybody, of all ages, more than 50 people will die as a result of accidents in this land between now and the time we finish lunch.

Today we are talking about the home—man's perilous castle—and there is good reason for it. Among all age groups we expect about 27,000 deaths from home accidents this year.

As you know, statistics on deaths are misleading and only part of the picture. If we maintain a level rate of deaths from home accidents we can delude ourselves into thinking that we are at least not losing ground, but this is not so. Modern methods of treatment are saving many more injured persons than a few decades ago—the role of antibiotics in the treatment of infections is only one obvious example—so that an even home accident death rate really means a rising number of accidents.

Our information on numbers of accidents, as you know, is much less solid than our information on accidental deaths, but we believe that the deaths are only the tip of what might be called a very black iceberg.

For instance, a recent report of the National Health Education Committee quoted the National Safety Council as estimating that in 1955 there were more than nine million persons in this country to some degree handicapped as a result of accidents. The National Health Survey found that in one year there were 19 million home accident injuries serious enough to require medical attention or to restrict the victim's activities, and some years ago the Metropolitan Life Insurance Co. estimated that every four minutes some one in this land receives a permanent disability as a result of a home accident. This is about 130,000 a year and is generally in line with a number of similar informed estimates.

I won't go deeply into the economic cost of accident—it is huge, probably more than 11 billion dollars a year, of which I believe more than half is due to home accidents. It is hard to imagine 11 billion dollars. I don't know if you find it any easier to imagine two million dollars, but that is what the State of California recently discovered it was paying annually to care for needy children whose parents had been incapacitated by home accidents. Two million in one state for one year for just one piece of this tragic picture.

Statistics are awfully dull to talk about—and awfully inadequate in the field of accidents—but it is clear that we are dealing with a major cause of death, far more important than many diseases, and an appalling cause of crippling and disability. We are faced with a serious situation and ought to act accordingly.

In many ways the impact of home accidents on the family is like the impact of disease and illness. Most people still do not realize that even a family that is hard working, self supporting, with money in the bank plus health insurance, can be brought to indigence by a single protracted illness, especially when the bread winner is involved. Take a woman with four children whose husband is injured so that he must be bedridden for a year. The woman can't work because she has to care for the children and her husband (unless she's lucky enough to be able to earn enough to support the family, *Mrs.* a housekeeper), and the husband's income sooner or later stops.

One important difference between the impact of accidents and illness lies in the emotional field. People feel guilty about many accidents while, in most instances, they believe that contracting an illness is no one's fault. This only adds to the problem. Take a family where mother's momentary carelessness in the kitchen is held responsible for a child's being horribly burned, and you have a tremendous emotional burden piled on top of all the other problems. It may take months or years of psychiatric care to help such a family.

Most of us have dramatized accidents at one time or another, because we are so desperately eager to make people do something about them. But I thought this morn-

ing I would give you just a few reports on accidents in New York City, in the cold and unemotional language of our official reports. Just let me say that in New York we go into these things, we follow them up, we try to find reasons. These are exactly as reported, except that I've shortened some of them a little.

Report No. 1: "Substance: benzene. Place of occurrence: kitchen. Accident: Father had been painting and left some benzene in a Pepsi-Cola bottle in back of a washing machine to be used for cleaning up; machine was subsequently moved away; child found uncorked bottle and drank one to two ounces. After hospital treatment, this child recovered.

Report No. 2: "According to the grant-mother the family members were having wine with their noon meal. The patient (a four year old child) went to the refrigerator where the wine bottle was kept and drank some of its contents. She went to the living room to watch television and soon had convulsions. She was taken to the hospital where her stomach was lavaged; she apparently made a complete recovery. There is a further note in this case: 'The general accessibility of alcoholic beverages to children constitutes a major hazard.'

Report No. 3: "While the father and grandfather were building a closet in the cellar of their new home, the child was riding on his bicycle and playing around in the cellar. The patient became thirsty, and since there was no water in the cellar, he obtained a can filled with fluid. It was an orange juice can filled with turpentine. . . . This child was also lucky, and recovered.

Report No. 4: "Baby (was) seated on high chair near gas stove where mother had placed rice to boil. Mother turned her back for a moment, baby reached for handle of hot on stove and tilted entire contents over himself. This baby died. There was a note on the report: 'Pot handle should have been turned away from child.'

Report No. 5: This child was a little over five and a half years old. This is the report: 'Fracture of the skull—shock. Child was flying a kite on the roof of another building and fell off as he tried to follow the kite. This was a fatal accident. There was a note on this report, too: 'Child should never have been permitted to play on a roof.'

Report No. 6: "Child climbed on a chair and took bottle of baby aspirin out of kitchen cupboard while mother was working washing machine in an adjacent bathroom. . . . Mother is a good housekeeper and takes excellent care of two young children. She did not know that aspirin was poisonous since there is nothing on label to indicate that it was."

Report No. 7: This is the last one. "Both parents were away at the time of accident. Uncle visiting from South Carolina was at home with three children. The uncle lit kerosene stove to warm room. It exploded instantly. One child died and a three-months old baby was burned but survived.

We all are gratified that medical care techniques for treating accident victims have improved and are still improving, but what we are interested in is preventing accidents before they happen. To do this we naturally

want to find out what causes them, and here we get into trouble. For years we took a rather simple view of things. We said people slipped and fell because the floors were slippery, and they cut themselves because knives were sharp.

Then we began to talk about accident proneness, since it was found that some people had more accidents than others. This concept came into being at about the time of World War I, largely in connection with industrial accidents. It was seized upon for use in personnel work, and was used as a predictive instrument—a reason for not hiring people. It was thought of as something inherent, something constitutional, rather like an intelligence quotient. Subsequent studies have thoroughly discredited the idea of accident proneness. Dr. Jacobson, for example, in his research on child accidents in New York City, has shown that "repeaters" are a very small percentage of the total, and certainly not an important factor. And we know that some of the people who were formerly considered accident prone had more accidents because they were in hazardous occupations and situations.

Perhaps accident proneness served some purpose as a concept, but it also did harm because it helped reinforce the already prevalent idea that accidents are things that don't happen to us, but to other people—people who are somehow faulty by nature. It is time now to lay accident proneness quietly to rest and get to specific factors.

Today we think more and more about behavioral factors, which may vary from day to day, or even from minute to minute, and are not inherent as accident proneness was supposed to be. Does the child have an accident partly because he is trying to attract attention? After all, children do many bad things to attract attention. Or is the child trying to punish himself, or his parents? Or do the parents have aggressions against the children, so that they may push the child away so sharply that it has an accident?

We find ourselves with a complicated problem. It is pretty obvious that razor blades, sharp knives, poisons, are dangerous, but it is equally clear that this is not the whole story. Many people handle razor blades, sharp knives and poisons without injury.

We begin to think more and more of a complex situation involving risk-taking and good and poor decision making and of safe and unsafe environment. Dr. Edward Suchman, of the New York City Health Department, has written extensively on this. For example, take a person whose judgment is awful and decision-making poor and put him in a very safe environment—a padded cell, for instance, and he is extremely unlikely to hurt himself because there's nothing for him to have an accident with. His environment is so safe that he is safe.

On the other hand, take a person with extremely good judgment and decision-making and put him in a chemical laboratory filled with poisons, and possibly sharp knives and other potential dangers, and he is not likely to injure himself because he is experienced and careful.

But take the person with bad judgment and poor decision-making and place him in the extremely unsafe environment and there is likely to be trouble.

In the home we generally fall between the two extremes. We have a safer environment than the chemical laboratory, and we have decision making that ranges in quality between bad and good. There are different people in the household, from the infant, whose responsibility, judgment and decision-making are very poor—close to zero—to the well trained, alert adult, whose decision-making may be quite good, to the older person, whose alertness and decision-making ability are declining. So we have peaks of home accidents among children and older people—at the ends of the seven ages of man. I was amazed to find that in one recent year 46 persons were killed in falls who were 100 years old or older.

Then we have the problem of risk-taking. We live in a risk-taking society, a society where taking a chance is equated with manliness. The boy who climbs the tree is admired above the one who does not. Children drive cars at one another, calling "chicken" at the one who turns off first.

We also live in a society where risks are not always made clear to the growing individual. We give children plastic guns, which they shoot at each other safely, and are shocked when they get hold of a real gun and behave the same way with it.

killing or injuring somebody. We expose youngsters to television programs in which extremely unsafe risks are made to appear worth taking, where the act of shooting fire arms is dramatically shown, but the after-effects played down, or not shown at all.

A friend of mine was saying the other day that he sees a television program in which the detective is always being hit on the head with a bottle or other blunt instrument. This stuns the detective briefly, but in a very few minutes he is back at the chase, bright-eyed and alert. In actuality, judging from the force of the blows, he'd have been buried with full honors long ago, or at minimum have suffered horrible brain injury. But suffering a crushing blow on the head is made to seem only an incident. Obviously if a child isn't made to learn what he may suffer as a result of taking a certain risk, he cannot very well judge whether it is worth taking or not.

We cannot seek to avoid risk-taking altogether, nor will we ever completely eliminate accidents. Without risks we would have no space men, no exploration of the depths of the sea, no progress, probably. But there is a difference between taking a risk just for the sake of the risk and taking a calculated risk for the sake of accomplishing something.

Paraphrasing, in situations where we have control of the environment, as in factories, we are able to encourage a certain pride in safety and the use of safety techniques. We have scarcely done this at all in the home, or, I might add, on the highway, where safety belts could probably save 5,000 lives a year, and are almost universally sneered at.

In any event, we have finally learned that the causes of accidents are many and complicated. They involve the state of the environment, the condition, the abilities and judgments of the individuals concerned, and they involve transient conditions such as anger and sudden illness.

There are a lot of things we don't know about accidents, and if we don't know what we don't know we are in bad shape. We don't know how many accidents there are, we don't know if accidents do occur deliberately, we are not really sure what should be called accidents and what should

not. We do not know in detail the effect of different mores on accidents and why.

We do know, from studies in this country, that there are more home accidents in low socio-economic groups, but we only partly know why. Even on this point there is some dispute, since the National Health Survey showed a high reporting of accidents from higher income families. Yet, from our experience in New York City and many studies elsewhere, we would conclude that low socio-economic groups do have a higher rate of serious, non-fatal home accidents, as well as fatal home accidents.

In other words, those least able to afford accidents have more of them. We conjecture that these people may be too overburdened with other things to keep a good household. They are often overcrowded in poor housing. We know they are more apt to leave poisonous chemicals around, that their environment has more hazards, but we have not yet a clear picture.

A recent very interesting study investigated home accidents among families connected with a U. S. military establishment in Japan. Thirty per cent of the mothers involved were Japanese, but the husbands were American and the living conditions predominantly American. Yet there were significantly fewer accidents in the homes with the Japanese wives. Why? We should like to know.

How do you train children to avoid accidents? Some people think if the child is burned just a little bit this is his best education about fire. Is this true? What is the difference between children brought up in strict and permissive families? We don't know.

We have tremendous problems in communication. One of my people, helping recently to gather materials on home safety, went through the files and when he finished he said: "Boy, am I going to clean up the cellar steps." He'd been reading pamphlets, which were in our files. But these pamphlets had never reached him before—at least they had never reached his consciousness. We tend to be pamphlet-happy and in our pleasure at seeing a nicely designed pamphlet we tend to forget whether we are going to be able to get it into the consciousness of the people who need it.

I guess you can lead a man to a pamphlet but you can't make him read.

We know that homes can be made much safer through safety engineering—through the inclusion of such sensible things as handrails in tubs and showers. With an aging population these are increasingly important. There are scores of other safety measures that can be taken. It has been estimated that the average house can be reasonably equipped with safety features for less than the cost of a picture window. But builders are selling glamour and invincibility and don't include these things. And they don't include them because the public doesn't demand them. And the public doesn't demand them because we have not convinced the public that it is important to demand them.

In the automotive field, of course, manufacturers have done much laudable research, but are not generally selling features designed to protect lives. I'm sure many of you saw the cartoon not long ago. I forgot the exact words, but a man was about to buy a car and he was saying to the salesman, "Will you go over once again the part about how the 200 horsepower engine makes it safer?"

People who would drive 100 miles to avoid exposure to an infectious disease are quite content to expose themselves to accidental hazards far more likely to cause serious injury or death. If we were to predict that there would be an epidemic over a weekend that would result in 400 deaths and maimed crippling, I can well imagine the rush by people to stuff themselves with penicillin, and to do almost anything to escape. But when this toll is caused by automobile accidents over a holiday it is almost impossible to get people to do anything about it, to drive with care.

I think we have to admit that in home accidents we are doing a generally poor job. There are a few sparks here and there, but this is a generally unattended, neglected field. There is agreement, I think, that by and large the research that is being done is not first rate, that there is not enough of it, and that able young people are simply not being attracted to the field in sufficient quality or quantity.

It seems to me the worst obstacle in this field is the word "accidents" and its con-

notations. Many accidents, we like to think, are things that happen to the other fellow. They are unpredictable. They are acts of God. They don't really have causes. They just happen. How can you get hold of them?

What we are dealing with is not accidents in the traditional sense. If you eliminate accidents that produce no injury you are left with a large group of incidents which I would prefer to call injuries, frequently fatal, of complex and not wholly understood etiology. There are more similarities between these injuries and disease than might at first be apparent.

Let us consider, for example, a child in an environment that includes polio virus. We know some children, if they get this virus inside of them will get paralytic polio. Others will be saved by their natural bodily defenses. Some will not take in the virus at all, even though it is present in the environment.

Now let us consider a child in an environment in his home that includes a poison in a cabinet under the sink. We know that if the child eats or drinks this poison he may be killed or made terribly sick. We know that some children will not get the poison at all. But we know that a substantial hazard exists.

In polio we developed a vaccine which prevents the virus from reaching the central nervous system. We have protected the sensitive part of the child from the danger, and if the vaccine is used we are able to control the problem.

In home accidents, it seems to me we are trying to do much the same thing. As in the conquest of a disease, the problem is complex, but not necessarily insoluble.

There are a lot of things we can do. We can put a lock on the cabinet. Or we can transfer the poison to a cabinet out of reach of the child. We can put a big poison label on the chemical, so that the mother and eventually the child will be warned. We can educate the mother, and eventually the child, to the meaning of the label, and to safe methods of handling the poison.

In both cases we have a hazard and a child, and we develop means of preventing one from harming the other. A vaccine seems nice and neat as a solution, while a combination of safety engineering and

education seems fuzzier and less easy to grasp.

I think the development of the germ theory has tended to make us oversimplify—or want to oversimplify—the causes of human ailments. We like to think that a single disease is, or ought to be, caused by a single bug. Simple cause and effect. But even in disease we are learning that this is not the whole truth. If it was simple cause and effect, every one getting the bug would suffer the disease. This does not happen and we realize that matters of resistance, stress and other factors are also involved. We tend to be annoyed by these more complex explanations, although we must accept the fact that most human ills are brought about by a combination of factors.

It was hard for us to accept the idea that accidents have causes in the first place, and having accepted it we are distressed to find that accidents have a whole variety of causes, some of them extremely subtle, many still unknown or not fully understood. The problem seems so complicated, so lacking in handles to hold it by, that we tend to lose heart.

We ought to realize that our problem is not as peculiar as we think it is, and in many ways not so different from disease problems we tend to think of as much simpler.

Let's take an example from the infectious diseases. In 1938, for example, when the medical advisory committee of the National Foundation for Infantile Paralysis met for the first time it developed over a dozen points that would have to be covered before polio could be brought under control. Dr. Thomas Rivers was a member of that group, and he emphasized again and again at that meeting that man did not really know what polio was.

It is hard to believe in retrospect, but it wasn't until 1950 that scientists definitely nailed down the crucial point that polio was due not to one but to three different kinds of virus. All the earlier research went on without that vital piece of knowledge, and it wasn't until even later that some of the basic mechanisms of the virus transmission in the host were illuminated. In fact, we still don't know about all of them.

I think that in home accidents we are about where polio was in 1938, or perhaps

some years earlier. It might be argued that we have less understanding of our problem, but it is certainly true that even without a full understanding of causes, we have more that we can do now than the polio people had for their disease in 1938. Safety engineering and education can save tremendous numbers of lives and injuries in one field now, while we seek more knowledge for the future. There was much less that could be done in these areas in polio in 1938.

Our uncertainty about causes is shared by those in the field of cancer. No one knows the cause of most cancers, and there is increasing evidence that multiple factors are involved. We know that cigarette smoking is an important factor in lung cancer, but I don't know any one who thinks it is the only one. So the cancer people have a tremendous quest to find the full picture of the cause of their disease. In the meantime, they are saving lives with what they have.

I mention all these things because I think we ought to stop feeling sorry for ourselves and to point out some of the similarities between accidents and disease. We aren't the only people with a difficult problem on our hands. In fact, I suspect that the answers which will provide reasonable control of home accidents may be somewhat easier to come by than some of the answers which have been and will be dug out in the field of disease. We must not let ourselves move from considering our problem difficult, which it is, to considering it insoluble, which it is not.

Here are some points that seem to be important:

1. We must wipe out the idea that accidents are accidents. They are not. They are injuries and deaths of multiple cause. But caused they are, every one of them. Is it an accident when you put a child on a dangerous roof and provide him with a kite that will attract him over the edge so he kills himself? I hardly think so. Is it an accident when a child picks up a Pepsi-Cola bottle, which he thinks of in a friendly way, and drinks poison? I think not. I think if it is an accident it is one prepared in advance. After all, what would you do if you wanted to poison some one? I think you would put the poison in some-

thing he might be expected to eat or drink. Is it an accident when we allow a child to see us drinking cocktails over and over again, and the child empties the remains in our glasses and kills himself? It is no such thing. Is it an accident when we provide an older person with a tub made slippery with soap, and with no handrails and he falls and hurts himself. Of course not. It is a prepared and predictable result.

2. We must make accident research more appealing. It isn't essentially a question of money. Able young people need to be informed about this problem to an extent commensurate with its size. Medical schools especially need men on their staffs who are concerned with the home accident problem and who can act as catalysts to interest first-rate minds in research on it.

3. We must accept the fact that we will have to use what we know until better methods become available. Public health progress, over the years, has come about largely through the application of knowledge we already had. We know we need to improve the safety of man's environment in the home, and at the same time improve his decision-making ability in this area. We will need education and plenty of it, and greatly increased research toward better means of communication. We are not getting through to the public—not even to ourselves, very often, and we must realize this and do something about it. Communication in this field is as important as penicillin. At the moment we are very poor at it. We must recognize this and move forward.

4. We must realize what we know and don't know, and act accordingly. We must look at our situation coldly and then move. We must examine the areas where we are

failing and work to make our performance better.

5. We must realize that home safety is everybody's business. It is the business of the schools, of families, of safety engineers, of doctors, of social scientists. It is a health problem. The doctor who learns to treat children, for example, in a variety of disease situations, finds that they are being destroyed by accidents, over which he feels but little control. A multi-disciplinary, multi-faceted approach is essential. Nothing can kill off our effort more surely than for any one group to think this problem is its personal property. It isn't.

In my city we have worked long and hard on accidents. No one could feel more keenly than I do the complexity of the problem, and the frustration that comes from tangling with it. We have worked with paint manufacturers to keep lead out of interior paints to cut down lead poisoning. We have worked with gas refrigerator manufacturers to cut down deaths from this source. We have attacked the problem of side-bar water heaters. We are now working on radiation, and have helped make X-ray apparatus safer and have outlawed those ridiculous X-ray shoe fitting machines. We've cut the death rate from home accidents in half in 20 years in New York City. It has taken work in almost every imaginable combination of circumstances, with almost every type of person. We know how much more there is to be done.

I want to leave you with only one thought. This problem of home accidents can be solved. Let us move into it. Let us give it the hard work it deserves, the imagination, the research. We can cut these unnecessary deaths and injuries, and when we do, it will be no accident.

(b) ON COMMUNITY GROUPS

By GEORGE W. LOWIS

Accident Prevention Rept., Pennsylvania Department of Health, Harrisburg, Pa.

The purpose of this paper is to review briefly some of the important research considerations concerning a community study of social class and home accidents. This investigation is being directed by me and

is conducted and sponsored by the Division of Environmental Safety, Pennsylvania Department of Health. Because the data from this research have not been completely analyzed, no findings will be presented here.

The report will therefore be confined to summarizing the research plans and actual methodological procedures used in the study. Discussion of the first of the two aspects contained in this paper, namely, that of the research plans, follows presently.

Recently, Professors Hollingshead and Redlich, of the departments of sociology and psychiatry respectively, at Yale University, demonstrated in their community study of New Haven, Conn.,¹ a significant relationship between social class membership and mental illness, two formerly unexplored facets of life. It is this speaker's contention that social class and home accidents also represent two major unexplored problem areas in our society, problem areas that can be dealt with quantitatively and qualitatively.

The purpose of this study is to determine for the city of Bethlehem, Pa., the relationship between social class and home accidents. There are four major research questions in this study:

1. Are home accidents related to social class in Bethlehem society?
2. Does an accident person's position in the Bethlehem status system affect how he is treated for his home accident?
3. Does an accident person's household activities relate to class in Bethlehem society?
4. Does the position of an accident or non-accident household in the Bethlehem status system affect this household's attitudes toward home accidents?

The major conceptual assumption of the research is that there is a functional and reciprocal interdependence between the class structure of Bethlehem and a number of different aspects of home accidents such as expenditure and treatment for, and attitudes toward, home accidents. Six working hypotheses were written into the research design. Each hypothesis will connect social class and home accidents in such a way that the resulting proposition can be tested empirically. The six hypotheses are:

1. The prevalence of home accidents is related significantly to an individual's position in the class structure.
2. The types of home accidents are connected significantly to an individual's position in the class structure.

3. The expenditure for treatment on home accidents by the accident population is related significantly to an individual's position in the class structure.

4. The household activities of the accident population are connected significantly to an individual's position in the class structure.

5. The reporting or not reporting of a home accident for treatment by the accident population is related significantly to an individual's position in the class structure.

6. The attitudes toward home accidents maintained by the accident and non-accident households are significantly related to a household's position in the class structure.

The negation or affirmation of the first hypothesis, which concerns the relationship between class status and prevalence of home accidents, depends on the outcome of the two major questions posed in this hypothesis:

- a. How many home accidents are there in the population of the Bethlehem community?
- b. Is the distribution of home accidents linked to class status?

Prevalence is defined in this research as the number of cases of home accidents present in the sample population during the one year recall period of June, 1960 to June, 1961. In the first hypothesis we are interested in learning whether class status is connected with the fact that residents of Bethlehem are or are not accident persons. The respondent reporting the home accident is the primary unit around which the tests of hypothesis one will be built.

But in order to determine whether the prevalence of home accidents in the population of Bethlehem is related to class status, a comparison of the reported accident persons in each class in the population will be made with persons in the appropriate class who are non-accident persons. In other words, the comparison will be between the accident and non-accident persons by class. All tests of hypothesis one, then, will be made by comparing the general population in each class with the number of accident persons in the class.

The negation or affirmation of the second hypothesis which concerns the relationship between types of home accidents and class position depends on the outcome of

the three major questions posed in this hypothesis:

- a. Are types of home accidents connected significantly to an individual's position in the class structure?
- b. Is the nature of the accident significantly related to an individual's position in the class structure?
- c. Is the severity (i.e., disabling vs. non-disabling effect) of the accident related significantly to an individual's position in the class structure?

This second hypothesis postulates essentially the existence of significant relationships between the types of home accidents persons have and their positions in the class structure. If this hypothesis is not true, the accident persons' accidents should be distributed in the status structure in a random manner. However, if it is correct, we will find that class status is connected with the kinds of home accidents persons have. We will examine in this second hypothesis, then, the types of home accidents persons have to see if they are associated with class status.

The negation or affirmation of the third hypothesis, which concerns the relationship between economic cost of the accident and class position, depends on the outcome of the three major questions asked below:

- a. Were there any expenses associated with the treatment of the accident?
- b. What were these expenses, i.e., what was the nature of the expenses?
- c. How much were these expenses, i.e., what was the actual cost involved in treatment of the accident?

It is contended in this research that all three components that comprise this third hypothesis are linked significantly and distinctly with class status.

The negation or affirmation of the fourth hypothesis, which concerns the relationship between household activities of injured persons and class status, depends on the outcome of the six major questions asked below:

- a. What kinds of things do injured persons do in their spare time?
- b. What kinds of things take up most of the injured persons spare time?

Time and Activity: General Reference

- c. Where do injured persons spend most of their time?
- d. What kinds of things take up most of the injured person's time?
- e. What is the amount of time spent by injured persons in the home?
- f. What kinds of household chores are performed regularly by accident persons?

It is contended in this research that all six components that comprise this fourth hypothesis are linked distinctly and significantly with class structure.

The negation or affirmation of the fifth hypothesis, which concerns the relationship between reporting of the accident for medical treatment to a medical agent outside the household and class status, depends on the outcome of the five major questions asked below:

- a. Did the injured persons report the accident for medical treatment to medical agents outside the household?
- b. Who were the medical and non-medical agents that treated the injured persons?
- c. Where did the injured who were treated by medical or non-medical agents go for medical treatment or the accident?
- d. What kinds or types of medical care or treatment were prescribed for those injured persons who were treated by medical agents?
- e. What was the length or period of time that the injured persons, who were treated by medical or non-medical agents, were under medical care or treatment for their accident?

It is contended in this research that all five components that comprise this fifth hypothesis are distinctly and significantly linked with class status.

The negation or affirmation of the sixth hypothesis, which concerns the relationship between attitudes of accident and non-accident households toward home accidents and class status, depends on the outcome of the six major questions asked below:

- a. Do the household activities of both accident and non-accident households relate significantly to a household's position in the class structure? If yes, what is the nature of the relationship?
- b. Is membership in a particular class of

both accident and non-accident households connected significantly with attitudes toward expectation of home accidents?

c. Is membership in a particular class of both accident and non-accident households related significantly with attitudes toward accident causation?

d. Is membership in a particular class of both accident and non-accident households significantly related with attitudes toward accident safety and prevention?

e. Is membership in a particular class of both accident and non-accident households connected significantly with attitudes toward medical treatment of the accident?

f. Is membership in a particular class of both accident and non-accident households related significantly with attitudes toward economic cost of the accident?

It is contended in this research that all six components that comprise this sixth hypothesis are linked distinctly and significantly with class status.

All six hypotheses will be tested from data collected and analyzed by way of an interview schedule. Over twenty experienced Pennsylvania Department of Health interviewers administered the schedule to 1,987 sample households or dwelling units during June, July, and August of 1961. Only adult members, (that is, 18 years and over) of the sample population were interviewed. The number of persons permitted to be interviewed was confined to one person per household. Any adult member of the household agreeing to be interviewed was acceptable as a respondent. Due to the nature of the programming of the interview schedule so that an almost equal proportion of interviews were taken in the day time as well as evening hours—to include those persons who were not at home during the day because of social functions, employment, etc.—it is expected that the respondent selection bias will be kept to a minimum.

A home accident was defined in this research as any injury having been sustained by one or more family and non-family members living in a household, and having occurred within or immediately outside the home during June, 1960 to June, 1961. In addition, such an accident must have fulfilled one or more of the following requirements:

a. That it required any monetary expense for medical treatment.

b. That it required some form of medical treatment by a medical agent such as a doctor.

c. That it interrupted the normal daily routine of doing things for any length of time.

Determination of accident and non-accident households was made during the interview when 1,987 adult respondents were asked a question of whether they or any member of their household had a home accident within the past year. If the answer to this question was yes, and it made no difference which family member had the accident, this household constituted an accident dwelling unit; if no, this obviously constituted a non-accident household. A total of 170 households or about 12 per cent of the 1,987 sample households were consequently determined to be accident households.

The second major division of this report concerns a discussion of the major methodological techniques utilized in the study. Briefly stated they are: (1) the interview schedule, (2) a two-stage probability sample, (3) the Hollingshead index of social position, (4) data processing, and (5) the use of statistical techniques.

The interview schedule was used to collect data from both the accident and non-accident populations. The schedule was divided into two sections, the first of which both accident and non-accident households were required to answer, and the second where only accident households were asked questions. Both straight and open-ended questions comprise the schedule. The interviewing time respectively for the non-accident and accident households was, on the average, 40 and 60 minutes. Problems of non-response were handled as follows: A minimum of three and maximum of six recall visits were made for respondent refusals. In addition, the most experienced and qualified of interviewers were assigned specifically to handle this refusal problem. As a result, the refusal rate for the survey approximated only 4 per cent or 86 households. Some typical "causes" of refusal by respondents enumerated in the study are:

a. Respondent reported as being too busy.

b. Respondent was interviewed previously -- a sampling error.

c. No reason given by the respondent—in cases such as these the interviewer received a flat "NO" or "NOT INTERESTED" type of answer.

d. Respondent slammed the door upon seeing a "stranger."

e. Respondent expressed an anti-government, or anti-administration, or anti-business feeling.

f. Respondent reported working (at place of employment or around house) and could not or would not take time for an interview.

g. Respondent reported having already been interviewed by other organizations who misrepresented reason for the visit.

h. Foreign language involved with some suspicion of the interviewer's mission.

i. Respondent expressed the feeling that surveys are "silly" or "not worth while."

j. Evidence of some antagonism towards the interviewer by the respondent with no real reason given for not wanting to give interview.

k. Old age, illness, or illiteracy involved.

The various types of major refusals in the survey were seen to be five:

a. Illness, old age, and illiteracy.

b. Don't know.

c. Partial refusals. Respondents here gave part of the information requested but not all.

d. Outright refusal to answer any questions.

e. Too busy.

Other problems of non-response, in addition to the one just discussed—that of refusals—are in order of pending discussion, problems of foreign language, race, and not at homes. Foreign language problems associated with lack of comprehension were handled by interviewers versed in the language concerned. Most Negro respondents were interviewed by a Negro interviewer.

For those respondents not found at home on the initial visit, no fewer than three and no more than ten revisits were made. Consequently, respondents classified as "permanent not-at-homes" were kept, percentage-wise, below 2 per cent or 35 households. The percentage of non-response households, then, in this survey, and including refusals

and not-at-homes, approximates 120 dwelling units or 6 per cent of the sample population.

The sample design utilized in this research conforms to a probability model because the probability of selection of every block and dwelling unit was known in advance of the actual selection of the sample. These probabilities give the fraction of times that each possible block and dwelling unit would be drawn if the sampling procedure were repeated an indefinitely large number of times. For each block and dwelling unit in Bethlehem, then, some specific probability was assigned.

Several months prior to initiation of the interviewing, the total number of occupied blocks and dwelling units in Bethlehem was determined to be respectively 1,633 and 23,840. Using essentially a sampling procedure suggested by Dr. Leslie Kish of the University of Michigan a sample of blocks was made with the interval 6—that is, every sixth block of the total 1,633 was selected. The total number of sample blocks, therefore, was determined to be 272. Within the 272 selected sample blocks the sample of dwelling units or households was then made with the interval 2—that is, an average number of 2 sample dwelling units per sample block was used. Following this, another sampling procedure demonstrated that the total number of dwelling units in the sample was to be 1,987.

Complete listings of all 272 sample blocks and dwelling units within these blocks was then made. This was done prior to the interviewing phase of the study by trained Pennsylvania Department of Health personnel. The method of listing addresses was uniform for all sample blocks. The system involved the starting of the listing of addresses for each block on the northwest corner and proceeding in a clockwise direction around the block, listing the addresses of each dwelling unit as it was passed until the starting point was again reached. The method of listing within dwellings containing more than one dwelling unit was also uniform. For those dwelling units using the same numerical street address, the order of listing was by apartment number or flat number if such number appeared on doorbells, mailboxes, or doors of individual apartments. The lowest number and lowest letter of the alphabet was listed first

(e.g., a, b, c, etc. or 1, 2, 3, etc., or 1a, 1b, 1c, 2a, 2b, 2c, etc.). When there was no numerical or alphabetical identification of individual rooms, apartments, or flats the listing was done in the following order: right to left; basement to ground floor, to second floor, etc.; front to back on any given floor. This process of complete listing of addresses within sample blocks, or "identification" is it is sometimes called, is the crux of probability sampling. It is the guarantee that 10 interviewers or 10,000 interviewers instructed to visit dwelling unit number 16 could all find the same one.

Upon completion of the listing of all addresses within the 272 sample blocks, it was found that 4,014 dwelling units existed. Following the within-block sample interval of 2, every second dwelling unit or address was selected, for purposes of interviewing from the total of 4,014 enumerated, until the required number of 1,987 dwelling units was reached.

The social position individuals and families occupy in the status structure of Bethlehem will be determined through the modified use of the Hollingshead index of social position. (See Hollingshead and Redlich,¹ pp. 387-397). To determine an individual's class status the Hollingshead index utilized three scales: occupation, ecological area of residence, and education. The index used in this research will also consist of these three scales. It does not, however, have the same six residence positions or categories that comprise the Hollingshead residence scale.

For reasons of unadaptability, i.e., of not being able to apply the New Haven oriented Hollingshead residence scale to Bethlehem, the W. L. Warner residence scale, comprising seven positions and modified to the extent that the seven categories are reduced to six, will be utilized instead. (See Warner,² pp. 151-154). The seven occupation and seven education positions, however, comprising the occupation and education scales in this study are similar to the Hollingshead categories in number and in substance.

The procedure for determining the index of social position is rather complex. Very generally stated, however, to obtain a social class score on an individual or/and family, one must know the head of the household's

occupation and education (that is, number of years of school completed) plus the address of the dwelling unit. Information pertinent to determining the occupation and education class score, and placing each respondent into one of seven positions in the education and occupation scales, was obtained from the interview with the respondent. Residence determination, on the other hand, was made by way of visiting each of the 272 sample blocks plus their surrounding areas and placing each of these blocks into one of six positions on the residence scale.

Following this each of the 1,987 dwelling units was given an appropriate 1-6 residence scale score in conformance with the sample block score. These scores for each of these three variables, ranging from 1-6 for residence, 1-7 for occupation, and 1-7 for education constitute the *scale position score* or *value* for the household. There will be but one such score for each of the three variables and three per household. Each of these scores will then be multiplied by a *factor weight* which will be assigned to each of these three variables. This *factor weight* will be determined by a standard regression equation. The three products will then be summed, and the resultant score will be taken as an index of this household's position in the community's class system.

The data gathered from the interview schedule will be edited and coded and then punched on cards for IBM processing by the Statistical Bureau of the Pennsylvania State Department of Health. The coding will be done in red pencil. Every interview schedule will be coded with an identifying number that will be punched into several IBM cards. This will be done so that at any phase of the analysis we can return from referral to a particular interview schedule and make an investigation on a punch mark in the cards.

The primary emphasis in this study is to test the six hypotheses on relationships between class status and various aspects of home accidents. Our main interest is to see what happens if the independent variable, class status, is varied in terms of each of the six major hypotheses under study. The chi square test will be utilized in statistical analyses of data under consideration. The 5 per cent probability level

will be used throughout the study as the minimum for the determination of significance. Each of the six hypotheses will be tested through use of the "null hypothesis." This states that there is no relationship between, for example, in hypothesis two, class status and type of home accident. If this is true, we would expect to find the same proportions of accident persons having received disabling and non-disabling accidents in each of the five classes.

For example, if in the total group of accident persons 20 per cent experienced disabling accidents and the null hypothesis is true, 20 per cent of the Class I accident persons should have experienced disabling accidents along with 20 per cent of the Class II, 20 per cent of the Class III, 20 per cent of the Class IV, and 20 per cent

of the Class V. However, if the observed proportions in the different classes differ greatly from this expected proportion, our null hypothesis will be rejected and the conclusion made that there is a relationship between class status and type of home accidents.

The statistical procedure of "null hypothesis" will be used to test all six hypotheses. It is expected that the major findings of this research will be published sometime during this coming summer.

(c) ON COMMUNITY PLANNING

By DENNIS O'HARROW

Executive Dir., American Society of Planning Officials, Chicago

(Outline of Talk)

- I. Serious impact—son of community planner leaves roller skates
 - A. What I know about home accidents
 1. Roller skates
 2. Rocking chair
 3. Wife slicing meat
 - B. Change title—"Impact of Community Planning on Safety"
- II. Two points
 - A. Community planning—police power, regulations to promote the "health, safety, moral" and general welfare of the community"
 1. Sometimes wonder about "morals"—what nonsense
 2. Note "safety" specifically stated
 - B. If one dominant principle—all actions, regulations, plans must be considered in context, with all others—*coordinate* (many ways)
 1. Economic, social, physical
 2. Health, safety, morals, general welfare
 3. Transportation, land use
- III. Precise field of home safety, other aspects of safety, safety with all other aspects of community development
 4. Perfection in home safety absurd if external conditions unsafe—and vice versa (what good to travel home safe if only to fall down cellar steps)
- IV. Community planning is applying best intelligence, gained from past experience and continuing research, to producing the best human environment, the community that permits its citizens to reach maximum potential—insofar as community can do so
 - A. Done through preparation of plans, guides, standards for
 1. Streets and highways
 2. Land use
 3. Schools
 4. Parks and playgrounds
 5. Water supply and sewers
 6. Libraries, fire and police stations
 7. Airports, railroads, ports
 8. Host of other things that make up a community

B. We see planning carried out

1. Zoning ordinance
2. Urban renewal
3. Construction of public works
4. Smoke abatement, housing, building codes

V. Back to revised title—talk about several aspects

A. Backyard swimming pools

1. In 1953 sensed trend
2. Tried to find out about safety
3. Called National Safety Council, insurance companies—nothing!
4. Pull out report—specific warnings—out of our head
5. Our fears have been borne out, but were able to bring dangers to our attention of civic authorities

B. Billboards—people don't like them—on what to base control

1. Police power—health, safety, morals, general welfare
2. Fastened on safety—bad men could lurk
3. Also morals—weeds hid immoral acts
4. Although probably has happened, I knew no incidents

C. Billboards—strongest objection aesthetic—still safety

1. Two-second distraction at 75 mph—220 feet
2. Outdoor advertisers argue, with some justification, that billboard breaks hypnotic spell cast by modern hi-speed monotonous thoroughfares

D. Brings to one of most important fields in which community planning contributes to safety—transportation

1. In the transportation house, there are many mansions
2. Safety of limited access highways
3. Design of neighborhoods and cities to reduce traffic in residential areas
4. Problem combatting integral curb-gutter sidewalks

5. Radburn—design of superblock neighborhood to give footpaths for children

6. Location of schools away from major traffic arteries—still fighting (safeway—teach kids how to avoid traffic; Marines—train with live ammo)

E. Airport problems

1. Approach areas clear
2. Proper land uses in area (Tennessee State Hospital)

3. Location of jet ports

F. Planners make mistakes

1. For years advocated thru streets
2. Warped centerline
3. Suddenly, someone decided to study—T intersections about 25 per cent as hazardous as +

G. Planners advocate mass transit

1. On economic basis
2. Concomitant safety improvement

H. Uses in zoning ordinance grouped for general compatibility, mutual needs—schools and churches in residential areas

1. Also where pertinent isolate fire-work factories, cleaning plants using inflammable cleaning agents

I. A few years ago—research report on storage of LPG butane—worked with LPG Institute

1. We decided was hazardous
2. LPG Inst. wrote a problem letter
3. Gruesome, but one of those fortunate catastrophes—as went to press
4. LPG storage blew up—killed a dozen people
5. Added letter and newspaper clipping without comment

J. Problems with "safe" land uses

1. Petrol people keep city safety of filling stations—low insurance rate, etc.
2. Most Z. O. keep away from schools—certainly slim chance, but you can't afford to take even that chance

K. Nuclear power plants—we are at

loss to assess danger—but our present attitude is same—cannot afford to take a chance

1. Difficult to differentiate in planning power between health and safety—health hazard is unsafe
2. Very active efforts to abate or avoid air pollution (recognition—National Advisory Committee on Community Air Pollution of USPHS)

3. Downwind placement of industry—basic premise of one prominent consultant—so much so know as Smokey Joe—knocked into a cocked hat with new smokeless fuel industry

4. Avoidance of sanitary pollution—unsafe dirty water

5. The abolition of slums, unsanitary and hazardous—good mixture of

economic, social, and physical health, safety, even words, general welfare

- VI. In conclusion, I want to revert to special pleading for the planner's chief qualification—his ever-present attempt to see the community as a whole, to plan it as a whole, to take into account the inter-relationship of every aspect of community development, social, economic, political, and physical, health, moral, spiritual, and general welfare, as well as safety. We know that specialists are indispensable, but we also believe that generalists are also indispensable. So when we are propagandizing to a group of specialists, we ask that from time to time they lift their eyes and try to recognize the general picture, to recognize the *gestalt*—the whole is greater than the sum of its parts.

HERE'S HOW WE DID IT!

(a) VOLUNTARY AGENCIES

By CHRISTIAN SMITH

Dir. of Health Education,

Province of Saskatchewan Department of Public Health, Regina, Sask., Canada

To come here and speak on voluntary agencies seems a bit like carrying coals to Newcastle. I suppose there is no country in the world where voluntary service has been more developed than in the United States—where there are more citizens engaged in it and where volunteers have a greater impact on the welfare of a nation.

However, voluntary effort is also a highly developed and influential social phenomenon in a number of European countries and, notably, in the United Kingdom. I recall that, during World War II, Robert Priestley, the novelist, remarked in a book that "the free societies are the bedrock of English democracy." That is also the way in which citizen volunteers and their organizations on this side of the Atlantic are regarded.

In the Canadian province of Saskatchewan there is a great variety of voluntary services and the number seems to be growing.

In some ways the small towns seem to be overorganized. I recall a survey of one town of about 2,000 population which had more than 50 voluntary agencies. Moreover, a relatively small number of very active persons seemed to be the core of many of them.

Our own attitude in the Province of Saskatchewan, Department of Public Health is one of "better too many than too few." We have a very keen appreciation of the value of voluntary effort. When we speak of a partnership between the people and their government, we really mean it; and in many, many ways, it is a reality in our province. We are under no illusions that the people can be made or kept healthy and safe by our efforts alone.

That is why, although we have a very active health education service, we welcomed the formation of a Saskatchewan

division of the Canadian Mental Health Association a decade ago and pruned the pump to get it started with both federal and provincial grants. Mention of federal aid brings to mind that the Canadian Arthritis and Rheumatism Society was founded with the encouragement and assistance of the Department of National Health and Welfare.

Another good illustration of how we operate is our food hygiene institutes, or safe food fairs, as we call them, which are designed to prevent food poisoning, a type of accident that sometimes lands many people in hospital. Now it would be possible for our provincial department or a health unit to organize such an institute, but we believe it better to encourage local people to do this themselves with a little guidance from us. Thus, a community organization, such as a Women's Institute or a Farm Union local or perhaps a religious group like the Catholic Women's League, may sponsor a safe food fair.

There are, of course, actions which such a voluntary group can take which a government or public agency could not very well consider, such as the matter of door prizes. The voluntary agency can solicit food hampers, sets of paper tableware, and other prizes from local merchants. This an official agency cannot do, nor would it be likely to meet with much success. When a government agency runs anything, everybody expects it to pay all the way, and then some.

Now to come specifically to the field of accident prevention, I might mention that our provincial government has financially backed the Saskatchewan Highway Safety Council since its inception a number of years ago. The Council has now recognized the need to broaden its program and has approached the government for an annual grant of \$40,000. It expects to raise nearly as much again by voluntary subscription. I have no doubt that this request will be favorably considered because the government recognizes the vital role of the voluntary safety organization. This is so in spite of the fact that the Department of Public Health conducts a comprehensive safety program and various other government agencies conduct preventive programs in some specific areas.

When I was asked to organize and direct the health education services of the health

department 17 years ago, I was under no illusions that my division, or even the whole department, could do an effective job in isolation from the people. From its inception, the Division of Health Education set out to work through and with existing community organizations of all kinds—the Parent-Teacher Associations, Women's Institutes and other women's organizations, professional and business groups, lodges, churches, agricultural organizations, and so on.

Through the years, we have maintained a close liaison with these bodies through their provincial and regional officers and by means of our Saskatchewan Health Newsletter, a bulletin that goes monthly to some 12,000 community leaders, professional persons, local governments, school authorities, teachers, and voluntary groups of all kinds.

Perhaps I should tell you how compulsory pasteurization of milk was achieved a number of years ago; in fact, within a relatively short period after the health education service was set up. After a year's public education regarding the hazards of raw milk, we found the government unwilling to risk public opposition by putting in the legislation. Actually, in my opinion, the government misjudged the situation.

However, our next step was to approach the Provincial Council of Women, a body which, at that time, represented about 125,000 organized women in Saskatchewan. The Council conducted a year's educational and action program among all its affiliates so that women from the smallest hamlets to the largest urban centres were equally involved. At the end of a year it had collected the views of hundreds of organizations and went to the government with a brief. Very soon after this, the legislation was approved unanimously by the Saskatchewan Legislative Assembly.

In 1952, our Health Education Division was given the task of organizing and conducting a comprehensive accident prevention program. I might interject that we began to give major emphasis in those areas where no other agency, official or voluntary, was conducting a preventive program, but, at the same time, we supported the work already being done. There was no point, for instance, in developing a great water

safety activity when this was already being done by the Red Cross. Nor did it seem wise to launch a fire prevention program of some magnitude when this was the specific responsibility of the provincial fire commissioner.

For these reasons, we put most of our effort into the prevention of home and agricultural accidents, later tackling special areas such as child safety and the prevention of accidents in hospitals and other institutions. Some special attention has also been given the safety of elderly citizens.

After the success we had had in working with voluntary associations in health education, it was natural to follow the same course with respect to accident prevention, so we began immediately to develop partnerships with a variety of organizations. These included the Provincial Federation of Parent-Teacher Associations, the Saskatchewan Teachers Federation, the Women's Institutes, the Saskatchewan Farmers Union (and its 1,000 women's locals), the school system, the farm implement companies and other agricultural supply enterprises, provincial 4-H groups and, of course, the churches, in name but some principal agencies.

For a government department to set out deliberately to organize a voluntary agency is almost unheard of in Canada and perhaps even in the United States but, in our farm safety program, the need of a voluntary agency was so evident that, one day, we called together the representatives of some 30 organizations to organize the Saskatchewan Farm Safety Committee. Today it has some 300 members. This group is the obvious nucleus of a farm division when the Saskatchewan Safety Council comes into existence.

Our happiest liaison, however, is with the Saskatchewan Junior Chamber of Commerce. To tell about this, I have to explain Canada's annual Child Safety Day, observed annually on the first Sunday of May. This is how it came about. In the early spring of 1954, after two years of hard work, we seemed to have made very little progress in interesting the people of Saskatchewan in the accident tragedy. The indifference, based on ignorance, because the people just hadn't listened, was reflected by the newspapers. Stories on accidents, even the shocking totals for a year, invariably

were mutilated and buried somewhere back of the financial pages under meaningless label headings.

Personally, I found this very disturbing, so much so, in fact, that it gave me bad nights. One morning about three o'clock I lay awake worrying about it and the solution came very easily. It occurred to me that, when a problem proves too tough, why not bite off a piece one can handle? I remembered someone saying that the way to a man's mind lies through his heart. Now we well know in public health that people who are indifferent or careless about their own health and safety will go to all lengths for the protection of their children. We have seen this in recent years in the prevention of paralytic poliomyelitis. A check last year indicated that 94 per cent of the children to age 16 had been adequately immunized with Salk vaccine, but only 67 per cent of the adults, 17 to 40 years of age, had taken advantage of our free clinics.

Having found an apparent solution, I went back to sleep and, when I arose later, I telephoned the head of my department who approved the institution of a child safety day. It was our assumption that, if we could induce grownups to make the environment safer for children and if we could induce parents to teach safety by precept and example, not only the children but their parents and others would be safer.

So, with rather short notice, we observed our first Saskatchewan Child Safety Day on the first Sunday of May, 1954. Sunday was chosen advisedly because we decided immediately to involve the churches and stress the moral responsibility of everyone for the safety of children (and adults), and we also considered it likely that we could reach more people in the press and by radio and television on a Sunday than any other day of the week. We wanted to reach the fathers as well as the mothers.

The venture caught on immediately with the press, the churches, and some scattered organizations. Then, as since then, we wrote to clergy of all denominations and asked their cooperation. We sent them sample materials and sermon suggestions. Later this became a prepared sermon. Each year a selected minister or priest contributes the sermon, which we print and send out to all clergy. We also lithographed a Child Safety Day poster, and every year we have

produced a different poster illustrating an attractive Saskatchewan child.

However, it was soon evident that we needed the assistance of some organized group with the enthusiasm and energy one often finds among young persons, and we hit on the idea of involving the Junior Chambers of Commerce.

Here I should interject that already, several years ago, we had thought about the total Canadian problem and not just the loss of children in our own province. We wanted Child Safety Day to become a national event. We approached the national president of the Jaycees for advice and followed his suggestion that we try out a pilot program with the Jaycees in one of our cities. This was to be followed by a province-wide pilot program involving all Jaycee units in Saskatchewan. A national project might follow—and it has.

The Junior Chamber of Commerce in Saskatoon has a well-established record for "firsts" in public-service projects . . . for instance, it was the first in Canada to launch a venereal disease education campaign, a project in which 35 other units later joined. It fought prewar Nazi activities and set . . . not a movement in Canada to counter enemy activity. It took the lead in forming the second credit union in Saskatchewan. It was instrumental in the development of an entirely new child welfare program and in providing better juvenile court practices.

This Saskatoon group readily accepted the Child Safety Day project and it was an immediate success. The following year, the remainder of the Jaycee units in the province followed suit and, a year ago, the national organization unanimously adopted Child Safety Day as a project. There are 270 Jaycee units in Canada and it was necessary to write them three times this past winter with suggestions and ideas.

Now voluntary associations are often strapped for funds and the Jaycees are by no means wealthy, at least in our country. We had offered cash prizes to farm and community organizations for the best local safety programs. We did not need to offer the Jaycees any money, but we did have to supply them with posters, literature, radio and television materials, exhibits, and other vital materials. Of course, we could not do this on a national scale, but even when

such assistance is provided only in our own province, it runs to considerable volume.

Having enlisted the Canadian Jaycees, it would be unwise to assume that everything necessary has been done. It seems best to try to interest other agencies, both official and voluntary, to support and supplement the Junior Chambers.

This summer, the Canadian Federation of Home and School, and Parent-Teacher Association held its annual conference near Montreal, Quebec. I had been its provincial and national health convener and have maintained close contact with the organization. I must say that I have been disappointed that so few of the locals in my own province showed any sustained interest in any project for the health and safety of school children, and I had almost despaired of restoring their partnership.

However, one day last June, just before the national convention, the editor of our parent-teacher magazine wrote me that the Province of British Columbia Federation proposed to bring in a resolution to make it a crime to use plastic bags which were not specifically labelled as dangerous. Now we have had very few plastic bag accidents in Canada and only one in Saskatchewan since plastic bags came into use. I wrote immediately to the magazine editor urging her to get the Saskatchewan delegates to press for a much more comprehensive attack on accidents among children and, in fact, accidents generally.

I could not go to the convention but learned later that my views had been incorporated in an amendment to the British Columbia resolution and passed unanimously. The federal authorities were pressed to give leadership and also to encourage the formation of a National Safety Council similar to the American organization.

Subsequently, I wrote a piece for the magazine urging the parent-teacher members to carry on vigorously for the prevention of accidents now that they had made a good start, and I reminded them of their influence and power. I told a story of something that had happened not long ago in Saskatchewan which well illustrated the power and influence of women in voluntary organizations.

Several years ago, I was asked to speak on mental health at a series of farm women's

days, promoted in small rural centres by the Farmers Union. Just before this, a demented woman had shot and killed one of her children and wounded two others on a lonely farm. This woman had only recently been a patient in a psychiatric institution, but she was cast into a local jail and then sent to a provincial jail for women to await trial like any common criminal.

The woman who chaired the Farm Women's Days programs and introduced me asked me if I would make a reference to this incident. I did so in the course of my talk and said that the most shocking aspect of the treatment of this apparently sick woman was not the action of the police or the magistrate who conducted the preliminary hearing, it was the silence of the people of Saskatchewan, particularly the women. Saskatchewan is a province which prides itself on its sophistication and humaneness in the treatment of the ill and less fortunate.

Immediately after my paper there was a five minute break, and one of the women asked me to help with a resolution addressed to the attorney-general of Saskatchewan proposing the treatment of the farm woman as inconsistent with Saskatchewan's progressive and humane policies. The resolution was passed unanimously.

"Now what do we do with it?" the chairwoman asked.

"If you do like so many other organizations, you'll file it and forget about it," I answered. "However, if this case shocked you and you don't want something like that to happen to you or any other person, I suggest you send the resolution to the attorney-general with a covering letter and that you publicize your action in the press and by radio and television," I said.

Similar resolutions were drafted, passed, and handled at a number of such meetings in the weeks that followed.

One day I was chatting with an official of our Psychiatric Services Branch and, somehow, the story of the mentally ill farm woman came into the conversation. He told

how our department had urged the removal of the prisoner from a jail to a mental hospital and how this had been rebuffed with a legalistic statement that "the law must take its course." Suddenly, however, the Department of the Attorney-General had reversed its decision and moved the unfortunate woman from prison to hospital.

I think this well illustrates the power of voluntary effort in influencing public affairs, and I submit it can be just as powerful in dealing with the prevention of accidents. There are two English quotations I want to leave with you:

"That community is greatest where the greatest number of persons accept unimposed obligations."

This is by Lord Moulton, an English lawyer. I think of it when I see a community which seems to be over-organized.

The other quotation is this and, unfortunately, I can't recall the author:

"There is no limit to the kind of good a man can do if he doesn't care who gets the credit."

I think of this when sometimes a voluntary association seems to get the credit for something we have done.

One day I spoke at a public health conference about the value of voluntary associations to the medical health officer or unit director.

A health officer asked: "But isn't there a danger of the volunteers wanting to take over your work?"

The reply was that volunteers only want to wear the pants in the community household when the head of the family isn't doing a good job and, even then, only long enough to make him do it.

I think there is a tremendous challenge to American volunteers in the tragedy of child accidents. Perhaps you can bring yourselves to accept an idea from your neighbors in Canada, and make Child Safety Day an international event.

(b) INDUSTRYBy **WILLIAM J. KERNS**

Safety Advisor, Humble Oil & Refining Co., Bayway Refinery, Linden, N. J.

We, at Bayway Refinery of Humble Oil & Refining Co., believe that a comprehensive and progressive off-the-job safety program is essential before any continuing degree of success can be achieved in an industrial safety program. We believe that to significantly reduce industrial injuries we must try to eliminate all injuries whether they occur at work or off-the-job.

After all, safety is primarily a matter of attitude and, as you know, attitudes are difficult to change. Employees do not suddenly become safety conscious when they walk into our plants and put their safety hats on, any more than they become reckless and violators of good safety practices when they leave the refinery. We believe people tend to work, drive, and play as they live. Therefore, if we can influence them to live safely, we believe this will improve their safety performance in all areas of their activity.

In order to accomplish this, our safety program must be one of "Safety Around the Clock" as shown on one of our 130-foot diameter storage tanks. The National Safety Council states it—"Safety. Everywhere. All the Time." The off-the-job safety program must naturally supplement a sound industrial safety program.

Any good safety program should be based on the three traditional "E's" of safety. It is essential that operations be well engineered, employees be well educated in safety rules and in their safety responsibilities, and that rules be adequately enforced. A good safety program has been referred to by safety experts as being like a three-legged stool. Take away any leg, engineering, education, or enforcement and it comes.

We believe that this analogy should be carried further to point out that a good safety program can bog down just like this stool through monotony unless it has other essential ingredients in addition to the three traditional "E's" of safety. Our top management must be sincerely interested, but just as important must actively participate in the safety program. All levels of management must accept employee safety as their

responsibility on equal terms with cost, quality, and production, and there must be a real opportunity for participation by both management and wage employees in the development and execution of the safety program.

We have found that these ingredients can add a base of enthusiasm, a fourth and very essential "E" to our safety activities. We have found that a solid base of enthusiasm will prevent our safety activities both on and off the job from bogging down. It is one of the keys to the progress we have made at Bayway Refinery.

One of the areas where this influence of enthusiasm can be most forcefully demonstrated is in the reduction of off-the-job disabling injuries. Off-the-job injuries are considered less subject to management control than industrial injuries, and the principal tools available to management are the motivation and education of the employee and his family. We believe the employee must be given standards of conduct in the area of off-the-job safety and the stimulation to meet these standards of conduct.

The situation we had at Bayway in off-the-job disabling injuries in 1956, the first year we began our off-the-job safety activities, was this: 263 disabling off-the-job injuries, resulting in our employees losing 3,391 mandays of work. In 1956 by comparison we had 13 on-the-job disabling injuries. In other words, we had 20 off-the-job disabling injuries for every industrial disabling injury we had at the refinery. How could we possibly believe that our industrial safety program was for real? Our employees were hurting themselves off the job in exactly the same ways they were hurting themselves on the job.

For comparison of performance, both with ourselves year by year and with other industries, it is customary to express off-the-job disabling injuries in terms of frequency, injuries per million manhours, assigning 312 manhours per month per employee. Our frequency in 1956 was 17 off-the-job disabling injuries per million manhours.

Our progress since we began our off-the-job safety activities in 1956 is noted in that our frequency was reduced from 17 disabling injuries per million manhours in 1956, to 11.8 in 1957, and 6.5 in 1958. We made little progress in 1959, for an interesting reason I will describe later. In 1960, our frequency reached a low of 4.75. So far this year, we are not doing nearly as well. Our frequency is up to 6.5 and again I will describe the reasons later. I would like now to outline some of the activities we have conducted beginning in 1956 to secure a rapid reduction in off-the-job injuries.

Our Central Safety Committee has as its chairman, the refinery manager and includes all of his department heads as members, with the safety advisor as secretary. When this committee recognized our problem of off-the-job safety in 1956, an analysis disclosed that one-half of these disabling injuries were due to home accidents. A Home Safety Carnival was developed to be held at the refinery on a series of Saturday mornings. As part of the carnival activity, a home safety essay contest was conducted for the children of employees, with awards of over \$3,000 in cash. The theme of the carnival was the relation between industrial safety and home safety, or "Safety Around the Clock."

A collection was made of every safety sign used in the refinery. We were surprised to find we had so many types.

A display was made of all the protective equipment used in the refinery along with the home hazards that are similar to refinery hazards. We built a little garage with a dummy lying in it to show the hazard of carbon monoxide poisoning from automobile exhaust.

We demonstrated the right and wrong ways for medicine chests, showing the typical home medicine chest and how it could be.

We had a demonstration of home electrical circuits and showed how fires start when oversized fuses are placed in the box or the fuse is short-circuited with a penny.

The committee collected samples of all the common household chemicals and enlarged the warning labels, relating these chemicals to the chemicals we used in the refinery and the cautions to be observed.

We had a booth demonstrating the vari-

ous do-it-yourself hazards around the home as well as a modern kitchen with all of its hazards; and our rescue squad gave a demonstration of artificial respiration and heavy rescue. Our fire department put on a spectacular demonstration.

We found that the displays which had been set up for the guests' participation were most effective. For example, kids and employees could slam a steel ball against safety spectacles to see how effective they are in preventing eye injury.

Incidentally, we are quite proud of the reduction in foreign body in eye cases we have secured at the refinery through our safety spectacle program which was instituted in 1956. We have cut our foreign body in eye frequency from 192 foreign bodies in eyes per million manhours in 1955, to a range of 11-14 in the years 1958 through 1960.

A little model was used to demonstrate techniques in lifting heavy objects.

Over 5,000 company employees and their families attended our first safety carnival, with over 600 children entering the home safety essay contest. As a result, we decided to repeat the essay contest and carnival in 1957, and to give more attention to participation. In addition, we added a home safety poster contest for employee children.

We held a safety quiz in the refinery auditorium for all the employee children. We believe the safety quiz was effective for our employees also.

The winners of the home safety essay contest and poster contest were presented their prizes by the quizmaster. Each child answering a safety question received a token prize.

We again had demonstrations of the common home hazards such as an attic showing both the normal disorder as well as a properly equipped and maintained attic. We also had a workshop and a garage showing the normal disorder vs. good order.

We even set up a bathroom showing all the common hazards in this vital room of the home.

The local police put on a demonstration of their drunkometer machine. This secured a lot of interest, particularly on the part of the man being tested as did the

various driver testing or psycho-physical testing units.

Local police put on a dramatic outside demonstration of the use of radar in catching speeders.

Both the winning home safety essay and winning safety posters were placed on display. We used the winning safety posters from this contest to design our safety calendar for all of our employees this year.

We believe that home safety carnivals such as these are very effective in setting the stage for an off-the-job safety program. It is a good way to involve a large group of employees in preparation and to demonstrate the company activity and interest in off-the-job safety to employee families.

One of the programs which has had a continuing effect on our off-the-job safety since the middle of 1957 is our individual employee safety award program. In both 1955 and 1956, we had made group safety awards for all employees when the refinery went 30, 60, or 90 days without an industrial disabling injury. We decided to develop a program which would include performance in off-the-job safety as well as industrial safety.

And in line with our philosophy of eliminating all accidents, we decided to include minor or dispensary type injuries as well as industrial disabling injuries for contest purposes. Each employee must go a specified time without having an industrial disabling injury, a non-disabling industrial injury of any type, and just as important, must not have an off-the-job disabling injury.

The employee competes only for himself and his family. He becomes eligible first for the Red Esso Regular prize, and as he continues injury-free, he graduates to the Blue Esso Extra, and then to the top, Golden Esso Extra. As he continues injury-free, he continues to win awards.

The catalogues are mailed to the employee's home with an appropriate congratulatory letter from the refinery manager. The employee and his family then make the award selection together, and the award is mailed to the employee's home from the supplier.

The individual employees' safety awards are continuously displayed on the main thoroughfare of the refinery. And you can tell from the lack of grass in front of

this cabinet the high degree of interest on the part of the employee. We believe this approach to safety awards is somewhat unique in industry and that it is a good way to show an employee and his family frequently, that he is doing a good job as an individual both on and off the job and that he is meeting high standards of conduct. We believe the award program helps to maintain a base of enthusiasm for our safety activities.

Carrying the thought of individual recognition further, the refinery manager presents a gold tie pin to the employee upon his completing 20 accident-free years on the same basis of no non-disabling or disabling industrial injuries and no off-the-job disabling injuries. In addition, verbal and written commendation are given to our employees upon their completing five, ten, or fifteen years on the same basis. An honor roll has been established with their names.

Another inexpensive safety activity revolves around our company picnics. In the past several years, we have given demonstrations of recreation safety by having the American Red Cross water safety instructors conduct swimming instruction and water rescue demonstrations such as this life preserver rescue, canoe rescue, and surfboard rescue.

Local sportsmen clubs have given demonstrations of fishing, archery, and hunting safety at our picnics and we have had the local police put on bicycle safety contests, with over 700 of our employees' children competing.

The New Jersey Bureau of Navigation brought a power boat to our picnic and gave a demonstration of boat safety.

The New Jersey State Police gave a skin diving demonstration including rescue techniques. In addition, our Rescue Squad has also given spectacular demonstrations, and we have again included psycho-physical testing as well as radar and drunkometer demonstrations. With 5-7,000 employee and family members attending, these demonstrations are well received with a good return at little expense.

During 1959, we held a highly successful contest for the wives of our employees who submitted their family home safety programs. Approximately 43 per cent par-

ticipated. This program, "How to Keep My Family Safe," was designed to have the whole family think hard about safety for at least several hours. The quality of the essays was excellent, and some 60 wage employees and supervisors made up judging teams for the 868 entries. The final judging was supervised by the chairman of the Home Safety Committee of the New Jersey State Safety Council. The winners shared \$250 in cash prizes and all participants received a safety award.

We capitalized on the excellent ideas in these safety essays by preparing a safety reminder calendar which was mailed each month to all employees. Each day of the month carried a safety thought from one of our employee wives with credit given to her.

We believe that our safety program in the plant and off the job is strengthened when employees and members of their families make safety commitments to themselves through contests and programs such as, "How to Keep My Family Safe." We believe it strengthens our base of enthusiasm.

Up to now, I have been reporting some of the activities that have enabled us to reduce our off-the-job injury frequency steadily downward through 1958. You will recall that in 1939 we showed no further improvement, even though we continued our activity in the area of home safety.

As we reduced off-the-job disabling injuries in 1937 through 1938, we found we were making little progress in the area of traffic accidents. Traffic accidents, which accounted for only 18 per cent of our off-the-job accidents in 1936, rapidly increased to 34 per cent in 1939, and this increase offset the reduction in other areas in 1939. Also, in 1939, 54 per cent of all the days lost as a result of off-the-job accidents were due to traffic injuries. This then was our main problem area in off-the-job safety in early 1960 as well as 1959.

Early in 1960, our Central Safety Committee decided to have an adult training program developed for our employees, and what safety experts tell us is unique, for their wives and teenage children who drive or soon would drive. The decision to budget funds was based on our desire to cut traffic accident costs in half. In 1959, our employees had 20 off-the-job disabling injuries

as a result of traffic accidents, including one fatality. The Defensive Driving Program was developed early in 1960 with the help of the Esso Safety Foundation, now the Humble Safety Foundation, and various New Jersey state agencies. The program was designed primarily to explore attitudes and their effect on driving habits and how to improve them.

Because of our success in past years in motivating employees to participate in safety activities, they and their families were invited to a full course dinner party prior to each of the four evening sessions of the program. This gave Mom a night away from the stove, the family a free meal, and provided an opportunity for our supervisor and employee families to mix.

We wanted to have the maximum number of employees attend the course so each participant who attended all four sessions received an incentive award, whether an employee or member of his family.

We widely publicized the program to our employees with nine feature articles in our bi-weekly newspaper, through a letter of invitation from the manager, and with local newspaper coverage. Incidentally, the main in space is being rescued in one of our disaster drills.

The program was held in the refinery auditorium with portable microphones used to gain maximum audience participation. Throughout the four sessions, full use was made of visual aids and movies dealing with traffic safety. The program was conducted by the very best traffic experts we could secure within traveling distance. Representatives of the New Jersey State Police and the New Jersey Division of Motor Vehicles attended all sessions to answer questions.

The first session was devoted to the basic causes of traffic accidents which were developed through audience discussion. The meaning of defensive driving, namely avoiding mistakes by others by anticipation and early recognition, was also developed as well as the point that the individual behind the wheel is responsible for and can control his own safety.

Prior to the second session after dinner, a spectacular demonstration of stopping distance was made. One of the program participants drove the car with an instructor alongside.

When the instructor fired this detonator, the pavement was marked with a burst of yellow powder. When the driver removed his foot from the accelerator and hit the brakes, the detonator fired automatically again. The point of the final stop was marked, and the audience could clearly see the distance of reaction time and that you could not stop a car on a dime.

The second session was devoted to a demonstration of psycho-physical testing and the significance of these tests. Also, sell them the truth—the alcohol story, showing physiological functions, and that there are no warning signs at the time drinking becomes dangerous. Also, a development of what makes us tick, a discussion of how emotions are related to attitude development, and how attitudes influence our actions in practical situations.

The third session was devoted to the differences of throughway driving and the development of safe driving practices and specific steps to meet the more common driving emergencies; also, to improve perception in driving and to provide audience practice in early recognition and anticipation principles.

The fourth session was devoted to a panel discussion including representatives of the State Motor Vehicle Division, the State Police, the New Jersey State Safety Council, and the course instructor, and covered "things I would like to know," a question and answer discussion built around the questions submitted on cards prior to and during the session. At the concluding session, a voluntary test taking about one-half hour was given and 85 per cent participated. As a further incentive, the top five per cent in grades became eligible to complete in a driving skill rodeo with the first prize of \$100 and second of \$50 for both men and women. Consolation prizes were also awarded to contestants in the driver skill rodeo who did not place.

Nearly 1,200 employees, their wives and teenage children, participated in the Defensive Driving Program and represented approximately 25 per cent of our employee group. We found the program a wonderful mixer for management, employee, and family all learning together. Ninety-nine per cent of the participants taking the course indicated they thought the course was either

excellent or good as submitted on evaluation cards. We believe the night out for the family, the attendance awards, and most importantly, the quality of the course were the reasons that only two and one-half per cent failed to attend all four sessions of the program, a program devoted to exploring attitudes and acceptance by the individual that he can improve his own.

We will continue to keep employee interest alive in traffic safety throughout the year with ideas like a road marker, which was mailed to the employee's home with a letter on traffic safety from the refinery manager, and through further feature articles in our local communications and stunts—like the crash scene developed by one of our wage safety committees for the Christmas holiday season.

It is too early to predict the ultimate benefits of the program on defensive driving. However, these are the results to date. Where our employees had 20 off-the-job disabling injuries as a result of traffic accidents in 1959, we had six in 1960 following the program and nine for the year. We have had nine through September of this year. Only two accidents out of the 15 following the program involved Defensive Driving participants. I mentioned earlier that our days lost as a result of traffic accidents had steadily climbed to 54 per cent in 1959. Our days lost as a result of traffic accidents in 1960 decreased to 30 per cent and the days lost in 1961 have decreased to 23 per cent.

Our total off-the-job injury frequency was reduced to 4.75 injuries per million man-hours in 1960, due primarily to our breakthrough in control of traffic accidents. We recovered our full investment in the Defensive Driving Program through reduced accident costs last year, and the savings are continuing to date. Just as important to us is the fact that fewer of our families had the suffering and misery associated with a bad traffic accident.

I mentioned earlier in my talk that we have not done nearly as well this year as we did last year. There have been problems and also shifts have taken place in our off-the-job accident experience. Below is an analysis of our off-the-job accidents by the categories of home, traffic, pedestrian, and recreation for the years 1956 through

1960, and for the nine months of this year. All categories are expressed as a per cent of total days lost.

In 1956 and 1957, our main problem was in the area of home accidents and this motivated the Home Safety Carnival, essay and poster contests for our employee children. Traffic accidents, perhaps less subject to control, crept upwards in 1958 and 1959. Home accidents, substantially reduced in 1958, climbed in 1959 and 1960. Pedestrian accidents jumped up in 1960, and snow-balled in 1961 to 40 per cent. In fact, in the first three months of this year, as we experienced one of the most severe winters in our history, 75 per cent of all the days lost were due to falls in ice and snow either pedestrian or on the outside steps at home.

An analysis of the number of accidents rather than the days lost highlights the fact that in 1960 and 1961 home accidents again became our predominant problem.

This spring, we made a test by sending the *Home Safety Review*, now named *Family Safety*, to all of our employees and asked them if they wished to continue receiving it. We were amazed at the results. Over 65 per cent of all our employees have returned IBM cards signifying their desire to continue receiving the magazine. Over one-half of these people took the time to write enthusiastic comments about the excellent quality of the magazine and its effect on their families' safety thinking.

Because of our continuing concern about off-the-job accidents, we developed a new home safety plan contest this summer that would involve the whole employee family working as a unit. The contest was purposely designed to require many hours of group thinking. A merchandise prize was offered to each family that made an entry in the contest and \$750 cash prizes were awarded to the six best family entries.

The contest was divided into two parts. The first part, "What's Wrong Here?" required each family as a group to find as many unsafe situations in a specially created cartoon as possible. The 20 families finding the most unsafe situations received a merchandise award. Incidentally, there are approximately 270 unsafe situations portrayed covering all areas of off-the-job safety in the cartoon.

The second part of the contest required each family to develop their Home Safety Plan, "How We Keep Our Family Safe," pointing out what each family is doing to prevent accidents in the general areas of falls, traffic, pedestrian, do-it-yourself, recreation, vacation, electrical, fires and burns, poisons and chemicals, and gardening and backyards. All members of the family signed the home safety plan. Where a child couldn't write, his parent was required to sign for him.

Over 600 families entered the contest in spite of the hot, humid weather of August and early September, and vacation period, and from the quality of the entries, had invested hours of thought.

The judging, taking four days, was done by 30 wage and management employees; again supervised by Miss Edith Doane of the Home Safety Department, New Jersey State Safety Council. We presented the cash awards at a special luncheon attended by the complete families of the winners.

We have accumulated so many novel ideas that we are planning to shortly publish a booklet of safety tips from Bayway families; again, capitalizing on their excellent safety thoughts.

In September of this year, we secured a significant decrease in number of off-the-job injuries continuing to date. We believe this contest will have some lasting effect and will be interested in following the off-the-job accident experience of the contestant group and judges in comparison to the rest of our employees.

I stated at the beginning that we believe that to significantly reduce both disabling and non-disabling industrial injuries we have to try to reduce all accidents whether they occur at work or off-the-job.

In the period 1956 to date, we have not yet seen a gratifying improvement in our industrial disabling injury frequency. It has held in a range of 3.9 to 1.7 injuries/million manhours. However, we have secured a substantial reduction in non-disabling industrial injury frequency. We have cut our frequency from 413 injuries per million manhours in 1955 to 53 in 1960. We believe that continuing concern for our employees' "Safety Around-the-Clock" is paying dividends in the reduction of injuries, both industrial and off-the-job.

We strongly feel that our most successful activities are the ones that involve the employee and members of his family in active participation, where they have to give something of themselves and make commitments to themselves.

We believe that the contests and other programs we have described here today

have been helpful in motivating our employees to do a better job through an improved safety attitude. This in turn has led to establishing a base of enthusiasm on the part of our employees for our safety program.

We know that this enthusiasm has made our safety program better.

(c) SAFETY ORGANIZATIONS

By AL McGEE

Home and Public Safety Dir., Seattle-King County Safety Council, Seattle 4, Wash.

We have a brand new Public Enemy No. 1 out in King County Washington. *Home accidents* are now killing more of our citizens than *traffic accidents*. The change is due both to rising home accidents and declining traffic fatalities. This is the first time this has happened to us, except for a brief period during World War II when gasoline rationing sharply cut the use of cars. In 1960, 139 King County residents died from home accidents, while only 116 were killed in traffic.

Looking at the national figures for 1960 (38,000 traffic deaths, 27,500 home accident deaths), it appears to me that before long many more areas across the country must face the same problem. Perhaps you and your community may profit from our experience out in Washington.

Re-Educating a Million People— With Volunteer Teachers

The most startling aspect of our experience in King County has been the fact that hardly anyone wants to believe what the Coroner's figures show. We have spent so many years publicizing traffic as the No. 1 killer that this notion has become a fixed belief for many of our people. When told that they are now safer on a busy freeway than in their own living rooms, they simply can't believe it. So our Home Safety Committee has the task of reeducating nearly a million people.

Fortunately, our Committee is composed of persons who are well qualified to teach others. One member is a lecturer on public health at the University of Washington. We have the top health educators from our city, county and state health departments.

We have a doctor, fire chief and the director of nurses for Children's Orthopedic Hospital. The Committee has more than 30 members, each a specialist in some area related to home safety.

Drafting a Positive Program

Our Committee chose to approach the problem from three directions at once. First, we decided to edit, publish and circulate a quarterly home safety leaflet containing seasonal warnings and advice. Second, we planned to invite representatives from community groups to attend a home safety workshop where they would be urged to start home safety projects within their respective groups. And third, we decided to hold a county-wide Home Safety Week once each year, with massive publicity via newspapers, radio and TV. Then we discovered that we didn't have enough money to finance any of these things.

How to Get Something for Nothing

Because we had so little money for postage, we designed our quarterly home safety publication as an envelope stuffer. We made it the size of a business envelope, and asked some of our member business firms to see if any of their office mail was going out "light." That is, we asked them to see if they could slip one of our stuffers into each outgoing letter without increasing the weight enough so that more postage would be needed. We discovered that the average business letter contains one sheet of paper, weight one-fourth of an ounce and carries postage for a full ounce.

Moreover, no one seemed to object to getting the stuffers along with their monthly statement or interoffice communication. So

we called this our "Piggyback Distribution System," and it worked so well that when our fourth issue was published, an even dozen business firms distributed a total of 21,000 copies. There was no cost to us. If our Home Safety Committee had mailed each of these individually from our office, the postage would have amounted to \$840.

Although we were able to get our distribution costs down to absolute zero, we didn't quite manage this with our printing costs. Printing costs for the 21,000 copies of our latest issue were \$21.32. We paid that to a small offset printing shop for making the paste-up, negatives and plate. Then one of our member firms, the Washington Natural Gas Co., took the plate, furnished their own paper and ran off 10,000 copies for us on their company press. When the gas company had finished, Pacific Northwest Bell Telephone Co. took the plate, ran off 11,000 copies on their press and sent them to their employees. We call this our "Panhandle Printing Program," and on this issue alone, it saved us more than \$100.

Our Home Safety Workshop was somewhat less than a rousing success. We invited representatives from more than 300 community organizations and some 60 showed up. Each one received a copy of *Sixty-Five Home Safety Program Ideas*, an 11-page booklet. The back-page contained a coupon to be returned when a club home safety project was started. To my knowledge, not one of these coupons was ever returned. We did, however, get several phone calls reporting on fresh home safety activities, and two or three of these groups did go on to complete fine projects.

Planning Home Safety Week

Our Committee gave Home Safety Week a trial run in 1960. Nothing much happened. When we made plans for this year, we decided that an "out-of-town" expert was needed to lend mystery and glamour. We persuaded General Stewart to send us Lois Mersdorf, senior home safety consultant for NSC. By the time she arrived, we had her booked almost solid for four days.

She conducted seminars for doctors and nurses at city, county and state departments of health and was drafted for similar duty

by the health officer of a neighboring county. She addressed the Seattle Council of Parents and Teachers and met with the safety chairmen of 23 homemakers clubs. She had lunch with staff members at a 70,000-member medical co-op and made six radio and television appearances. As Miss Mersdorf herself remarked, "You just can't beat the 'out-of-town expert' for getting attention."

Getting Our Name in the Papers

Since we had no funds with which to purchase paid advertising, we had to play up the news and public service value of Home Safety Week: the two big metropolitan newspapers in King County (combined circulation, 444,000) were quite willing to help, but the 46 weeklies (combined circulation, 501,000) demanded string local (neighborhood) news angles. We tried to give them these by asking the mayors of all 31 incorporated towns and cities in King County to proclaim Home Safety Week. Fifteen of them did, and when the clips were in we found that 18 newspapers with a combined circulation of nearly 700,000 had given us 211 column-inches of space worth more than \$750 at their general advertising rates.

Public Service—at \$100 Per Minute

Radio and television have had a rough time at the hands of congressional committees during the past couple of years, and we on the staff of the Seattle-King County Safety Council have religiously reported to the Federal Communications Commission each public service effort by Seattle stations in behalf of safety. We have defended them repeatedly, so we were not surprised when each of them scheduled Miss Mersdorf for an interview, during Home Safety Week. One station used her twice, and when we got through counting the minutes and multiplying the minutes by commercial rates which averaged \$100 per sixty seconds, we discovered that the TV stations had given us \$2,910.00 worth of time. A radio station gave us \$60 worth, so when we added the free newspaper space to the free radio and TV time, we discovered that these mass media had given us \$3,731.72 worth of the only things they have to sell.

What to Do When Nobody Comes

One of our Home Safety Week projects fell flat on its face. This was our Child

Accident Workshop, held at Children's Orthopedic Hospital. We gave it enough publicity to fill the Hollywood Bowl and exactly 12 people showed up. The director of nurses hurriedly rounded up a bunch of student nurses and shoed them into the auditorium so that the doctors would not have to lecture to empty seats.

This Child Accident Workshop was far from a brand new project. It had been put on more or less successfully each of the past six years. The program featured one doctor explaining the operation of the Poison Control Center, another lecturing on burns, a third on broken bones and at times a fourth on cuts and bruises. Each of these performers used excellent visual aids and made a fine presentation. Why didn't the audience show up? We did our best to find out.

The audience we were trying to pull was composed entirely of mothers of small children. That meant each one of them had to get a baby sitter. If father had driven the family car to work, then mother had to get on one bus, ride downtown, get on another bus, ride out to the Orthopedic Hospital, and then repeat the whole tiresome process to get home again. Mothers with cars were not much better off, the Orthopedic parking lot is small and perpetually full.

Next year, we will let these mothers stay home and we will bring them the Child Accident Workshop via television. We'll take the mountain to Mahomet, by hauling the doctors and their props to the studio. Mother will get it without baby sitter problems or traffic hazards, right in her own living room. It has already been definitely scheduled on KOMO-TV.

Those Men in the Funny Hats

When you are trying to re-educate a million people through the efforts of one staff man and 20 volunteers, you will quite likely need help. We certainly did, and we got it from the firemen. King County has 32 fire districts, each with one or more stations staffed with paid and/or volunteer crews.

The cultural myth, which casts the fireman as an imbecile in a funny hat who chops holes in your roof for no good reason, dies hard. For this reason, firemen always need public relations aid and will work

hard for it. Today's fireman is a highly-skilled, highly-trained, alert and knowledgeable individual who is likely to know more about home safety problems than anyone else in the entire community!

What's more, he's likely to have a bit of free time—once he has polished the pumper and dried out the hose—to put his ideas into practice. We signed up every fireman we could reach, and used them as volunteer home safety consultants during Home Safety Week. Those who participated spread the word to the rest and it wasn't long before they began asking and finally demanding to be allowed to serve on our Home Safety Committee. We are mighty glad to have them.

What can firemen do in home safety? There is hardly anything that they cannot do, if they really want to. They can teach kindergarten courses in first aid to youngsters. They can expand home inspections to include most home hazards. And if just one fireman's wife in each district would clip home accidents from the local paper and send them to Jess Carper, we could make the *Home Safety Review* grow as big as *Life* or *Look* or even *Reader's Digest*.

How to Keep Your Home from Killing Your Family

King County, Wash., is not always considered the best of all possible worlds, even by those of us who live there. It does, however, have a mild climate, and this feature has turned out to be both a blessing and a curse.

Many years ago, northwest architects began taking advantage of this mild climate by "extending the living room into the front yard." They designed outdoor patios with floors that were a continuation of living room floors. A large section of living room wall was replaced by sliding glass doors which could be opened wide during warm summer days and closed in the chill of evening.

At first, these sliding glass doors cost a small fortune and were thick enough to withstand Indian attacks. But price competition soon took care of this. Down, down, down went the price—and the quality too. Now you can buy a sliding glass patio door for \$39.95, but it is much more dangerous than the Indians ever were. When bumped slightly, the thin crystal glass in

these doors explodes into dozens of razor-edged shards which slash the victims' tendons and arteries to ribbons. We have documented cases where:

- (1) 184 stitches were required to sew up A SINGLE CUT on a 9-year-old boy;
- (2) Fourteen permanent scars on an 8-year-old will require years of plastic surgery to remove;
- (3) death resulted from severed arteries for a boy nine and a girl 19, in separate accidents two years apart.

The mother of the boy with the fourteen permanent scars is now a member of the Home Safety Committee of the Seattle-King County Safety Council. Already, her research into this problem has resulted in a feature article in *Home Safety Review* (Spring, 1961). We have not yet been able to impress the building code authorities of either Seattle or King County with the urgency of this problem. They keep asking for more accident statistics, and these are harder to come by than figures on the incidence of incest.

Hospital emergency wards and doctors' offices, where these statistics are spattered in blood on the walls and floors, are considered sacred to the patient. Both hospital administrators and doctors are bound by the ethics of their profession to keep the patients' problems in strict confidence. But we have found a few doctors and hospital administrators who also recognize a simple duty to all humanity—the duty to keep people alive and unmaimed, if possible. We hope that these few can convince the many to help us collect the statistics, and that the statistics will convince the building code people that only shatter-proof glass is safe in sliding doors.

(d) HEALTH DEPARTMENTS

By RICHARD E. GALLAGHER
Super., Roxborough Research Project in Accident Control
Philadelphia Dept. of Public Health, Philadelphia, Pa.

Here's how we did it in the Shenandoah Valley of Virginia.

In the fall of 1957 the Virginia State Department of Health and the United States Public Health Service selected a five county area, including one independent city, in the

The Kaboom is Now Kaput in Washington

Explosive fireworks were outlawed by the 1961 State Legislature. The Seattle-King County Safety Council and the Washington State Safety Council teamed up with the firemen on this and in about two months had secured signed resolutions from 50 cities and towns, 25 municipal fire departments, 23 fire protection districts, 18 professional associations and 39 civic and community clubs. The statewide geographical distribution of this support was almost perfect, and the editorial support was likewise well spread. In one ten-day period, the Seattle-King County Safety Council mimeographed and gave statewide distribution to some 40,000 pieces of literature.

When we started this anti-fireworks campaign, the old pros in the legislature smiled tolerantly and shook their heads. At the 1945, 1947, 1949, 1951, 1953, 1957 and 1959 sessions, they said, the firemen, police officers and humane societies had introduced fireworks control bills and taken a licking every time. For seven sessions in a row, the bills got bottled up and died in committee. Why? Because the firemen and policemen always had other legislation to worry about too—pensions, equipment, working rules, etc.—and in the dim, dark final hours of the session, they always had to trade off the fireworks bill for something more vital to survival. You can't beat solid money with resolutions, they said, even when 80 per cent of the people of the state are represented by the resolutions. The devil you can't! You can't do it very often and old John Q. Citizen has to be pretty mad, but you can do it. We know—we did it—through the good offices of our Seattle-King County Safety Council.

Robert Anderson, Director, Bureau of Health Education, Virginia State Department of Health.

The valley area was selected for the study because it was generally comparable to many rural areas with its economy based on agriculture and light industry. The population was generally stable and there was a lack of any organized accident prevention program.

The project included two health districts each with a population of approximately 30,000. In the Rockingham-Harrisonburg Health District the staff was centrally located in a new health center. The Page, Rappahannock, Shenandoah, and Warren County District was composed of four separate offices under the jurisdiction of a single director.

The project was divided into two phases. The first a fact finding phase began July 1, 1958, and ended June 30, 1959. During this period the "normal" accident experience of the five counties and city was recorded. The purpose of the first year's baseline study was to determine the number of deaths due to accidents and to determine the number of nonfatal injuries which required inpatient or outpatient hospital care or were serious enough to require a physician's attention. The knowledge derived from these reports provided the foundation for the activities of the second or educational phase.

The second part of this project, began July 1, 1959 and was an intensive education campaign to determine if community education could prevent accidents.

The study had its headquarters in the Rockingham Health Center. Mr. Lewis G. Polk was assigned to the project in January 1958 and I came on board in April 1959. We were both on loan from the U. S. Public Health Service to the Virginia State Department of Health to staff the project. Mr. Polk coordinated the statistical activities and I was charged with the education program.

Physicians and hospitals reported all accidents requiring medical attention throughout the three year project. This involved 84 physicians, 34 dentists, 2 doctors of osteopathy, 4 hospitals, and 2 clinics. Mr. Polk visited each of them each month and in addition to sustaining interest accom-

plished a great deal of professional education.

Education Phase

Education has been accepted as an essential activity in raising the standards of health of the community, and it is a method common to all accident prevention programs. There is, however, a continuing need to evaluate the effectiveness of the educational techniques currently being used in accident prevention programs.

In the two year education campaign we worked to involve as many community institutions and organizations as possible in accident prevention, utilizing the usual methods and techniques of community motivation.

Working with fraternal, civic, and farm organizations with the cooperation of the press, radio, and television outlets, the educational effort was directed not only toward recognition of hazard situations in order to create a general awareness of safe habits and practices, but also towards teaching safety measures applicable to specific situations i.e., seat belts and rescue breathing.

Objectives

To reduce, or lessen the severity of, accidental injuries.

To focus community attention on the principal accident hazards, through use of project statistics, and to generate public opinion in support of the necessary action to meet these needs.

To increase the public's understanding of specific actions that individuals, groups, and communities can take to reduce the toll of accidental injuries and deaths.

To obtain information about barriers, resources, and methods related to achieving the above objectives.

To work closely and cooperatively with all groups to stimulate and assist in building sound programs in accident prevention.

It should be recognized that only the first of these objectives could be evaluated by our statistical procedures. The reporting system could only provide information on accidental injuries and baseline information on safety knowledge, attitudes and skills was not obtained.

How to meet these objectives, how to begin, were questions that faced us as we

resolved the action program into six basic approaches. These were community organization, public information, training meetings and workshops, consultation, physician education, and in-service training of the health department staff. Nothing new here and yet as you will see some did involve a slightly different twist.

Central to our community organization effort was a policy decision to build the program on the involvement and strengthening of the safety chairmen in the existing organizations rather than attempt to form safety councils during the early stages of the project. Therefore, it was proposed that a considerable portion of staff time would be spent working directly with groups such as home demonstration clubs, Ruritan, 4-H, and PTA to encourage, stimulate and expand their efforts in planning accident prevention activities.

Four radio stations, one television station, four weekly and two daily newspapers covered the five county area. Throughout the life of the project we received wonderful support from them. To maintain interest and reinforce our ongoing community programs we furnished the news media with spot announcements, discussion panels, talks by community leaders, safety experts and members of our staff. In addition news releases of seasonal and local interest were provided. Stories on poison hazards, firearm safety, and children's accidents were sent out periodically.

A staff speaker's bureau, consisting of Mr. Polk and me during the first year, and involving public health nurses in the final year, provided over 250 programs to organized groups in the study area.

Two summer workshops for teachers were offered in school safety by Madison College, a state teachers college located in Harrisonburg. It was my privilege to help plan and serve as co-instructor in each of these courses. Two regional safety conferences sponsored by the Virginia Safety Association were held in Harrisonburg.

Community Organization

In initiating community organization plans the first task that faced the Health Department was to create an awareness of the accident problem in the minds of as many of our citizens as it was feasible. To aid in this the "speaker's bureau" con-

sisting of the two staff members was formed and a post card, listing three safety topics was mailed to more than two-hundred organizations in the five county area. The names of these organizations were gleaned from sources such as chambers of commerce, civic club posters, and from county agent's offices.

The response was immediate and during the fall of that first year, almost overwhelming. The staff spent as many as five nights a week talking to these organizations, fulfilling as many as four speaking engagements in one evening. The programs were purposely kept short and limited to a maximum of 20 minutes.

In addition to presenting information on the safety problems in their particular area, as recorded in the statistics of the baseline year, the staff was able to ascertain many of the attributes, knowledge, and safety skills to be found in these clubs. Whenever possible the safety chairman of the club was encouraged to organize and/or reactivate his safety committee.

It was hoped that accident prevention would be recognized as a much needed program and that with a little help and recognition an appreciable amount of activity and involvement could be initiated.

Through these contacts with the groups in our study area we developed many of our working relationships. It was also felt that these appearances aided in sensitizing the audiences to the continual display of safety material found every day in our newspapers and on our radio and television stations. The men's organizations though seldom involved in direct participation at least were aware of the need for their wives and children's participation in safety projects.

Examples of some of the projects initiated during this study are:

The Harrisonburg Kiwanis Club sponsored a 4-H Safety Award in Rockingham County. Each 4-H club was given information on the award and requested to keep a scrapbook and other data which they could submit at the end of the year to the judging committee. Prizes totaling \$75.00 were appropriated. This type of activity tended to be typical of the contributions from men's groups. They were most generous in providing funds but because

of the pressures of earning a living, seldom directly involved their membership in specific accident prevention activities.

The business and professional women, in addition to devoting their regularly scheduled meeting on community health to the safety project, also planned for an additional meeting during the year.

Perhaps outstanding in terms of depth and organization was the work of the home demonstration clubs. With their trained staff leaders, the home demonstration agents, these clubs demanded and received a high priority. The project was also fortunate in that the state safety chairman for this organization resided in the study area.

The home demonstration agents had been involved in the project from its beginning with the result that two of the counties voted to make safety their "federation program of work" for 1960. By this they meant that this would be the program emphasis for all clubs in the county. In Rockingham County this meant 27 clubs and some 600 women. We met with the county safety chairman and with the individual club chairmen in the fall of 1959 to help plan the 1960 program. Materials were studied and a series of monthly safety topics outlined.

The outstanding features of this program were the devotion of ten minutes of each meeting to safety and the direct participation of each member in the safety program. Each member was required to survey her home with a home safety checklist and eliminate five hazards during the year.

During the year two additional training meetings were held for the county safety chairmen. The staff worked with them by suggesting materials and ideas for topic presentations during the coming months. Problems were reviewed and answers provided to technical questions. An interesting sidelight to this program was that over 90 per cent of these women purchased copies of the booklet, "What to do About Home Injuries," from the National Safety Council.

I will have to retract slightly one of my earlier statements concerning evaluation. We did have one other program with a measurable impact. Early in the study a sample of automobile dealers had been contacted to determine the status of seat belt sales.

Much to our chagrin, we found them gathering dust or not stocked at all.

To remedy this situation we contacted the Northern Virginia Automobile Dealers Association and made arrangements to appear at their next meeting. The film "Safety Through Seat Belts" was shown and the matter discussed quite freely. They recognized the problem but said that as businessmen they could not afford to stock an item that did not sell. We accepted the challenge and actually involved them in our efforts to the extent of including a seat belt pamphlet in the packet of material placed in each new car. When the survey was repeated at the end of the project over half of the dealers were stocking seat belts and reporting many sales and installations.

Public Information

A rural area such as the study area provides or at least approaches an information person's dream. Over 90 per cent of our news releases, feature stories, and editorials were used. We had ready access to public service time on the primary television and radio station.

At one time we had two radio shows, on Thursday from 1:15 P.M. until 2:00 P.M. where four ladies from a local club would appear and discuss their safety projects and a five minute spot on Friday morning at 10:30 A.M. when Mr. Polk or I would discuss a pertinent safety topic.

Posters were distributed bi-weekly to doctors' offices and the 70 schools in the five counties. These were produced locally and our main objective was the recognition of the phrase "Accidents Don't Just Happen" printed across the top of each poster.

Safety Association Workshops

Throughout the accident prevention project the cooperation from the Virginia Safety Association was excellent. Because of the interest in accident prevention in the five county area the safety association sponsored two one-day workshops, the first in October 1959 and the second in April 1961. While these conferences were sponsored by the state association, in each instance the project staff served as coordinators and were responsible for local arrangements and invitations.

The contrast in audience participation in

the first and second workshop was striking. The 1959 conference was primarily an information-giving session with little interaction and long silences serving as the question period.

In the 1961 session it was obvious that a change had taken place. There was little need for the staff to participate in the discussion sessions. The "laymen" were telling us what needed to be done. No longer were the suggestions in terms of correcting environment hazards, nor were many ideas presented for quick, easy superficial solutions, rather the discussions centered on the need for long range programs necessary to change attitudes and behavior.

What did we learn? Our decision to strengthen existing safety programs resulted in four of the five counties forming safety councils. Safety councils that came from common needs for cooperation and coordination rather than councils formed because someone suggested them.

There is a tremendous untapped resource in these local safety chairmen. Did you ever stop to think that of the ten leading causes of death, accidental death is the only one that has a person designated in al-

most every club to combat it. The health chairman has many agencies vying for his attention. However, to reach him you will need to meet him in a face-to-face situation; he seldom gets the mail you send him, and he is not interested in problems that do not occur in his area.

You can be most successful with generalized safety education when it is coupled with something specific. Our most popular program was built around the film "That They Might Live," on mouth-to-mouth resuscitation. Each person felt that they had gained a valuable skill after seeing this film. It also allowed us to discuss the hazards that lead up to these traumatic situations and means of preventing them.

Did we prevent any injuries? You will have to wait for that answer. The final tabulations will not be completed until mid-October. For those of you who would like more information than I have been able to present in this short time, if you will write to Mr. J. Robert Anderson, Virginia State Department of Health, Richmond, Va., I am sure he will mail you a copy of the final report when it comes off the press in early 1962.

HOW TO COMMUNICATE HOME SAFETY INFORMATION EFFECTIVELY

By ROBERT A. JARNAGIN
University of Illinois, Urbana, Ill.

1. Ask such professional communicators as radio, TV and newspaper editors how to prepare messages for use by their media. They know better than anyone else who their audiences are. Each is interested in giving his readers, viewers and listeners what they will listen to and watch and read.
2. Know your intended audience.
3. Prepare your message in the language of the audience.
 - a. Use terms your audience will understand in reference to their background of experience, not yours.
4. Use simple, clear, direct language whenever possible.
5. Use illustration whenever you can.
6. Use as many available media outlets or communication channels as possible to send your message. The more times and places your message appears, the better chance it has to be noticed and acted upon.
7. Evaluate the results of your communication efforts, and change them if they don't seem to be doing the job that you want them to do.

JOINT SESSION WITH TRAFFIC

TRAFFIC SAFETY AND DRIVING SIMULATION

By SLADE HULBERT
Asst. Research Psychologist, Institute of Transportation and Traffic Engineering
University of California, Los Angeles, Calif.

It would be worthwhile at the outset to say what is meant by driving simulation (which is accomplished by a driving simulator). It means that a driver is placed in an automobile in a laboratory. He is then surrounded with a potential driving environment and upon commencing to drive he sees pictures, hears sounds and feels physical forces all of which are as realistic as is necessary for the particular study.

Essentially what it amounts to is that this fellow is pretending to drive but he is actually standing still; his reactions can be observed in detail. It also enables duplication of the exact highway situation for many subjects; that is to say, the same series of traffic events can be presented to a hundred people thus getting a statistical measure of what a hundred drivers do when faced with one set of traffic circumstances.

In addition to the ability to repeat identical situations, it also is possible to present traffic conditions that would be too hazardous or too costly for field experimentation on the road. The simulator also enables isolation of a single variable by holding all conditions constant except the one to be studied.

A national conference on driving simulation was held last March in Los Angeles under the sponsorship of the Automotive Safety Foundation, the U. S. Bureau of Public Roads, and the U. S. Public Health Service. Participants included engineers, highway administrators, scientists, and educators. There were representatives of industry, government, universities, safety organizations and research institutes.

The conference report¹ included on page 16 the following: "Driving simulation has been defined. Its role in highway safety research has been suggested, its benefits and limitations put into perspective. The assessment makes clear that new and useful

techniques are available for experimental research which can contribute importantly to safer highway transportation.

"Ultimately, a step-by-step development of increasingly complex simulators offers promise of new and urgently needed information on the functioning of the vehicle-driver-road system. This could lead to a major break-through in the program to increase traffic safety."

Simulators range in cost and complexity from million dollar flight trainers for jet pilots on down to devices that can be purchased for less than a thousand dollars to train high school students to drive. For research uses, the cost is dictated by the behavior to be studied. Complex traffic situations will require complex simulators; however, the cost will be more than balanced by savings in lives, insurance, repair charges, and time, as we put research results into practice.

The need for creating driving simulation research facilities was pointed out in the Williamsburg Conference Report in 1959. In a recent publication of the Special Committee on Highway Research Priorities of the Highway Research Board of the National Research Council, the driving simulator was included among the "19 broad areas of highway research, each of which is adjudged to rate A-1 in importance and urgency."

We believe that important advances may result from laboratory and field research into problems arising in driver licensing, highway design, vehicle design, traffic engineering control, and law enforcement and education. Driver reactions and habits play a large role in all of these fields and to that extent they can benefit from driving simulation laboratory research and evaluation studies. At this time, by way of example, I shall discuss only three promising types of investigation: fatigue, aging, and

experience. Each is representative of a different type of study.

*Fatigue*² can be generally defined as a mental and physical condition of decreasing efficiency from which full recovery is possible. Some characteristics of importance for research are:

1. The act of measuring can drastically alter the condition.
2. The condition is likely to be irregular over time and specific to sub-tasks.
3. The experimenter must control environments and direct behavior in order to produce the condition.
4. All drivers can be affected by the condition.

I suggest that these characteristics also describe the following conditions:

A. Effects of some ingested chemicals, such as drugs, alcohol, food, etc., excluding irreversible effects, e.g., poisons.

B. Emotional states, such as anger, despair, frustration, etc.

These conditions represent research interests that today are somewhat diverse, each with its devoted groups of investigators. If there are the common characteristics suggested above, and because of this a consolidated research effort can be mounted using driving simulators as a general tool, it might herald a number of simultaneous breakthroughs in previously unrelated areas.

Even if the driving simulator laboratory approach only serves to bring these researchers together, it will be worth the expenditure in terms of the interdisciplinary mental cross-fertilization that can result. I have yet to talk with a researcher interested in human behavior who did not become enthusiastic over the possibilities of doing his research within a simulation laboratory.

*Aging*³ can be generally described as a gradual process of organic change eventually resulting in irreversible impairments to function.

Research characteristics are:

1. The act of measuring has little if any effect on the condition.
2. The behavioral effect is likely to be consistent and predictable and resistant to change.
3. The condition must be investigated as

Joint Session with Traffic

it is found in various individuals and groups of drivers; it is not subject to experimental manipulation.

These research characteristics apply at least in part to the following:

- A. Physical disabilities, sensory and motor.
- B. Mental disabilities, such as emotionalism, rigidity, persecution feelings, etc.

Experience in this context refers to exposure to a series of critical driving situations which affect subsequent driving behavior. Learning through experience provides driving training for the bulk of our population.

Research characteristics are:

1. The act of experiencing greatly effects responses to subsequent exposures of identical events.
2. Past exposures are difficult to determine and evaluate.
3. Some experiences terminate the drive.
4. Experiences can be vicarious in nature.
5. Negative transfer must be evaluated.

Research into the learning process as it continually occurs on our highways can result in more effective programs of public education and implement a positive approach of guidance to replace the current practice of scolding and punishment.

All three types of human factors exemplified by fatigue, aging, and experience lend themselves to vigorous and fruitful investigation in driving simulation laboratories. If science can discover what exactly happens to the abilities of the temporarily incapacitated, and the disabled and just how it is that drivers are learning to survive, a wealth of remedial efforts can be launched to offset the traffic toll.

Progress to Date

The simulation techniques that have been used so far at the University of California at Los Angeles are built around the showing of movies that were taken from cars moving on the highway. This work, on a limited scale, was initiated in 1948 by J. H. Mathewson and has resulted in a series of Institute studies of the human factors in highway transportation. Some simple task simulation techniques were developed and

the feasibility of more complex simulators has been studied and in some aspects demonstrated. In several publications¹ the following descriptions appear of the Institute's simulation devices:

In a 30 x 20 x 10-foot room, an automobile with its rear wheels on the steel rollers of a chassis dynamometer can be operated in response to two motion pictures. One picture presents the forward view and the other the rearward scene which is seen in the rear-view mirror. On a curved screen, eight feet from the driver, the forward picture is shown by a projector above the car in line with the driver's position. The rear scene is projected onto a screen just behind the rear window. Stray light from the projectors provides fairly uniform illumination inside and outside the vehicle at between five and ten foot candles. The adjustable dash light is set to balance the illumination and make the speedometer clearly visible.

Steering wheel movements displace the forward picture from side-to-side which gives the driver a strong impression of controllability of his lateral position on the highway. A "highway feel" of steering is accomplished by having the front wheels rest on turntables to increase ease of movement. The steering system is spring loaded to simulate the self-aligning tendency of a rolling vehicle so that the steering wheel tends to return to center. Engine noise is real, but indicated speed has been made twice that of the actual speed of the wheels on the rollers. This doubling of the indicated speed has the effect of equating it with vehicle noise (engine noise and tire-on-roller noise). A flywheel attached to the rollers simulates vehicle momentum and contributes to realism of engine performance and speed changes.

Engine temperature is controlled directly by an auxiliary radiator and indirectly by a refrigerated air-conditioning unit which controls room air temperature. Tire overheating is prevented by a cooled-air system blowing on the tires. Exhaust fumes are ducted outside the building and there is a continuous change in room air.

The vehicle undergoes some low-amplitude vibration at approximately 30 cps produced by the action of the tires on rollers. This action is similar to that experienced and

recorded while driving on a newly surfaced road.

Driver responses are recorded on five channels of a Brush six-channel, ink writing recorder. Vehicle speed, steering movements, brake and accelerator pedal action, and the driver's galvanic skin response and breathing rate are recorded along with written notations about the motion picture events being shown to him.

The Tilting Chair

To provide simulation of the physical forces experienced while driving, a driver's compartment is mounted so that it can be tilted fore and aft (pitch) and from side-to-side (roll) as well as rotated (yaw). The driver's outside view is restricted to a motion picture projected on a cylindrical screen six feet from him. This picture, from an extremely wide-angle (160 degree) lens, completely fills the driver's field of vision through the windshield. Because this picture is of low brightness the entire room is made dark during projection with all stray light being trapped by a ventilated box that houses the projector.

The essence of this device lies in the fact that both the projection screen and projector are attached to the driver's compartment and, therefore, move with that cockpit when it is tilted. Thus, when he is tilted the driver's visual world including his horizon reference does not move for him and the changing physical forces exerted on his body by gravity are then perceived as acceleration forces or centrifugal forces depending on the direction of tilt (pitch or roll), respectively.

At the present time this device is tilted by an operator in response to the driver's actions and the motion picture scene. When, for example, the driver removes his foot from the accelerator pedal or applies the brake, a signal light informs the operator and he tilts (pitch) the device an appropriate amount and at a rate depending on the traffic situation. The laboratory apparatus described above is only a beginning step, but it serves to demonstrate the great promise of this approach in traffic safety research.

The Institute's work has led to a more advanced design for a proposed simulator that will use closed-circuit television to project the traffic scene from a model landscape. The driver's actions will guide a T.V.

camera along the miniature roads and thus provide the freedom of choice that a motion picture display cannot.

The entire assembly—dynamometer, projectors, projection screens and enclosing shell—would be mounted on a tilting platform whose movements would be dictated by the driver's actions. An electronic control system would handle the complex and rapid interchange of signals among the various units of the simulator and at the same time serve as a data recording device that would create records that could be fed to electronic computers for analysis.

PERIODIC PHYSICAL EXAMINATION FOR DRIVERS

By CHARLES L. WILBAR, JR., M.D.
Secretary of Health for Pennsylvania, Harrisburg, Pa.

This report on the medical examinations for licensing of drivers in Pennsylvania is similar to a report on this subject given by me at the annual meeting of the American Medical Association this year. Since that paper was presented on June 27 and this is October 19, there are but a few new items to report. Such new items have been added.

On June 1, 1960, the official program of required medical examinations for drivers in Pennsylvania was placed in operation. This was one item of a thirteen point traffic safety program announced by Governor David L. Lawrence at a special press conference on February 2, 1960. The entire motor vehicle and driver licensing responsibility in Pennsylvania rests in the Department of Revenue, and that department, therefore, enforces the requirements for driver examinations.

The driver examination program did not spring forth suddenly. Its inception might be considered as dating back to three years before it actually became effective. In the middle of 1956, a Section of Traffic Epidemiology was established in the Pennsylvania Department of Health. The need for health departments to become intimately involved with traffic safety has been clearly

delineated at three workshops on traffic safety held in Washington at which representatives from the American Association of Motor Vehicle Administrators met with state health officers.¹

It has become clearly evident from a number of studies, including those of the Committee on Medical Aspects of Automobile Injuries and Deaths, that human failures overshadow all other factors in the production of highway accidents. Thus, the work of a health department in this area has to do with the human factors in accidents. It was decided that the Pennsylvania health department's program would confine its endeavors essentially to three subjects—(1) physical standards for licensing of drivers; (2) the alcoholic and his driving ability; and (3) studies of accident repeaters.

The Governor's Traffic Safety Council and the Board of Trustees of the Pennsylvania Medical Society agreed upon the need for having uniform physical standards established for drivers licensed to drive within the Commonwealth. Consequently, under the chairman for traffic safety of the State Medical Society, there were formed in October of 1958 at the annual meeting of the Society, subcommittees dealing with spe-

rific areas of standardization. The subcommittee titles included general medicine, cardiovascular diseases, neurological disorders, visual standards, auditory standards, orthopedic standards, mental health and drug and chemical aspects. These titles were similar to those used by a Symposium on Medical Aspects of Motor Vehicle Accident Prevention held in December, 1956, by the New York University—Bellevue Medical Center and the Center for Safety Education of New York University.²

Using all available studies they could obtain, these committees reported a year later to the Board of Trustees of the medical society, which then accepted the report. The report was forwarded to the Secretary of Health and to the Governor's Traffic Safety Council. The Secretary of Health served as a liaison person between the medical society and the Secretary of Revenue. The Pennsylvania Optometric Association had submitted a somewhat different set of standards for visual testing, but one meeting between the committee of that association and the medical committee on visual standards quickly resolved the differences in favor of the standards set by the committee of ophthalmologists. The standards were then approved in principle by the Governor's Traffic Safety Council. They were later accepted by the Governor and the Secretary of Revenue, and after a tooling up period, put into effect a little over a year ago.

Least there be any thought that these standards might be considered final or unequivocal, there is hereby quoted from the introduction of the prepared driver standards the following: "Because of the sparsity and unreliability of statistical data, the standards which follow are based on an armchair analysis. Since automobile transportation is such an important economic factor, the emphasis is on restricting rather than revoking licenses. A functional approach has been attempted wherever possible. The diagnostic entity is important in predicting progression and recurrence of signs and symptoms."

It was further pointed out that because the periodicity of the examination of drivers is an important factor which must be considered from an ideal and practical standpoint, the report recommended that the examination be given all drivers on initial

application and re-examinations given at ages 30, 40, 50, 60, 65 and every five years thereafter. Periodic examination is still our aim, but it will take several years to get the initial examination of the five and a half million licensed drivers in Pennsylvania and to definitely establish the periodicity of examinations. In fact, we estimate that at the rate of 15,000 examinations per week, it will take seven and a half years to cover all of Pennsylvania's drivers.

Considering the importance of the human factors in driving safely and how lethal the modern vehicle is, today's driver unquestionably should be in a physical and mental condition which is not a severe hazard to himself and to his fellowmen. For many years, the Pennsylvania law concerned with driver licenses has had a general clause requiring the licensee to be free of any disorder which might prevent him from properly driving an automobile. Licenses have been removed, suspended or given on a restricted basis upon decision of the Bureau of Traffic Safety of the Department of Revenue that the individual was incapable of properly handling an automobile. The Bureau, however, had no well-defined medical standards for making its decision until the present ones were established.

A number of case histories of severe accidents clearly indicated the dangers to life and limb caused by drivers suffering from severe physical and mental disorders. In one instance, an individual was on the blind pension payroll and was operating a light truck, with his steering being directed by a child sitting between his legs. He was, not surprisingly, involved in a fatal crash.

In another instance, a truck driver hauling gasoline on a tractor-trailer truck was involved in seven or eight accidents before it was discovered that these accidents were caused by convulsive seizures. Not long ago, a mentally disturbed young man who had some psychiatric treatment drove east in the west bound lane on one of the high speed highways of the state for about 40 miles. Although it was night, he turned off his lights and drove at speeds of 90 to 100 miles per hour. He was killed when his car crashed into a roadblock the police had thrown across the highway. In

other instances, before the required examination for drivers went into effect, individuals were sporadically prohibited from driving because of reports sent in by practicing physicians.

The standards approved by the medical society and others concerned were condensed into categories or disqualifying groups which are listed on an IBM punch card for the purposes of simplicity, identity and ease of mailing, filing and tabulating. As listed on the card, disqualifying factors include the loss of use of both hands; 20/70 vision or less in the better eye with correction; neurological disorders, such as to prevent responsible control of a motor vehicle; any cardio-vascular disorder, including hypertension, such as to prevent control of a motor vehicle; neuropsychiatric disorders such as to prevent control of a motor vehicle; conditions causing lapses of consciousness, e.g., epilepsy, narcolepsy, hysteria, etc. (may be considered for licensure if episode free for two years with or without medication); alcoholism, addiction to narcotics; and uncontrolled diabetes.

Inasmuch as the Pennsylvania State Police has for many years been charged with the responsibility for visual acuity tests and were equipped with instruments and testing areas, it was decided that the visual testing and the testing for the loss of use of both hands would be done by the State Police. Thus, the individual who is to be tested first takes these two tests from a state policeman and then takes his testing card to a physician of his choice. He is encouraged to use his family physician for this purpose, since in some conditions, the medical history is a pertinent factor, but the individual makes the final choice as to his examining physician. The physician then mails the completed form directly to the Bureau of Traffic Safety of the Department of Revenue.

Prior to the initiation of the physical examination program for drivers, each physician in Pennsylvania was furnished by the State Health Department with a copy of the American Medical Association pamphlet "Medical Guide for Physicians in Determining Fitness to Drive a Motor Vehicle" as well as a short guide specifically concerned with completing the examination form.

Results of First Year of Operation

As of the first of June of 1961, this program had been in operation for a year. Like other large, new programs, this one started slowly and had a few difficulties at its inception, but is gaining momentum. The State Police have a limited number of persons and facilities for the examinations. It was therefore decided that for the first six months, only those newly examined. It had been hoped that the next to be examined would be drivers licensed before 1924, a time when no examination whatsoever was required for obtaining a license; but, unfortunately, a flood in 1936 in Harrisburg destroyed or ruined a number of record files, so that this was not possible. Consequently, since the beginning of 1961, driver names have been selected at random for examination. In addition, all persons driving automobiles on state business have been required to be examined.

The physicians of Pennsylvania have cooperated extensively in promoting this program. At first, there was some fear on the part of a number of physicians about their legal liability in case an individual who had been examined had an injury-causing accident. However, the Attorney General of the Commonwealth has quieted these fears by an opinion which stated that the physician's responsibility as to the condition of the individual applied only to the individual's condition at the time of the examination and to those elements included in the examination. Furthermore, the legal department of the American Medical Association has stated that for the physician to be held liable, it is necessary to show: (1) he was guilty of negligence in conducting the examination or in reporting his findings to the state; (2) that the negligent act was the primary cause of injury or accident; and (3) that damages resulting from the negligence were foreseeable, since an injury which cannot be foreseen, or reasonably anticipated as the result of negligence is not actionable. The decision as to whether an individual receives a renewal of his driving permit, receives a limited permit, or has his permit suspended or revoked rests with the Secretary of Revenue, so that the legal decision is made not by the physician doing the examination.

tion, but by the Secretary of Revenue in view of the information forwarded to him.

A number of borderline cases are received by the Bureau of Highway Safety. These cases are referred daily to the physician working full-time on traffic epidemiology in the Department of Health for opinions as to the categories in which the applicants should be placed. One of the most striking observations that he has made from these reviews is that many applicants with severe—possibly dangerous—physical conditions seem to have a complete disregard for, or unawareness of, the possible consequences of operating a motor vehicle under these conditions. Hundreds of physicians have taken it upon themselves, in addition to completing the physical examination form, to write clinical summaries; this is ideal and very helpful in making the decision for approval or rejection.

In an attempt to validate the often-made "highway diagnosis" of heart attack as a cause of fatal traffic accidents, a study project in this area has recently been started. All accident reports in the Commonwealth bearing such information are sent to the Section of Traffic Epidemiology of the Department of Health. The data are checked against the official death certificates. In each case the coroner having jurisdiction is contacted and asked to outline his reasons for the diagnosis. Such a query is also made of the one medical examiner in Pennsylvania—in the city of Philadelphia. The family physician is contacted to determine whether the individual was under treatment for cardiac disease. Pertinent information

is also obtained from the individual's family. Forty-five persons died of alleged heart attacks on our highways while operating a motor vehicle during 1960. One coroner has stated "From my 28 years of experience as coroner, I feel many fatalities are due to unknown and untreated cardiac conditions and not by blackouts." Before long we shall be able to present some statistical data as to the accuracy of such an observation.

Of the total 421,857, examination forms received, 245,809 or 58 per cent were males, 176,048 or 42 per cent were females, 151,135 or 36 per cent must wear glasses, and 602 or 0.14 per cent were rejects.

Table 1 shows that the number of applicants for new licenses and for renewal of licenses examined during the first year of the medical examination program totaled 421,857, and of these, 602 were rejected for disabilities discovered by the examination. Thus, rejections constituted 0.14 per cent of the total. It can reasonably be expected that this percentage of rejections will be higher in the future, since the first year was weighted toward the younger age group due to the first half of the year being given over to examinations only of those with learner's permits and these were mostly individuals in the 16 to 20 year age bracket. As would be expected, the older the age group, the higher the percentage of failure. This is particularly noticeable in the age group 61 and over where 0.79 per cent were rejected. The oldest individual to apply for a learner's permit was 91 years of age and he received his permit.

Table 1—Complete Total of All Physical Examinations (Learners and Re-Examinations) June 1, 1960 to June 1, 1961

Age	Number of Applicants	Percentage	Number of Rejects	Percentage of Rejects per Group
16-20	181,657	43.1%	108	0.06%
21-30	70,340	16.7%	37	0.05%
31-40	29,600	7.0%	39	0.06%
41-50	58,521	13.9%	56	0.10%
51-60	42,948	10.2%	83	0.19%
61-70	30,227	7.2%	238	0.79%
Not Stated	63		96	
	421,857	100%	602	

Table 2 depicts the reasons for the 602 rejections. There were 613 total disorders, some individuals having more than one disorder. The largest single category is comprised of those who withdrew voluntarily because they felt they would not be able

to pass the examination. Next, in order of magnitude, are those with severe cardiac or circulatory disorders and third were those with conditions causing repeated lapses of consciousness. Uncontrolled epileptics have been, for the purpose of this table, singled

Table 2—Total Disorders and Rejections from Beginning of Program June 1, 1960 to June 1, 1961—exclusive of Learners Permits and Physical Re-Examinations

Reason	Number
1. The loss of use of both hands.....	3
2. 20/20 vision or less in better eye.....	61
3. Neurological disorders such as to prevent reasonable control of a motor vehicle.....	46
4. Any cardiac or circulatory disorder including hypertension such as to prevent reasonable control of a motor vehicle.....	97
5. Neuropsychiatric disorders such as to prevent reasonable control of a motor vehicle.....	42
6. Conditions causing repeated lapses of consciousness, etc.....	79
7. Alcoholism.....	31
8. Narcotic addiction.....	3
9. Uncontrolled diabetes.....	25
10. Uncontrolled epilepsy.....	15
11. Person does not have the intellectual maturity of his chronological age.....	6
12. Doctor states operator unfit.....	47
13. Voluntary withdrawals.....	133
Total Disorders	613

Accounting for 602 rejects
Male rejections—435 (72 per cent)
Female rejections—167 (28 per cent)
Total 602

out from other conditions causing lapses of consciousness. Nearly three-fourths of the rejections were males. No only were a greater number of males examined, but cardiac disorders, alcoholism and narcotic addiction are conditions with a much greater preponderance in males than in females.

In accordance with the findings resulting from the 422,000 applicants who were examined and the 133 voluntary withdrawals, a house-to-house survey was made to determine the reasons why 978 persons scheduled for physical re-examination failed to take the examination.

Table 3 shows that 130 of these persons did not take the examination because they felt they could not pass for the reasons shown in this table. Unlike the 133 voluntary withdrawals, they had made no effort previously to report their reasons for not taking the examination. Thus, actually a total of 263 persons did not take the examination because of their own diagnoses of physical incapacity in accordance with the criteria set up for the examinations.

Table 3—Survey on Applicants Who Failed to Take Physical Re-Examination—Total 978 Physical Conditions..... 120 or 12 per cent

1. Need glasses.....	10
2. Eyes failing (cataract), etc.....	23
3. Applicant was afraid to take eye examination.....	1
4. Total cases pertaining to eyes.....	34
5. Hard of hearing.....	2
6. Heart condition.....	6
7. Felt unfit to drive (age).....	40
8. Physically unfit to drive (diabetes, stroke, nervous).....	29
9. Doctor states applicant unfit.....	6
10. Applicant was afraid to take physical examination.....	4
11. Total cases pertaining to other than eyes.....	96
Total	130

In the last group of 130, the 10 who needed glasses were informed that should they be able to pass the eye examination, they could renew their licenses and the individual who was hard of hearing was told that this was not a criterion for rejection. These 130 who thought their physical conditions precluded their passing the examination represent 13 per cent of those who failed to take the physical examination. However, included among those who did not take it are 313 who moved out of the state, so that if one disregards these 313, then the percentage of individuals who failed to take the physical re-examination because they felt they would not pass, but had not reported such previous to the survey, rises to 19.6 per cent.

One other table may be of interest. Table 4 shows for 1960 the comparison of the death rate from traffic accidents per one hundred million miles traveled in Pennsylvania as compared with other states of a like class. Last month the National Safety Council presented Pennsylvania's Governor with a Certificate of Achievement in special recognition of the exceptional death record and progressive accident prevention

Table 4—Pennsylvania's Comparison of Death Rate from Traffic Accidents per 100,000,000 Miles Traveled with Other States of Like Class 1960

State	Death Rate
1. Pennsylvania.....	4.0
2. New York.....	4.5
3. Illinois.....	4.4
4. Texas.....	4.9
5. Michigan.....	5.0
6. Ohio.....	5.2
7. Indiana.....	5.2
8. California.....	6.8

program activities as shown in the annual traffic inventory. Of the eight major states in the group in which Pennsylvania falls, Pennsylvania was the only state to receive such an award. The fact that Pennsylvania has the lowest rate here is, of course, not necessarily tied in with the driver examination program nor even necessarily the result of the thirteen-point improved traffic safety program inaugurated in February of 1960.

Of these thirteen points, the only one other than the medical examination program which might be considered in the health field is an educational program to encourage the use of chemical testing for intoxication. It is interesting to note in this respect that a survey by the State Police to determine the attitude of judges and district attorneys in the 67 counties of the Commonwealth on this matter indicated that in 55 counties there was favorable reaction toward chemical testing, but in the remaining 12 counties the authorities involved were either indifferent or against chemical testing. The 1961 session of the Pennsylvania Legislature passed a state-wide chemical testing law. As passed, it is a much weakened version of the original bill, using 0.15 per cent by weight in the blood as presumptive of intoxication instead of the recommended 0.10 per cent, and requiring specific consent of the driver for the testing rather than the recommended implied consent.

Pennsylvania is pioneering in an attempt to remove from behind the steering wheels of its automobiles, drivers with handicaps so severe as to make them, in the best of medical judgment, hazardous to themselves and to other individuals. The comparatively low percentage of rejections encountered among the 422,000 persons examined during the first year indicates that not many individuals are losing their driving privileges because of this examination requirement. We feel that the driving license is a privilege. In some respects it may be considered a right of an individual, but one individual's rights end where the other one's begin and therefore because of society's right to determine various types of licensure, the term privilege might be the best one to use.

Case histories, not only in Pennsylvania but elsewhere, have shown individuals with

the types of disorders used for rejections in Pennsylvania to be dangerous drivers in many instances. While we cannot, without more specific research data, such as some obtained by studies by McFarland* in Boston, Goldberg* in Sweden, Popham* in Toronto and McCarroll and Haddock* in New York City, adequately predict the number of severe or fatal accidents which will be prevented by removing such hazardous drivers from our highways, the "functional approach" as it is called by the medical society's committee, seems to be justified and reasonable.

It might be pointed out that this type of reasoning is behind many traffic accident preventive measures and many public health measures. The number of lives or disabilities saved by a traffic light at a given corner, by an unbroken white line in the middle of the road on a given hill, by the installation of a sewage treatment plant or by an air pollution abatement program cannot be well documented, but from the case history approach and in some cases from years of experience, (but experience which would not have been attained had ultimate, definitive cause and effect research been allowed to delay application) we continue to vigorously encourage and support these preventive measures.

It is to be hoped that the findings of the medical examination program in Pennsylvania will provide useful data to other parts of the nation in their evaluation of this aspect of working with human behavior factors of traffic accidents, the most important causative factor involved. It is believed that as the general public becomes more aware of the gravity of the problem, persons in ever-increasing numbers will turn to their physicians for advice and assistance in this field. Although the role of the physician in making decisions in this regard is not always an easy one, it is hoped that more and more physicians will accept this responsibility as a part of their role and duty and will realize how vital to the saving of lives and the prevention of injuries is an honest, critical evaluation of the driver.

Much more detailed consideration needs to be given to the age component for the major chronic disabilities of our people increase considerably as they get into the older age brackets. Pennsylvania has not yet completely decided on the periodicity of its ex-

aminations, but as has been pointed out by the medical society study, this component must be seriously faced and a decision made before long.

An important auxiliary benefit of the examination program is the uncovering of a number of cases of heart diseases and other disabilities of a chronic nature, often unknown to the individuals involved. Such conditions are being discovered on a rather large scale, and individuals with these conditions are receiving earlier treatment and subsequently have a better chance of preventing death or disability from them than would have been the case without early discovery due to the examination program.

The Governor's Traffic Safety Council, the Commissioner of Traffic Safety and the Department of Health feel that a further constructive step in driver safety would be a requirement that taxicab, bus, truck and other commercial vehicle drivers have a more frequent and a more rigid physical examination than the one currently in use for all drivers. Bills have been introduced into the state legislature along this line but none has, as yet, been enacted.

SUMMARY

1. Since the behavior of human beings seems to be the most important factor involved in causation of traffic accidents, physicians and health departments should play a major role in helping to reduce traffic mortality and morbidity by focusing their time and efforts towards solving the problems of the physical and mental behavioral components that lead to accidents.

2. In the Commonwealth of Pennsylvania one point of a thirteen-point traffic safety program inaugurated by the Governor at the beginning of 1960 has been a medical examination for all individuals obtaining new driver licenses or renewing driver licenses. The compilation of this program took three years before it was actually put into effect. During this period of compilation, the Pennsylvania Medical Society, the Pennsylvania Department of Health and the Governor's Traffic Safety Council worked

tatives of American Association of Motor Vehicle Administrators and State Health Officers, Washington, D. C., June 7-8, 1960.

3. The results of the first year of application of the physical examination of drivers program are reported. Of 421,857 learners and re-examined drivers, 0.14 per cent were rejected as being unfit to drive in accordance with the established criteria. By age, percentage of failures ran from 0.05 per cent in the 21 to 30 age group to 0.79 per cent in the 61 and over age group. Of this group of failures, there were 133 individuals who voluntarily surrendered their licenses because they felt they would be unable to pass the examination and so notified the Bureau of Highway Safety. In addition, a house-to-house survey of 978 applicants who failed to take the physical re-examination after notification found 130 to have failed to take the examination because they felt they could not pass it. This latter group had not officially notified the Bureau of Highway Safety.

4. Heart diseases and other disabilities of a chronic nature are being discovered due to the mass examination of drivers and potential drivers. Individuals with these conditions are thus enabled to receive earlier treatment than would have been the case without such screening examinations.

5. It is felt that in consideration of the marked increase in severe chronic disabilities in the older age groups, the examinations will need to be given on a periodic basis, although this periodicity has not yet been determined. The medical society's study recommends that examinations be repeated at ten-year intervals to age 60 and at five-year intervals thereafter.

6. It would seem to be desirable for drivers who spend much of their time on the road as commercial drivers of such vehicles as taxicabs, buses and trucks to have a more frequent and a more rigid physical examination than the one now required for all drivers.

THE RATIONALE FOR MOUTH-TO-MOUTH RESUSCITATION

By DR. A. V. MONTO

Chief, Traffic Safety Branch, Div. of Accident Prevention
U. S. Public Health Service, Washington, D. C.

Probably all of you are familiar with the fact that in 1957, the National Academy of Sciences—National Research Council's Ad Hoc Panel on Manual Methods of Artificial Respiration—changed from previous recommendations to the recommendation of the mouth-to-mouth method of artificial resuscitation. If asked as to why this change was made, many of you might state in a general way that the mouth-to-mouth method was "better," but if asked to discuss in detail why it was better, perhaps some of you would find some difficulty in describing all of its advantages.

That is my task here today: to discuss the rationale—the reasons why—the mouth-to-mouth method is now universally recommended as the best available method.

It has been pointed out in films on the subject that the mouth-to-mouth method can be started at the top of an electric pole, inside a car, in a small boat, or even in the water, where methods requiring that the victim be laid flat on a firm surface would not be possible.

But these advantages alone, I think, would not be sufficient to recommend the new method over those which have had as wide acceptance and use as have the various back- and chest-pressure and arm-lift methods. However, the mouth-to-mouth technique has decided physiological advantages. More surely, and in greater quantities, it gets the required oxygen into the victim. The de-

tails of this process will take up the remainder of my presentation.

To consider the subject, we must first have an understanding of certain elements of anatomy and physiology. The normal adult has a total lung capacity of about 6 liters or 6,000 cubic centimeters, usually abbreviated as cc's. A liter, of course, is approximately equal to one quart. However, in normal breathing, only the middle 500 cc's of this total capacity is used, that is, in a normal breath, 500 cc's of air approximately, is taken in and expelled. If maximum effort to deflate the lungs is made, an additional liter of air can be expelled. This leaves a residual air in the lungs which cannot be expelled by any human effort, of about one and one-half liters.

On the other hand, upon inhaling with maximum effort, the normal adult can inhale about three liters more air than he inhales in a normal breath. This additional capacity for inhalation or inspiration of three liters is referred to as the complementary air. Thus, with maximum effort, the normal adult can breathe in and out, four and one-half liters of air, which quantity is referred to as his vital capacity. In contrast, his own respiratory needs are satisfied with about 500 cc's, or half of a liter of air. The remainder is available for use in inflating the lungs of a victim who is not breathing.

Returning to the normal breathing of 500 cc's or half a liter taken in and out in a normal breath, it can be seen that with a remaining amount of air in the lungs of about two and one-half liters, the air in the lungs is at no time entirely "fresh air" from the outside, but is always a mixture with a relatively small amount of fresh air and a relatively large amount of air which remains from previous breathing. In a sense, the breathing process is normally somewhat inefficient, in that it would be possible to get much greater quantities of fresh air in and out in one breath.

However, this relatively slight movement of air in and out of half a liter, and the consequent mixing process in the lungs, suffice to take care of normal needs while breathing at the normal rate of about 16 times a minute. Actually even the 500 cc's of air moved in and out in a normal breath does not become mixed completely.

If you consider the breathing apparatus for a moment, you will realize there is a certain amount of space in the nose and mouth, a space where they join at the back of the throat called the pharynx, and additional space in the larynx, the trachea, and the bronchi which carry the air into the lungs. Actually, all these passages down to the finest subdivisions of the bronchi, the bronchioles, do not have the kind of lining which will permit the oxygen to go in and the carbon dioxide to come out of the blood, and therefore, are of no use in the primary process of external respiration which might be termed aeration of the blood.

This space occupied by the above tubular structures which carry the air in and out of the lungs is termed the *dead space*, and has an average volume of 150 cc's. Thus it can be seen that, of a normal breath, only 350 cc's actually goes to ventilate the true respiratory parts of the lungs, which are the respiratory bronchioles, atria, and alveolar structures. The remainder, 150 cc's merely moves in and out of the dead space, and is not useful in exchanging carbon dioxide and oxygen.

From the above considerations, it can be seen that the rescuer, by making use of the entire vital capacity of his lungs, can easily take care of his own respiratory

needs and have ample air to ventilate the lungs of a victim by mouth-to-mouth resuscitation. In fact, he has such an ample excess capacity, that he can actually move more air in and out of the victim's lungs than the victim's normal breathing. However, what we have considered so far are chiefly theoretical measurements. How does this method work out in actual practice, in comparison to other methods of artificial respiration?

In making comparisons of methods of artificial respiration, we must be very careful to use conditions which duplicate as closely as possible the conditions which would be available in the average rescue situation, where artificial aid such as tubes would frequently be unavailable, and in which the rescuers would frequently be untrained, and, as fact, frequently be applying the method for the first time.

Actually, the idea that the chest- and back-pressure and arm-lift methods could provide adequate ventilation of the lungs, apparently arose because the tests were conducted in an artificial situation in which the subjects were ventilated by these methods when a tube had been inserted all the way into the trachea through the mouth (endotracheal), thus insuring an open passageway from the outside down into the lungs. This situation does not correspond very well to the average situation in emergency rescue.

An experiment performed by Safar and his colleagues utilized 107 untrained rescuers who had not used the mouth-to-mouth method previously, who were given one demonstration on the spot, and for comparison, 18 trained rescuers to perform the chest-pressure and arm-lift methods. The subjects were 25 volunteers who had been anesthetized and completely paralyzed with a curare-like drug. Artificial respiration was tried both without any artificial aid, and with an oropharyngeal airway of the type which could easily be carried by a rescuer.

Two variations of the mouth-to-mouth technique were tested: the first with the jaw held forward by a finger in the mouth; the second, with the jaw held forward by external pressure. Both variations were done on a simulated victim lying prone and with the head extended, that is, flexed backward on the neck.

The performance of the 167 rescuers was as follows: of the untrained rescuers, 90 per cent were able to produce tidal respiratory volumes above 500 cc's within one minute by the first variation of the mouth-to-mouth technique, and 89 per cent were successful in the same task with the second variation. By the mouth-to-airway technique, 100 per cent were successful, 50 per cent were successful with the mouth-to-nose technique, all within 60 seconds.

Of the trained rescuers using the back-pressure, arm-lift method (Holger Nielsen) under the same conditions, only 14 per cent were able to produce tidal volumes above 500 cc's within 60 seconds with that method and with the addition of an artificial oropharyngeal airway, 39 per cent were successful. Using a chest-pressure, arm-lift method (Sylvester) alone, 31 per cent were successful, and with the same method and an artificial oropharyngeal airway, 50 per cent were successful.

Thus, it can be seen that under these conditions, the mouth-to-mouth technique in the hands of untrained rescuers with minimum instruction was much more frequently successful than the back- and chest-pressure and arm-lift methods in the hands of trained rescuers.

What is the reason for the success of the mouth-to-mouth technique in this comparative study? I think that the essential difference is in the position of the head and neck, and jaw, of the victim in the mouth-to-mouth technique, in extension, by which the air passageway to the lungs is kept open; whereas with the back- and chest-pressure and arm-lift methods, this position of the head and jaw in extension cannot be maintained by the rescuer, who must devote his full attention to applying the pressure. The tendency of the tongue and jaw muscles in the relaxed, paralyzed position of the victim is to collapse, thus blocking the airway unless the head and jaw are extended, even with the insertion of an artificial oropharyngeal device.

The preceding points are illustrated by the following study on 80 anesthetized women, also done by Safar and his colleagues. These women were breathing normally and spontaneously, but their jaw and neck muscles were relaxed by the influence of the anesthetic. In other words,

they were asleep as during an operation (light, general anesthesia, stage 3, plane 1-2).

The airway of these patients was recorded as being open when the anesthesia-machine breathing bag was moving freely and there was no noise in breathing. The airway was recorded as being partially obstructed when the bag was moving but there was noisy breathing. The airway was recorded as being obstructed when the breathing bag was not moving and no air exchange could be heard despite respiratory motion of the patient's chest and abdomen.

In the supine position (lying on back) with the head flexed and the chin down, 100 per cent had an obstructed airway, and even with an artificial oropharyngeal airway, 98 per cent were still obstructed and 2 per cent partially obstructed. With the head in mid-position between flexion and extension, 36 per cent were obstructed in natural breathing and 54 per cent partially obstructed, and only 10 per cent had an open airway. With an artificial oropharyngeal airway inserted, 29 per cent were still obstructed, 51 per cent partially obstructed, and 20 per cent had an open airway.

In the extended position of the head, with the chin up, 5 per cent had an obstructed airway, 46 per cent had a partially obstructed airway, and 49 per cent had an open airway. With an artificial oropharyngeal airway, none were obstructed, 12 per cent partially obstructed, and 88 per cent had an open airway. With extension plus support of the jaw in a forward position, with natural breathing, 1 per cent were obstructed, 21 per cent partially obstructed, and 78 per cent open.

With an artificial oropharyngeal airway, none were obstructed, 2 per cent partially obstructed, and 98 per cent had an open airway. A similar incidence of airway obstruction was found with the patients in the prone position (lying on the stomach), both with the face directly downward, and with the face to the side, as in the usual back-pressure, arm-lift method.

I think that the preceding study corrects a number of popular misconceptions. To quote Safar, "It is a common belief that airway obstruction due to 'swallowing of the tongue' is prevented by the patient in the prone position. Our data and roentgeno-

grams (x-rays) indicate that in the prone position the tongue does not simply 'fall forward' but rather that the site, mechanism, incidence, and degree of pharyngeal obstruction is similar in the prone as in the supine position.

The thought that foreign matter such as vomitus or water would drain from the mouth by gravity provided another basis for the recommendation of the prone position in the past. In actual resuscitation, we often found semisolid vomitus and other foreign matter which did not 'drain.' Water and mucus formed foam which could only be removed by wiping out or by the use of a suction machine. Drainage of foreign matter from the lungs in the prone position is as unlikely as in the supine position since the trachea is horizontal in both."

The performance of artificial resuscitation on the unconscious infant has long been a matter of considerable difficulty. The reasons are in part anatomical. Not only are the infant's ribs and chest softer, but the ribs are in a different position than in the adult, extending more directly forward from the spinal column. For this reason, the infant's breathing is more completely due to diaphragm motion than the adult's breathing.

The chest- and back-pressure and arm-lift methods of artificial respiration are intended to produce movement of the chest wall, but such movement as is produced is often negated by the contrary motion of the relaxed, flaccid diaphragm which moves back and forth instead of air moving in and out of the lungs.

This is, of course, not true in the normal conscious person, in whom the diaphragm is contracted and tends to move with, rather than against, the respiratory motion produced by chest-wall expansion and contraction. Suffice it to say, in infants, methods to overcome the special problems they present, such as the rocking method (Eve), have been shown to be relatively unsuccessful; and the only method which

can be relied on to successfully produce sufficient air movement in and out of the infant is the mouth-to-mouth technique.

Detailed studies of the oxygenated hemoglobin and carbon dioxide levels in simulated victims' blood have shown that these are maintained within or close to normal limits, and that they are rapidly attained when the mouth-to-mouth technique is started. Additional advantages of the technique are the fact that additional pressure can be exerted by forced expiration on the part of the rescuer to overcome partial obstruction of the airway that may exist despite the most skillful effort, due to the anatomy, the presence of excessive obesity, or other peculiar conditions existing in the victim which would preclude success by any other method of artificial respiration.

Large differences in the size of the rescuer and the victim are easily offset, and boys and small women have been successful at resuscitating victims twice their size. Mouth-to-mouth breathing can be done for over an hour by the untrained rescuer without excessive fatigue; this has been demonstrated a number of times.

Due to the advantages of the mouth-to-mouth technique of artificial respiration which have been detailed above, the National Academy of Sciences—National Research Council's Ad Hoc Panel on Manual Methods of Artificial Respiration—unanimously recommended this technique. Subsequently, the American National Red Cross, the several departments of the Armed Forces, the Public Health Service, and numerous other organizations adopted the mouth-to-mouth technique as the method of choice.

Case histories of many successful resuscitations performed by laymen with this method demonstrated that it is readily acceptable, easily learned, and has been, on a number of occasions, successfully applied without previous practice in the method by the rescuer.

RELIGIOUS SAFETY ACTIVITIES SESSIONS

HOW CHURCHES AND SYNAGOGUES CAN HELP PREVENT ACCIDENTS

By DAN HOLLINGSWORTH
Chief of Police, Oklahoma City

The keynote address of the Safety and Religion Section of the National Safety Congress, Conrad Hilton Hotel, Chicago, Illinois, Tuesday, October 17, 1961.

There are three situations in a person's life where they can have their attitude toward traffic accident making situations changed; that is, changed either for better or for worse.

One of these situations comes when a policeman at the scene of an arrest has the violator in tow, with ticket book in hand.

The second time a person can have his thinking changed and his views altered is when a Traffic Court Judge has the violator before the Bench and says to him, "Are you guilty or not guilty?"

These are both cases after the fact. As a result, the person is always on the defensive and when on the defensive we are not in a very receptive mood.

The third case is before the fact. The situation and location may vary but the person who can change this attitude and viewpoint is a minister, a Priest, a Rabbi, a Religious Counselor or Church School Teacher.

Policemen generally are not equipped with the necessary knowledge, nor do they possess the appeal factors to do this changing of views. Nor does their work take place in an atmosphere conducive to changing a man's attitude.

The Traffic Court Judge has the edge on the Policeman in so far as atmosphere is concerned, but he usually has to grind out cases by the minute and the time element completely whips him.

But when a person is in his church, his synagogue, or his Sunday School room, or whatever his place of worship, he went there in a frame of mind to receive the level and degree and a type of spiritual guidance that can and will change his view of things. The atmosphere, the climate, the

surroundings of his sanctuary causes him to drop his false defenses and open his mind, his heart and his soul.

Man in his pew is in a mood which causes him to accept the idea of changing his attitude, his views, his sense of values, his standards, and probably he is never in that position at any other time during the week.

The minister, the Rabbi, the Priest, the teacher, the leader, the counselor, or whoever delivers the message, has the sales opportunity that no one else can ever get; a sales opportunity to make that person a better driver, a better citizen and a better church member, and a safer member of society.

In every lesson or sermon presentation another need—another situation exists, and this first thing—the opportunity, and the second thing—the need, are compatible. They serve to complement and to aid each other.

Because, you see, at the same time this minister, this speaker, spiritual leader, advisor, has a problem and I think this is a universal problem. Regardless of faith or belief, age or situation, this speaker needs examples. The good teacher uses real life cases to illustrate his point that is on an experience level with the membership of his audience. He needs to, if he is effective, talk about life situations, experiences, problems that face as many of his listeners as possible.

True, he can talk about the pleasures of raising roses. The problems of the parents of teenage boys and girls. The happiness of having a house full of boys. The question of what constitutes gambling. But in these and hundreds of other examples, he misses most of his congregation, they just don't know about the experience to which he refers.

But every person in that audience has had experience in traffic, not just one of them, but literally hundreds of them. Furthermore, five minutes before they sat in that pew, they had an experience in traffic. Five minutes after they leave the Church they'll have another experience in it.

And if you hear the same stories I hear, most of these traffic experiences are had with feeling. Apparently few people drive the streets and highways today without developing strong feelings about some phase of the traffic problem, and that feeling is usually of a critical, negative nature.

You know in our business of policing, we listen to lots of complaints, and if you don't like to listen to complaints, you won't be very happy in the Police business.

But one of the things which worries me about our people is that it has been a long time since I've heard anyone say anything good about our individual transportation system, all of these good automobiles which we own and drive and really enjoy, although we don't admit it. Evidently, we've forgotten there can be some nice things about them. The word "joy-riding" has disappeared from our vocabulary except its use to describe a type of auto theft in the police field.

In the past several years, Mrs. Hollingsworth and I have had the pleasure of entertaining in our home dozens of Police Officials from around the world. These men were brought here by our government to study the Policing system in this country.

One of them a few months ago, a Moslem, was visiting in our home and we talked to him through an interpreter. Just by chance I asked him the question, "What thing impresses you most about our country and our people?" He replied, "What I am about to say to you may hurt your feelings, but in speaking in truth I must tell you that the lack of gratitude and thankfulness and appreciation on the part of the American people for what they have, shocks me." He went on to say that as he people had all the nice things that we have, including homes and conveniences and comforts and automobiles and highways and the freedom to travel, that his people would spend half of each day in prayers of thanksgiving.

Traffic Safety—The problems of Traffic

Religious Safety Activities Sessions

Safety. We have been trying to get a thing done through the newspapers, billboards, schools, radio, television, Safety Education units and other activities that will change people's minds about this automobile and its use and maybe as the Police Official from Iraq said, "Make us more grateful." Certainly these activities help, at least they plant the seed of the idea, but you see, you as a religious leader can cause that seed to bear fruit.

One of your own ministers in one of these Safety Congress Sessions just a few years ago said, "The greatest force and power in a democratic society are the newspapers, the lecturers, the person who has the responsibility for creating public opinion."

Dr. Preston Bradley, Pastor, People's Church, here in Chicago is right as far as mass action, mass decision is concerned. But you prevent automobile accidents one at a time. You chance and improve man's attitude just one man at a time and you make him a better driver right here in his heart and not in his mind. I think it was the mind Dr. Bradley had reference to.

You do not sell a man on the idea of loving and appreciating his neighbor, the same way you sell him a Cadillac or cause him to buy an Arrow shirt.

The automobile, which brought us the world's finest individual transportation system and made us the envy of the world has become a status symbol and representative of one's individual freedom in this highly regulated world in which we live.

May I cite this example, you'll find women who will not shampoo their hair, trim their toenails nor give themselves a manicure, but every week they will wash, to a spit and polish job, their automobile. Sometimes watch them wash this car. Watch them stand back in a stance of awe and worship. Why? Because that automobile represents, in many instances, about half their income. To them it is a golden calf. It is their vehicle of pleasure, self-satisfaction and it feeds their ego and makes them equal with, and so, a lot of things and situations. And men have an equal reaction. You may well say, people have been doing this for years, oversize homes, sterling silver, two carat diamonds, mink coats. All these too are status symbols.

Yes, but the automobile is different. These other status symbols may break a little girl's heart. They may cause temptation to overcome a man's moral fiber. They may upset a little boy. But none of those things ever killed 38,000 people and injured a million and a half and caused an economic loss of two billion dollars a year. This is the thing which makes it sinful to feel the intoxication of the power of 300 horses under the hood of an automobile and fail to control that power.

Someone the other day asked the question, "Have we become a nation that worships and bows down to a shorter and quicker way?" When we do things this quicker, shorter way, we say it's justified because it is the expedient thing. It may be expedient. But the question is, in the case of the automobile, is it morally sound? Is it the right thing? Is it in the best interest of the American system of justice? Is it in keeping with the principles you religious leaders propose and propound each Sunday? We justify our misuse of our cars on the grounds that this is the expedient way. Therefore, it is good. Well, is it?

If you haven't read Vance Parkard's "Hidden Persuaders," read it. If you don't have time to read it all, read the last chapter, "The question of morality." If you can't spare the time to read the last chapter, read the lead paragraph in the last chapter, which quotes the President of the Public Relations Society of America, "The very presumptuousness of molding the human mind through the techniques we use has created a deep sense of uneasiness in our minds." Look about you and see if you don't become uneasy about the things this automobile is doing to our people. Talk to your people, talk to them about what are the real meaningful things in their lives and see how many of them think more of that car than any other concrete or abstract thing they possess.

Any preacher or Rabbi or speaker delivering a message with a religious theme admits the need of a vehicle to make his point more meaningful. He can call his point laws, statements of eternal truth, or quideposts. Take our traffic signs, they are actually a brief statement of the law. Some of them are absolute, some of them are merely warning and some of them are con-

ditional. This same principle applies to some of the laws you propound.

I believe one of the most understandable sermons on the Ten Commandments I ever heard was one which was based on a parallel comparison to highway signs and how they were alike, one to the other.

"Slow down and live," could easily be a doctor's slogan as well as a highway sign and it could be an excellent spring board for a sermon, even with a highway safety overtones.

You talk about our obligation to God, obligation to the Church, what about our mutual obligation to each other on the streets and highways or in the plant. A simple yet important obligation, just to help each other stay alive and stay in one piece.

The encouragement for the support of the laws we now have on our books is the thing in which all ministers could help. Among the paradoxes of law enforcement and there are many of them . . . Not the least is this self-endorsed righteous one who wouldn't violate any law, who supports all things which are good, but was on a jury and failed to convict the flagrant drunken driver.

He probably will have a lot of good, sound reasons why he didn't convict that person, but the real reason was that he lacked the moral courage. We need a lot of things in traffic safety work, but citizens with the moral courage in jury boxes is pretty close to the top of the list, and you, as that person's spiritual advisor and counselor, are the only person who can say to the prospective juror, "You must, if you believe this man guilty, find him guilty. This is your obligation to God and to your fellow man."

If you ask a preacher what he sells and ask him to define it in one word, he might find difficulty in finding that one word. I find it simple, being a simple person. I think the one word to describe the sales package of the preacher is a four letter word "Love."

What does a preacher stand for and what does he stand against, make it simple and keep it in two words, He's for "love" and he's against "hate."

As I view it, there's little love lost between motorists. Motorists are believing

more and more every day that they should hate each other, when, if you, as a spiritual advisor, would remind them they should love each other. I have got to love every other user of the road. I just cannot take any other position. Why? Because, I'm alive and know it, because some other users of the highway, maybe one of you, in the thousands upon thousands of miles of my travels in this country, some few people have zigged when I zagged the wrong way and by their willingness to get out of my way, I'm still alive. And I know this is going to occur again. This is the reason I try to be a liberal driver and not to be too insistent on that right of way.

My life on the highway literally depends, not only on the ability of somebody to think and act faster than I can, but he must be willing to do it. You can't teach that person to think and act fast at the wheel, but as a spiritual leader, you can cause that person to be willing to do it. This is the important thing.

Not only do I love every other user of the highway, but I appreciate their being there. They're not in my way because, you see, they make it possible for me to be out there with them. I realize that if X-millions of people didn't own and use cars, I couldn't afford to own one.

When we look at America and the American home and the American scene and we look at all the influences on man's behavior and we take this thing apart and try to single out what one thing stands out far above all other things, we find several factors. Over here is the love of a woman for a man and the love of a man for a woman. And their mutual love for their children. Here is the spirit of sharing with each other good things and things not so good.

You grew up in a home. Will you just for a moment, think back and go back to your childhood and remember the simple lessons, the elementary church school lessons, family prayers, the choir activities, and the calls of the preacher.

As those years passed as we grew from a child into a youngster, into an older person and we became the head of a family, we recall vividly the words of the minister who said in substance, after he had pointed out the things he was talking about, "These

things are wrong, these things are sinful these things good people do not do."

These simple admonitions, the quiet expression of any opinion by a man, based on the word of God. This in my opinion is the greatest influence on our civilization, our lives and the communities in which we live.

If we can get our ministers, our church school teachers, our counselors and our rabbis, using as their authority the word of God, and say to us repeatedly and quietly it is wrong to kill, to injure and to maim people. It is sinful to damage another person's property, even though your only contribution was simple carelessness. If we can get the religious leaders of this country to do this, that action alone will have a tremendous impact on the traffic accident problem and other types of accidents as well.

It would be presumptuous on my part to offer you suggestions on the theology of safety.

My religion is not a theory, not a set of rules, but a way of life. A way that is permissive instead of restrictive. Positive rather than negative.

I believe His question to Cain, and Cain's reply, "Am I my brother's keeper?" . . . followed by His answer, "Thy brother's blood crieth unto you from the ground," . . . are as true today as they were when they were first spoken.

The golden rule, the act of the good Samaritan, the commandment not to kill, the admonition about temperance in all things. The commandment to love thy neighbor and not to take or covet what is his . . . all these are here and are true today, and they are as workable here on Michigan Avenue, or on Highway 66 between Chicago and Oklahoma City as they were on the road from Jerusalem to Jericho, and where the good Samaritan found one opportunity, today we can find hundreds of them.

I think He meant and still means it to be just as wrong to kill by negligence or carelessness, or by excessive speed, or through a flare of temper in the use of a car or any other kind of a machine as it was to kill with a stone.

On a Global basis, we are all concerned about this question of survival. Actually, the problem of safety and the solution to this

problem of individual survival may be a lot closer to us than the United Nations Building in New York or a Button Pusher in Siberia.

If we are to survive this battle between each other on the streets and highways, my religious belief, my experiences in the investigation of over 17,000 accidents at the scene and a quarter century's study of the causes of accidents, and my professional training, all tell me we must, if we profess to believe the things you propound, learn to respect the dignity of life and the life of man in the accident making situations which takes so many lives and maims so many, and costs this nation a disgraceful economic loss.

We must follow the Golden Rule, right along with the right-of-way rule and we must learn to love our neighbor in the next traffic lane as well as next door.

Individually, and this is what all these teachings are about actually, it won't do us any good to survive a missile war if day after tomorrow we die under the wheels of

a car between our house and the corner grocery.

Yes, my Master was on that road from Jericho to Jerusalem and just as sure as he was there, he is out yonder on the Congress Street Expressway today.

Well, I said it would be presumptuous for me to impose upon you my thoughts on the theology of safety. If I became too involved and stepped too far into your field, please forgive me.

A fellow says to me the other day when we were talking about this topic, he says: "Do you believe you can convince the religious leaders of their obligation to take on this task? Do you think you can sell them on the advantage of using an occasional traffic safety example in their services?" "Do you believe the religious leaders will accept their obligation to build better attitudes for traffic safety?"

Being an inherent optimist, I certainly do believe that.

But if perchance the religious leaders of this country don't help us, God help us!

RELIGIOUS ACTIVITIES

Panel Discussion on the Religious Role in preventing Traffic Accidents

Participants: Rabbi Jacob Pressman, Temple Beth Am, Los Angeles, Calif.; the Rev. Warren Ebinger, Illinois Council of Churches, Springfield, Ill.; the Rev. Gregory Bezy, S.C.J., Sacred Heart Southern Missions, Walls, Miss.; J. Lloyd Evans, National Conference of Christians and Jews, Dallas, Texas, and Chaplain James W. Keys, Christian Transport Association, Toronto, Ontario, Canada.

Rabbi Pressman said his congregation is developing a program of voluntary vehicle inspection as a means of cutting down on accidents. He said his state does not have such a program. Rabbi Pressman also has used posters on safety rules in his synagogue and has preached specific sermons on safety.

The Rev. Mr. Ebinger, who is a registered lobbyist in the state legislature, has urged the clergy to work for legislation that will help save lives. He said the clergy should work for stiffer regulations in traffic laws. He used some examples of drinking drivers in connection with traffic accidents to stress the need.

Father Bezy founded the Sacred Heart Auto League in an effort to make every driver a religious driver. He said that drivers must respect other drivers because all drivers have a personal relationship to God.

Mr. Evans pointed out there is a necessity for education about the safety problem. He said the conference has organized seminars for this purpose in his area of Texas in an effort to educate the clergy and religiously motivated persons. He said safety should never become a religion but should be an outward expression of religion. He said there is a need for a Religious Activities Committee on every safety council. He said the seminars often include panel discussions, films about safety, etc., so the clergy can give direct answers to questions from members of their congregations and others.

Chaplain Keys said his organization works closely with the trucking industry. It has organized a publication, "Transport For Christ," for the truckers giving safety tips from the moral aspect. He said it stresses safe driving as a moral obligation to one's fellow man.

WOMEN IN SAFETY SAFETY AND THE PHYSICALLY HANDICAPPED HOMEMAKER

By DR. LILLIAN M. GILBRETH
New York City

The National Safety Council has always interested itself in the problems of safety in the home, and of course the Women's Department is much concerned with what happens in this most important area of our lives.

Any household which includes a physically handicapped member or a guest—either permanent or temporary—is keenly interested in avoiding accidents, and in making sure at the same time that no one is made to feel conspicuous by equipment which makes him look or feel "different."

The projects which have been developed for work simplification in the home have helped us evaluate the safety factors. The questions constantly asked: "Is this necessary? Why?" always assume that safety is of paramount importance. For example, in planning the kitchen initiated and sponsored by the Heart Association, the physician's estimate of his patient's "safe" expenditure of energy set the limits within which the planning was undertaken and provided the incentive to make minimum demands on the homemaker's time and energy.

In the case of the young mother, physically limited as the result of polio, but eager to do a fine job in housekeeping and family relations, it was recognized that safety raised special problems for her.

This became evident in the work with physically handicapped homemakers carried on at the University of Connecticut. Here these homemakers cooperated with the

university staff in making an extensive study of their problems. The results of the study show:

1. They face the same problems as all homemakers.

2. Because of their disabilities there are added problems, such as learning to accept help graciously but at the same time refusing to be over-protected.

3. They must make sure that their children understand what they may do and may not do—and why. The children must obey and understand why they must obey.

4. They believe they can "live with" their families, at work and at play.

5. Their experiences can help other homemakers, whether these other women have obvious physical handicaps or not.

The literature, films, etc., available at the University of Connecticut are being used increasingly, both here and abroad. A research project which would lay emphasis on the safety features of this homemaking program would be an appropriate and valuable activity for the Women's Division to sponsor.

At your invitation, I am privileged to speak to you about it today and I hope you will want to think about such a project and initiate it. I can assure you that it will create worldwide interest and participation and will not only make a real contribution by solving some of today's problems but will help us face the new ones which await us tomorrow.

OFFICERS OF THE PUBLIC SAFETY COMMITTEE NATIONAL SAFETY COUNCIL 1961-62

Chairman—WALTER F. CAREY, President, Automobile Carriers, Inc.

Chairman of the Recreational Boating and Water Safety Committee—ADM. A. C. RICHMOND, Commandant, United States Coast Guard.

Chairman of the Recreational Shooting Safety Committee—LOUIS F. LUCAS, Executive Director, National Rifle Association of America.

Chairman of the General Aviation Safety Committee—FREDERICK B. LEE, Director of the Washington Office, Olin.

Chairman of the 1962 Congress Program Committee—ALAN L. KLING, Director of Loss Prevention, Olin.

Secretary of the Public Safety Committee and its three sections—RALPH KUHLE, Director, Public Safety Department, National Safety Council.

Members-at-Large:

Advisory Agencies—U. S. Department of Agriculture, Forest Service, DR. RICHARD E. McANULTY, Chief; U. S. Department of Commerce, Weather Bureau, F. W. REICHELBAUER, Chief; N. A. LITERANCE, Associate Chief; U. S. Department of Defense, Department of the Army, Corps of Engineers, Civil Works, MARK S. GUNNER, Chief, Operations Division; U. S. Department of Health, Education, and Welfare, Public Health Service, Division of Accident Prevention, A. L. CHAPMAN, M.D., Chief, PAUL V. JORJET, M.D., Deputy Chief, JOHN T. COLLIER, Chief, Recreational Safety Branch; U. S. Department of the Interior, National Park Service, CONRAD L. WIRTH, Director; Outdoor Recreation Resources Review Commission, FRANCIS W. SARGENT, Executive Director.

and organizations of public officials—American Institute of Park Executives, Inc., ALFRED B. LAGARSE, Executive Secretary.

Non-official Organizations—Amateur Athletic Union of the United States, DR. HAROLD W. HENNING, Chairman, National Men's Swimming Committee; American Association for Health-Physical Education and Recreation, DR. A. E. FLORIO, University of Illinois; American Association for the Surgery of Trauma, JAMES K. STACK, M.D., Past President; American Camping Association, Inc., GERRARD A. HARRISON, Assistant Executive Director; CLIFFORD PULIS, Chairman, National Health and Safety Committee (alt.); American College of Surgeons, JOHN PAUL NORTH, M.D., The Director; American Medical Association (Committee on the Medical Aspects of Sports) FRED V. HIFAN, M.D., Secretary; American Public Health Association, EDWARD PRESS, M.D., Chairman, Accident Prevention Committee; American Recreation Society, RAY R. BUTLER, Executive Director; American Rocket Society, Inc., CHARLES C. MIESSE, President; Chicago Section, Athletic Institute, Inc., THEODORE P. BANK, President; Automobile Carriers, Inc., WALTER F. CAREY, President; Bowling Proprietors' Association of America, HOWARD C. SEZHAUSEN, Executive Director, JOHN J. FLAHERTY; Chattanooga Safety Council (Tennessee), EUGENE D. GLAZE, JR., Director; Consumers' Research, Inc., F. J. SCHLINK, President and Technical Director; Institute of Makers of Explosives, HARRY L. HAMPTON, JR., Secretary; International Rescue and First Aid Association, MAX L. SPRAY, Executive Director; National Campers and Hikers Association, H. ELLSWORTH NATHAN, National Director; National Industrial Recreation Association,

IRON L. NEEB, Executive Secretary, ROBERT TURNER, President; *National Recreation Association*, JOSEPH PENDERGAST, Executive Director; *National Ski Association*, WARREN E. GILBERTSON, Rules of the Road Committee; *National Ski Patrol System*, GARY CARLTON, Chairman, Ski Safety Division; *Ontario Safety League* (Toronto, Ontario, Canada), ERNEST M. TAYLOR, Director, Outdoor Recreation Division; *Seattle-King County Safety Council* (Washington), AL. MCGEE, Public Safety Director.

Business and Industry—Automobile Carriers, Inc., WALTER F. CAREY, President; *Metropolitan Life Insurance Company*, DR. MELVIN M. UDEL, Director, Safety and Occupational Health; *National Sporting Goods Association*, G. MARVIN SHUTT, Executive Director; *Olin Mathieson Chemical Corporation*, ALAN L. KLING, Director, Loss Prevention.

Recreational Boating and Water Safety Committee:

Chairman—ADMIRAL A. C. RICHMOND, Commandant, United States Coast Guard.

Official Agencies—U. S. Department of Agriculture, Soil Conservation Service, E. J. PETERSON, Chief, Safety and Training; U. S. Department of Commerce, Coast and Geodetic Survey, CAPTAIN JENNIS T. JARMAN, Assistant Director, Office of Cartography; U. S. Department of Defense, Department of the Army, Corps of Engineers, MATT C. HUFFPUCH, Chief, Project Management Section; U. S. Department of the Interior, Bureau of Reclamation, HAROLD E. WERSEN, Regional Safety Engineer, Region 1; Fish and Wildlife, JOHN N. BALL, Safety Coordinator; *National Park Service*, CONRAD L. WIRTH, Director, NATHAN G. BAKER, Chief Safety Officer, ALVIN F. HANKS, Chief of Visitor Protection, Division of Ranger Activities (all.); U. S. Department of the Treasury, United States Coast Guard, ADMIRAL A. C. RICHMOND, Commandant, CAPTAIN S. G. GUILLE, Chief, Merchant Vessel Inspection, CAPTAIN B. D. SHOEMAKER, JR., Executive Secretary, Merchant Marine Council.

And organizations of public officials—Council of State Governments, CHARLES F. SCHWAN, JR., Washington Representative; *International Association of Game, Fish and Conservation Commissioners*, L. P. VOIGT, Executive Committee.

Non-official Organizations—American Boat and Yacht Council, Inc., E. S. TERWILLIGER, Secretary, *American National Red Cross*, ALFRED W. CANTWELL, National Director, Safety Services, RICHARD L. BROWN, Assistant Director, Safety Services, Water Safety, CHARLES W. RUSSELL, Assistant Director, Safety Services, Small Craft; *American Power Boat Association*, HARRY SMITH, JR., Executive Secretary, FRANK J. SHINNEY, Chairman, Safety Commission; *American Water Ski Association*, WILLIAM D. CLIFFORD, Executive Manager; *American Yachmen's Association*, R. M. PHILIPS, Executive Director; *Conference for National Cooperation in Aquatics*, E. E. HOISINGTON, Boy Scouts of America; *National Safe Boating Association*, G. H. CHAPMAN, Chairman, F. B. LITTON, Secretary; *Underwater Society of America*, C. B. DAVIS, Director of Safety; *United States Coast Guard Auxiliary*, BLISS WOODWARD, National Commodore, CAPTAIN RICHARD BAXTER, USCG, Chief Director; *United States Power Squadrons*, PAST CHIEF COMMANDER KENNETH B. CHAMP, JN., Chairman, Planning Committee; *Yacht Safety Bureau, Inc.*, E. S. TERWILLIGER, Executive Vice-President and General Manager; *Young Men's Christian Association*, H. T. FRIERMOOD, Senior Secretary, Health and Physical Education; *Young Women's Christian Association*, MISS GLADYS L. BROWN, Consultant, Health, Physical Education and Recreation.

Business and Industry—American Institute of Marine Underwriters, CARL E. McDOWELL, Executive Vice-President; *American Merchant Marine Institute, Inc.*, RALPH E. CASEY, President, RADM. H. C. SHEPHERD, USCG, Ret. (alt.); *American Pad & Textile Company*, HENRI MARC, Vice-Chairman of the Board; *American Waterways Operators, Inc.*, BRAXTON B. CARR, President; *Boating Industry Magazine*, CHARLES A. JONES, Editor; *Century Boat Company*, F. L. HEWITT, JR., President; *Chris-Craft Corporation*, H. H. COLL, President, GERALD E. MALLON, Plant Manager, Algoma Division (alt.); *Esso Standard Division*, Humble Oil & Refining Company, NORRIS C. BARNARD, Man-

ager, Shallow Draft Marine Sales; *Eyerly Associates*, JAMES H. CARRAHAN, Director of Water Safety; *General Motors Corporation*, Detroit Diesel Engine Marine Division, CLYDE W. TRUAX, General Manager; *Gray Marine Motor Company*, JOHN W. MURPHY, Chairman of the Board; *Hoffman Publications, Inc.*, DONALD H. HOFFMAN, President; *Kickhafer Corporation*, Subsidiary of Brunswick Corporation, E. C. KICKHAFFER, President and Corporate Vice President of Brunswick, FRANK SALPONE, Public Relations Director (alt.); *Lune Star Boat Company*, T. EISELT, President; *McCulloch Corporation*, Scott Division, H. B. ATWATER, President; *Motorboating Magazine*, CHARLES F. CHAPMAN, M.E., Editor; *National Association of Amusement Parks, Pools and Beaches*, JOHN S. BOWMAN, Executive Secretary; *National Association of Engine and Boat Manufacturers, Inc.*, JOSEPH F. CHOYTE, Secretary, GORDON W. RULE, Washington Representative, R. D. GUDGEON, Director of Public Relations, *National Association of Marine Dealers*, GATES HARPEL, Executive Director; *National Fire Protection Association*, CHARLES S. MORGAN, Assistant General Manager; *National Swimming Pool Institute*, ROBERT S. GREENE, Executive Secretary; *Outboard Boating Club of America*, GUY W. HUGHES, Executive Director, MATTHEW J. KAUFMAN, Manager, Boating Services and Education; *Outboard Magazine*, THOMAS C. HARDMAN, Editor; *Outboard Marine Corporation*, W. C. SCOTT, Chairman of the Board; *Owens Yacht Division of Brunswick Corporation*, CHARLES J. OWEN, President; *Popular Boating Magazine*, ROBERT W. CARRICK, Editor; *Sport Fishing Institute*, RICHARD H. STROUB, Executive Vice-President; *Universal Motor Company*, RALPH G. KIRKLEIGH, President; *Yachting Magazine*, CRITCHFIELD RIMINGTON, Editor and Publisher.

Recreational Shooting Safety Committee:

Chairman—LOUIS F. LUCAS, Executive Director, National Rifle Association of America.

Official Agencies—U. S. Department of Defense, Department of the Air Force, COL. PETER W. AGNELL, Chief, Marksmanship & Support Branch, Technical Training Division; Department of the Army, LT. COL. THOMAS J. SHAW, Directorate of Organization and Training, Training Division; Department of the Navy, CAPT. OTTO A. FINLEY, Bureau of Naval Personnel.

Non-official Organizations—American Association for Health, Physical Education, and Recreation, DR. WILLIAM H. CRESWELL, JR., Assistant Executive Secretary, JULIAN W. SMITH, Director, Outdoor Education Project; *Isaak Walton League of America*, WILLIAM A. RIANKI, Executive Secretary; *National Rifle Association of America*, LOUIS F. LUCAS, Executive Director; FRANK L. WYMAN, Director, Program Division; *National Wildlife Federation*, THOMAS L. KIMBALL, Executive Director.

Business and Industry—Sporting Arms and Ammunition Manufacturers Institute, DR. EDWARD L. KOZICKY, Chairman, Committee on the Prevention of Accidents with Firearms.

General Aviation Safety Committee:

Chairman—FREDERICK B. LEE, Director of Washington Office Olin Mathieson Chemical Corporation.

Official Agencies—Civil Aeronautics Board, JOSEPH O. FLUET, Chief, Safety Investigation Division; *Federal Aviation Agency*, GEORGE PHILL, Director, Flight Standards Service, R. R. LOVERINK, Assistant Chief, Operations Division; U. S. Department of Agriculture, Forest Service, MONTE PIERCE, Chief Aviation Officer, Division of Fire Control; U. S. Department of Commerce, Weather Bureau, F. W. REICHELDERFER, Chief, N. A. LIEUWANCE, Associate Chief; U. S. Department of the Treasury, United States Coast Guard, LCDR M. G. SHROUSE, JR., Chief, Flight Safety Branch.

And organizations of public officials—National Association of State Aviation Officials, A. B. McMULLAN, Executive Director, C. E. A. BROWN, Chairman, Aviation Safety Committee.

Non-military Organizations—Aerospace Medical Association, RADM JAMES L. HOLLAND, MC, USN, President; Aircraft Owners and Pilots Association, J. B. HAKTIANPT, JR., President; American Medical Association, B. DIXON HOLLAND, M.D., Secretary, Committee on Aerospace Medicine; Aviation/Space Writers Association, RALPH H. McCLAVIN, Executive Secretary; Civil Air Patrol, STEPHEN D. McELROY, Brigadier General, USAF, National Commander, CURTIS H. W. RUTHER, Colonel, USAF, Chief of Staff, WILLIAM W. DEALL, Captain, USAF, Chief of Safety; Flight Safety Foundation, JEROME LEDERER, Managing Director, MERWYN A. KRAFT, Research Coordinator (alt.), MISS GLORIA W. HEATH, Director, Private Flying (alt.), Flying Physicians Association, HAROLD N. BROWN, M.D., President-Elect and Chairman, Safety Committee; General Aviation Council, WILLIAM REQUARTH, M.D., Chairman; Harvard University (Guggenheim Center for Aviation Health and Safety, Harvard School of Public Health), DR. ROSS A. MACFARLAND, Professor of Environmental Health and Safety, and Director of Guggenheim Center; National Aviation Education Council, EVAN EVANS, Executive Director; National Business Aircraft Association, Inc., B. J. BERGSEN, President; National Flying Farmers' Association, L. T. SUTTER, President; National Pilots Association, DAVID H. SCOTT, Secretary; Ninety-Nines, Inc., Mrs. EUGENIA R. HEISE, Past President; Society of Automotive Engineers, M. LEROY STONER, Secretary, Technical Board; University of Southern California, CARL HANLEY, Dean, University College, and Administrator, Aviation and Missile Safety Division.

Business and Industry—Aerospace Industries Association of America, JOSEPH T. GEUTING, Jr., Manager, Utility Airplane Council; Air Facts Magazine, LEIGHTON COLLINS, Editor; American Association of Airport Executives, R. RUSSELL HOYT, Executive Secretary; Business/Commercial Aviation Magazine, W. G. OSMUN, Editor; Flying Magazine, GILL ROSS WILSON, Editor and Publisher; Link Foundation, Miss MARILYN LINK, Executive Secretary; National Aviation Insurance Group, D. W. KEATZ, President; National Aviation Trades Association, Inc., ROBERT E. MONROE, Executive Director.

OFFICERS OF THE NATIONAL CONFERENCE FOR FARM SAFETY NATIONAL SAFETY COUNCIL 1961-62

Members—EDWARD S. ADAMS, Director of Safety, Iowa Farm Bureau Federation, Des Moines, Iowa; Mrs. ALICE ARMSTRONG, Indiana Farm Bureau Cooperative Assn., Indianapolis, Ind.; HARRY BEYSON, Executive Vice President, Agricultural Hall of Fame, Kansas City, Mo.; DR. JOHN B. CLARK, Director of Extension Service, College of Agriculture, University of Illinois, Urbana, Ill.; GRAHAM T. COULTER, Kraft Foods Co., Chicago, Ill.; JOHN F. DANLKE, General Motors Corp., Detroit, Mich.; JACK DREXSEN, National Agricultural Chemicals Assn., Washington, D. C.; KENNETH V. FISKE, Director of Farm Operations, Velsicol Chemical Corp., Chicago, Ill.; CHARLES FRIEDRICH, National Retail Farm Equipment Assn., St. Louis, Mo.; DR. CARL FURCH, Assistant, Director, Extension Service, Utah State University, Logan, Utah; Mrs. HOMER GREENE, Tuwiler, Miss.; WILLIAM GORMAN, Aurora, Ill.; HAROLD B. HALTER, Farm Equipment Manufacturers Assn., St. Louis, Mo.; PROFESSOR G. E. HENDERSON, Barrow Hall, University of Georgia, Athens, Ga.; RUSSELL HESTON, Farmers Mutual Insurance Co., Grinnell, Iowa; DOUGLAS HEWITT, Farm Equipment Institute, Chicago, Ill.; EDWARD F. HOLTER, Director, Farmers Home Administration, United States Dept. of Agriculture, Baltimore, Md.; ROBERT HOWEY, National Vo-Ag Teachers Assn., Sycamore, Ill.; Miss AMY KELLY, College of Agriculture, University of Missouri, Columbia, Mo.; KEITH KIRKPATRICK, Radio Station W.H.O., Des Moines, Iowa; EDWARD K. KLAMM, Allstate Insurance Co., Skokie, Ill.; Mrs. DORSEY KIRK, Illinois State Grange, Oblong, Ill.; DR. L. W. KNAPP, Assistant Professor and Agricultural Safety Engineer, Institute of Agricultural Medicine, College of Agriculture, State University of Iowa, Iowa City, Iowa; WILLIAM KUHN, President, Illinois Agricultural Association, Bloomington, Ill.; FRANK LADNER, Director of Safety, Nationwide Insurance Co., Columbus, Ohio; S. E. LARSEN, Michigan Farm Equipment Association, Grand Rapids, Mich.; PROFESSOR E. W. LERMAN, Urbana, Ill.; MARY F. LYLE, 4-H and YMW Programs, Federal Extension Service, United States Dept. of Agriculture, Washington, D. C.; S. P. LYLE, Extension Service, United States Dept. of Agriculture, Washington, D. C.; Mrs. MABEL C. MACK, Extension Service, Oregon State University, Corvallis, Ore.; JOHN MARKS, Rural and Education Division, Automotive Safety Foundation, Washington, D. C.; NORMAN MINBRUM, Director, National 4-H Service Committee, Chicago, Ill.; HERSCHEL NEWSON, Master, National Grange, Washington, D. C.; GUY L. NOBLE, Chicago, Ill.; V. S. PETERSON, E. I. du Pont de Nemours & Co., Atlanta, Ga.; HARRY PORTIUS, Columbus, Ohio; HARRY POWELL, Goodyear Tire and Rubber Co., Akron, Ohio; L. W. RAMSEY, Oliver Corp., Chicago, Ill.; FRANK REYNOLDS, Manager, Agricultural Extension, United States Steel Corp., Pittsburgh, Pa.; Miss LOUISE ROSENFIELD, Assistant Director, Home Economics, Cooperative Extension Work, University of Iowa, Ames, Iowa; PAUL SANDERS, Editor, Southern Planter, Richmond, Va.; PROFESSOR A. J. SCHWANTES, Head, Dept. of Agricultural Engineering, University of Minnesota, St. Paul, Minn.; C. G. SCRUGGS, Progressive Farmer, Dallas, Texas; CHARLES B. SHUMAN, President, American Farm Bureau Federation, Chicago, Ill.; DR. W. T. SPANTON, Dept. of Health, Education and Welfare, United States Office of Education, Washington, D. C.; ARTHUR STAPEL, Fox Valley Cooperative, Inc., Appleton, Wis.; RANDALL C. SWANSON, Farm Safety Specialist, College of Agriculture, University of Wisconsin, Madison, Wis.; E. W. TANQUARY, International Harvester Co., Hinsdale, Ill.; ROBERT E. TAYLOR, Advertising Division, Republic Steel Corp., Cleveland, Ohio; Mrs. HELEN TURNER, Division of Home Economics, Federal Extension Service, United States Dept. of Agriculture, Washington, D. C.; F. R. WILLIAMS, Farm Safety Specialist, Dept. of Agricultural Engineering, Purdue University, Lafayette, Ind.; DR. W. B. WOOD, Director, Extension Service, College of Agriculture, Ohio State University, Columbus, Ohio; CARLTON ZINK, Product Research Department, Deere and Co., Moline, Ill.

OFFICERS OF THE HOME CONFERENCE NATIONAL SAFETY COUNCIL 1961-62

ROBERT ANDERSON, Director, Bureau of Health Education, Virginia Department of Health, Richmond, Va.; Mrs. HARRIETT G. BAKER, Des Plaines, Ill.; PAUL E. BASELER, Executive Secretary, Building Officials Conference of America, Chicago, Ill.; W. W. BAUER, M.D., Director, Bureau of Health Education, American Medical Association, Chicago, Ill.; Mrs. P. D. BEVIL, Sacramento, Calif.; TOM BLANKLEY, Director of Technical and Maintenance, National Association of Housing & Redevelopment Officials, Chicago, Ill.; HARRY H. BRAINERD, Executive Manager, Western Pennsylvania Safety Council, Pittsburgh, Pa.; PERCY BUGREX, General Manager, National Fire Protection Association, Boston, Mass.; Mrs. LUCILE BUSH, Consumer Education Director, Johnson's Wax, Racine, Wis.; DENNIS M. BUTLER, Advisory Coordinator, Accident Prevention Program, Mississippi State Board of Health, Jackson, Miss.; WARD V. BUZZELL, Assistant Director of Technical Services, Research and Technology Division, National Association of Home Builders, Washington, D. C.; ALFRED W. CANTWELL, National Director, Safety Services, American National Red Cross, National Headquarters, Washington, D. C.; Miss JESSIE CARTWRIGHT, Director of Home Economics, Norge Sales Corporation, Chicago, Ill.; Mrs. MARILEE B. CAVENDER, Accident Prevention Coordinator, Tennessee Department of Public Health, Nashville, Tenn.; Miss BERNARDINE CERVINSKI, Director, Division of Health Education, North Dakota State Department of Health, Bismarck, N. D.; A. L. CHAPMAN, M.D., Assistant Surgeon General, Chief, Division of Accident Prevention, Public Health Service, Washington, D. C.; AUSTIN C. CHIDISTER, Jr., Field Representative, Delaware Safety Council, Inc., Wilmington, Del.; MARIAN M. CRANE, M.D., Assistant Director, Division of Research, Children's Bureau, Social Security Administration, Washington, D. C.; WALTER A. CUTLER, Ph.D., Director, Center for Safety Education, New York University, New York, N. Y.; Miss NETTIE DAV, Chief, Accident Prevention Section, Division of Epidemiology, North Carolina State Board of Health, Raleigh, N. C.; Miss HELEN DEMING, Acting Director, Division of School, Farm & Home Safety, Iowa State Department of Health, Des Moines, Iowa; Miss ERIK R. DOANE, Director, Women's Division, New Jersey State Safety Council, Newark, N. J.; CLINTON W. DREYER, Managing Director, Eastbay Chapter National Safety Council, Oakland, Calif.; DONALD A. Y.; FAY VALENTINE, Executive Secretary, Christian Life Commission of the Southern Baptist Convention, Nashville, Tenn.; REV. CHARLES C. WEBER, Department of Religious Relations, AFL-CIO, Washington, D. C.; REV. EDWIN T. WILLIAMS, St. Andrews Episcopal Church, Lawrenceville, Va.; MARTIN WORK, National Council of Catholic Men, Washington, D. C.

OFFICERS OF THE

WOMEN'S CONFERENCE

NATIONAL SAFETY COUNCIL 1961-62

Members—Mrs. HELEN V. AGNEW, President, Quota Club International, Inc., Neon Sign Service Co., Monroe, La.; *Miss VIRGINIA R. ALLAN, Second Vice President, National Federation of Business and Professional Women's Clubs, Inc., Wyandotte, Mich.; *Miss DORA LEE ALLEN, General Secretary, Quota Club International, Washington, D. C.; Mrs. SIDNEY R. ALMQUIST, President, Woman's Auxiliary to the National Federation of Post Office Clerks, Seattle, Wash.; Mrs. M. VIRGINIA ANDERSON, President, Pilot Club International, Poplin, Mo.; Mrs. ALMER ARMSTRONG, Coordinator, Organization Relations, Indiana Farm Bureau Cooperative Assn., Indianapolis, Ind. (Member-at-large); Miss MARY KATHARINE BARNES, Safety Chairman, General Federation of Women's Clubs, Charleston, W. Va.; Mrs. W. B. BAUER, National Council of State Garden Clubs, Wilmette, Ill.; Mrs. AGNES D. BEATON, Director, Women's Division, Allstate Insurance Company, Washington, D. C. (Member-at-large); Mrs. MILDRED BELL, Foster & Kleiser, San Francisco, Calif. (Member-at-large); Mrs. REX BEZEL, Women's Activities Office, Office of Emergency Planning, Washington, D. C.; Mrs. RAE V. BIKSTER, Superintendent, United States Mint, Philadelphia, Pa. (Member-at-large); Mrs. HERMAN BEZMAN, B'nai B'rith Women, Chicago, Ill.; Mrs. LUCILLE BLAKESLEY, Factory Insurance Association, Chicago, Ill. (Member-at-large); *Miss RUTH A. BOTTOMLY, Consultant for Safety and Health, National Congress of Parents and Teachers, Chicago, Ill. (Observer); Mrs. LUCILE BUSH, Consumer Education Director, Johnson's Wax, Racine, Wis. (Member-at-large); Mrs. COULA P. BUTLER, National Association of Women Lawyers, Chicago, Ill.; Hon. MARGUERITE S. CHURCH, Member of Congress, Congressional Office Building, Washington, D. C. (Member-at-large); *Mrs. GLORIA I. CLARK, Amvets Auxiliary, Lincolnwood, Ill.; Miss MARTHA CRAZE, President-elect, American Women in Radio and Television, Director, Women's Programs, WLS Radio Station, Chicago, Ill.; *Mrs. ROBERT B. CRAZE, American Farm Bureau Women's Committee, Pittsdown, N. J.; Dr. DOROTHY DARLING, Director, Northeast Central Region, American Medical Women's Association, Gary, Ind.; Hon. MATTIE BELLE DAVIS, Judge, Metropolitan Court of Dade County, Miami, Fla. (Member-at-large); Hon. FRANCES L. DAWSON, National Order of Women Legislators, Evanston, Ill.; Miss MARGARET DRIVER, Second Vice President, John Hancock Mutual Life Insurance Co., Boston, Mass. (Member-at-large); Miss DOROTHY DOWNS, Assistant to Director of Engineering, Firemen's Mutual Insurance Company, Providence, R. I. (Member-at-large and Conference Chairman); Mrs. MARGUERITE McCABE DRUM, Assistant Engineer, American Telephone and Telegraph Company, New York, N. Y. (Member-at-large); Miss MARION EASTMAN, Chicago, Ill. (Member-at-large); Mrs. HARLAN ENGLISH, President, Woman's Auxiliary to American Medical Association, Danville, Ill.; Mrs. RANDALL W. EVERETT, Jr., Thomasville, Ga. (Member-at-large); Mrs. J. RALPH EWING, Safety Chairman, Woman's Auxiliary to the American Optometric Association, Fort Worth, Texas; *Mrs. GLENNE W. FOLKERS, Ladies' Auxiliary to the National Rural Letter Carriers' Association, Joliet, Ill.; Miss ELANOR FREEMAN, Public Safety Chairman, Zonta International, Evanston, Ill.; Mrs. GERTRUDE H. FRIESE, General Personnel Supervisor, New York Telephone Company, Brooklyn, N. Y. (Member-at-large and Board Representative); Mrs. JEAN WOOD FULLER, Western Instructor Training Center, Office of Civil and Defense Mobilization, Alameda, Calif. (Member-at-large); Miss RUTH GALLINOT, President, National Secretaries Association, Chicago, Ill.; Mrs. ROSS GEAHAN, Chairman, Women's Division, Safety Council of Greater Lansing, Lansing, Mich.; Dr. LILLIAN M. GILBRETH, New York, N. Y. (Member-at-large); Mrs. MARJORIE GILLESPIE, President, National Home Demonstration Agents' Association,

Burley, Idaho; Miss ALICE M. GIBSON, Safety Chairman, American Council of Railroad Women, Supervisor of Stewardess Service, Baltimore and Ohio Railroad Company, Chicago, Ill.; Mrs. L. H. GOLSON, President, Ladies Auxiliary to the National Rural Letter Carriers Assn., Prattville, Ala.; Mrs. MARY GORMAN, Grand President, Ladies Auxiliary to the Brotherhood of Railroad Trainmen, Columbus, Ohio; Mrs. ROSA L. GRAGA, President, National Association of Colored Women's Clubs, Detroit, Mich.; Mrs. ROBERT S. GUNDERSON, Rapid City, S. Dak. (Member-at-large); Mrs. VICTOR HARLICH, State Chairman, Farm Bureau Women, Garden City, Kan. (Member-at-large); Mrs. RALPH HALL, National President, Amvets Auxiliary, North Attleboro, Mass.; Mrs. MAME MASON HIGGINS, National Council of Negro Women, Chicago, Ill.; Mrs. ARTHUR R. HILL, Chairman, Women's Division, Seattle-King County Safety Council, Seattle, Wash.; Mrs. GEORGE L. HOLM, Ladies' Auxiliary to the Veterans of Foreign Wars of the United States, Chicago, Ill.; Mrs. FLORENCE ALLEN HOLMES, President, National Association of Negro Business and Professional Women's Clubs, Massapequa, N. Y.; Miss MERCEDES HUNST, Public Relations Consultant, International Harvester Company, Chicago, Ill. (Member-at-large); Mrs. BERNIE JACOBSEN, Safety Chairman, National Congress of Parents and Teachers, Seattle, Wash. (Observer); *Miss CATHERINE JARBO, Publications Editor, National Council of Catholic Women, Washington, D. C.; Mrs. LIONEL JARVIS, Safety Chairman, National Home Demonstration Council, Esmond, R. I.; Mrs. ERMEST A. JOHNSON, National Board Member, Young Women's Christian Association of the U. S., Lake Forest, Ill.; Miss MARY KERRIGAN, Public Relations Department, Firestone Tire and Rubber Company, Akron, Ohio (Member-at-large); Mrs. JOHN E. KUEFNER, Milwaukee, Wis. (Member-at-large, Board Representative and Conference Vice Chairman); Dr. LILLIAN LINDEMANN, Richmond, Va. (Member-at-large); *Mrs. SAMUEL S. LOWMAN, National Safety Chairman, Woman's Auxiliary to the American Medical Association, Jacksonville, Fla.; Mrs. ELDA LUEBERT, Secretary-Treasurer, A.F.L.-C.I.O. Auxiliaries, Washington, D. C.; Mrs. H. EDMUND LUNKER, President, Association of the Junior Leagues of America, Inc., Cincinnati, Ohio; Mrs. DOROTHY SIEBERT LYLE, President, American Home Economics Association, Washington, D. C.; Miss MARIE C. MCGUIRE, Commissioner, Public Housing Administration, Washington, D. C. (Member-at-large); Mrs. J. HOWARD MCKAY, National President, The American Legion Auxiliary, Indianapolis, Ind.; *Miss MARION A. MCKINSEY, American Council of Railroad Women, Chicago, Ill.; Mrs. ETHEL McLELLAN, Director of Women's Activities, Department of Transport, Toronto, Ont. (Member-at-large); Hon. GERARDINE MACELWANE, Judge, Court of Common Pleas, Lucas County, Toledo, Ohio (Member-at-large); Miss MARION E. MARTIN, Commissioner, Department of Labor and Industry, Augusta, Me. (Member-at-large); Miss JESSIE B. MATSON, Public Affairs Committee, Soroptimist Federation of the Americas, Inc., St. Paul, Minn.; Dr. ELEANOR MILNER, President, Mtrusa International, Inc., Professor of Psychology, Guilford College, N. C.; Dr. RUTH MORRIS, Vice President in Charge of Women's Activities Division, Toledo-Lucas County Safety Council, Toledo, Ohio; Mrs. CARRIE NOELLING, Kansas City, Mo. (Member-at-large); Mrs. HENRY G. NULTON, President, Reserve Officers Association Ladies Clubs of the U. S., Hillside, N. J.; Miss KATHERINE PLEDEN, President, National Federation of Business and Professional Women's Clubs, Hopkinsville, Ky.; Mrs. LOUIS L. PERLMAN, Wilmette, Ill. (Member-at-large and Board Representative); Mrs. ESTHER PETERSON, Assistant to Secretary of Labor, Director of Women's Bureau, Department of Labor, Washington, D. C.; Mrs. HENRY S. PIERSON, Des Plaines, Ill. (Member-at-large); *Miss WILDA RICHARDSON, Executive Director, Pilot Club International, Macon, Ga.; Mrs. JEAN WADE RINDAUR, Vice President, Batten, Barton, Durstine & Osborn, Inc., New York, N. Y. (Member-at-large); Mrs. CATHERINE RYAN, Women's Division, Greater Minneapolis Safety Council, Chief Operator, Northwestern Bell Telephone Company, Minneapolis, Minn.; Mrs. EVELYN NELSON RYAN, Vice President, Women's Division, The Greater Kansas City Area Safety Council, Kansas City, Mo.; Mrs. RAYMONA SAYRE, Ackworth, Iowa (Member-at-large and Vice President for Women, N.S.C., Board Member); Mrs. HAVEN SMITH, Chairman, American Farm Bureau Women's Committee, Chicago, Ill.; Mrs. SIDNEY W. STEVENS, Beverly Hills, Calif. (Member-at-large); Mrs. FRED STRAUSS,

Seguin, Texas (Member-at-large); Mrs. J. FOUNT TILMAN, President, Women's Division of Christian Service, Methodist Church Board of Missions, Lewisburg, Tenn.; Mrs. B. V. TUSE, Director, Women's Division, Automotive Safety Foundation, Washington, D. C. (Member-at-large); Mrs. FRED J. TOZZE, President, National Women's Christian Temperance Union, Evanston, Ill.; Mrs. HELEN TURNER, Assistant Director, Division of Home Economics Programs, Federal Extension Service, U. S. Department of Agriculture, Washington, D. C.; Mrs. E. ARTHUR UNDERWOOD, Vancouver, Wash. (Member-at-large and Board Representative); Mrs. BERNICE T. VAN DER VEER, Member, Chicago Transit Board, Chicago Transit Authority, Winnetka, Ill. (Member-at-large and Board Representative); Miss CAROL VAN SICKLE, Staff Editor, National Board of Fire Underwriters, New York, N. Y. (Member-at-large); *Miss HAZEL P. WILLIAMS, Executive Director, Altrusa International, Chicago, Ill.; Miss CHARLENE WILSON, Public Safety Chairman, National Association of Insurance Women, Omaha, Neb.; Mrs. ARTHUR L. ZEPF, President, National Council of Catholic Women, Washington, D. C.

*Alternates

OFFICERS OF THE YOUTH SERVICE COMMITTEE NATIONAL SAFETY COUNCIL 1961-62

Chairman—DONALD M. HUGHES, Director, Health and Safety Service, National Council, Boy Scouts of America, New Brunswick, N. J.
National 4-H Service Committee Inc.—KENNETH ANDERSON, Associate Director, National 4-H Service Committee, Inc., Chicago, Ill.
Distributive Education Clubs of America—HARRY APPELGATE, Executive Secretary, Distributive Education Clubs of America, Washington, D. C.
American Junior Red Cross—LIVINGSTON L. BLAIR, National Director, American Junior Red Cross, Washington, D. C.
National Catholic Welfare Conference—THE REVEREND JOHN J. CONNIFF, Acting Director, Youth Department, National Catholic Welfare Conference, Washington, D. C.
National Farmers Union—DR. JOHN M. EKLUND, Director of Education, National Farmers Union, Denver, Colo.
National Jewish Welfare Board—MIRIAM EPHRAIM, Program Director, Jewish Community Center Division, National Jewish Welfare Board, New York, N. Y.
Girls Clubs of America, Inc.—SONDRA GORNEY, Director, Public Relations, Girls Clubs of America, Inc., New York, N. Y.
Future Farmers of America—WILLIAM PAUL GRAY, National Executive Secretary, Future Farmers of America, U. S. Office of Education, Department of Health, Education, and Welfare, Washington, D. C.
Boy Scouts of America—DONALD M. HUGHES, Director, Health and Safety Service, National Council, Boy Scouts of America, New Brunswick, N. J.
National Grange Youth—WES JUSTI, Director of Youth Activities, National Grange Youth, Washington, D. C.
Nationwide Insurance Company—FRANK E. LADERER, Director of Safety, Nationwide Insurance Company, Columbus, Ohio.
Cooperative Extension Service—DR. MARY FRANCES LYLE, State Home Demonstration Leader, Cooperative Extension Service, Agricultural College, South Dakota State College, Brookings, S. D.
Boys' Clubs of America—ALEX A. MALESKI, Assistant Director, Boys' Clubs of America, New York, N. Y.
Automotive Safety Foundation—JOHN L. MARKS, Director, Rural and Education Division, Automotive Safety Foundation, Washington, D. C.
Kiwanis International—J. FRANK MCCABE, Director, Key Clubs, Kiwanis International, Chicago, Ill.
National Council of the Young Men's Christian Association—SANFORD M. REECE, Secretary for Work with High School Youth, National Council of the Young Men's Christian Association, New York, N. Y.

Future Homemakers of America—MILDRED REEL, Assistant National Adviser, Future Homemakers of America, U. S. Office of Education, Department of Health, Education, and Welfare, Washington, D. C.

American Farm Bureau Federation—CLAUDE DE ST. PAER, Program Assistant, American Farm Bureau Federation, Chicago, Ill.

Camp Fire Girls, Inc.—ELIZABETH STROM, Assistant Director of Camping, Camp Fire Girls, Inc., New York, N. Y.

Junior Achievement, Inc.—HUGH B. SWEENEY, JR., Program Director, Junior Achievement, Inc., New York, N. Y.

National Student Nurses' Association, Inc.—FRANCES TOMPKINS, Executive Secretary, National Student Nurses' Association, Inc., New York, N. Y.

Science Clubs of America—LESLIE V. WATKINS, Executive Secretary, Science Clubs of America, Washington, D. C.

Girl Scouts of the USA—MARY WEEKS, Health and Safety Adviser, Girl Scouts of the USA, New York, N. Y.

United Christian Youth Movement—JOHN S. WOOD, Associate Executive Secretary, United Christian Youth Movement, New York, N. Y.

Young Women's Christian Association—SARA-ALYCE P. WRIGHT, Consultant, Teenage Programs, Young Women's Christian Association, New York, N. Y.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

**See the Latest in Safety Equipment
At the Greatly Expanded Congress Exhibit Hall**

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

COAL MINING INDUSTRY

SAFETY ASPECTS IN THE MODERNIZATION OF A COAL MINE

By T. K. DALE
Safety Director
Alabama By-Products Corporation
Birmingham, Alabama

Southern Electric Generating Company Mine, No. 1, is opened in the Mary Lee seam of the Warrior Coal Field, near the town of Parrish which is located about 35 miles west of Birmingham. It was constructed and is operated by the Alabama By-Products Corporation on a management fee basis.

Access to the coal seam is gained by two vertical shafts and one slope. One of the shafts is used for return air and the other is used for an intake.

An automatic elevator is installed in the intake shaft for transporting personnel and small supplies. The slope serves as an additional intake and a second escapeway to the surface. It is also equipped with a supply track and a belt which hauls the coal from the slope bottom to the surface.

The coal seam averages 55 inches in thickness, which includes 6 inches of rock near the bottom of the seam. It is essentially flat, however, local grades up to 10 per cent have been encountered. Generally the top is shale of good structure. However, it does vary considerably throughout the mine.

Coal production was started in September, 1959 and reached the contract tonnage rate of 1,500,000 tons of washed coal per year in December, 1960. All of the coal is consumed at the Electric Utility Plant at Wilsonville.

Production is from conventional type, off-track equipment and haulage is by means of conveyor belts.

In designing and developing this mine the aim was to make it the safest and most efficient mine possible. Safety in the selection of equipment and mining plans was given primary consideration to protect the health and lives of the employees. Equal

consideration was given toward selecting and training of personnel.

Production was commenced by using a nucleus of trained men from a previously closed Alabama By-Products' mine. Then a personnel department was set up to interview and obtain a biographical record of all prospective employees. Later the background of the applicant was investigated with emphasis being placed on past work experience and his ability to get along with other people.

To further assist in selecting employees, especially the young inexperienced men, mental ability and manual dexterity tests were given. Failure of any of these tests did not necessarily eliminate a man from consideration as there are jobs which do not require these qualifications.

Each man has to pass a rigid physical examination which includes a back and chest X-ray. We feel that these examinations are essential in building a sound safety program because "physical fitness" is one of the great factors we have in eliminating accidents.

The safety department initiates the training program for all new employees. We firmly believe that getting the men started off on "the right foot" is very influential in developing a safe workman for the future. After briefing by the safety department the new man is transferred to the operating department as a trainee. There he is given on-the-job training until, in the opinion of the supervisor, he can safely handle the job he is performing.

Other educational programs include accident prevention courses, first-aid and mine rescue training. There is also a program set up to train competent young men for future supervisors and to upgrade our present foremen. Group safety meetings are

also held with all employees at regular intervals.

Two full time safety inspectors are employed. Their duties consist of coordinating all phases of safety, including inspections, educational and other related subjects.

Mine facilities for the department include a large training room equipped with chairs, tables, blackboard and other accessories needed to conduct various safety courses.

Large quantities of methane gas are released from the mine which requires positive ventilation at the working faces at all times. For this reason the main entry system is used, consisting of six intakes in the center and five returns on each side. They are driven in separate sets with a solid barrier of coal left between the adjacent sets to reduce the number of stoppings.

Permanent stoppings are built out of 6"x8"x16" solid concrete blocks. At temporary locations they are constructed of wood and are covered with a layer of plastic cloth.

Each production section is provided with a separate split of air and a minimum requirement of 15,000 c.f.m. is maintained in the last open cross-cut.

Overcasts, constructed of steel and concrete slabs, are provided at permanent locations. At temporary locations they are built of pre-fabricated metal and are recovered.

Air is induced by two modern fans, one of which is standby. Each fan has a capacity of 500,000 c.f.m. at a 3.1 inch water gauge. The operating fan is powered with an electric motor and the standby is driven with a diesel engine of equal capacity.

These fans are provided with controls which will automatically start the standby unit if the operating fan fails for any reason.

Air is conducted to the immediate face areas by means of curtains which are nailed to a 2"x2" wood strip supported from the roof.

In general the mine is dry and rock dust has to be applied. High pressure rock dust machines, equipped with 300 feet of hose, are provided for this purpose. About twelve pounds of rock dust is used for each ton of coal that is mined.

Water, for allaying dust, is used on all cutting, loading and roof drilling operations.

The source of the water supply is from a nearby creek. Two pumps, one a standby, discharge into a three and one-half million gallon reservoir located on top of a hill near the mine. A high water level is maintained at the reservoir at all times.

Water flows by gravity through a pipe line from the reservoir into the mine. Pipes extend along the main entries and are provided with fire plugs every 250 feet. A supply of fire hose, equipped with fittings and nozzles, is located at each belt drive.

All producing sections are provided with two, 20-lb. dry chemical fire extinguishers, a supply of rock dust, self-rescuers for each man and two all-service gas masks. There is also 500 pounds of dry chemical powder stored in metal containers to be used in connection with the rock dust machine for fire fighting purposes.

In addition, all electrical installations, pumps, portable welding machines, belt drives and material locomotives are equipped with fire extinguishers.

The surface facilities are constructed of incombustible material. However, for additional protection, fire hydrants, with sufficient hoses and nozzles, are provided at strategic locations. Chemical fire extinguishers are placed at suitable locations in the buildings.

Fire drills are conducted at regular intervals and two mine rescue teams are trained to assist in emergencies.

To insure that fire fighting equipment is in readiness at all times three inspections are made each month. One is made by the mine superintendent, one by the safety department and one by an outside agency.

Segco Mine No. 1 is the first large mine in the state of Alabama to employ AC current for face equipment and as the primary mine-power system. The decision of AC over DC resulted from a series of studies and field examinations made by officials of the power company and was concurred in by management of Alabama By-Products.

The main power supply is from the utility company at 44,000 volts, and 440 volts, alternating current, is used to operate all electrical equipment on the surface and underground, except the DC trolley system which is used to transport men and supplies. The primary current for underground use is 4160 volts and all transformers are dry type, delta

wire connected with a resistance grounded neutral.

One of the safety features incorporated in the underground power system is a very unique cable monitoring scheme for tripping an automatic circuit recloser in the event any apparatus in the secondary circuit should become ungrounded. The cable is equipped with pilot wires which are continuously monitored. Any time these pilot wires are disconnected the substation circuit breaker will open. The cable connectors are so designed that these pilot pins will disconnect before the phase plugs, thereby preventing the plugs from being disconnected with power on.

Additional safety is provided by using a key "interlock system" at high voltage switches. The key is removable only after the switch has been locked out.

Power cables, with fire resistant covering, are hung on copper coated messenger wires suspended from the roof. They are hung in 50 foot sections and are equipped with high voltage connectors which are "pad locked" to prevent separation from strain or tampering.

Function boxes are provided at points along the main entries where it is necessary for a power take-off to be made at secondary entries, belt drives, and pumps.

Other electrical equipment includes a portable switch house for sectionalization purposes, a 300 KVA transformer for reducing the primary voltage (4160) to operational voltage (440) and safety circuit centers for operating equipment. They are provided with overload and ground fault protection.

A systematic method of roof support was adopted. Coal is mined under roof bolts installed in full compliance with the U. S. Bureau of Mines approved plans.

Roof bolts, of the expansion shell type, are installed with a hydraulically operated rotary type roof bolt machine. They are installed on five foot centers and as close as possible to the face.

Safety jacks are set temporarily in the working faces until the bolts are installed.

Along beltways and in all permanent airways it has been found advisable to bolt a treated wood header 2"x8"x24" for additional support. This type of support prevents spalling around the individual bolt.

Generally it has been possible to support

the roof almost entirely with bolts. However, where faults, slips and other unconsolidated materials are found wood and steel timbering has to be done.

Coal is transported by means of cable-reel shuttle cars and belt conveyors.

Shuttle cars are kept in a safe operating condition by careful and regular maintenance. Additional safety is provided by keeping haulage roads free of obstruction and providing adequate side clearance.

Belts are constructed of fire resistant material as approved by the U.S. Bureau of Mines. When installed they are leveled and aligned in such a manner that good tracking is obtained to prevent edge-wear and spillage.

To prevent slippage belt drives are provided with pneumatic or hydraulic "take ups" to insure that uniform tension is maintained when the belt is operating.

Electrical controls are provided to start and stop the conveyor anywhere along its entirety. The control wires are installed directly over the belt and are provided with switches that are easily accessible to personnel riding or maintaining the belt.

Permanent belt drives and electrical controls are housed in a well lighted, fire-proof room and all electrical wiring is installed in conduit.

All employees are encouraged to take first aid training at least once each year. At the present time about 50 per cent of our employees have been trained. Although this training has not been as successful as we had hoped, we do feel that enough men have been trained to effectively take care of an injury when it occurs.

Two well-trained mine rescue teams are kept in readiness at all times. Men for these teams are selected from all shifts, surface and underground. This distribution is made to prevent having "all our eggs in one basket" should an emergency arise. The latest type of rescue equipment is provided, which includes the full face mask, communication system and other related accessories.

Safety in handling and storing of material is given primary consideration. Old coal cars, with the sides cut out, are provided for hauling such materials as concrete blocks, roof bolts, timbers, oil and rock dust. One of the safety features incorporated in

this type of car is that it minimizes the lifting hazard. Also, one other factor to take into consideration is that adequate cars are provided to allow the vendor to unload supplies directly into the car, thus minimizing handling.

One unique safety feature incorporated in material storage is the manner in which oil barrels are handled. Racks built similar to those in which baby food is dispensed in food stores are provided. You simply have to pull a lever and a barrel will roll directly into the material car.

The production plant is one of the most modern in the South and is designed to utilize high speed washing facilities with a maximum degree of safety.

Good housekeeping is practiced at all times. Such practices include cleanliness, orderly storage of materials and the removal of tumbling hazards.

Stairways, elevated platforms, floor openings and runways are equipped with hand rails and toe-boards.

Railroad cars are loaded by an almost fully automated system. This system consists of a winch operated from the car loading

station, an endless rope, two dolly cars and sheave wheels mounted between the rails of the two loading tracks.

The railroad engine crew simply couples a train of cars onto the dolly cars. The cars on one track are loaded while the cars on the other track are being positioned for loading. No uncoupling of individual cars is required and the setting of brakes is unnecessary.

Safety was not overlooked in the design of the repair shop. It is constructed of fire-proof materials, is adequately lighted and well ventilated. Such equipment as a shop "jeep," overhead crane and chain hoist are provided to handle heavy equipment and materials.

Storage of supplies and assemblies is maintained in an orderly manner and good housekeeping is practiced.

In conclusion I would simply like to state that it would be naive to predict what the ultimate outcome will be. We only hope that with the installation of these safety and labor-saving devices, in conjunction with a progressive safety program, we are headed in the right direction in preventing accidents.

METHODS OF USING AUXILIARY FANS FOR FACE VENTILATION WITH CONTINUOUS MINING SYSTEMS

By PAUL C. LINGO
Assistant Safety Director
Bituminous Coal Operators' Association
Washington, D. C.

About 30 years ago, when conveyor mining was widely practiced, auxiliary or booster fans became rather common in underground coal mines. During that period it was common practice to drive a single room 300 to 400 feet long utilizing a room and face conveyor. These rooms were generally driven as wide as top conditions would permit.

When the room advanced to a point where the ventilating current would not clear away the smoke and powder fumes, a small booster fan would be placed at the room entrance

and a tube extended into the room. This was done to provide enough movement of air to clear the working face. These fans were generally very small, sometimes no larger than an ordinary house fan, and as a result of their use in this manner the air returning from the face was often recirculated back through the fan and tubing to the face. The use of these fans constituted an attempt to overcome a deficient main ventilating system, rather than to dilute and render harmless explosive mixtures of air and methane.

The indiscriminate application of auxiliary fans resulted in, or contributed to a number of mine fires and explosions. The Federal report of a mine explosion and fire at a mine in Kentucky, in which 25 persons were killed, lists a blower fan motor as a likely source of the ignition. The report goes on to show that the blower fan was positioned so that a large portion of the air at the face was recirculated. As a result of this and other similar incidents, the use of auxiliary or booster fans was placed under severe restrictions by State and Federal authorities.

The Federal Mine Safety Code, which became effective July 24, 1946, vested in the Director of the Bureau of Mines the authority to approve the use of auxiliary fans under certain conditions specified in the Code. These conditions were very stringent and tended to discourage their use.

As continuous mining developed and was applied in more gassy coal beds and more deeply in virgin blocks of coal, conventional jute line brattice in many cases proved inadequate. Plastic and other more impermeable brattice materials in some cases were satisfactory, but more positive ventilation methods were sought. Auxiliary fans long in disrepute, and barred by the Federal Mine Safety Code from coal mines (except by special permit) appeared to offer a possible solution.

With the passage of the Federal Coal Mine Safety Act, the Code was accordingly revised as of October 8, 1953. The revised Code omitted many of the previous conditions under which auxiliary fans could be used, but made it mandatory for mine operators bound by the National Bituminous Coal Wage Agreement to obtain a permit from the Joint Industry Safety Committee. Under this plan all requests for permission are submitted to the Joint Industry Safety Committee, which in turn refers the request to the Director of the Bureau of Mines. Following an inspection of the mine and a study of the proposed plan for use of the auxiliary ventilating system and equipment by Federal inspectors, the Bureau develops rules and standards covering the particular installation and refers them back to the Committee for approval or disapproval.

This system remained in effect without modification until April, 1957, when the Joint Safety Committee granted permission to the

Bureau of Mines to conduct experiments with auxiliary fans and tubing without individual permits from the Committee. However, it was stipulated in granting this permission that the Committee be notified of the name and location of each mine in which experiments are to be conducted, and periodic reports are to be made on the progress of these experiments. At the conclusion of the experiments, if the mine operator wishes to continue to use the auxiliary fans, a permit must be obtained from the Committee. Under this arrangement the permit can usually be granted more expeditiously, since the Committee has at its disposal the progress reports on the experiments.

Since 1953 the Committee has granted 35 permits for use of blower fans with continuous mining systems. The geographic distribution of these permits is as follows:

- 10 in Pennsylvania
- 9 in Illinois
- 4 each in West Virginia and Kentucky
- 2 each in Ohio and Colorado
- 1 each in Utah, Indiana, Washington, and Alaska

The requirements for auxiliary fan installations are now fairly well standardized, but specific variations may be required in any given case. Requirements of state mining laws must be given consideration; these laws are presently in wide variance.

The primary function of the ventilating current in the face regions is to supply fresh air to the workers and to remove any methane released from the coal or the enclosing rock strata. Additional objectives are maintenance of good working temperatures and the removal of dust and mist.

In continuous mining systems, the mining face is advanced at a steady rate. There is no chance for the released methane to bleed off as there is between the cycles of conventional mining. This is particularly true of borer-type mining machines since they virtually fill the working place and block or retard the flow of air to and across the face. The production crew on a continuous mining machine must work for extensive periods of time in one place. If methane is encountered a comparatively steady flow is to be expected, and it must be met with sufficient air flow to remove the gas quickly. Methane is prone to accumulate, particularly

in the face corners, and to stratify near the roof. Stratification is likely to occur throughout the length of the working place, rather than just in the face region.

There have been numerous occasions where gas was detected outby the operator's position at the mining machine. To prevent the accumulation of methane anywhere in the working place the entire space must be swept continuously by controlled air currents. In extremely gassy conditions methane is given off so rapidly that the moving parts of the machine do not allow it to accumulate or stratify. Instead it is found in varying amounts in different parts of the face area. In these circumstances a small fan mounted in a strategic location on the machine diffuses the methane and prevents it from accumulating before it is removed by the auxiliary fans.

The safety aspects of maintaining a safe atmosphere in any coal mine are well known to everyone in this audience. There have been instances of fires and explosions caused by the ignition of gas in the working face, both with conventional and continuous miners. The elimination of these ignitions is the prime concern of those persons who have worked so diligently to improve face ventilation. While safety remains the most important consideration it should be remembered that productivity is a factor too. There are numerous instances on record in which inadequacy of ventilation has made it necessary to stop work until a safe atmosphere could be restored. In some instances this delay is reported to have become 50 per cent of the available production time. In some mines the use of continuous mining machines has been alternated between places, letting one place stand idle for gas clearance while the other is being mined. The time consumed in moving the machine is lost from its productive time.

Soon after the introduction of continuous miners it was found that unassisted coursing of air into a panel in a gassy coal bed was inadequate for effective methane removal. The first approach to the face ventilation problem was the use of line brattice. One company using a borer-type miner ran some rather extensive tests to determine the effectiveness of line brattice installations. It was found that with the line brattice erected on the intake side on which 80,000 c.f.m.

of air was delivered to the mouth of the working place, that only 4,000 c.f.m. at a velocity of 500 ft./min. reached the end of the curtain. On this setup the shuttle car did not pass through the cloth and a tight curtain, made of No. 10 brattice cloth, was maintained. Even so, 95 per cent of the available air was lost before it reached the face area.

In driving multiple entries with a double split ventilation system, which is almost always used in gaseous mines, this situation is rarely encountered. Instead, when the line brattice is installed on the intake side, it is usually necessary for the shuttle cars to pass through the curtain. With shuttle haulage through the curtain at the crosscut, air leakage was so great that it was very difficult to maintain a safe atmosphere at the face.

In order to eliminate haulage through the line brattice, an installation was made with the brattice on the return side. In this setup the line brattice could not be extended beyond the back end of the miner due to the close clearance around the machine. This left the end of the brattice some 20 feet from the face. With the area behind the line brattice restricted, a large volume of air could not be forced to the face area. It was found the velocities along the line brattice were much greater than along the far rib.

Another step taken to improve face ventilation, using line brattice, was the installation of a door in the shuttle car haulway. This method too was ineffective when large methane liberations were encountered.

In addition to the above-mentioned deficiencies, it was found that objectionable amounts of fine coal dust hung in suspension or settled out in the face area. Experience in continuous mining of coal has shown that face ventilation and dust control are interrelated problems. Either may become critical in a given situation.

The results of these experiments with line brattice and the experience of similar applications by other coal companies led several of the more progressive and safety-minded companies to start experimenting with auxiliary fans. These experiments were conducted under a permit issued by the Joint Industry Safety Committee or in conjunction with the Bureau of Mines under the permission granted by the Committee in April 1957.

The first permit issued by the Joint Industry Safety Committee for use of an auxiliary fan with tubing in connection with a continuous mining system was granted to a mine in Illinois in 1953. The permit was granted for a period of one year and a renewal was not sought by the company when it expired. The oldest active permit was issued to a mine in Western Pennsylvania on April 13, 1954. The mine operates in the Pittsburgh coal bed, which averages 90 inches in thickness in the active workings. It produces about 3,000 tons of coal a day, all mined by ripper-type continuous miners.

The exhaust fan is placed in the last crosscut and a 2-foot diameter tubing is extended from it to approximately 15 feet from the face. A check made from plastic or double layers of jute brattice cloth is built around the fan so that the motor drive is on the intake side of the check, but the fan discharge is on the return side. A by-pass for the air in the ventilating circuit in excess of the amount that the fan takes is constructed by having an opening in the check at the fan. A piece of plastic brattice cloth with a suitable weight fastened to the bottom is hung from the top side of the check in such a way that the opening is completely covered.

When a greater quantity of air is flowing in the section than the fan uses, the excess air blows the by-pass open and goes directly into the return. If the quantity of air circulating in the section is less than the fan uses, the pressure in the return side of the check will become greater than on the intake side, then the by-pass will be blown shut and prevent any recirculation of air back through the working place.

In an attempt to alleviate the hazard from float coal dust being deposited in the return of air courses, a hopper for discharging rock dust into the fan discharge stream has been mounted on the fan housing. This has proven to be fairly successful, but the rock dust is fed solely by the vibration of the fan housing and some difficulty in maintaining a steady flow of rock dust has been encountered. In order to overcome this difficulty, the company has ordered two coaxial motor fans which will be equipped with a rock-dust hopper from which rock dust will be automatically and continuously fed into the fan discharge stream by a star feeder.

Another system is now employed by a mine in northern West Virginia in conjunction with borer-type miners. This mine operates in the Pittsburgh coal bed and at times extremely heavy liberations of methane are encountered. A small 12-inch electrically driven fan with a free flow capacity of 2,500 c.f.m. is mounted on the miner and forces air through 12-inch tubing with a velocity of about 3,000 feet per minute. This blast of air is sufficient to provide air flow in the far corner and force it into a larger volume circulated by the exhaust fan. In order to prevent recirculation, the end of the exhaust tubing is maintained in by the blower fan inlet at all times. The 16-inch diameter exhaust tubing must be kept close to the face to be effective, and without the aid of a blower does not provide adequate ventilation in highly gassy faces.

It has been found that when extremely heavy liberations are encountered the installation of two fans and two sets of tubing are necessary. In such a case one tubing line is extended to the immediate face while the extreme end of the second is located within the area between the miner and pick-up loader, where stratification of methane occurs when the single exhaust fan is used beyond its ventilating capacity. When such extreme methane liberations are encountered, aid can be given to the double fan setup by erecting a short wing brattice in the crosscut to facilitate splitting the air current within the working place instead of at the intersection. Part of the working place is then ventilated by the extra air forced in by the short line brattice.

Another system worthy of mention is one used by a mine in Central Pennsylvania. This mine operates in the Lower Kittanning coal bed, which averages 42 inches in the present workings. The mine is classed as gassy by the State and Bureau of Mines, and at times fairly heavy methane liberations are encountered.

In coal 42 inches in height, tubing as used in the two previous methods would be quite cumbersome to install, and with a borer-type miner almost impossible to maintain near the face.

These difficulties were overcome by installing a network of sheet metal air ducts on the miner along with a dual intake fan. The fan, a centrifugal blower-type capable of various capacities depending on the mo-

tive force, is driven by an explosion-tested 2 h.p., 250-volt d.c. motor. At the present time the fan operates at 3,400 r.p.m., and the air output at the face is about 900 c.f.m. The fan is mounted on the rear bumper of the miner and connected to a system of rigid ducts that convey air to the face. The arrangement of ducts permits drawing fresh air from either side of the miner and also directing it to either side of the machine at the face.

It should be emphasized that with this system the line brattice is kept to within 4 feet of the fan. This diffuser system acts as a supplement to, and not in place of the line brattice. If the fan should fail or stop, the primary source of ventilation is still in effect.

A mine in Illinois employs a system utilizing a blowing fan and tubing. This mine operates in the No. 6 coal bed which averages 86 inches in thickness in the present areas being mined.

Due to top conditions which are peculiar to this coal bed, permission has been given to drive crosscuts at 300-foot intervals. Two adjacent entries are developed simultaneously, employing continuous miners, extensible belts and/or shuttle cars. Entries are developed by a single cut by the miners, with crosscut intervals a maximum distance of 300 feet. Positive face ventilation is accomplished by the use of 12-inch permissible blower fans equipped with fire-resistant "spiral-tube," suspended from the roof. The fans are placed on the intake side of the place, or in the last open crosscut, and operate blowing. The effectiveness of the system is evidenced by a special report made by the Mine Ventilation Section, Branch of Health Research, Bureau of Mines, which states in part:

"These auxiliary blower installations, used to ventilate Goodman continuous miners, were providing good face ventilation. The tubing was advanced promptly and was properly installed and maintained. Equivalent face ventilation by means of line brattice without auxiliary blowers would be very difficult to obtain."

The final system to be discussed is one

used in a mine in Utah. This mine operates in the Lower Sunnyside coal bed which varies from 8 to 16 feet in thickness and dips in an easterly direction from 12° to 26°. Coal is mined by six continuous miners of various types.

The system itself is not unique. The fan operates exhausting and tubing kept up to the miner. The thing that makes this installation of interest is that the mine is classed nongassy by the State of Utah, and the auxiliary fan is utilized for the express purpose of improving health and safety standards for employees operating the continuous miners. In granting this permit the Joint Industry Safety Committee imposed the same strict conditions that are required by operating auxiliary fans in gassy mines.

The results obtained from experiments and the application of auxiliary fans used with continuous miners under actual mining conditions have emphasized several points:

1. Line brattice systems of ventilation are inefficient and very often fail to meet all the requirements of proper face ventilation.
2. Auxiliary fans and tubing, properly used, offer a much more positive, efficient and reliable method of face ventilation.
3. Coal companies, signatory to the National Bituminous Coal Wage Agreement, who want to incorporate auxiliary fans and tubing in their mining systems, must obtain a permit from the Joint Industry Safety Committee or request the Bureau of Mines to conduct experiments under the special permit granted it by the Committee.
4. The Joint Industry Safety Committee has shown an alertness to the potential hazard of misuse of auxiliary fans. It has also demonstrated an understanding of the operating problems involved in effecting proper face ventilation with continuous mining systems.

The writer would like to express his appreciation to the several coal companies whose face ventilation systems were reviewed, the Joint Industry Safety Committee and the Federal Bureau of Mines for their cooperation in supplying the information that made this paper possible.

CONTROL OR EXTINGUISHMENT OF GOB FIRES

By PAUL M. BUDZAK
Safety Dir., Freeman Coal Mining Corp., West Frankfort, Ill.
and

GEORGE R. EADIE
Assoc. Prof., Mining Engineering, University of Illinois

The Orient #3 mine of the Freeman Coal Mining Corp., located about one and a half miles southwest of Waltonville, in Jefferson Co., Ill., has, during the past year and a half, experienced several instances of spontaneous heating. This mine is working in the Illinois #6 seam which in this area has a cover of approximately 800 feet and a thickness of from seven to twelve feet. The mine is ventilated by an exhaust system with bleeder entries.

All of the production since the mine opened in 1951 has been from continuous mining machines with shuttle cars and belts for haulage. The mine was designed to produce 7,000 tons of coal on each of two shifts but has surpassed this production with a record of 15,458 tons of prepared coal representing about 17,000 tons of run-of-mine.

History

During the period from 1951 to 1956 there were no records of heating conditions in the mine. Although there have been no major changes in mining procedure since that time, there have been several cases of spontaneous heating. These "hot spots" have occurred in areas where the gob has been less than two years old.

From May 1956 until October 1961, the Orient #3 mine has experienced eight separate instances of spontaneous heating in gob areas. Since fire has been defined as "the evolution of heat and light by combustion," it should be pointed out that these have not been gob fires, in the true sense of the word, since flame has not been present.

The first indication of spontaneous heating occurs when a haze or fog-like atmosphere is noted in the return airways. The second indication is the presence of beads of condensed moisture on the roof near the g.b. The third indication is the presence of an odor of heated bituminous material and the fourth is a measurable content of carbon monoxide.

In one area where heating was discovered in July of 1960, there was a small synclinal area about fifteen feet in depth for a distance of approximately one thousand feet. Since the heat and carbon monoxide being generated seemed to be coming from near the bottom of the basin, a three inch water line was laid and water was discharged into this low area until approximately eight acres was flooded. At this point the heat and carbon monoxide could no longer be detected. Because of the natural conditions, control of this area was relatively simple.

In each instance the exact location of the point where heat and carbon monoxide were being generated could not be ascertained. The general consensus was that the zones were near the outer edge of the gob and were relatively close to the bleeder entries.

Seven of the areas where spontaneous heating has occurred have been controlled by sealing with masonry stoppings and flooding with carbon dioxide. These areas varied in size from 20 to 800 acres and the amount of carbon dioxide used varied from 18 to 300 tons depending essentially upon the area involved. After sealing all access openings to the gob area where spontaneous heating has been discovered, CO₂ is then introduced.

There is a three inch fresh water line from the surface which is connected to all parts of the mine. This line is drained and then purged with compressed air. The line is connected to the sealed area by use of a rubber hose. An expansion joint is provided at a point approximately fifteen hundred feet from the surface connection to the CO₂ delivery truck. This rubber expansion joint, approximately six feet long, is used to compensate for the contraction in the pipeline following introduction of the liquid carbon dioxide. The greatest distance that CO₂ has been transported through a pipe line at this mine was about three miles. A delivery truck containing nine tons of liquid CO₂ can be drained into the gob area in four hours.

The volume of gas resulting from the eighteen thousand pounds of liquid carbon dioxide would fill a six by twelve foot entry two thousand feet long. There are about eight cubic feet of CO_2 gas per pound of liquid.

With the established criteria for discovery of the spontaneous heating condition (haze, moisture, odor and carbon monoxide), the mine officials take the necessary steps to control the condition as soon as any one of the symptoms is discovered. With the primary purpose of reducing the oxygen content in the affected zone, the usual procedure is to build masonry stoppings in all access airways to the area, minimize and equalize the pressure differential by placing all of these seals on intake or return in preference to a combination of intake and return, and then flood the area with carbon dioxide.

In every instance the precautionary measures taken at the time of the discovery of the spontaneous heating condition have been successful. In February of this year, when the seventh case of heating was discovered, the Freeman management along with the state and federal bureaus and approval of the union, decided to try to discover the source of the heating. Using conventional loading machines, the gob was penetrated in various locations through cross-cuts in an attempt to ascertain the hot spot. After outlining the zone, and determining the approximate location, a cross-cut was driven through a pillar to the gob and, the suspected area probed.

It was at this point, twenty-six days after discovery of the affected area, that flame was observed. We think that we speeded the flame activity by opening the "hot spot" in introducing oxygen by increasing ventilation to this spot. As soon as the flame was seen the men were withdrawn, seals built, and carbon dioxide was used to flood the area. This is the only instance where flame has been observed in connection with the heating.

Coal Oxidation and Spontaneous Combustion Research

In order to get to the bottom of the cause of these "hot spots" we made a study of the research work that has been done on the oxidation and spontaneous heating of coal.

The mysteries of coal oxidation and spontaneous combustion have been studied over a very long period of time by many investi-

gators and current research on these subjects is continuing in many research institutions throughout the world. The results of past research have been published to a considerable extent so that several hundred papers on the subject are available to interested persons. A rather extensive review of the literature has been completed. In many cases the original publication has been consulted but, because of language difficulties and the inaccessibility of some of the articles, some information has been taken from *CHEMICAL ABSTRACTS* and is so noted in the bibliography of this paper.

As soon as a fresh coal surface is exposed to the atmosphere, oxygen will immediately begin to react on the surface of the particles. Howard¹ reports that the rates of primary reactions are a function of the rank of the coal, the surface area, temperature, oxygen partial pressure and the time that oxidation continues.

In his work to determine the rates of oxidation of Illinois, Pittsburgh and Pocahontas coals at 75°, 100° and 125°, he found that a difference of 18 to 32 per cent volatile matter showed relatively small differences in the oxidation rate. However, he points out that very little quantitative information is available on the relation between rates and surface area because of the uncertainties in measurements.

In a study of oxidation as a factor in self-ignition, Orleanakaya² observed ignition temperatures from 300-400° and concluded that initial oxidation (e.g. during mining) lowered ignition temperature. Veselovskii³ reported on his work on the surface oxidation of coal that the moisture adsorbed from the air had an accelerating effect on the oxidation process.

Adsorption of oxygen, which is fairly high above 50°, is rather small compared with chemisorption, which increases rapidly with the rise of temperature, according to Olpinski.⁴ At the same time the amount of oxygen that forms carbon dioxide and carbon monoxide increases. At 100-150° the chemisorption reaches its maximum. At low temperatures the rate of carbon dioxide formation depends on the decomposition of the surface complex rather than on the rate of formation of this complex.

Olpinski⁴ stated in 1960 that knowledge of the heat of reaction during the oxidation of bituminous coal at room temperature is of

value in connection with spontaneous heating and ignition of coal. Neither heating nor ignition can take place unless the heat of reaction exceeds the heat losses. Because of the lack of data in the pertinent literature, the heat of reaction during oxidation of bituminous coals at room temperature was experimentally determined in a twin calorimeter submerged in a constant temperature bath. The bath was maintained at a temperature of 50.4° while the heat of reaction was determined on four coals containing from 45.0 to 9.06 per cent volatiles on a moisture and ash free basis.

The results indicated the heat of reaction depends upon type and degree of coalification of the coal. High volatile coals developed more heat of reaction than semi anthracite. This observation is in agreement with the frequency of spontaneous ignition of the coal seams. Heat of reaction was higher at the beginning of an experiment and progressively decreased with time of exposure. For coal number 1 with 43 per cent volatiles the heat of reaction was 10.1 cal/g. of coal during the first five hours of the experiment while it had dropped to 0.5 cal/g. after 365 hours of exposure.

Budryk⁵ reported on his studies of the temperature of spontaneous ignition of coals as an index of the degree of oxidation. The influence of this degree of oxidation on spontaneous ignition were determined under laboratory conditions. It was found that there is a close correlation between the volatile content of coals and their ignition temperature, vitrain and durain constituents have practically identical ignition temperatures, and unoxidized coals have similar temperatures of spontaneous ignition.

However, another investigator studying Russian coals in 1956 concluded that vitrain was more easily oxidized than fusain and that the petrographic composition of coal had a definite effect on its oxidation. Mazumdar⁶ et al report that vitrains require 800-1200 hours to attain complete immunity towards further oxidation at 170° C whereas whole coals require 300-400 hours to attain the same condition. They concluded that this phenomenon may be due to the catalytic effect of the mineral matter content of the coal being studied.

The role of pyrite in spontaneous combustion of coals has been the subject of study for many investigators. In 1954 Napton⁷

published his spontaneous combustion theory in a letter to the editor of *Chemistry and Industry* stating that the rate of weathering of pyrite is a function of the surface area available for oxidation but although it appears that the spontaneous heating of finely divided pyrite may be responsible for the ignition of stored pyrite, this does not appear to be probable with most pyritic coals.

In this case the influence of pyrite is usually considered to be due to the disintegration of the coal by its expansion on weathering, and thus exposing a greater area of the coal to the action of the oxygen. In view of the fact that ferrous sulphide is a normal weathering product of pyrite, and that it is pyrophoric when finely divided (as it would be when formed by the oxidation of pyrite) the possibility that this material may be responsible for some cases of spontaneous combustion of pyrite or pyritic coal should not be overlooked.

A report by the Ruhr Coal Community Organizations, Essen, Germany, states that the rate of oxidation is a function of particle size (area phenomena), nature of particle packing, and an oxidation potential. Self-ignition is related to the rate of absorption of oxygen. Oxidation of impurities does not cause coal self-ignition, although soluble Fe salts in which Fe may change valence catalyze the reactions.

Chalupa and Drabek⁸ studied a method for the determination of the tendency of coal to self-ignition and analyzed the causes of self-ignition underground. They criticized the present method used for determining the tendency of coal to self-ignition and designed a new one, in which the relative tendency of coal to self-ignition is expressed by means of the following values:

- a) the rate constant for the oxidation of the coal substance;
- b) the amount of oxygen consumed at defined conditions;
- c) thermal losses during the oxidation process;
- d) the deficit ratio of oxygen, which means the ratio between the amount of the oxygen, and the amount of oxygen that entered the reaction.

Doomum⁹, in his publication dated 1954 made an attempt to put the evaluation of the self-heating tendencies of coal on a rigid basis for a quantitative analysis. He states

that the main external factors affecting the rate of heat generation in a particular coal of specific chemical and physical characteristics are: 1) temperature, 2) elapsed time, and 3) oxygen concentration. Since he was working with coal storage problems, one of the important determinations was the bulk density as well as values for specific heat and thermal conductivity.

Chalupa, Drabek and Doornum have probably made two of the better attempts to arrive at a method of evaluation for the self-ignition of coal. While many researchers are content with an evaluation on a relative basis (coal A is more liable to spontaneous heating than coal B) these men have tried to put their findings into a formula for a quantitative analysis. Of course this method of determination is subject to considerable criticism in the case of field determinations, because of the lack of knowledge in the area where the hot spots are occurring in Orient #3 mine.

The chemical factors of the coal involved would probably not be too much different in the place where the heating is going on and the place from which a sample can be obtained. However the physical factors are the ones about which practically nothing is known. Three of the more important items which must be known are size of coal particles, temperature, and oxygen concentration. Since each of the hot spots in Orient #3 have occurred in gob areas, it would be strictly a guess in arriving at values for these three items.

Elder, in 1945, published a list of variables used to determine the rate and extent of the reaction of coal with oxygen: 1) nature of the coal, 2) temperatures, 3) past history (when mined, etc.), 4) availability of oxygen, which is a function of oxygen concentration in the atmosphere present, 5) particle size, which determines effective surface area, and 6) moisture and ash content.

With this information available he established equations for the per cent oxygen consumed, therefore he could derive "R" which he calls the rate of reaction in per cent oxygen consumed per day by weight of dry mineral matter free coal. The surface area of the coal he found by empirical equation developed from Needham and Hall which is that the rate of heating is proportional to the cube root of the surface area present. He found that the ash seemed to diminish

the tendency to heat and that the rate of oxidation was proportional to the oxygen concentration in contact with the coal raised to the 0.66 power.

Berkowitz and Schein¹ studied the heats of wetting and the spontaneous combustion of coal in prolonged storage and state that the heat release resulting from the oxidation of coal will be determined by the end products of the reaction and not by the stages via which these are formed. Thus, if carbon dioxide is formed, the heat release is 94,400 cal/gm atom of carbon, and if carbon monoxide is formed, it will be 26,800 cal/gm atom. These may be significant values when considering the volume of carbon monoxide present in Orient #3 Mine.

In a review of the literature on the oxidation of coal made by Yohe,² he points out that Jones and Townsend report that below 70-80 degrees carbon monoxide is the main gaseous product of oxidation, whereas above this temperature carbon dioxide and water are formed in much greater proportion than carbon monoxide.

In regard to bacterial action as a possibility in bringing about spontaneous ignition in coals, Yohe reports that Zavarzina³ concluded from his experiments that spontaneous heating and ignition in coal piles are chemical chain processes, not bacterial processes.

Yohe also reports that in investigations made by Terposova,⁴ petroleum products, their emulsions, soaps, fatty acids, calcium hydroxide, and "other substances" were studied for the inhibiting action on coal oxidation. All petroleum products and their emulsions protected coal from oxidation, but the other substances mentioned were "less effective."

In 1928 Davis⁵ listed the factors known or thought to affect self-heating of coal and classified them as chemical or physical.

Chemical

1. Pyrite finely-divided is a factor
2. Rank of coal-constitution of coal. High water content increases ease of ignition. According to Winnill (1916) a high content of natural moisture is a poor (but used) indication of the oxygen absorbing capacity of coal, and complete removal of the water markedly reduces oxidation rate.

3. Weathering
4. Water
5. Organic Sulphur
6. Alkali, calcium chloride, sodium bicarbonate
7. Ozone
8. Bacteria

Physical

1. Size
2. Water
3. Oxygen supply
4. Temperature
5. Occluded gases
6. Ventilation and conductivity.

Winnill has shown that the rate of oxidation varies as the square root of the oxygen percentage of oxidizing atmosphere.

Spontaneous combustion is the result of a progressive oxidation under specific conditions but according to leading coal chemists it is impossible at the present time to chemically analyze coals and determine the extent of the oxidation process. It would not be possible therefore, to take samples from areas in the #3 mine where spontaneous ignition could possibly occur and by chemical analysis anticipate the occurrence of a hot spot.

Although large quantities of fusain have been found in the Orient #3 mine, the coal petrographers have considerable doubt that the petrographic constituents are instrumental in the heating tendencies of this coal.

U. S. Bureau of Mines Cooperation

Because it seemed that the chemical composition of the Orient #3 coal may be important in determining the cause of the hot spots, the Pittsburgh Coal Research Center of the U. S. Bureau of Mines was asked to cooperate in the study. Samples of coal from carefully selected points in the mine were sent to Pittsburgh for analysis. Dr. Arthur A. Orning, supervisory technologist (fuels), agreed to run relative ignitability tests as well as proximate analysis and BTU's on the samples submitted.

Six two-hundred-pound samples and three fifteen-pound samples were collected in June 1961 according to the following plan. The first sample was collected near a "wan" area where a fire was suspected but flame was never seen. The purpose of this sample was to see if it showed any signs of being dif-

ferent from other samples which could be related to its position of being near a geological disturbance. Following the channel sampling method, a large and small sample, representative of the mining height of the seam, was collected.

The second sample was collected from the floor in an active working section. This material was intended to be representative of the type of loose coal which is being left in an abandoned section after mining. The sample was noticeably wet as a result of the sprays on the miner.

The third sample was intended to be representative of the one area in the mine where a fire was actually seen in order to try to determine if it was significantly different from the other samples. A large and small sample, both representative of the mining height of the seam were taken within 350 feet of the known fire.

The fourth sample was taken in an area which had no known geological disturbance and which had experienced no hot spots. It was a sample intended to be representative of those portions of the mine which have caused no difficulties in mining.

The fifth sample was taken in an area which is known to contain a large amount of exceptionally thick coal. In the particular location where the sample was taken, the roof coal, above the mining height, was about three feet thick. This coal was representative of that which would be present in large quantities following caving. This could be the coal which has an opportunity to experience a temperature rise as a result of the caving action, therefore it was desirable to see if the sample showed any significant differences from the other samples.

The sixth sample, like the third, was taken as close to a hot spot condition as possible.

Relative ignitability tests were run on the Orient #3 samples and the results were compared with Pittsburgh seam coal and Wyoming sub-bituminous coal. The critical point in the tests conducted by Dr. Orning was defined as "that temperature at which a measurable self-heating takes place."

Dr. Orning reported that the oversized material was crushed to pass a one-inch square screen opening and sized to plus

one-half inch, one-half inch by one-quarter inch, and minus one-quarter inch. A fifty-pound sample was externally heated with one cubic foot of air per minute with a heater temperature rise of two to three degrees Fahrenheit per minute. The self-heating point was detected by a change in the form of thermal wave from the cylindrical heating surface into the sample.

A copious evolution of carbon monoxide occurred at the self-heating point for each sample. The amount of carbon monoxide being generated exceeded the scale of the MSA colorimetric tester. The self-heating point in degrees Fahrenheit for each sample was as follows: 1) 401, 2) 304, 3) 395, 4) 396, 5) 415, 6) 391. A similar point for the Pittsburgh coal is 472° F., and for the Wyoming coal is 327° F.

Analysis of Relative Ignitability Tests

As a result of the data collected by the Bureau of Mines about the only factual statement which can be made is that the Orient #3 coal is more likely to ignite spontaneously than the Wyoming coal tested.

Further interpretation of the test results may be risky, but would seem that one or two other conclusions may be drawn. For instance, although the samples were carefully selected from areas which would contrast, the range of self-heating temperatures was only 21° F., from 391 to 415. This would seem to indicate that there is practically no difference in the relative ignitability of the six samples of Orient #3 coal tested.

Equally important is the finding that large amounts of carbon monoxide are released before the self-heating temperatures. This fact may explain why the inspection method at Orient #3 has been so effective in finding the hot spots. Some people have suggested that the reason carbon monoxide can be detected is because it is present as a product of active combustion, or burning fire, whereas the data from tests indicate that the carbon monoxide is a result of oxidation which will cause it to be produced in large quantities before any sign of active combustion occurs.

One conclusion, which seems obvious from the test data, is that there are practically no discernible chemical differences in the samples submitted and that therefore one

or more of the physical factors involved are probably more important in the determination of the reasons for the hot spots.

Other Factors in Spontaneous Heating in Orient #3 Mine

In addition to the chemical and geological similarities which may occur in Orient #3 Mine and have a bearing on the reasons for the occurrences of the hot spots, there are several physical factors to be considered. One which would seem to be of utmost importance is the time element. On the basis of available information it seems that the time elapsed between the mining of the coal and the discovery of a hot spot in the same area has varied from about 13 months to 29 months with two years as the apparent optimum period.

Hearsay evidence, rumors and vague memories combined with a few known facts have caused some to believe that sources of ignition have been present in the hot spot areas other than just the coal itself. It is known that machines must be repaired and in the process of doing this work oil must be cleaned from the parts, usually with a rag or waste. Lubricating oil is stored in various locations underground and drippings may accumulate. Poor connections or a leaky hose can cause considerable loss of hydraulic fluid which may accumulate in quantity in some particular areas of the section.

Because management is insistent upon good housekeeping and "clean" sections, we know that sorts of scrap materials are discarded in the gob or "hidden" in back entries or abandoned rooms. Worn-out brattice cloth, wood, paper and even oily rags are sometimes discarded in this fashion. Granted that Orient #3 mine would probably not be an exception to this long practice in coal mining, and that many of the items so discarded could be instrumental as the source of the beginning of a hot spot, the fact remains that in spite of this general practice in coal mining, Orient #3 experiences hot spots and most of the others do not. These discarded materials may, in some cases, be a contributing factor, they do not make up the principle cause.

Other events and conditions which were investigated for a correlation among the hot spots were: time of year of occurrence, but the mining and discovery of the hot spots

have occurred in at least three seasons of the year; underground differences in elevation, the thought here being that maybe a stressed condition of the overburden or coal was creating a condition conducive to the generation of heat to the point that normal spontaneous ignition conditions were greatly advanced, but the hot spots have occurred in low places in the mine as well as in high places.

Although the rate of oxidation of coal in a mine is impossible to determine at the present time, we do know that it goes on. From laboratory experiments it has been determined that the surface area exposed is an important factor in oxidation. To determine the surface area available in the coal particles remaining in an abandoned portion of a mine would be at best a wild guess, however we are sure that in the normal sequence of mining and sloughing that the surface area of coal would be enormous and that in a gob area it would be even larger. It is possible for oxygen to come in contact with these fine coal particles because atmospheric air is available.

The large surface area is present and oxidation takes place since one way to detect the presence of a hot spot is to find carbon monoxide in the near vicinity. One researcher pointed out that when carbon monoxide is formed there is a heat release of 26,800 calories per gram atom of carbon, therefore we have the beginning of heat generation.

Of course the conditions surrounding the creation of a hot spot must be "ideal," but what factors effect the ideal condition. The critical point seems to be that the heat generated must exceed the heat transferred from the area by conduction and convection. This is not a difficult situation to visualize in an abandoned portion of a mine, particularly when some attempt is being made to ventilate these parts.

CONCLUSIONS

In every instance of the occurrence of a hot spot in Orient #3 mine, the location of the hot spot has been in a gob area. The exact location of each occurrence cannot be positively ascertained, however the evidence indicates that in each instance the hot spot was near the location of the concentration of a small amount of air. This leads one to believe that in the middle of

the gob area the conditions are not conducive to the creation of a hot spot, possibly because of a lack of oxygen, and in the bleeder entries around the gob area there is probably enough air to carry off the excess heat from the oxidation process. But in some location in between these two zones there is just enough oxygen available to keep the oxidation process active and not enough air current to dissipate the heat generated. This would be an almost impossible theory to prove and yet it is a logical one.

In every instance of spontaneous heating in the gob at Orient #3 mine, control has been achieved by: 1) sealing all openings to the gob with masonry stoppings, 2) equalizing and minimizing the ventilation pressure differential on the seals, and 3) flooding the area with carbon dioxide or water.

Anticipated changes in the future mining plans in order to help the control of hot spots in the gob areas are that the size of the gob area will be diminished and the number of access openings from the bleeder entries to the gob will be kept at a minimum in order to reduce the number of seals required to isolate the area.

HAZARDS ENCOUNTERED IN MINING THICK, INCLINED COAL BEDS

By EMERY C. OLSEN

Supervisor, Mine Inspection, Coal Mines & Quarries
Columbia-Geneva Steel Division
United States Steel Corporation, Draper, Utah

Most coal mining areas of the western United States are characterized either by thick beds, steep pitches or heavy cover. Individually, each of these may present certain inherent safety hazards that influence the mining operation. When all are met at one location, the combined effect is to make the safe operation of the mining property a real challenge to mine management.

These combined conditions are met in the coal mines of the Columbia-Geneva Steel Division of the United States Steel Corporation, located in Southeastern Utah. This coal bed measures up to 16 feet in thickness, the pitch is as much as 25 percent, and mining is being conducted under cover approaching 3,000 feet.

The Sunnyside coal bed is found in the Book Cliff Mountains, a great escarpment extending from west of Castle Gate, Utah, some 180 miles to Grand Junction, Colorado. West of Green River, Utah, the Book Cliffs swing sharply to the north because of the domelike uplift of the San Rafael Swell to the southwest.

It is in this northerly extension of the Book Cliffs in which is found the Sunnyside coal in the Blackhawk formation of the Mesa Verde group, Upper Cretaceous age. The strata is transected by numerous faults, with from a few inches to as much as a hundred feet of displacement. All of these faults have had some effect on the mining operation, either in the form of presenting roof control problems or in the case of major faulting, of dictating the pattern of mine development.

Mining has generally been confined to the Lower Sunnyside Seam which measures from 7 to 16 feet in thickness. The floor of this seam is formed by a massive sandstone member. The immediate roof is a variable thickness of siltstone, laminated sandstone and sandy shale overlain by the Upper Sunnyside Seam. This rock interval between the Upper and Lower Sunnyside Seam ranges from a few inches to many feet. When the rock interval is thin, the 2½ foot upper coal seam may be recovered with the lower seam. The high volatile coal produced is used for the manufacture of coke for blast furnace use.

The mines are opened by slopes off which are driven sets of strike entries, or levels, which are carried to the property boundaries. Coal lying between these sets of entries is recovered from belt conveyor raises driven up the pitch. Retreat is from the property boundary to the main slope and pillars are recovered. Haulage from the belt raises is by track to the slope, then by either belt or rope haulage to the surface.

While at first thought, a seam thickness of up to 16 feet would seem to afford an unparalleled opportunity to achieve high production tonnages, this has not always been true. Above a convenient working height, the natural hazards and increased difficulty of the work functions combine to nullify the advantages that might be expected with high coal.

This is particularly true if the nature of the coal and the weight of the overlying rock result in unstable rib conditions. These high ribs and the high faces present a constant hazard to the men working below. When a bumping condition exists this hazard is intensified. The roof cannot readily be checked and the installation of roof support is a major undertaking.

The standing of a 14- or 16-foot prop is a job requiring the efforts of no less than three men and a well developed technique. Roof bolts can be installed only with special equipment. Face preparation requires special high coal machines equipped with hydraulically controlled drills so that the operator may be removed from the immediate face area. Loading and tamping of holes in this height necessitates working from a ladder or the use of loading troughs.

What at first appears to be a wonderful expression of nature's bounty turns out to be a questionable blessing.

While the hazards encountered during mining of this bed may sometimes be related specifically to the thickness of the seam, the pitch or to the depth of cover, more commonly the unfavorable condition is the result of effects from all of these.

As in most mining operations, the first consideration is given to adequate roof support. The standard bolting plan calls for use of full ¾ inch high strength steel roof bolts with 6 inch square bearing plates anchored in 1½ inch diameter holes with expansion shells. These are installed at

maximum 5 foot centers; however, the local conditions determine spacing and bolt length and the average spacing in the mines approximates 4 feet.

When continuous support is required between bolts, steel mats 9 feet long and minimum of 16 gauge are used with roof bolts. Timbers are used to supplement bolting as required. Poor roof conditions may require the extensive use of timber. However, timber used in conjunction with roof bolts in retreat work are generally used as indicators of roof action or "squealers" and the bolts serve as the principal means of support.

In most areas of the mines this standard roof support system does an excellent job. There are occasional areas where the standard bolting does not suffice and either these areas are reinforced with additional bolting in conjunction with timber or a roof failure is experienced. These roof failures are investigated by a roof control committee to determine the cause and take remedial action when this is indicated.

Probably one of the most prevalent causes of the roof failures experienced has been some hidden geologic phenomenon discernible only after the failure occurs. Investigation frequently discloses cross bedding, fractures, faults, water courses, old stream channels or other features that contribute directly to the failure. Little can be done in these instances except to attempt projection of these features into adjoining areas so that above standard support may be provided.

The thickness of the seam has an indirect effect upon roof control. Although the standard width of development work is 16 feet and that of rooms 19 feet, ultimately when the full seam thickness is being extracted, it is difficult to maintain these spans and silt trim the high ribs of loose coal and slope them back at an angle to afford some protection to the men working below.

The depth of cover has a very definite relationship to the roof control problem. The effect may be direct upon the roof rock, and roof conditions have generally deteriorated as mining depth increased. The effect may also be indirect in the widening of the pillars. That this is severe is evidenced by the fact that, in an area of 14 foot coal, the pillars may be reduced to a

height of 10 feet before final recovery is made.

A characteristic action of heavy cover on the ribs is a crushing or cutting action in the center of the exposed rib. As this extends into the rib and loose coal sloughs away, the result is a V-shaped rib, the point of which may be four or more feet in from the original rib line. In order to stabilize such ribs and also to support the resulting overhang, ribs are frequently bolted. Wooden header blocks may be used with the bolts and wire fencing has also been bolted to the ribs. More commonly the conventional steel mat used for roof support is used, and bolts will be anchored in the coal; or angled holes may be drilled into the roof, and anchorage will be in rock.

This widening of roof span, whether from necessary trimming of ribs or from crushing due to weight, can eventually lead to a roof failure.

The location of the Upper Sunnyside coal bed above the immediate roof rock also poses a constant problem in roof support. Bolts used to support the roof are from four to eight feet in length in six inch increments. If the rock interval to the upper seam is $4\frac{1}{2}$ feet or more, bolts are generally anchored below the upper seam. If the interval is less than $4\frac{1}{2}$ feet, longer bolts are used to anchor in the rock overlying the upper seam. In some instances the upper seam may be of such a thickness and so located that anchorage cannot be made above or below, in which case bolts are anchored in the coal and supplemental timbering installed.

Every effort is expended in providing the best possible roof support and constant attention is given to testing of roof, face and ribs by the production crews. A roof bolt testing program is also followed to insure that bolts are installed to proper torque and that adequate anchorage is being attained.

The effect of the pitch on roof control and any possible effect it might have on the bumping experienced in these mines is largely undetermined. Normal retreat lines are on approximately 45 degrees with the pitch, although comparatively flat lines have been carried down the pitch with favorable recovery and without unusual roof problems. Retreating lines up the pitch as in the case of slope pillar recovery have in

some instances led to unfavorable roof conditions.

However, there is at least one example of this under comparatively light cover, less than 1,000 feet, that worked out very well. There is occasional evidence of lateral movement at the contact of the coal bed with the roof rock and in some instances, where overlying rock is exposed because of roof failures, this lateral movement is evident in the bedding planes of the rock four or five feet above the coal. The resulting thin, slickensided layers are sometimes the horizon to which the roof failure occurs.

Closely allied with the roof control problem is the occurrence of bumps which, depending upon degree of severity, may present a serious hazard. Some minor bumping during the mining operation is actually beneficial, since it makes for easier mining and by speeding up the mining operation reduces exposure in the immediate face area.

However, when bumps assume such major proportions as to affect several pillars or a whole mining district, with the dislodgement of large amounts of rib coal, heaving of the bottom and possible roof failure, all with the possibility of injury to members of the mining crew, they become a problem of paramount importance. Such bumps usually come suddenly, without warning, and consequently without time for evasive action.

Interestingly enough, in many instances there is no major involvement of the roof. The bump results from the sudden collapse of supporting pillars loaded beyond their capacity and usually the major effect is that of displacement of rib coal. Coal from the ribs may completely fill the roadways and rib coal remaining in place may be badly crushed. The top of the remaining pillar may be separated from the roof rock for a distance of several feet back of the original point of contact.

All factors affecting the occurrence of bumps are as yet unknown. However, depth of cover, nature of overlying and underlying rocks, size of supporting pillars and degree of recovery in worked-out areas play major roles.

The effect of the depth of cover assumes added significance in these mines because of the land form assumed by the overlying rocks. The Book Cliffs rise abruptly from the valley below so that there are only minor

areas available with less than 500 feet of cover. The steep walled canyons and side canyons give rapid changes in depth of cover over comparatively short distances in the mine. For example, the depth of cover may change from 1,000 feet to 1,500 feet in a horizontal distance of less than 500 feet, the distance along a district pillar line.

The depth of cover and the character of the overlying rock which includes the massive sandstone layers conducive to bumping cannot be controlled. To some extent, the other factors can be influenced.

The mining plan recognizes the desirability of uniformity in pillar size in order to distribute equally the weight of the overlying rock. The standard 80-foot centers result in uniform pillar size and an effort is made to have a series of such blocks well ahead of the abutment zone of a retreat line. Occasionally the importance of this is pointed out by having a non-uniform sized block adjacent to the retreat line, in which case the bumping may be particularly severe.

It can be seen that the proper engineering of the mining property plays a significant role in its safe operation.

High recovery in pillar work is important to good caving action and results in relief of roof stresses. The premium value of this coking coal makes high recovery essential from an economic standpoint as well. The pillar pocket system of pillar mining permits a high recovery and the final stumps left are normally drilled and shot to induce caving.

Because of the many hazards associated in working adjacent to high ribs and against a high face, a longtime objective has been the removal of the men back as far as possible from the danger area. The use of rubber-tired, universal cutting machines equipped with automatic bug dusters, dual controls, and hydraulically operated coal drills, is an example of how modern equipment can accomplish this object.

The dual boom roof bolting machines are equipped with hydraulically rotated percussion drills. All movements are hydraulically controlled which allow the operators to drill and install roof bolts while standing well back from the face and under previously supported roof.

Most of the hazards of working a thick, pitching seam under heavy cover, that relate directly to roof and rib control, have now been mentioned. In a large measure these have been met through a top bench system of mining.

Prior to the advent of roof bolting it was the common practice to mine under thick top coal which would be recovered as the final step of mining. This served to keep the rib height to a practical limit and the top coal served to support and protect the comparatively weak rock forming the immediate roof. Since roof bolting has now become the standard roof support, much the reverse of this is now the standard practice in the top bench system of mining. All development headings, rooms and the initial splits in pillars are driven at a height of 9 feet against the rock roof which is supported with roof bolts and the balance of coal is left as bottom coal.

In the bench system of mining the upper portion of the seam is mined on advance, and the lower portion of the seam is recovered on retreat.

This 9-foot working height materially affects the efficiency of the various mining operations and has a pronounced effect upon the safety of the operation through ease of roof inspection and control, reduced hazards from high, unstable ribs and face, and increased efficiency of the ventilation structures. Full seam mining is done only in the last stages of pillar recovery.

The first pillar split and the first mining of the inby tender of the split are done as top bench mining. A ramp is then made into the bottom coal under the first split; the inby stumps and the outby tender are then recovered at full seam height. Most of this final recovery at full seam height may be made under roof support installed during the top bench phase.

To some degree, the trend to continuous miners has led logically to the top bench system of mining, because of the height limitations of this type of equipment. Driving against the rock roof with the installation of support being made at a convenient height is preferable to driving under top coal which necessitates later top coal recovery with conventional equipment and installation of final roof support at full seam height.

The top bench system is not without certain problems, one of which is maintaining satisfactory roadways on top of the bottom coal. Usually this is not a major problem, although continuous miners weighing over 30 tons tram over it. Occasionally, however, there are local areas where the bottom coal breaks out and roadways must be rebuilt. Many times these areas relate to faulting where the coal shows some alteration. The usual remedy is filling, in an attempt to maintain the bench height. Sometimes it is necessary to load out the bottom coal, but only as a last resort since it results in the high ribs that are so objectionable.

It is felt that adapting this top bench mining system as a solution to many of the problems relating to the mining of thick, pitching seams under heavy cover has resulted directly in providing safer working conditions. This is borne out by the continuing downward trend of injuries resulting from falls of roof, face or ribs.

The shotfirer is the man most closely exposed to high face conditions, however, his job, too, has become safer through the use of milli-second delay blasting which cuts his exposure in the face area by eliminating the necessity of returning to the face between shots as was previously required. The top bench mining system has also limited the height of the face and, of course, the use of continuous miners very nearly eliminates the need for any shooting.

The problem of protecting workmen from the hazards of roof falls and from unstable rib conditions, particularly coal dislodged by bumping, has been met in one way by providing protective cages for the operators. The value of these cages has been proven conclusively over the past few years and many disabling injuries have been prevented. Use of these cages has until recently been limited to the continuous miners and all types of miners, boring, ripping and milling have been so equipped.

A similar cage was recently installed on an 11-BU type loading machine. In no case do miners advance ahead of supported roof so the cage serves its principal function as protection against falling rib coal. Occasionally there have been instances where it has proven, spectacularly, its value in protecting against roof falls as well.

While it is not intended that these cages

replace proper testing and trimming procedures, they do serve a valuable and proven role in injury prevention.

The most obvious effect of the steep pitch in these operations is that of the service imposed on the use of the mining equipment. Most of this equipment was designed for use on cooperatively minor grades. Traction power and braking capacity are severely taxed by the steep grades encountered in these mines. The mining plan has been developed to keep up-pitch movement of coal to the minimum but obviously there are instances when this must be done.

In slope development, and in development of the lower entry of a set of strike entries, the shuttle cars must travel loaded up the pitch of the seam. Bringing loaded shuttle cars and other mining equipment down these steep grades also poses a serious problem. A failure of the brake system, or inadequate capacity, or failure in the steering system, could have disastrous results. Maintenance problems, involved in keeping equipment in shape for safe operation under these conditions, have been monumental.

In some instances major redesign and rebuilding of brake systems and increasing traction power has been necessary. Even with the brake system in top condition, if the wheels of a shuttle car are completely stopped from rotating, the unit may continue to slide down pitch for some distance in much the same manner as an automobile sliding down a steep, icy hill. It is common practice to weld cleats on crawler mounted equipment to provide additional traction. Wear on tires is limited so as to always have a good tread remaining.

Haulage problems resulting from the pitch exist away from the face area as well. While motor roads are driven on the strike, local rolls or the necessity of grading through faults preclude the uniformity graded haulage roads that are desired. Large locomotives with mechanical and dynamic braking are provided and, when necessary, sand shoes are used to control the trip. Use of a brake car is now being considered with some of these haulages. Electrically controlled derails are used on motor haulages and rope slopes to provide protection in case of a runaway. Trolley phones are standard equipment on main haulages to con-

trol trip movement. Men working in slope development are protected from rope failure on the slope above by a combination of derails, track blocks and car drags.

Adequate mine ventilation is a necessity in any operation. At these two mines a total of four fans are exhausting 900,000 cubic feet of air per minute. Installation and maintenance of curtains and line brattice in full seam height is a real problem and here, too, the top bench system of mining has been a distinct advantage.

The pitch has a decided effect upon the ventilation of the mine. The warning air flow has a natural tendency to move up the pitch and when possible this is considered when laying out the district ventilators. Rarely, hydrogen sulphide gas is encountered and when this occurs in a downhill place movement of the heavy gas is difficult.

Currently all new belt conveyor installations are being made in multiple entry raises with the belt isolated from the district ventilation. This would be a distinct advantage in case of fire.

Avoid from the hazards that relate directly to the unusual conditions encountered in these mines, there are those commonly found in any mining operation and the safety program takes proper recognition of these.

Experience has pointed out the hazards associated with operating belt conveyors, and these installations are subject to a complete guarding program; a well developed control system is in use which incorporates audible and visual warning before movement of the belt is made.

The mine electrical system has certain inherent safety hazards, and overload protection is provided throughout. All electrical circuits, AC and DC, are provided with means of lock-out protection while maintenance is being done. Lock-out is also

provided on trailing cables and mining equipment.

The safety program at this location follows in general principles a basic program established in all facilities of the United States Steel Corporation. It is implemented by direction from the Columbia-Geneva Steel Division, and locally, the problems peculiar to coal mining are incorporated into the basic program by the Mine Inspection Department.

In a large measure the safety program is dependent upon almost constant employee contact to develop the safety awareness necessary to prevent mine injuries. This is brought about through weekly safety meetings scheduled in each mining district and held on company time and also through an individual contact program. Records of all contacts are made to insure that all men are receiving the proper number of contacts and variety through the safety program.

The physical condition of the operation is subject to routine inspection by the Mine Inspection Department, by the general superintendent's safety committee, and by division inspection and audit committees.

Surely the effectiveness of the safety program is ultimately measured in the results attained. The goal at these mines is the same as that of all segments of United States Steel Corporation, frequency zero. It was with great pride that Columbia Mine attained this goal in 1960, and in so doing, won the Sentinel's 101 Safety trophy in the Bituminous Coal group.

While past accomplishments may be reviewed with pride, the ever present hazards associated with mining thick, inclined coal beds under heavy cover are fully recognized by all those associated with this operation. All possible effort will continue to be directed to meeting these hazards with a forward looking safety program and continuing the safe operation of these mines.

DUST STUDY PROGRAM, PENNSYLVANIA DEPARTMENT OF MINES AND MINERAL INDUSTRIES

By W. ROY CUNNINGHAM
Deputy Secretary

At the time of this presentation, our active participation in this program is one year old. While we are too new at this work to offer definite conclusions, we are hopeful that through this discussion we will be able to give you some helpful information.

We in Pennsylvania, as well as you from other coal-producing states, have long been concerned with the explosion hazard of bituminous coal dust. Through intelligent research we have learned how to guard against coal dust explosions. The same consideration has not been given health hazards from coal dust in all areas. This could be due to the fact that medical authorities are not in unanimous agreement that the breathing of bituminous coal dust is harmful. Be that as it may, the growing lists of those suffering from silicosis among our bituminous coal mining people are reason enough for those of us having to do with the health and safety of persons employed in our mines to study the problem and attempt to offer corrective solutions.

There have been limited studies made in the bituminous area of Pennsylvania by various agencies and some by individual companies, but it has not been done on a large enough scale to be sufficiently valuable to health authorities in enabling them to evaluate the harmful effects of breathing such dust. In the anthracite area, more concentrated studies of coal dust conditions have been made. It is recognized that the breathing of quantities of anthracite coal dust is harmful, but even in this area, these studies were not comprehensive enough to offer any definite conclusions.

In the bituminous area, we do know that various processes of mining aggravate and increase the silica content of the suspended dust. Medical authorities are in unanimous agreement that silica dust is harmful when breathed over an extended period.

In 1933 the Governor of Pennsylvania requested the United States Public Health Service to make a study of certain phases

of the people associated with occupational disease possibilities in the anthracite region of Pennsylvania. It was hoped that such a study would offer some criterion that would enable the establishment of safe limits of dust concentration. This study was made and a report submitted to the Governor of the Commonwealth. Among other conclusions, the report contained the following:

"Analysis of the data for the purpose of determining safe limits of dust exposure indicated that employment in an atmosphere containing less than 50 million dust particles per cubic foot would produce a negligible sum of cases of anthracite-silicosis when the quartz contents of the dust was less than 3 per cent. In the gangways where the silica content of the dust was about 13 per cent, a safe limit appeared to be 10 to 15 million particles per cubic foot. The limit of toleration for rock workers was set tentatively at 3 to 10 million dust particles per cubic foot of air."

The above listed allowable limits apparently were the basis for threshold limit values adopted by the American Conference of Governmental Industrial Hygienists. These threshold limit values were first adopted about 25 years ago and were reaffirmed at the meeting of this organization in New York, April 23 to 26, 1960. They are as follows:

1. Below 5 per cent free silica, 50 MPPCF*.
2. From 5 to 10 per cent free silica, 20 MPPCF*.
3. Above 10 per cent free silica, 5 MPPCF*.

*Million particles per cubic foot.

I have not had the opportunity to become fully acquainted with occupational disease laws of the various coal mining states. That part of Pennsylvania's occupational disease law pertaining to lung disorders is contained in Pamphlet Law 520, Act of June 21, 1939, as amended in 1957:

"The employer liable for the compensation provided by this article shall be the employer in whose employment the employee was last exposed to the hazard of the occupational disease claimed regardless of the length of time of such last exposure, provided that when a claimant alleges that disability or death was due to silicosis, anthracite-silicosis, asbestosis, or any other occupational disease which developed to the point of disablement only after an exposure of 5 or more years, the only employer liable shall be the last employer in whose employment the employee was last exposed to the hazard of such occupational disease during a period of six months or more and providing further that in those cases where disability or death is not conclusively proven to be the result of such last exposure, all compensation shall be paid by the Commonwealth."

A greater part of the bill for occupational disease falls on the taxpayers of Pennsylvania. This is due to the fact that because of the very economic conditions of the coal industry, miners are forced to change employment from one mine to the other frequently. During the last biennium ending June 1, 1961, the total occupational disease bill to the taxpayers of Pennsylvania was upwards of \$27 million. Approximately 90 per cent of this was paid to miners for lung disorders. In my opinion, the authors of our present legislation are to be commended for their humane effort in alleviating suffering and financial distress among our mining people because of health disorders that originated during their work in various mines. My purpose in describing a part of our law is to point this out to further explain why the Pennsylvania Department of Health and the Department of Mines and Mineral Industries started and will continue this study. You can readily understand that a compensation bill to the state of this magnitude excited public opinion to the point that the reasons therefor were demanded.

Some years ago the Pennsylvania Department of Health started a study wherein chest X-rays were taken of individuals working in our mines both in the anthracite and bituminous regions. This X-ray study is continuing and will continue throughout both areas of Pennsylvania. Because of the Department of Health's findings through their study of the various X-rays, they felt that

they would be in a better position to offer intelligent solutions to this problem if they could likewise study the dust conditions in our mines. An Attorney General's decision gave the Department of Health personnel the right of entry into the mines for the purpose of making this dust study.

The Department of Health personnel were most proficient in dust sampling techniques. However, they were not familiar with the various mining practices in the anthracite and bituminous divisions. The Secretary of the Department of Health at that time realized that his people would need assistance from trained mining personnel, and requested the Secretary of Mines and Mineral Industries to have a mine inspector accompany the survey team and be responsible for their safe conduct during the study. In Pennsylvania as in other states, mine inspectors are charged with certain mandated duties. One provision of our mine law requires mine inspections at regular intervals. Time taken from legally required duties for the purpose of conducting dust study survey teams into the mines necessarily interrupted regular mine inspections.

Our department felt that the mine inspectors could not continue this additional work and still comply with the mine inspection laws. A meeting was arranged and attended by representatives from mine management, United Mine Workers of America, the Secretary of the Department of Health, and the Secretary of the Department of Mines and Mineral Industries. At this meeting coal operators justly objected to having personnel unfamiliar with coal mines unaccompanied by representatives of some state agency who would be responsible for their safety. They felt that the Department of Mines and Mineral Industries should be charged with taking dust samples underground in the coal mines.

The Secretary of the Department of Health and the Secretary of the Department of Mines and Mineral Industries were both cognizant of the fact that to be of any value, a dust study would have to be a continuing function of one of the departments. Spot checks had been made in the past, and they were of little value. We are fully aware that the data being collected by our people during this continuing study must be made on a division-wide basis. Anything less than this would be of no more value

than those spot studies taken previously at infrequent intervals.

Secretary Lewis E. Evans of the Department of Mines stated at a later meeting, comprised of the same representatives who attended the original meeting, that it was his intention to employ first-grade mine foremen as dust study personnel both in the anthracite and bituminous divisions. Following this meeting, four first-grade mine foremen were employed—two assigned to the anthracite division and two to the bituminous division.

A comprehensive six-weeks training period was arranged to familiarize our dust study personnel with various techniques of sampling and analyzing coal dust. Following this training period, we equipped two complete laboratories—one in each division. Presently, dust counts are made with a microprojector. Some work has been done on direct counting, and our personnel are familiar with both methods. Qualitative samples are collected by our people and the determinations are made by the Department of Health. The laboratories are not presently equipped to make qualitative analyses.

At the end of the training period, Secretary Evans met with the dust study personnel from both the anthracite and bituminous divisions. He outlined a tentative procedure and described his expectations. Briefly, his instructions were:

1. He emphasized that dust study personnel must be concerned only with the work for which they were employed. This department had reports that on some occasions, personnel making similar studies had exceeded their authority and reported situations about which they had no knowledge or jurisdiction.

2. He insisted that before entering the mine, our personnel should have a thorough understanding of the property, thus enabling them to conduct a study that would be representative of the dust in suspension throughout the mine.

3. He suggested that periodically, procedures were to be discussed with representatives of the Department of Health and with mine management.

4. Our people were advised that the purpose of this study was to enable the Department of Health to evaluate the effects of dust on the lungs of our mining people,

and that any piece-meal publication of the report, could have undesired effect. Therefore, it had been agreed by all parties to this study that one copy of the report would be furnished to the Washington office of the United Mine Workers of America, the operator of the sampled mine, the Secretary of the Department of Health, and one copy was to be retained in the Department of Mines and Mineral Industries.

Before our entry into the first mine, three of the major companies operating in the bituminous area expressed the desire to conduct studies simultaneously with our personnel in their mines. We welcomed this idea and felt that in time other coal companies in Pennsylvania will express the same interest and conduct studies of their own.

At the time this was written, we had completed surveys in at least one mine of each of the companies who were making simultaneous studies. We then met with the coal company industrial hygienists from these companies and outlined our procedure. We invited their criticism, and I am happy to report that in the main, they were most complimentary. It was felt by all concerned that periodic meetings of this type would prove most beneficial in arriving at a standard procedure that would be indicative of the intended purpose.

Insofar as is possible, we have adopted similar procedures both for the anthracite and bituminous divisions. It might prove interesting and helpful to this group to outline this procedure:

1. The Deputy Secretary of Mines and Mineral Industries of the pertinent division makes arrangements with mine management to conduct a dust study in a specific mine.

2. The dust study personnel meet the state mine inspector at the mine for the purpose of becoming acquainted with local mine management. At this meeting, the mine inspector goes over the mine map and gives a description of the methods of mining being practiced. It is only for this one-day meeting that our state mine inspectors are delayed in their regular duties. They can, of course, as time permits, accompany our dust study personnel on at least a part of the survey.

3. No attempt is made to study every working place in the mine. During the orientation discussion, our dust study per-

sonnel ascertain the number of ventilation splits, the percentage of retreat mining compared to first mining, and a general description of the haulages over which men are transported. This orientation period has proven most helpful in making plans for the actual survey.

4. Determinations are made of each of the various classifications and in proportion to the number of such classifications in each mine. For example, if there are twenty continuous mining machines operating in a mine, we make an effort to take dust counts and samples at at least half of them. Likewise, the same procedure is followed for each of the various job classifications.

5. Daily samples are correlated into average time weighted exposures. For example, if a continuous mining operator is to be sampled on a certain day, the operator is met at the lamphouse by at least one of our dust study people. The sampling period starts on the incoming mantrip. Originally, we took 10-minute samples, but we learned that sampled periods of such short duration were not necessarily representative of each individual operation. Now, samples are extended over a one-hour period and at least 30 minutes of that hour represents the sampling time. This is done by sampling for 10 minutes and delaying for 10 minutes throughout the hour. By doing this, we feel that the entire day during high dust and low dust concentrations, periods can best be described.

6. With each time weighted exposure, a dry dust sample is taken. We have tried various devices for collecting dust from the atmosphere without success. Presently, we are collecting adhering dust from ribs and/or timbers. Along haulages, dust traps are installed so that this dust can be collected over an entire shift period.

The quantitative samples are collected in alcohol using a midge impinger. The Department of Health feels that counts should be taken within 24 hours. Some of the coal company-employed hygienists do not agree that this is necessary. However, since this information is sent to the Department of Health, we comply with their directions. The qualitative samples are collected and sent to the Department of Health for analysis. With each time weighted exposure, there is also listed a silica determination of the dust collected during the operation.

In our years of operation, we have sampled

five mines. To be of any value, there are not shortcuts to be taken in making a dust survey. Our dust study people are fully familiar with mining and mining operations. It is not necessary for mine management to assign personnel to accompany them into the mine. They stay with the individual classification being sampled on each particular shift and need not be taken into or brought from the mine during the shift. At the completion of a dust survey, reports are prepared and sent only to the interested representatives of each agency and mine management of the sampled mine. Since it was originally agreed that these reports would contain all information pertinent to the survey, they are quite voluminous and are composed of the following:

1. Letters of transmission.

2. A synopsis description of the mine. This description includes the number of persons employed, methods of ventilation, methods of alloying dust, transportation, and conclusions. If, during our dust study, we find that dust concentrations are beyond the allowable threshold limits for an entire average time weighted exposure, this information is given to our district mine inspector for his action. I am happy to report that in the mine study thus far, there has been little necessity for this procedure.

3. Location of qualitative dust sampling points.

4. Qualitative analysis results.

5. A description of the impinger samples taken and the determination of the dust count.

6. Dust size determination from 0 to 10.1 microns.

7. Copies of the various forms used in making this study are attached for your information.

The Department of Health is only interested in dust sizes from 0 to 5 microns. However, some of the coal companies continue these size determinations to 10 microns, and we for the present are doing likewise.

We are too new at this work to offer any definite conclusions. We have learned that ventilation alone is not sufficient for alloying micron-size dust. Likewise, spray systems alone will not sufficiently alloy dust particles of this size. We do feel that we have learned conclusively that a healthful atmosphere at working faces, particularly

where mechanical mining is being practiced, is dependent upon an efficient combination of both ventilation and water sprays.

In roof bolting operations, we have been able to determine the efficiency of certain dust collectors. I would like to say at this point that some of these collectors are most efficient. It is this dust containing from 35 per cent to 65 per cent silica, depending upon the nature of the material drilled, that is most harmful.

As this program continues, I am certain that we will be able to offer more conclusive and valuable information to groups of

this kind. I feel that I have had an invaluable experience in being permitted to initiate this program in the bituminous division of Pennsylvania. Secretary Evans has emphasized on many occasions that health is a function of our department, and if through this program we can prevent one case of silicosis, anthracosis, or pneumoconiosis, the program will be well worthwhile.

I am certain that this is not only Pennsylvania's problem, but a problem in all mining states throughout this nation. It is well deserving of our best efforts and consideration.

SAFE PRACTICES IN STRIP MINING

By EUGENE E. QUENON

Director of Safety, Peabody Coal Co., St. Louis, Mo.

Injury records at strip mines, compiled on a tonnage basis, have always been enviable when compared with deep mines, and one is likely to take for granted that serious hazards seldom exist in strip mines.

Shortly after being employed by Peabody Coal Co., I had a very rude awakening to the fact that hazards in the strip mines were numerous—and that many of these hazards were serious and decidedly dangerous.

While many hazards exist in strip mines under normal mining conditions, some of these same dangers become much more serious under adverse weather conditions, and cannot be entirely eliminated without the assistance of improved weather. Peabody Coal Company's injury records definitely indicate that adverse weather has a direct bearing on the increase in frequency and severity rates of accidents at our strip mine operations.

The following example will serve to point out the effect of severe weather changes on the operation and maintenance of our strip mines. Late last Fall, a round of inspections was made at our strip operations. The weather was ideal, and conditions of the pits, haulage roads, equipment, shops and cleaning plants, as well as newly painted buildings and well-kept lawns and yards, all seemed to coincide with the wonderful weather.

Working conditions such as were observed during this inspection, along with the attitude of employees toward adhering to safety practices, gave me a confident feeling that real progress was being made toward an over-all improvement in safe working conditions which would ultimately result in a much lower frequency and severity rate.

A prolonged cold spell of several weeks' duration followed these inspections. During this time, the surface had frozen to a depth of 15 inches; and when thawing started, the pleasant surroundings observed a few weeks earlier at many of our mines had, indeed, changed to such an extent that conditions throughout the operation seemed to invite accidents. The hardships caused by muddy terrain not only created new hazards, but were indirectly responsible for several equipment breakdowns. The overall adverse weather conditions actually appeared to discourage both workers and supervisors from following adopted safety practices that were normally in effect.

Other than the main haulage roads and uncovered coal at these mines, the surroundings were a mass of mud that definitely retarded the entire mining operation and created new hazards. Highwalls and spoil banks now presented a definite danger from falling or rolling material; handling power cables in the mud was much more

dangerous; walking and working under such conditions caused fatigue, resulting in a lack of alertness. A majority of strip mine officials, who were consulted regarding the greatest hazards involved in strip mining, stated that unusual weather conditions—such as heavy rains, extremely low or high temperatures, thawing of the surface following long periods of freezing, and extremely dry weather—were all conducive to accidents.

Frequently, a heavy rain will completely flood a pit, necessitating the setting of pumps, moving equipment to higher ground, causing slides along the spoil banks and unstable highwalls. Until conditions return to normal, employees are exposed to abnormal hazards.

Zero temperatures in the open pits retard the operation and tend to increase the frequency of accidents. One of the superintendents explained his reasons why an employee is subject to injury during low temperature: "His ears are covered up—he can't hear. He sometimes has his face covered up to where he can hardly see. He is so cold that he's numb, and has but one thought in mind—get the job done and get thawed out." The superintendent might have exaggerated a little, but from observations, I don't think he is too far wrong.

It was also the consensus of opinion that more breakdowns occurred in periods of extreme weather conditions. Temperature changes caused expansion and contraction of metals—in cold weather metal becomes brittle and lubrication becomes less effective—plus the fact that equipment working in mud and water is subject to overloading. Our experience in the past four and a half years proves that a large percentage of serious injuries resulted from employees doing repair work in the open pits during periods of inclement weather. Such injuries are partially due to weather and also due to the fact that the men are required to perform different types of work from their normal routine. Lack of experience makes any task more dangerous, and repair jobs always require haste, which is also unsafe.

The seriousness of safety problems involved in a modern preparation plant depends to a great extent on the construction, maintenance and operation of the plant. In recent years, Peabody Coal Co. has constructed several modern preparation plants,

building into them certain features that will enable management to operate them safely and efficiently.

While these types of cleaning plants are built to include the most modern equipment for maximum safety and efficiency, these modern devices will only help to eliminate accidents. Constant supervision is necessary to make certain that personnel think and work safely at all times.

An employee is less likely to be injured when he has been trained in his routine work and when the plant is being operated under normal conditions.

Since the cleaning plant at River Queen Mine is of modern construction and similar to those at other Peabody operations, it will serve as an example to describe, briefly, the importance of building the plant with certain features to increase efficiency and eliminate hazards.

The River Queen preparation plant is of fireproof construction throughout; all electrical wiring is in closed conduit; motors for driving the various pieces of equipment are moisture-proof. The equipment is arranged to provide adequate room for safe maintenance and repair work. The moving parts of equipment are adequately guarded. Stairways and cross-overs are installed at convenient locations and are guarded with toe boards and hand rails. Floors, stairways and cross-overs are, in most instances, constructed with metal grills, thus eliminating accumulations of coal and dust. A series of water jets, spaced about 30 inches apart, are installed on the ground floor for cleaning purposes.

The plant is adequately lighted throughout by windows and incandescent lights, and provisions are available for heating in cold weather. The entire plant can be cleaned with water, without damage to equipment. Switchboards and control panels are provided with rubber mats, and the equipment is controlled by a series of pushbuttons from a central location. A railroad car spotter, controlled by pushbuttons, eliminates the hazards of having workers exposed, as when conventional methods—such as dropping railroad cars by gravity—are employed.

The most hazardous period in the preparation plant is believed to be while repairs are being made to equipment following a breakdown—usually, because those doing the

repair work are in a hurry to get the plant back in operation and do not take time to do the job in the safest possible manner; and, again, are required to perform tasks which are not familiar to them.

Trailer trucks, with capacities as high as 95 tons, are used for transporting coal from the pits to the preparation plant. The safe and efficient operation of a transportation system at a strip mine depends almost entirely on a competent driver. The safe condition of the truck, maintenance of haulageways, and obedience to rules and regulations governing the movement of trucks, are contributing factors to the safety and efficiency obtained.

You can best appreciate the responsibility of the operator of a trailer truck if you take a trip with him to the pit. Under ideal weather conditions, there would be nothing unusual about the trip, except perhaps the driver may complain about a few rough spots on the road or occasional dusty conditions.

Take a similar ride in the same truck with the same driver following a heavy rain, or after the ground has thawed after freezing weather. On this trip, you will really learn about the hardships encountered in strip mines due to adverse weather conditions, not only by the truck operator but by everyone who works in or around the pit. The secondary haulageways, which were in A-1 condition prior to the change in weather, are now covered with two or three inches of soft material. The inclines into and out of the pits, which are only temporary haulage roads, are now slick and muddy. In some instances, the trucks are pushed into and out of the pits by bulldozers.

Traffic regulations governing the movement of vehicles are, in most instances, strictly followed by the truck operators. The crossing of railroads and public roads is done with great concern. Officials and other key employees, who are required to travel by automobile over the same routes as the coal trucks, offer no serious problem; as they are familiar with the hazards involved and will give the right-of-way to the coal hauling equipment.

Visitors, not familiar with the operation of traffic in the strip pits, should observe the posted signs reading "No Trespassing." And when it is necessary to enter the pits, they should be accompanied by a person

fully familiar with the transportation system at the mine and the regulations in force.

Overburden, ranging in thickness from 20 to 120 feet, in most instances must be drilled and blasted. Whether holes are drilled vertically or horizontally, much consideration must be given to the safety aspects as well as to the effectiveness and practicability of the adopted method. Without taking the practical viewpoint into consideration, drilling holes vertically from the highwall would appear to favor the safety aspect, since the drilling crew would not be exposed to the hazards of falling or rolling materials from the highwall; and the explosives, drilling equipment and power cables would be out of the pit and separated from the normal pit activities.

Whether the overburden is drilled vertically or horizontally will be governed, to a certain extent, by the character of the various formations that make up the materials to be blasted, and the surrounding conditions. Irregular surface, unconsolidated top material, and heavily wooded areas make vertically drilling, in some instances, inefficient and hazardous as well as impracticable.

The overall improvement in the heavy equipment employed in both horizontal and vertical drilling has not only added to the efficiency of drilling but has eliminated many of the hazards common to conventional drilling. These larger drills are operated from an enclosed cab, thus protecting the driller from exposure to inclement weather, as well as other hazards to which drillers are exposed when working in the open.

One of the most important advancements in recent years toward the improvement of safety in strip mines has been the adoption and use of commercial grades of ammonium nitrate as an explosive for blasting heavy overburden. The increased use of ammonium nitrate explosives since 1955 has been a major safety factor in the way of eliminating the hazards inherent in the transportation, handling, storage and use of explosives containing nitro-glycerines. The use of a safe primer, detonated with primacord for ammonium nitrate explosives, is also a big safety improvement when compared with methods employed in the past.

Ripper attachments mounted behind a heavy-duty crawler tractor are used in several of our strip mine pits to break up the coal beds prior to loading. Eliminating the

necessity for blasting coal also does away with the hazards caused by use of conventional-type explosives.

Although many dangers have been eliminated with the use of explosives containing non-nitro-glycerines, the same precautions employed in the transportation, handling, storage and use of dynamites are the recommended practice at our mines. At all Peabody strip mines where it is necessary to blast overburden, ammonium nitrate explosives are used. However, some of the strip mines continue to use dynamites for blasting coal beds where rippers are not in use.

Peabody Coal Co. has in service several machines that are used for loading and tamping horizontal holes. These machines reduce the hazard of having three or four workmen charging and tamping a single hole. Vertical holes are usually charged immediately after drilling, and fired between shifts, or as soon after the holes are charged as is practical. Before overburden shots are detonated, the area surrounding highwall and pits is inspected to ascertain that everybody is well in the clear. The operators of shovels or draglines give a warning whistle when a blast is to be fired. A second signal is given after everyone has had time to get in the clear. The charge of explosives is fired immediately after the second warning signal.

Falling or rolling materials from the highwalls can become extremely hazardous unless the cut is properly blasted and the loose material is removed during the time of stripping operations. Overburden composed entirely of sand and clay, and saturated with water, creates a difficult problem in stacking and presents a serious hazard to workers in the pit. Materials made up of such a composition have been known to flow across the open pit with such rapidity as to cover up persons working around the equipment.

Constant supervision is necessary to make certain that explosives, regardless of the type, are transported, handled and used in a safe and careful manner. When this is done, we can then reap the full benefit of the safety built into explosives.

Electricity, ranging in voltage from 110 to 6900 A.C., presents a serious shock and electrical burn hazard to the majority of employees at a mine. The hazards from

shock and burn are much more serious when the surrounding conditions are wet, following heavy precipitation. Proper maintenance and careful installation of electrical equipment at a strip mine are very essential to the prevention of injuries. The use of insulated cable hooks and the wearing of insulated shoes and gloves will minimize the ever-present dangers from electricity at the strip mines.

Employees are instructed to call the mine electrician when any electrical equipment is in need of repair or when connecting or disconnecting power conductors.

Erecting, dismantling, moving or repairing heavy stripping equipment is an everyday procedure with Peabody Coal Co.'s organization. This type of work is extremely hazardous, especially during inclement weather, and has resulted in several serious injuries in the past. Fortunately, supervisors assigned to this type of work are thoroughly skilled in their art and, from their past experience and knowledge of hazards, our injuries are reduced to a minimum.

General repair work on all types of equipment at the various mines is done daily, and those assigned to such work are highly trained through many years of experience. Capable supervisors, who supervise the repair work, are employed at each strip mine to make certain that the job is completed in the safest possible manner.

Federal and State mine inspectors have been of much help in the elimination of substandard safety conditions in and around our pits, shops and cleaning plants, and few violations of the state laws and Federal Mine Safety Code are reported by these agencies which are not corrected during the inspection. These agencies have, in most instances, done an outstanding job in helping to bring about better cooperation between employee and employer in the interest of safety and accident prevention.

Progress will continue in the reduction of injuries and fatalities at our strip mines through the improvement of equipment and the continued efforts of all employees to fully cooperate in the interest of preventing accidents. Elimination of substandard safety conditions in our strip pits is very close to a reality. Therefore, our future safety problem is to encourage all employees to work safely, at all times, and to take no unnecessary chances.

EXPERIENCE IN FIGHTING MINE FIRES WITH FOAM FIRE-FIGHTING APPARATUS

By WILL B. JAMISON
Safety Development Corp., Greensburg, Pa.

High expansion foam is an effective and proved tool for the control of mine fires. It has been proved by its actual and successful use at the Montour 4 mine of the Pittsburgh Coal Co. and at the mine of the Marquette Cement Manufacturing Co. at Oglesby, Ill. The effectiveness of high expansion foam on class A and B fires has been shown by extensive testing at the laboratory of the Factory Mutual Research Corp., at the testing facilities of Safety Development Corp., and at numerous demonstrations and tests held at state and municipal fire school training areas.

As with any new technique, high expansion foam is still under development. Recently, improvements have been tested which permit quicker erection of foam generating equipment. Other improvements are the development of new methods of creating an effective movement of foam into a dead end place. Perhaps one of the most significant improvements is the discovery of a new foam concentrate which overcomes the substantial limitations of the older foaming agents.

Credit for the concept of high expansion foam belongs to the Safety in Mines Research Establishment, Buxton, England.^{1,2,3,4} This group showed that a light detergent foam, developed by erecting a net across the mine entry, wetting the net with a detergent solution sprayed from a hand-held nozzle, and directing the air current from the mine ventilation system through the wetted net, would create a mass of bubbles which could control and extinguish a fire of timber and rubber belting. Foam "plugs" 600 feet in length were developed in roadways of some 60 square feet cross-section area.

Since the original British announcement, their work has been devoted to study of the chemistry of high expansion foam, to improvement of the hand-held nozzle, and to study of the flow characteristics of high expansion foam within the limitations imposed by their methods of foam generation.

The first British report came to the attention of Mr. C. R. Nailer, then president of the Christopher Coal Co., who arranged to run tests on this foam at one of his company's mines. These tests showed that the British method required considerable set-up time and that the normal air pressure available in an American mine was insufficient to develop a foam plug much over 200 feet in length. At the request of Mr. Nailer, the USBM undertook to study the method; as this agency was equipped, at its experimental mine, to simulate underground mine fires.

The Bureau worked on high expansion foam for some years making substantial contributions to it. The Bureau found that the foam developed by the British was effective against a wood fire but was not effective against a coal fire which has become very hot and deep seated. The Bureau undertook to study foaming agents and found one which provided a foam wet enough to be effective on coal fires. After repeated tests, the Bureau was able to suggest a minimum water content of the foam necessary to make the foam effective on a coal fire.^{5,6}

At the end of two years of fruitful work, the Bureau started to publicize the results. With the exception of some efforts on techniques for fighting mining machine fires, the Bureau seems to have completed its work on high expansion foam.⁷

Upon the completion of the major portion of the work of the Bureau, it was apparent that there was a need for further study and improvement of the method, for well-designed and effective equipment to make high expansion foam, and for the application engineering and instruction necessary to make the system a useful tool to the mining industry. With these purposes in mind, we formed Safety Development Corp.

The work of Safety Development Corp. which is of greatest interest to mining men, concerns the successful use of high ex-

pansion foam on mine fires. Equally interesting should be the various developments of the USBM and ourselves on the problem of fighting fire in a dead end place. Of less specific interest is the extensive program carried out by Safety Development Corp. of testing high expansion foam on fires of various types and, finally, certain new developments should be mentioned.

Perhaps best understanding of high expansion foam is promoted by discussing first the foam itself, how it is made and what it can and can't do; then recounting its use on actual mine fires; and, finally, the work on fires in dead ends and new developments.

How High Expansion Foam is Made

High expansion foam is made by spraying a special fabric net with a solution of water containing a foaming agent and, simultaneously, by blowing air through the net. How well these steps are carried out will determine the effectiveness and efficiency of any equipment designed to make high expansion foam.

The British used a cotton-fabric net having a relatively open weave. We decided against cotton fabric because it is vulnerable to mildew attack. The British used the open weave to conserve the limited available ventilation pressure. By providing fans able to furnish the required volume of air at substantial pressure, we are able to use a closer weave net which makes more uniform foam. Thus our fabric is a very heavy nylon, with relatively small holes, which is mechanically strong, mildew resistant, and less flammable than cotton.

This fabric and its arrangement in the net frame, coupled with careful attention to uniformity of liquid and air distribution, have permitted a rate of generation twice that successfully attained by the USBM, reduced liquid loss to about two per cent compared to 10 to 25 per cent, and achieved an amazing uniformity of bubble size. These are the important details which make for efficiency in performance of the foam generator.

Size of the equipment is a most important factor also. If too large, it may not be easily transportable or it may not be possible to keep it supplied continuously with water or foam concentrate. If too small, it may not do the job. We believe that

conservative judgment must be used in considering the results obtained during testing under controlled conditions.

At actual fires and in actual mines, our experience shows that the foam can travel many paths and often only a percentage of the foam generated will reach the location of a fire. A unit which is proportioned to a test fire may be too small and therefore ineffective.

The rate of foam generated also can affect the water content of the foam when it reaches a fire. Numerous tests have shown that the loss of water from a foam is negligible if the rate of movement of the foam is in the order of 10 to 20 feet per minute. If the foam moves too slowly, rapid drainage will take place, possibly rendering the foam ineffective. Since the foam often can take many paths, the rate of generation should be high enough to give this minimum velocity in all paths to avoid excessive draining.

The very important and general problem of foam chemistry will be discussed later in this paper.

The expansion ratio of foam is the ratio of the volume of foam to the volume of the liquid within the foam. In high expansion foam, this ratio can be varied from a low of about 50 to 1 to a high in the order of 1500 to 1. The low ratios may have some special uses in other fields but are too heavy for mining applications. The high ratios tend to be less stable.

We have found that a ratio in the order of 1000 to 1 is an excellent compromise of a foam wet enough to have very good extinguishing properties but still light enough to be driven long distances horizontally or to be forced up a shaft or raise. The foam used in fighting the mine fires, and in the various tests to which we have subjected high expansion foam, has had an expansion ratio of about 1000 to 1.

How High Expansion Foam Controls a Fire

When a foam having a ratio of 1000 to 1 is driven on to a fire, the heat of the fire will flash the water of the foam to steam. The expansion of water to steam at atmospheric pressure is on the order of 1700 times, with the result that there now exists a mixture of 1000 volumes of air and 1700 volumes of steam. This mixture

will have an oxygen content of about 7.5 per cent or well below 10 per cent, the level at which active burning of most flammable materials will cease.

The conversion of water to steam absorbs a great deal of heat. Hot objects break the foam causing the water of the foam to be deposited upon the object, cooling and wetting it. Steam is an effective coolant since its temperature can be raised when it is in the presence of hot material. All of these means can combine to cool and extinguish.

In a mine where the paths by which oxygen can feed a fire are limited, foam can be driven onto the fire and will quickly render the fire dormant. Cooling by the steam will take place immediately. The foam will cover and cool burning material. If this contact by steam or covering by foam is maintained for a sufficient period, complete extinguishment will be obtained. The nature of the burning material and the depth of the burning will determine the amount of cooling needed. Coal produces a great deal of heat and can build a relatively substantial depth of burning. A coal fire is difficult to extinguish completely, but is easy to knock down so that subsequent direct attack is easy. Wood ignites more readily than coal but does not produce quite so much heat.

A more important difference between coal and wood is that wood does not produce much depth of burning so that cooling is much more difficult. Flammable liquids produce the most violent easily ignited fires; but since there is little storage of heat, they are easy to cool and extinguish. The fires of more volatile, low flash point liquids are more difficult to extinguish; however, when they are covered by high expansion foam to sufficient depth, they will go out.

The USBM has shown that the foam can control relatively deep seated coal fires. Testing at the Factory Mutual Laboratory has shown that the foam can extinguish standard gasoline pan fires and standard wood pallet fires. We have carried out tests on such diverse fires or materials as tightly stacked rubber tires, large fires of gasoline and diesel fuel, acetone and ethyl alcohol. In all of these tests, the fires have been controlled and extinguished when the

foam covered the fire and the cover was maintained for a sufficient period.

The Montour Mine Fire

The large coal mine fire at Montour 4 mine of Pittsburgh Coal Co. has been reported in some detail by the USBM⁸ and before meetings of mining societies.⁹ In view of the ready availability of at least one of these reports, it would not be profitable to attempt to tell the complete story of this fire. Certain parts of the story should be recounted, however, because they represent the observations of others of us who were present and have noticed, or wish to stress certain other aspects.

Some of the following comments are made in the light of later facts and knowledge gained. They are not presented as a criticism of the handling of this fire; but are presented in the hope that useful lessons in the handling and use of high expansion foam can be learned and appreciated.

The long and unavoidable delay of about 10 hours between the discovery of the fire points up the importance of having the necessary equipment and material on hand to make high expansion foam. The effectiveness of high expansion foam on the fire after it had grown to very sizeable proportions makes it easy to conclude that the fire could have been controlled easily if foam had been applied shortly after the fire was discovered.

The long delay was very serious and in fact nearly critical. When foam was finally driven into the fire, the combustible gas in the return had reached a high level. The first gas analysis taken after the foam generator had been started showed that the combustible content had fallen, indicating that it was safe to stay and fight the fire.

The coal on the roof and ribs extending over many hundreds of feet of entry was afire when foam was first made. After sufficient foam had been put into the fire area to remove the danger of ignition of flammable gases, it was decided to start at the right hand side of the involved area. This side was coal as an extensive partially mined and pillared area existed to the right. If the fire had succeeded in getting to this area, it would have been very difficult and, conceivably, might have be-

come impossible to extinguish by any available means.

The foam generator was moved to the right side and foam was driven into the involved area immediately in front of the generator. This permitted the prompt extinguishment of the fire in this area. The area was then explored and the only active burning was found beneath a mine car where the foam could not move readily. This small fire was quickly extinguished with a hose stream.

Later the unit was moved back toward the left, to a point one entry short of the original location. Since the fire was out on the right, it was decided to move the equipment in steps to the left, permitting a logical progression of driving foam to cool and extinguish, followed by an exploration. Exploration was made by cutting the foam with a water spray while admitting a controlled amount of air at the back of the men, who were advancing. Breathing apparatus was not used or required. It was possible to explore in this manner without the presence of heat or smoke.

No fire was found until a large fall was encountered which had burning coal beneath it. The temperature in the area was low and it was possible to stand on top of the fall in the current of air. However, the fire could not be extinguished even with the hoses on hand. It was apparent that the fire had been controlled by the foam and that it would not be able to spread as the rock which shielded the fire from the foam would also prevent it from breaking out. The smoke beyond the fall was sufficient to prevent exploration beyond this point. No fire was visible beyond the fall.

Here, again, a major decision faced those in charge. A man door had been opened to prevent smoke from being carried into the working area. It was known that the air movement then would carry the fire to the man door. If the fire had gone through the man door, it might have spread into the adjacent partially mined area and even into an adjacent mine which was separated by a heavy stopping. The threat of such a spread was so serious that it was decided to carry fresh air around and behind the fire so that the area in the vicinity of the door could be checked.

When this was done, it was found that the fire actually had consumed the door and a part of the door frame. No fire was present in the vicinity of the door showing that the foam had extinguished the fire as it was going through the door and had prevented the fire from spreading. During the period required to bring fresh air to the door, the foam generator was used to hold the fire beneath the falls in check. No foam traveled far to the left of the man door as the direct path of movement to the return was through the man door. Thus foam was not forced to the left where the only active fire remained.

As the work of bringing fresh air to the door involved the building of a number of stoppings or seals, it was found that complete sealing of the relatively small fire remaining would be easy. The seals were so planned that a relatively small area was inclosed and the valuable face equipment was outside the seals, easily recoverable for use in another mining area.

Certain important facts should be noted:

1. The foam completely extinguished the fire in many hundreds of feet of entry.
2. The only points where the foam clearly traveled in volume and extinguishment was not obtained were places where something, such as a mine car or rock fall, shielded the fire against the foam.
3. Wherever the foam had traveled, control of the fire was established and temperature lowered so that men could move and fight any remaining fire directly and at close range.
4. The foam will tend to take a direct path between the point of generation and the return, particularly if the openings to the return are relatively close and clearly defined.
5. None of the posts or timber set during the exploration after driving foam showed evidence of having been subject to any heat when the area was inspected upon reopening some six months after sealing.
6. During the sealing operation foam was introduced into the fire area at a controlled rate. Many of the seals were erected at points quite close to the fire area. While the area was

only partially covered, and was being introduced a number of times of the gas present. The scale showed very low oxygen content, on the order of 1 per cent. There seems to be no explanation for this, unless it is that the foam completely filled the small area.

With the better understanding of the above facts that has come with continued study and thought, it is more probable to see where performance of the foam could have been made more effective, the fighting of the fire could have been easier and less prolonged, and complete control and extinguishment obtained without sending. These improvements could have been obtained by:

1. The course that the foam took could have been controlled and directed, just as air is controlled and directed, using temporary stoppings or checks of doubled brattice cloth. Thus, the time and effort used in relocating the foam generator were expended uselessly. Also it would have been relatively easy to direct the foam to the left into the area which was not reached.
2. The fire beneath the falls could have been flooded by building a few low dams, or merely held by periodic applications of foam until the remainder of the fire had been controlled.
3. Periodic and regular checks of the temperature and analysis of the gases returning from the fire area would have shown progress in controlling the fire. This is extremely important as falls, smoke, and dangerous roof may make the task of quick exploration of the fire area difficult or impossible.
4. By control of the area where the foam was driven, and by careful choice of route to be traversed, I feel that the man door could have been reached and inspected without the necessity of building stoppings. The foam could have been made to cover the falls beneath which fire still existed, sealing the smoke at least for the time required to inspect inby the door.

Marquette Cement Manufacturing Fire

This was a severe fire in a massive timbered area of the limestone mine of the Marquette Cement Manufacturing Co. at Ogishby, Ill. The mine had been converted to an open pit operation in about 1917, the entrance area of the old workings was used for storage of trucks, other equipment, and supplies including lubricating oil. Because of important facilities upon the surface and the relatively thin cap rock which overlaid the limestone bed, substantial amounts of heavy cross-tied timbers had been set over the years as tight cribs to support the exposed mine roof. The fire ignited the cross-tied timber and spread rapidly throughout the timbered area. The cause of the fire is not known.

The fire was discovered upon arrival of the day shift on a Monday morning. Smoke was found inside the mine in the areas used for parking vehicles. Employees recovered a few trucks but were unable to get six trucks, two bulldozers, two highlifts and some 150 drums of lubricating oil and non-flammable chemical. The night watchman's car was one of the last vehicles recovered.

Originally the mine was worked with natural ventilation using many openings in the outside along the exposed ledge of rock above the river and numerous small timbered shafts. Most of the shafts had caved or had been filled and many of the openings filled. The plan of mining left random pillars with the openings between pillars some 20 to 40 feet wide and 15 to 18 feet high. The roof material was limestone except, in some areas, where a shale cap rock was encountered.

We had been alerted earlier in the week that our equipment might be needed. On Thursday we were asked to help. By Friday morning the fire seemed to have spread widely throughout the area and smoke was being discharged from all openings in the vicinity of the plant. By the afternoon, three small fans had been set to pull smoke from the mine. The 60,000 cfm which these fans provided was sufficient to prevent smoke from issuing from the openings into the plant area and was much less than would be required to give the positive air current needed to enter the mine. The following day a fourth and larger fan was put in

operation. This fan was large enough to give a total air volume of 120,000 cfm.

It was decided to try to contain the smoke by ventilating the area. One of the doors of the left main portal was opened for about two hours. No improvement in smoke resulted and the fire seemed to be affecting the roof. A door at the main right portal was opened and a substantial fire could be seen on a crib with two trucks silhouetted against the fire. The foam generator was set up and foam was introduced for about 30 minutes into the area where the trucks and the fire had been visible. Foam appeared at the left hand portal indicating that the area was being filled.

The foam generator was shut down and we entered the left portal. We cut our way into the foam with a fog nozzle, taking the first cross cut to the right, working our way past a large truck and bulldozer. We reached the first of the two silhouetted trucks, and cleared the area around both trucks of foam. The only burning in the area was a slight flicker of flame from between the dual tires of the inby truck. The crib inby this truck was out and foam stood in all of the openings holding back heat and smoke from the fires farther in the mine.

To the right of the first silhouetted truck was a corrugated sheet iron stopping. Through cracks of this stopping, a substantial fire was visible. We pulled off one and then a second corrugated sheet and turned the stream of the fire hose on to the fire for about 10 minutes. The hose stream was beginning to get control when smoke started to come in on us forcing us to retire. It was apparent through the holes in the stopping that fires were burning inby and outby the small area which we could reach with the hose stream.

The foam generator was set up in order to deliver foam into the area visible through the stopping. Foam was delivered into this area for about one-half hour. While this area seemed warm, fire was not visible thereafter.

At this time the decision was made not to attempt to extinguish the fire, but to limit our objective to the recovery of the equipment and drums of lubricant. The reasons for this decision were:

1. The mine had no value. Its usefulness as a storage area was replaceable at a point where no timbering was present.
2. The extent of the fire was unknown, but it probably was quite large. Fighting such a fire would be costly and dangerous.
3. No trained mine firefighters were available. Until two inspectors from the USBM arrived with Chemov apparatus, no breathing apparatus was available.
4. The smoke contained a high percentage of carbon monoxide and was loaded with creosote.
5. While the fire could consume a substantial quantity of timber if permitted to burn unchecked, it would run out of fuel eventually and die out. The support of surface facilities could be provided relatively cheaply by hydraulic filling, if necessary.

Work on this limited objective was delayed until Tuesday morning, until the motor of the large fan was repaired and replaced. On that day all of the equipment—trucks, bulldozers, and highlifts—and the drums of lubricant and chemical were recovered. The procedure was to fill the area with foam, cut access through the foam to the equipment with a spray of water, erect canvas to hold back the smoke, or to permit the foam to hold it back and to pull the equipment out with a tractor. This was done without resorting to breathing apparatus and without having any personnel in a heavy concentration of smoke.

Important experience gained at this fire includes:

1. The high expansion foam was clearly able to extinguish the actively burning timber cribs.
2. The high expansion foam provided an effective barrier against heat and smoke, without which the entire operation would have been impossible.

In at least one location, a large crib was extinguished even though it was known that foam did not reach the full height of the crib. Cooling of the upper portion of the crib could have resulted only from the steam generated when the foam contacted the hot material in the lower part

of the crib. The sealing action of the foam prevented air from moving over the crib, allowing the steam to stay in contact with the upper part of the crib, cooling and extinguishing it.

Fires in Dead End Places

The most common fire which occurs in underground coal mines is that which originates on mobile mining equipment. In fact about 50 per cent of all of the serious coal mine fires reported by the USBM during 1960 started as machine fires. If the equipment is outby an open break-through and the ventilation is adequate or subject to control, the problem of approaching this type of fire is not too difficult.

Usually the equipment fire takes place in a working place where the equipment is only the last open break-through. Any fire in a dead end is difficult to approach as the smoke and heat of the fire must be faced or controlled.

A recent report of the USBM, RI 5846, entitled "Practical Aspects of Controlling an Underground Fire on a Mining Machine," is a useful study of the relative effectiveness of various techniques and extinguishing agents when tested under controlled conditions upon a simulated mining machine. These tests showed that water fog was most effective if the fire could be approached closely; however, loaded streams or wet water were more effective than water alone. The effectiveness of any type of stream or spray rapidly decreased as the distance between the fire and the nozzle increased.

Tests on dry powders of various types applied by shovel, necessarily at close range, showed that sodium and potassium bicarbonate were the most effective. Application of dry powders by rock dust distributor upon the test fire was uniformly unsuccessful. In all cases tested, high expansion foam was successful in controlling the test fire.

RI 5846 tells of the Bureau's development and construction of a small "foam-duct generator" to which a roll of 24-inch diameter polyethylene plastic tubing was attached. The fan of the foam-duct generator is capable of unrolling the tube and, by closing and opening the damper of the fan rapidly, the tube can be snapped by pres-

sure to attempt to straighten it if it becomes fouled. This unique scheme permits the foam to flow in the tube to the fire where the tube has been burnt off by the heat of the fire. Testing by the Bureau showed the usefulness of this approach, at least under the conditions of the experimental mine and simulated machine fire.

The authors of RI 5846 have placed substantial emphasis upon the development and performance of this "foam-duct generator." It is important to examine the concept and range of application of this machine critically as it is easy to overestimate the potential of the equipment. My purpose is not to be critical of mechanical deficiencies, if any, of the actual machine developed by the Bureau. An efficient machine of this size and pressure potential can be built. The points to be examined are what it can and cannot do.

In the tests at the experimental mine, the unit was able to extinguish the simulated mining machine fire. Thus, the equipment makes enough foam for its purpose if the simulated fire is a fair test. This question now becomes one of examining the simulated mining machine fire, the circumstances of location, and the facilities where the simulated fire was tested.

The simulated fire of oil containing a little coal dust with some rubber tires, makes a hot concentrated fire. The coal, oil, and part of one tire were placed in a rectangular tray and a tire was placed against the tray. The entire fire was partially shielded to make the control of the fire by hose streams more difficult. The fire was a reasonable test of a machine fire except that the shielding provided was far less than would normally be found on a piece of current mining equipment where cover plates, guards, and structural members shield the interior of the machine, particularly in locations where hydraulic oil is found.

The pre-burn of four and one-half minutes is reasonable in that all equipment tested could be functional in that period had it been closely available on the section. In fact the pre-burn might be too long when considering hand extinguishers.

One questionable element is that the test area had sheet iron as a roof; concrete for ribs and a concrete bottom. A simu-

lated fire, which was to be repeated many times, could not be permitted to ignite roof or ribs and to cause falls of roof; however, an actual fire generally spreads in the coal and causes falls of roof.

Unfortunately the area of the experimental mine chosen for the fire tests is not representative of actual conditions usually encountered in the area of a machine fire. The area chosen had ribs lined with concrete or concrete blocks and a bottom of concrete, slag, or crushed stone. The conditions more nearly duplicated a hall corridor than a mine entry. A mine entry is rough, may have debris on the bottom, and be obstructed by posts. If the fire has had much of a start, usually it will have falls of roof. More than one fire of a loading machine or continuous miner has caused the operator of an outby unit to leave his machine, in which case the outby unit becomes a substantial barrier to the plastic tube. Also, it is impossible to cause the tube to turn into a break-through.

It is apparent then that:

1. The test fire described in RI 5846 is a good effort to simulate a mining machine fire.
2. The pre-burn is reasonable.
3. The concrete-sheet metal lined entry prevented the normal spread of the fire and, to this extent made the problem easier.
4. The tube can be an efficient method for delivery of foam to the fire.
5. The test area was particularly favorable for the process of unrolling a tube.
6. While repeated and rapid opening and closing of the damper will snap the tube and tend to free it from obstructions, the tube can be diverted and obstructed by many objects to be found outby a machine fire.
7. The tube cannot be made to travel into a break-through.

Three important conclusions are incapable:

1. To provide the intended degree of protection, a foam-duct generator would have to be provided on each operating section. If the fire were given time to spread, the limited capacity of the foam generator could not cope with a sizeable fire of coal.
2. There is no certainty that the tube can be caused to reach a mining machine fire.

Obstructions and the possibility that the burning machine is in a break-through will assure that the tube cannot reach all fires. If the fire has caused falls of roof, the percentage is further reduced.

3. The small capacity of the foam-duct generator (5000 gpm or 667 cfm of foam) limits the usefulness of this equipment to small fires. Thus the foam-duct generator cannot be used to fight a sizeable fire.

Our approach to this problem has been to develop techniques and equipment which will permit delivery, with certainty, of foam from our much larger foam generators to the face of a dead end entry or break-through. In developing a high expansion foam fire truck for municipal fire fighting, we experimented with cloth tubes of various lengths, to be attached with zippers. This work has been the key to the delivery of foam into buildings from the fire truck. The mechanics of this tube have been proved by about eight months successful use of an experimental high expansion foam fire truck by a local fire company.

We have found that the foam will carry some 30 to 50 feet beyond the end of the tube into a dead end place and fill the entry, making a solid foam plug beyond the end of the tube. Thus the foam can be the shield against heat and smoke for men to reach the end of the tube. When there, a new length of tube about 20 or 25 feet long can be added.

If no major obstruction is expected, the length of tube so added can be straightened most easily by operating the foam generator. The procedure followed is for the men who have added the tube to return to the foam generator, which is started and operated initially at low air volume. Low air volume with normal liquid rate will make a heavy wet foam. When the generator has operated long enough to fill the tube with the heavy foam, the damper on the foam generator is opened and the heavy foam will be pushed out of the tube at high velocity. The weight of this foam will tend to carry it a substantial distance from the end of the tube. Then the generator is operated normally until it is apparent that good foam movement is visible back over the tube an appreciable distance. The liquid supply to the foam generator is cut off and the fan drives air through the tube. The air will

carry back out over the tube without disturbing the foam in the end of the tube. Thus, the tube has been extended, a new foam plug made in the end of the tube, and a visible opening made over the top of the tube for men to travel to the end of the tube so that it can be extended again if necessary.

If the tube, which had been added, caught or was diverted as it was being extended by the passage of foam, we find that it cannot become so entangled that it will shut off the foam completely. Since the foam will always move a little distance in the end of the tube, even if the tube has become so twisted that the velocity of the foam is not directed in, an effective foam plug will always be present in the end of the tube. Since access to the end of the tube is always possible, it can be straightened and the procedure repeated.

If, upon adding a length of tube, an obstruction is known or anticipated or it is necessary to turn the tube into a breakthrough, the foam plug in the end of the tube can be cut carefully, with a spray of water, the distance required to extend manually the added length of tube. Care must be used in cutting the foam to be sure that only the absolute minimum amount of foam is cut so as to leave the plug intact as a shield against heat and smoke.

When it is known that the foam has reached the fire, foam should be applied for a good length of time before any effort is made to explore or to extend the tube.

We feel that this technique offers a degree of certainty of delivery of foam not present with the foam-duct generator. Since it has been adapted for use with high capacity foam generating equipment, the technique broadens the range of usefulness of this proved equipment. The disadvantages which this technique introduces are that the method is slower in operation than the continuous plastic tube, the equipment is more bulky, and naturally requires more water than the foam-duct generator.

Other New Developments

Development and experience with tubes of various sizes which are expanded by the foam have led us to test a tube of substantial circumference in a mine entry. The circumference of the tube used was appreciably greater than the circumference of

the entry where the test was carried out. It was found that the tube would swell until it completely filled the entry making a tight seal, preventing the foam from recirculating to the fan of the foam generator. This tube effectively eliminates the necessity of building a special stopping into which the foam generator was formerly erected. Thus, the erection time of the equipment has been shortened to a small fraction of the old method.

The only problems introduced are the handling of a very large tube made of a strong neoprene coated nylon fabric. Since the tube must be so large and strong, it is heavy, especially when wet after use.

The other new development which should be covered is the discovery of a new foam concentrate. The need for an improved foam concentrate is quite apparent when the difficulties of the original material discovered by the USBM are listed. These difficulties are related to the high freezing temperature and sensitivity to water hardness found in the original material.

The relatively minor improvements which we were able to make on the first material forced us to search for new ones. Initially, our search in the laboratory involved the screening of some 400 surfactants. The result of this was a substantial list of materials which would not work. Fortunately, one material proved promising and is the basis of our new foam concentrate.

Now our laboratory work is aimed at developing the optimum physical properties of the new foam concentrate while retaining its excellent characteristics of foam formation and stability. The table below lists the physical and foaming characteristics of the two materials as we now know them. Because the laboratory work on the new material is still productive, its exact characteristics are not finally set; however, we do know that we can meet the specifications listed as a minimum.

This new foam concentrate represents a substantial breakthrough in the chemistry of high expansion foam. While we cannot be certain that the new concentrate will be able to make good stable foam with all mine waters, we do feel reasonably sure that many mine waters can be used. This material has not completely satisfied all of our hopes for a perfect foam concentrate, but it is close to it.

Characteristics of Foam Concentrates

	Old	New
Name	FDL-15	SA & I Series
Foam Laboratory	Excellent	Excellent
Foam Stability	Good	Excellent
Concentration required with 50 ppm water	2.5%	2.5% or less (1)
with 200 ppm water	5.0%	2.5% or less
with 1000 ppm water	Foam stability lost	2.5% or less
with 2000 ppm water	Labels	2.5% or less
with water (3)	Labels	2.5% or less
Freeze point	About 40°F	Rate at 20°F (2)
Viscosity	Steadily affected by temperature	Steadily affected by formulation

Notes: (1) There is a possibility that the concentration requirement can be reduced for 20°F formulation.

(2) Probably also safe at 0°F. Formulation can be changed to give freeze point less than minus 20°F but concentration requirement may increase.

(3) Over 18000 ppm hardness.

Over the course of some years, I have had more experience in fighting mine fires than I like to recall. Also, during the past two years of effort aimed at improving, developing, and finally marketing equipment for generating high expansion foam as a fire fighting tool, I have had many opportunities to discuss the problems of fire protection in mines and to examine the facilities present in a number of mines.

I have seen both extremes. There are too few mines with really adequate facilities, with equipment which is thoughtfully engineered and carefully maintained, and with fire-conscious employees and officials who believe in and work at fire drills and fire prevention. There are far too many mines which are trying to get by with luck and the bare minimum. There is a vast majority with some equipment, some training, and some thought; but, I am afraid, not enough. That a fire can get out of hand in a mine having adequate facilities, a planned program, and personnel awake to the problem such as Montour 4 mine, should emphasize the serious fire protection problem in all coal mines.

High expansion foam is a powerful new tool for combating mine fires, but it does not replace the old tools and methods which are time proved. High expansion foam can only supplement them. Without an adequate water supply, no mine is equipped to fight a sizeable fire.

Just what is an adequate water supply? I am sure that you can get a different answer each time the question is asked. I

feel that the ability to supply 150 gpm of water at 100 psi for an indefinite period would satisfy my idea of an adequate supply. My idea is expensive and probably can be satisfied only by a pipeline. The pipeline should be equipped with taps each 300 or 400 feet.

Large water cars are useful and can be especially effective in quickly supplying a large amount of water at high pressure. It is most difficult to provide my definition of an adequate supply with water cars however.

Hoses require special consideration at mines. Cotton or linen jacketed hose should not be used as they are subject to mildew attack. Hoses should be rubber lined and be rubber jacketed if of cotton fabric. Neoprene rubber is preferable. Some of the new constructions such as neoprene lined with dacron jacket appear to be very good as they are not affected by mildew or oil. Two-inch hose diameter seems to be about right. Coupling threads should be straight iron pipe threads and the pin-type coupling should be avoided. Too few people know that hose couplings should be finger tightened only. The hose coupling wrench is needed for breaking the coupling only.

The best nozzle is a combination type, able to give a good long range straight stream and also a good spray. I have the feeling that the nozzles which adjust continuously from a stream to a wide-angle spray cannot throw a stream as far as the lever type stream-spray nozzle. Because range is so critical in mines, I feel that the characteristics of the stream should decide the choice of nozzle.

Hand extinguishers are useful and have their place at strategic points in a mine and on portable equipment. Dry powder, loaded stream, and foam hand extinguishers all can be useful. Too often though, the simplest, most effective and cheapest fire extinguisher is neglected on equipment which uses water for dust control. By means of a simple valve this water for dust control can be converted instantly to fire use. A hand directed nozzle on a short length of hose gives the operator a simple, quick and effective extinguisher which will not be exhausted upon the delivery of a few pounds of dry chemical or a few gallons of liquid. Another approach is to fit the

machine with mounted and piped sprays to cover critical points. Thus, even if smoke should force the operator to retire, the sprays will continue to check the fire and prevent its spread. At least one company has used this scheme on cutting machines for over 15 years with excellent results.

Many special dry powders or additives to water have been tested and evaluated upon standard fires and simulated mine-type fires. While the dry powders are effective against special fires, they are not especially useful, except as a first quick shot, on mine-type fires. Additives can increase the effectiveness of water streams and will help if the water supply is not adequate in volume. However, water itself is hard to beat. It is cheap, can be transported easily, and is about the most effective coolant known. Since most modern mines must use water during many vital mining operations, it makes sense to have an adequate supply that will do the job when seconds count.

The vital ingredient in fighting any fire is training. Untrained men do not know or understand what must be done or what they can do. Usually, their reaction in an emergency is to run. Only training and leadership prevent panic. Training with all pieces of fire fighting equipment is important. Until a man has tried, can he be sure that he can operate a hand extinguisher? Unless he has been shown, he may direct it improperly and ineffectively. Most men can use a hose reasonably well, but with just a little practice the hose will be stretched, coupled, and put into operation more quickly. Practice sessions develop team work and speed. When every man has a job there is a minimum of confusion and wasted effort.

Training also tests equipment. Hoses which have been neglected for long periods may not be in shape when needed. Training includes putting the equipment away in a safe and workmanlike condition. There is nothing which will cause more confusion and delay than a few lengths of hose which have been rolled the wrong way. The need for training with gas masks and breathing apparatus is obvious, of course. I feel that high expansion foam equipment deserves the same attention and care. To accept delivery of the equipment, see it demonstrated, hear the discussion on its use, and then to leave it untouched in the warehouse

will not make it an effective fire fighting tool.

Most mines find that this training will create a consciousness of fire and fire hazards among personnel which, of itself, is sufficient justification for the training. The training need not be so frequent or prolonged that the training time will become a severe financial expense. Since supervisors have the responsibility of leadership, extra effort and attention must be devoted to training these key men. A man does not suddenly become an expert fire fighter the day he is made a supervisor. Nor does training take place until it becomes company policy and someone's responsibility.

While the title of this paper would tend to limit it to the subject of high expansion foam, it is important to understand that high expansion foam is another of the tools available for controlling and extinguishing a mine fire. Experience has proved that it is an amazingly capable tool which should be put to use as quickly as possible in an emergency. High expansion foam is the only tool which can be effective when a fire is beyond the range of a hose stream. It is sensible, therefore, to use it to kill the heat, control the smoke, and subdue the fire even in cases where it appears that control by hose stream is possible.

High expansion foam, hose streams, and other extinguishing means are purposely referred to as tools so as to emphasize that someone must use them. As with any tool, the skill and judgment of the men using them is the critical ingredient. With some notable exceptions, I feel that the greatest deficiency in the coal mining industry is in training. Effective training programs will do more toward solving the fire protection problem of the coal mining industry than any other approach. Other deficiencies are automatically exposed.

In any phase of human existence fire is a useful and necessary tool, but it can be a terrible and cruel enemy. Nowhere is fire more terrible and cruel than in mining.

DEVELOPMENTS IN THE USE OF FIRE RESISTANT HYDRAULIC FLUIDS FOR UNDERGROUND COAL MINING EQUIPMENT

By J. H. MINNICK

Staff Eng. Lubricant—Special Products Dept.
Shell Oil Co., New York City

Application and use of fire resistant hydraulic fluids by industry began some 15 years ago and has expanded rapidly since that time. As might be expected, much of the interest and progress in this field has been paced by groups concerned with industrial safety.

About five years ago, a project was initiated to investigate application of an hydraulic fluid in coal mining machinery which would be less hazardous than conventional petroleum hydraulic oils. Various fluids and their application were explored and it was agreed that the water-in-oil emulsion offered the most economical and practicable approach.

Much field experience was available with such a fluid from five years of development in other industrial activities and it was judged that many of the operating conditions would be similar in the new field of application in coal mining machinery.

However, during early field trials, it was recognized that certain conditions were more severe than anticipated and many recommendations for machine modifications were suggested and accomplished. As in any project involving a new approach with certain unfamiliar material characteristics, a cooperative program between equipment builders, equipment operators, and suppliers of

hydraulic fluid is required. In this project, an enthusiastic cooperation has been experienced, leading to the exchange of much valuable information.

With specific coal mining machinery, it is important to have available records of machinery history and operating conditions as a base line on which to judge appropriate modifications if required. Accepted industrial hydraulic practice involves recommended suction conditions in pumps, sump tank capacity, operating temperatures and use of screening and filtration elements for maintenance of system and fluid cleanliness. Much has been written to aid operating personnel in a better understanding of factors involved in a dependable machine and fluid performance.

Introduction of fire resistant fluids to industrial applications in general has not been accomplished without various problems related to the differences in characteristics of these fluids. However, the incentive to accomplish an additional improvement in safety underground will provide the justification for continued effort and solution to these problems. It is our understanding in the petroleum industry that national coal production is increasing and that an increasing percentage of this production is being mined by machine methods. To reduce any possible hazard involved in operation of

such machinery will be an objective of greater economic importance.

The prices of suitable fire resistant hydraulic fluids in the coal mining industry will generally be somewhat higher than the average paid for conventional hydraulic oils. However, the cost per ton of coal mined has in many cases been less than with the latter products, principally because of reduced machine consumption rates. This may be considered a somewhat minor point in the overall importance of improved operation safety, but it has been our experience

that introduction of such programs are facilitated when the operating economics are attractive.

From our viewpoint, in retrospect of the past two years' experience in this particular work with the coal mining industry, it seems likely that future developments will involve modifications in machine hydraulic systems to provide improved fluid operating conditions. These will be accompanied by continued research and development in the area of improved fluids for this application.

DEVELOPMENTS IN METHANE MONITORING

By D. H. ZELLERS

Chief, Research & Development Section, Branch of Electrical-Mechanical Testing
U. S. Bureau of Mines, Pittsburgh, Pa.

Since the development of the flame safety lamp by Davy, Clanny, and Stephenson early in the 19th century, this device with its numerous modifications and improvements has been universally accepted for detecting methane in mines. The principle of the flame safety lamp is well known to all informed mining men. When this device is maintained properly and is used correctly by a competent miner or official, it is reasonably safe and can be expected to detect methane concentrations of one per cent or greater.

Large-scale mechanization in coal mines has caused rapid extraction of virgin areas. This, in turn, has created a need for more accurate and more frequent determinations of methane so the effectiveness of ventilation and the rate of methane liberation can be measured.

The flame safety lamp will continue as a gas-detecting device for everyday use; it also can be used, with modifications, as the detector element in a methane-monitoring system. A deterrent to general acceptance of a flame lamp operating as a constant monitor in gaseous atmospheres is the fact that 154 of the 2,990 gas ignitions reported between 1857 and 1956 were attributed to flame safety lamps. Most of these ignitions were due to faulty or improperly used lamps. In a few cases, lamps suspected of having caused ignitions have been investi-

gated and found to be safe. However, they obviously can constitute a potential ignition source.

The degree of dependability reverts to the condition and assembly of the component parts and the competence of the user. This, of course, is true of any detecting device, but most other detecting devices are not disassembled and reassembled daily.

As a supplement to the flame safety lamp, a number of electrical methane detectors have been developed in the past 20 to 30 years. The American detectors approved by the Bureau are manufactured by the Mine Safety Appliances Company and the Union Carbide Corporation. Other detectors that are approved include the martinsen (F. W. Willhoit, U. S. Agent) and the riken (manufactured in Japan and sold in the U. S. by the National Mine Service Company).

Most of these detectors afford greater accuracy than the flame lamp, but they all have limitations, and their cost, compared to that of a flame safety lamp, enhances the continuing popularity of the latter. None of the electrical detectors mentioned will indicate a deficiency of oxygen, but, as a matter of interest, those utilizing a wheatstone bridge circuit will indicate concentrations of methane quite accurately in a deficiency of oxygen—as long as sufficient oxygen is present to completely oxidize the

methane. This ratio is approximately two parts of oxygen for each part of methane. The riken, which is an interferometer, is accurate only if the atmosphere contains no gases other than air and the gas for which it was calibrated. The presence of any other gas or vapor will result in inaccuracies, and an interferometer will not indicate an oxygen deficiency.

Flame lamps and portable electrical detectors only give spot determinations and must be observed by individuals, usually at irregular intervals. The need for an automatic, constant-monitoring methane detector resulted from modern rapid extraction in caving mines.

Monitoring devices may be divided into: (1) Those that continuously record methane concentrations but still require observation by individuals, and (2) those that sample methane and give a visible or audible warning or perhaps shut off electrical power or start up a fan when methane concentrations reach a predetermined level.

The director of the Bureau of Mines, recognizing the need for an automatic methane monitor of the second class, invited representatives of instrument, electronic equipment, and mining machinery manufacturers, operators' associations, the United Mine Workers, and the Bureau to a conference in Pittsburgh in February, 1958.

The desirable features to be incorporated in an automatic methane-monitoring system were outlined by the director as follows:

(1) The system shall give a visible or audible alarm if and when the concentration in the vicinity of the sensor reaches 1.0 to 1.5% methane.

(2) The system shall cut off all electrical power to the affected section if and when the concentration in the vicinity of the sensor reaches 2.0 to 2.5% methane.

The only restriction placed on the manner in which these two functions might be accomplished was that no ignition hazards were to be introduced.

The Bureau has subsequently established the requirements to be met by a manufacturer wishing to have a methane-monitoring system certified. These requirements are embodied in a proposed schedule which has not been published in its final form. Two preliminary drafts have been published in

the Federal Register. Subsequent to each publication, a meeting has been held with interested parties who had submitted comments concerning this proposed methane-monitoring schedule as it appeared in the Federal Register. The schedule in its final form should soon be available.

At the time of the director's conference, one manufacturer already had commercially available a device for cutting off electrical power at the source if a cable fault or a frame ground occurred. This device was readily adaptable to a methane-monitoring system.

Another manufacturer had a similar device not fully developed.

A third manufacturer had an approved methane alarm, which with some modifications, could be incorporated into a monitoring system.

Several other manufacturers submitted prototypes of monitoring detectors which were examined and evaluated, but none of these have reached final development.

It eventually became evident that private industry either was hesitant or, because of current business conditions, could not afford to invest in the research and development of monitoring equipment. Consequently, the Bureau undertook the development of a suitable monitoring detector.

In the Bureau's monitoring device, two elements, with well-known characteristics, were combined. One of these, which we call a "pellament," is a small catalytic mass which will oxidize low concentrations of methane. This element is mounted adjacent to the second element, which is a bimetallic switch such as that used in home-heating-system thermostats. The heat of combustion of the methane by the pellament is employed to actuate the switch.

The net result is a small, simple, inexpensive methane detector. The idea for this unit had occurred during experiments with a flame lamp in which a thermal switch was mounted. Subsequently, we learned that the idea was not original, for two patents had already been granted for a device employing these basic principles; one patent had been issued in this country and one in England—the latter had been granted to an Italian.

Although basically the Bureau's device is similar to those covered by these two

patents, it differs with respect to the catalytic element referred to previously as "the pellement." This element presents a relatively new concept in the combustion of low concentrations of methane by catalysis. Heretofore, the catalysis occurred on the surface of spongy coiled platinum filaments; however, with the Bureau's pellements, coiled platinum filaments are used only as heating elements. The catalysis occurs on the surface of a small bead of alumina which bead, so formed, is impregnated with platinum and/or palladium as catalysts. The pellement oxidizes methane at a relatively low initial temperature (approximately 400°F.) and gives ten times the life of a bare filament: 3,000 hours versus 300. Since the initial temperature need not be high, less energy is required to accomplish the heating.

As an example, a miniature methane detector has been developed in which two of these pellements are incorporated, one active and one inactive. The inactive pellement is made in the same manner as the active one except that it is not impregnated with the catalyst. Upon application of current to the bridge circuit, it is heated to the same initial temperature as the activated pellement, but it does not increase in temperature in the presence of methane because there is no combustion. The inactive element may be located in the same atmosphere as the activated sensing element or it may be housed in a cell containing fresh air, as it is in the case of the miniature detector.

This detector is energized with one D size flashlight cell. The pellements in it are wound with .002-inch wire and require a current of approximately 0.4 ampere. Those used for the monitoring detector are wound with .005-inch wire; consequently, more current (1.3 amperes) is required to heat them to the threshold temperature. Although pellements made with 2-mil wire may function satisfactorily for the monitoring detector, those made with the heavier wire seem to be more practical because of their additional mechanical strength. However, it is essential that the power requirement be kept to a minimum, since that determines the size of the power source required.

In the course of our investigations, numerous examinations with regard to both sensitivity and simplicity were made of various basic principles used in measuring low concentrations of methane.

In the table below, taken from a paper by Pritchard,¹ are listed the approximate percentage changes in output signal that will occur in instruments using various principles if 1% methane by volume is added to the air passing through the instrument.

	Percent
1. Gas temperature above a flame.....	16
2. Resistance of electrically heated filament on which methane is burned catalytically.....	3
3. Volume of pressure change on combustion.....	2
4. Density.....	0.5
5. Refractivity.....	0.3
6. Thermal conductivity.....	0.2
7. Velocity of sound.....	0.2
8. Viscosity.....	0.4
9. Infrared transmission (from path 600° C.—Black Body Source).....	0.3

Obviously the greatest degree of change is available if the methane is burned by an open flame. This principle was investigated, as already indicated, but it was shelved, at least temporarily, in favor of a device built on principle No. 2 because that one affords a much higher degree of safety.

In all field tests conducted to determine the performance and dependability of the Bureau's detecting device, methane recorders were employed. These recorders were developed at the Bureau using the wheatstone bridge circuit with pellement sensing units.

Preliminary field tests were first conducted at the Bureau's experimental mine under controlled conditions. Other tests were subsequently conducted at commercial mines located in Pennsylvania, West Virginia, and Indiana. From these field investigations, we learned the following:

- (1) The air flow pattern around a machine is very fluid; no homogeneity of gas-air mixtures can be expected.
- (2) Methane can be expected to rise to the roof and flow in a thin layer along the roof—even opposing ventilating currents.
- (3) Methane may be occluded in the coal and only liberated as the coal is broken down.
- (4) Methane may also be liberated from the solid face and ribs, in some cases floor or roof.

1. Pritchard, F. W., *Measurement of Methane by Combustion in a Flame*, London, August 1957, (21 pp.) (Great Britain, National Coal Board, Scientific Department, Mining Research Establishment, W.R.E. Report 2075), Research Programme Reference No. 8.2.

(5) Ventilation constitutes the most important factor for reducing methane concentrations but often may be inadequate or neglected.

(6) With relatively high rates of methane liberation, 40 to 50 c.f.m., one of the most effective means of delivering adequate air volume to the face with continuous mining is with auxiliary fans and tubing.

(7) The practice of piling coal behind a miner is an important factor in the restriction of air flow and consequently in the buildup of methane concentrations over the machine.

As for monitoring devices it was determined that

- (1) the detecting elements or sensors made with the catalytic mass and thermal switch could withstand normal shock and vibration when solidly attached to a continuous miner,
- (2) these sensors also functioned quite satisfactorily even in the presence of coal dust and/or moisture, and
- (3) they did not shut off power except when sensing methane concentrations at pre-set limits.

Recording equipment used in conjunction with the monitoring equipment was an excellent tool for studying the adequacy of face ventilation and the influence of operating practices to methane buildup.

The design of the machine dictates the location for the sensors. It was concluded that the sensors should be mounted as far forward and as high as practicable for adequate protection. No definite conclusion has been reached as to whether one sensor judiciously mounted will be adequate or whether in some cases two will be needed.

In the Bureau's investigations, two sensors were used; they were located from 7 to 15 feet from the face and from 12 to 18 inches from the roof, depending upon the machine with which they were used.

Recent concern because of numerous reported face ignitions in coal mines has placed definite emphasis, and I might add, pressure, on the progress of methane monitoring in this country. The problem is recognized and also has been given consideration in other countries.

In a paper titled "Recent Developments

in Methanometry" by F. J. Hartwell, M. Sc., of Great Britain, which was presented to the Sixth International Conference of Directors of Safety in Mines Research at Verneuil, France, in 1950, various handheld detectors were described as well as a "fire-damp recorder."

The first model of this recorder was built in 1936, and many improvements were later incorporated. This instrument measures the pressure changes following combustion in two independently operated chambers. A pointer is linked to an aneroid cell and registers the pressure in the combustion chambers on a chart fixed to a clockwork-driven drum that makes one revolution in 24 hours. The recording is not continuous; a .36 milliliter sample is pumped into the combustion chamber and burned. The complete cycle requires six minutes, and by having the cycles of the two chambers staggered by three minutes, 30 independent analyses are made every hour.

A second recorder is also described in the same paper. It is the ringrose methane recorder, a mechanized version of the ringrose methanometer. The basic principle for that instrument is somewhat the same as that first described; that is, the instrument gives a measure of the difference in pressure that results when combustion of methane occurs. The ringrose recorder gives one analysis every six minutes.

Another paper relating to methane monitoring in Great Britain, titled "A Recorder of Atmospheric Methane Concentration Based on a Butane Flame Lamp," by F. W. Pritchard and S. A. Phelps, was presented to the Tenth International Conference of Directors of Safety in Mines Research at Pittsburgh in May 1960. In brief, a thermopile is placed above the flame of a safety lamp in which butane as fuel is fed at a constant rate for stability. The electromotive force generated by the couple is used to close a relay which can be employed to initiate any desired sequence of operation.

With further reference to British methanometry, a recently published article titled "An Acoustic Methanometer" describes a unit used successfully in Great Britain in conjunction with methane drainage. It measures gas concentrations in the piping system ranging from 40% to 90% methane. Developing a practical methane-monitoring

detector on the acoustic principle may be rather difficult. Where the ratio of the gas to air is only one to ninety-nine, the degree of change is extremely small, and the resulting unit will be very critical, particularly to foreign gases, water vapor, and dust.

Dr. Maas of the Netherlands Department of Mines reports that a methanometer which is mounted against the wall of a roadway has been in use for about eight years in the Netherlands. This is presumably a stationary methane recorder, for he states that it is too fragile and too large to be mounted on heavy equipment. As he points out, any such instrument can be modified to actuate a relay and give an alarm at any preset value.

The following is a very brief article in the November 4, 1960, issue of the South African Mining and Engineering Journal which gives some insight into what the Russians have accomplished in the field of methane monitoring: "Methane measuring stations in various parts of a mine feed information through the mine telephone network to a computer which programs the ventilation system—as methane builds up in an area, more air is automatically directed into the area, thereby diluting the methane. If the methane builds up to a dangerous concentration, the mine power system is automatically cut off."

Methanometers built on seven of the nine principles (all but density and viscosity) listed in the table in Pritchard's paper, one based on the absorption of ultraviolet light passing through a methane-air mixture, and one that measures on a photoelectric cell the quantity of light emitted during the combustion of methane by a catalytic filament have been investigated, evaluated, or at least are familiar to those of us in the Bureau who have been involved in this problem. It is noteworthy that most of the successful methanometers and detectors for other combustible gases have been developed on the second principle listed, "resistance of electrically heated filament on which methane is burned catalytically." In most cases, the change in resistance that results from the combustion of the methane by a catalytic filament is employed to throw a bridge circuit out of balance. In the Bureau-developed detecting device, the heat transfer is used to mechanically actuate a thermal switch. The heat of combustion might also

be used in conjunction with thermistors and thermocouples.

Although a number of the listed principles might be applied in the development of satisfactory laboratory methanometers, certain limitations preclude their successful application as methanometers intended for use in coal mines. The resulting unit would be too delicate, too critical, or too expensive.

A study is in progress to determine the component parts best suited to the Bureau-developed sensor, the best arrangement of these parts, and an ideal source of electrical energy. The last is relatively simple if alternating-current power is available but somewhat more difficult if the mine power is direct current. Fortunately, alternating-current power is becoming more available. However, since the proposed schedule 32 requires that the system shall function for a period of 4 hours, independent of the mine power, the most logical source of energy for powering the methane monitor seems to be a storage battery which can be floated on the line, and thus kept at near full charge while power is delivered to the machine. The relatively new hermetically sealed nickel-cadmium batteries seem to offer the most nearly ideal source of energy.

Although a methane-monitoring system will not increase production other than by necessitating improved face ventilation and thereby preventing explosions, we have been encouraged by the response our experimental monitoring equipment has received from those in the industry who have seen it. There seems to be many officials in the coal mining industry who feel that there is a need for an automatic means of determining the methane concentrations in the face regions. This is particularly true in the case of those using continuous mining machines.

In conclusion, progress has been made, but the successful development of a complete methane-monitoring system is still not a reality. Furthermore, the Bureau-developed sensing element is not considered the ultimate in design and operation. There may be better ways of achieving the desired results. Considering all of the technological advances that have been made in recent years in this country, surely other satisfactory equipment can be developed. The Bureau will gladly cooperate in every way possible with anyone willing to undertake the task.

PREVENTION OF LOSS IN UNDERPINNING

By HARRY T. IMMERMANN

Vice Pres. & Chief Eng., Spencer, White & Prentiss, Inc.
New York City

I have been granted the privilege of addressing you on the subject of the prevention of loss in operations requiring the technique of underpinning, from the standpoint of design and of execution, or perhaps I had better say *improper* design and *faulty* execution.

Underpinning has been best defined as the adding of new permanent support to existing foundations, either to provide additional capacity or additional depth. It is both an art and science—an art in that it requires skilled workmanship in its installation, and a science in that proper design must be based upon systematized knowledge.

Generally, underpinning is performed as either a remedial or a precautionary measure. In order to prevent further damage to, or collapse of, a structure in the process of settling, underpinning is performed to provide the additional capacity required to arrest the settlement. Such underpinning is remedial.

On the other hand, where excavation for a proposed new structure is to be carried to a depth below the foundations of adjoining structures, those existing foundations are extended by underpinning methods to a depth such that the new excavation will not result in their disturbance or loss of carrying capacity. Underpinning so performed is precautionary.

Again, if additional loading is to be brought upon existing foundations, as by the addition of stories to an existing building, the foundations may have to be extended in area, or depth, or both, to prevent overloading of the soil supporting the structure; this too is precautionary underpinning.

We may reduce the incidence of remedial underpinning by improvement in design and in execution, so that what is installed today need not be corrected tomorrow. As to the incidence of precautionary underpinning, as

long as subways, sewers, tunnels, new foundations, etc., are to be constructed in populated areas, such work will be required; and insofar as it is a concomitant of progress, we do not wish for a reduction in the amount. We can wish, however, for a reduction in the volume of remedial underpinning, and I shall therefore devote most of my remaining time to a discussion of that.

Statistics are not available, but it may be stated without fear of exaggeration that millions of dollars are expended annually in this country for the repair and strengthening of structures founded upon inadequate foundations. The deficiency in the foundation may be the result of insufficient investigation, improper design, faulty interpretation of the information available, or poor workmanship in the construction of the foundations.

Lest we become too critical of the foundation designers of the past, bear in mind that early in this century, the cost of carrying foundations to a great depth in order to reach a firm stratum was prohibitive; many structures were therefore placed upon inferior strata at a higher level, and many of them have suffered serious settlement and damage.

In defense of the contemporary foundation designers and constructors guilty of these sins, bear in mind that of all the elements of a structure, the foundation is the least open to exact analysis. We may test and accurately determine the shearing, tensile and compressive capacities of steel, concrete, wood, brick, stone, etc. Insofar as such materials are employed in the construction of a foundation, our knowledge is sufficient to permit of their proper design, if they are subjected to the stresses which we assume to be brought upon them. But the foundation of a structure is that portion which is placed upon some material whose characteristics are not as well defined as the ma-

materials of the foundation itself, nor one that permits of as exact an analysis.

Even under light loads, soils will deform to a far greater extent than steel or concrete. Deformation of steel or concrete results in a change in shape and a relatively small change in volume; deformation of soils is not only a change in shape, but is accompanied by a considerable change in volume as well; it is a change that does not necessarily accompany the application of the load, as in all the materials of construction, but one that may develop some time thereafter.

Bear in mind, too, that it is not possible to determine all the properties of soil from borings and from laboratory tests; unexpected changes may be noticed when excavation is underway, or when the foundations are being constructed.

That there have not been many more cases of serious settlements of structures may be attributed to the fact that many buildings carry but a small portion of the live load for which they are designed, and which is used in the computation of the loadings to be brought upon the foundations. Office buildings are designed for a live load of about fifty pounds a square foot; there is probably no office building in Chicago today that has half that live load. Apartment houses are designed for forty pounds a square foot, ten pounds per square foot would be a much closer approximation of the actual loading.

I shall not take the time to enumerate the known causes of settlement of structures. For those founded on spread footings, or mats, there is a list of around fifteen. For those founded on piles, there is a list of over twenty-five. These lists are not complete. They are based upon known, recorded observations, not on theory. Paralleling these lists is one comprising half a dozen errors in design that have resulted in foundation failures.

Fortunately, the science of underpinning has progressed with that of foundation construction and design, the latter receiving its great impetus from the advent of the eminent Dr. Karl Terzaghi and the science of soil mechanics which he founded, and from the practical application of his basic principles by great foundation engineers such as Daniel Moran and Lazarus White.

Yet, strangely enough, the dissemination of this science and its wide-spread application to the solution of foundation problems has not been accompanied by a diminution in the percentage of foundations improperly designed and improperly constructed. This has been a great surprise to me, and I can account for it only in this way: the principles of the science formulated by Dr. Terzaghi have been well taught, enlarged upon, and promulgated by an extraordinary group of disciples, great teachers like Casagrande, Peck, Rutledge, Baumister, Terzhobataroff and others.

But the principles of this science may not be successfully applied by the mere substitution of figures for symbols in some formula, nor may results be obtained in the same manner as you get a beam size from a steel hand-book, having previously determined the section modulus. The successful application of this fine science requires the combination of mature judgment with a realization of the possible shortcomings in the formula being applied; or a realization that the formula presupposes conditions difficult of attainment in the field. The science has not failed—the tool has just been improperly handled.

You may construe this, if you wish, as a suggestion—even a recommendation—that difficult foundation problems be referred only to consultants experienced in the solution of such problems, for underpinning is a specialized form of construction, and is generally considered quite hazardous. It can be as safe as many other features of construction if it has been planned by experienced engineers, and is performed by skilled field personnel.

As to the actual performance of the underpinning work, I should like to call your attention to the fact that the success of an underpinning operation depends primarily upon three things, namely, the care exercised in excavating so as to prevent loss of ground; secondly, the method of transferring the load of the structure being underpinned to the underpinning element installed to receive it; and thirdly the provision of proper lateral support to the underpinning as it becomes exposed during the course of adjacent excavation. We may discuss these three points briefly:

The first is care in excavating; here, skill is required, in the placing of louvered hori-

zontal partitions, and packing behind them in sand, until the placing of tight boards is self-evident.

The second point is the transfer of load; where the underpinning is of concrete, it is brought up to about 3 inches below the underside of the existing footing, and that space filled with a stiff mortar consisting of cement and sand, with very little water added. This is placed, a small amount at a time, and rammed solid by hammer blows on a short piece of 2 x 4. Such dry-packing is preferable to grouting, as no air pockets will be formed, and no shrinkage will result. It may not suffice however if at some subsequent period pile driving is to be performed near this underpinning, and there is the risk of the underpinning being pulled down by such work; here, recesses should be left in the top of the underpinning concrete for the insertion of jacks, and steel plates and wedges used for the filling of this space until the final transfer of load, when dry-packing may be used for final closure.

The third point is lateral support; it must be borne in mind that underpinning installed as a means of providing vertical support to adjacent walls, or columns, often has the added duty of serving as a retaining wall as excavation proceeds on one side of it. It must be braced, and care exercised in the design and preparation of "heels" installed for the retention of such braces.

There has been, in recent years, an unfortunate percentage of failures of one-story buildings, such as super-markets and bowling alleys—not so much of the shells of the buildings themselves, but of the floors on the ground. No longer may we heed the old-timer who is of the opinion that all soils are capable of supporting some load; surely you do not need much of a foundation for the support of a 30-pound bowling ball passing by every few minutes.

But the old theory of ability to support "some" load is erroneous, if the material is

consolidating and is therefore incapable of supporting any load without settlement. It is worth while remembering that the cost of installing a proper support for a floor, after the building is erected, is generally from four to six times the amount it would have cost, had it been done at the time the building was constructed.

We have, on occasion, been requested to install an absolute minimum of underpinning, or "temporary" underpinning beneath structures which are scheduled for removal in the near future. I reject such a request, for that leads to another subject on which I would like to touch, if I may be permitted this digression; it is not a matter of underpinning, but it is a matter of safety, and as we are discussing safety, I am not going far afield. The subject is "Temporary Construction."

The history of construction in recent years has been stained with records of the failure and collapse of shoring of forms for the pouring of floor arches and walls, of sheeting and bracing of the banks of excavations, and of scaffolding for building construction. Note particularly that these are all temporary structures. There must be a hundred failures of such temporary structures to one failure of a permanent structure. Why? Does the average engineer or constructor, under these circumstances of providing merely a temporary support, feel that he can take more liberties, which is tantamount to saving risks with life and limb? Is he less conservative when designing something that is not to be a permanent installation? The answer to these questions, I fear, is in the affirmative.

The danger has been recognized in some areas. In New York City, for example, the design of sheeting, and bracing of excavations, and of scaffolding and form work must be prepared by a professional engineer and submitted for approval along with the plans of the finished structure.

THE PRE-CONSTRUCTION CONFERENCE AS A MEANS OF ESTABLISHING SAFE WORKING PRACTICES

By GRANT L. SIVIER

Pres., Sivier Construction Corp., Oak Park, Mich.

I am a contractor from Michigan, and I suppose that as contractors in general go, we Michiganders are no better or no worse than others throughout the United States in our attitude toward job safety. We don't like to have accidents on our jobs and we like to see our insurance rates reduced; but to get us to do something constructive about it is another matter.

Concerning safety on one of the expressway jobs in the City of Detroit, William Leighton of the City's Department of Streets and Traffic put the situation this way: "This is a tough job from the standpoint of safety and one that will require real cooperation from all concerned. If a man puts his rear out a few inches too far on this job, he has had it."

We are quite proud, however, of our Michigan State Highway Department and the work they have done, and I would like to tell you a bit about how we try to cooperate with them in improving our job working conditions.

Beginning in 1954, and for two years thereafter, the Michigan Road Builders Association conducted six separate courses for the training in job safety of supervisors of highway and bridge contractors. They were held during the winter season when construction work was at a low ebb and were well attended. However, as these things have a habit of doing, interest lagged. Safety ratings which had started to improve became static and further improvement seemed impossible to achieve.

In October, 1958, the Association's safety committee, then headed by Ammon Schreier, decided something should be done and done soon, or the safety record of road and bridge building contractors was going to worsen and trouble would lay ahead.

About this same time the Michigan State Highway Department became cognizant of the fact that job safety records of their

contractors were not what they might be. Following the election of Commissioner John C. Mackie, the regulation of accident and fire prevention through the offices of the Highway Department was explored with the then Chief Engineer, Howard E. Hill. Mr. Hill's background in the Corps of Engineers, permitted him to visualize the benefits that might accrue from some type of contractual requirement. Also, several of the road and bridge building companies, not necessarily those in the Road Builders Association, were becoming concerned about their safety performance.

In addition to this, the handling of traffic control, both pedestrian and vehicular, around and through construction areas was not consistent, and quite often the placing of responsibility for such controls was not clearly defined.

Strange as it may seem to contractors elsewhere, according to Michigan custom, when a problem arises that concerns any part of the roadbuilding industry, the State Highway Department and the Road Builders Association get a joint committee together and work out the problem. It is as simple as that. The State Highway Department was embarking on a rapidly accelerated program of highway construction—as much as double that of previous years. Such a heavy work program demanded that something be done to improve safety practices, both for the workman on the job and for the traveling public which would be inconvenienced by the construction in progress.

At the annual joint meeting of the standing committees of the Michigan Road Builders Association and the central office personnel of the Michigan State Highway Department, held in October, 1958, the Accident Prevention Committee of the Association made the following recommendation: That the Association petition the Highway Department to institute regulatory

procedures for safe working conditions on the jobs and for fire prevention controls on the jobs. This recommendation was approved by all parties concerned and a joint committee was formed to work out the details.

During the early part of 1959, and well into the summer, the joint committee worked out a set of minimum specifications for job safety and for fire prevention that could be incorporated into the contract documents, and which could be a nucleus for any program that a contractor might care to use. It was recognized that this was a new approach to an important problem. It was obvious that the days were past when the elements of safety on a roadbuilding job were left to the after-thought of a job foreman. This new approach was not a legislated program wherein bureaus would be set up and many people hired as administrators, but rather a program worked on jointly by the participating parties.

The task of hammering out a set of rules and regulations to cover all the problems encountered was a difficult one. It was finally decided that, except for regulations covering trench excavation where rules could be specific, other safe working conditions could be better evaluated at the time of the Pre-Construction Conference. The contractor would be required to submit his program, using these safety specifications as a base, and the department, through its own safety department and its project engineers on the job, would be responsible for enforcement. If the contractor failed to live up to the requirements of the program, the engineer had the authority to stop all work until corrections were made. A quick-acting penalty—but a very forceful one.

Now let me explain what we mean by pre-construction conference. Subsequent to the determination of the low bidder on any project and prior to signing the contract documents for this project, it is required that a pre-construction conference be held. As its name implies it takes place before any construction begins. Those attending are the contractor, any subcontractor he desires, representatives from affected utility companies, traffic regulatory personnel, the district engineer and project engineer of

the highway department, plus other interested parties.

At this time, details as to progress schedules, traffic diversions, special job construction problems, right-of-way problems, interferences with public utilities, and any other special problems peculiar to the job in question are discussed and finalized. The results are recorded and then become a part of the contract documents subsequently signed by both parties.

You can see that this pre-construction conference is a very important part of the start of any project. I can cite here an example of one job in progress now. The John C. Lodge Expressway in Detroit is a difficult one to build. The expressway is depressed which requires the relocation of all utilities. The street on which this construction takes place carries great volumes of traffic daily into and out of downtown Detroit, and must continue to do so all during the construction period. Because of the many problems that these conditions can cause and the many people involved, the pre-construction conference becomes a most valuable aid to all parties concerned.

The joint committee in developing the safety specifications decided that this pre-construction conference would be the ideal place to begin the safety program for any job. Here the contractor could present his program based on the specifications, and the Highway Department could correct or augment it in accordance with these same specifications. The department safety engineer and the project engineer could discuss means of inspection and all the discussions would become a part of the contract documents, thus binding on both parties. The specifications state that "To properly plan the integration of an accident and fire prevention program with construction operations and activities," the contractor shall comply with certain provisions, one of which is, and I quote, "meet in conference with the engineer to discuss the 'Construction Safety Program' and to develop mutual understandings to govern the administration of the program. The agreements and understandings reached at the meeting will be recorded by the engineer and will be made a part of the contract, and will further form the basis on which the accident and fire prevention program will be administered."

The program works just this way. At the pre-construction conference the contractor presents in writing his plan for accident and fire prevention on the work to be done under the contract, and the manner in which he plans to carry out the specifications. The plan is discussed by those present and when approved by the highway department representatives, becomes a part of the contract documents. The project engineer, under the direction of the department safety engineer, outlines his proposed inspection procedures, and this, too, is mutually agreed upon. In this respect our Road Builders Association has been most helpful. The executive secretary, C. J. Carroll, has prepared check lists, outlines for a proposed contractor safety program, and has compiled other information for member contractors' use.

Also at this conference are representatives of utility companies involved, and representatives from local traffic safety departments. Procedures to insure safe operation around the specific utility are outlined and agreed upon. Local rules for traffic safety requirements for safe movement of both pedestrian and vehicular traffic are presented and steps outlined to enforce these requirements.

The contractor is given the forms on which he is required to report (1) the total number of employee-hours worked on the job, (2) all accidents and fires resulting in death or injury to persons, and (3) all accidents and fires resulting in damage to property, materials and equipment. This compiled information helps both the contractor and the highway department to evaluate the program and to point up areas of needed correction.

Several items in these specifications are worthy of special mention:

1. The contractor must designate a person in his organization known as the "Safety Supervisor" who has authority and responsibility to administer the accident and fire prevention program on the job.

2. The contractor must instruct his employees as follows:

(a) Location of first aid facilities on the project.

(b) Names, addresses, and telephone numbers of nearest doctors, hospitals, ambulance services, local fire fighting units, and inhalator squads.

(c) Location of fire extinguishers and other fire fighting apparatus on the project.

3. The contractor must designate certain employees to be in charge of administering first aid and have first aid kits available at designated locations.

4. Designate an area or areas as first aid stations, minimum size to be 8' x 10'.

5. Inform supervisors of traffic flow so emergency services might have adequate ingress and egress.

6. Designate "hard hat areas" and require wearing of protective headgear in these areas.

7. Properly equip employees with protective devices where eyes might be injured, and check on proper protection for hands, feet, and other clothing where necessary.

8. Designate areas for combustibles.

9. Locate sufficient fire extinguishers, especially near fuel and oil supplies and near welding equipment.

10. Properly brace and/or sheet trenches according to Manual of Accident Prevention of the Associated General Contractors.

Included in the general specifications of the State Highway Department are the rules governing the movement of vehicular traffic around and through the construction area. Standards for construction and placement of traffic control signs have been developed in accordance with existing state laws and all these became a part of the agenda of the pre-construction conference.

You will note that though the specifications are a minimum standard, they are rather all encompassing and do provide a sound basis for a good job safety program.

Needless to say, this plan is not a panacea to correct all ills in job safety. It would be wonderful to be able to say it has worked to perfection. While it is a very good start, one must crawl before he walks, and there are a number of areas that need strengthening. The workman must be made aware that the wife of a careless man is almost a widow. Specifically, the program needs more active participation by the contractors involved. Their job-safety programs must be enlarged and employees must be given more evidence that the program is meant to be carried out and is not used just for face-saving purposes.

As an example, during the past season one of our contractors who operates an asphalt plant had shut it down for a day or so and one of the bins needed cleaning. This was one of the newer automatic plants equipped with power operated discharge gates. One of the plant men, a responsible employee with more than 30 years service, was working on this bin with his body in the opened gates. If the power fails these gates automatically close, and while this employee was working on the bin a fuse blew shutting off the power. The man was decapitated.

The highway department must more actively inspect and enforce the programs approved at the pre-construction conference. But these problems are only those of a beginning program and time and effort will correct them.

The pre-construction conference plan has without doubt produced good results. The frequency and severity rate of Michigan's highway contractors during the period from 1959-1961 has dropped 17 per cent over that of the three previous years, which is evidence that the program is working. Insurance rates for highway contractors have

been reduced and this reduction is in the face of much higher awards for compensation for job accidents. Contractors are beginning to realize that it means money in their pockets. When they receive refund checks from their insurance companies due to their good rating, they become confirmed evangelists in the cause of safety. Also in the field of public relations much good has been accomplished. With the heavy program of highway building in Michigan, the public has been served well. Less difficulty with detours, with traffic control, with resulting savings in life and property damage has given the Michigan resident a friendly feeling toward the State's roadbuilding industry.

And last but by no means least, this program which utilizes the pre-construction conference has proven conclusively that the recognition of a common problem and the joint solution of such a problem by the people involved is the way to successfully insure the establishment of safe-working practices.

The moral of the story is: "He is safe from danger who is on guard, even when safe."

VISUAL AIDS AND THEIR USE IN SAFETY AND MAINTENANCE TRAINING

By J. W. SYMONDS

Equipment Superintendent, Peter Kiewit Sons, Inc., Omaha, Neb.

The story of how our company has been using visual aids in safety and maintenance training goes back to the closing days of the war in 1945. Our management realized that some drastic steps would have to be taken to overcome the losses in personal development of younger men during the war years as well as to get all of our people back to the competitive spirit of the pre-war construction period which would surely be with us in the post-war era.

We were impressed with the effective manner in which the various services had been able to rapidly train recruits, not only in the arts of warfare but in the maintenance

of construction equipment. Through the courtesy of some of the construction equipment manufacturers who had developed visual aids for the service, we were able to preview some of the films that they had developed for their respective equipment.

As a result of this preview session, a decision was made to proceed at once on setting up a training program. Facilities were constructed at our Grand Island, Nebraska, equipment depot which included a projection and lecture room, class rooms, and a shop area for the dismantle and repair of equipment.

In January of 1946, the first class met with our president, Peter Kiewit, and top management people as chief instructors, assisted by a staff being developed to continue the school project as well as representatives of various equipment manufacturers.

The student body of the early session consisted largely of our top project supervisors plus some new men who were being brought into the company, most of whom had military experience with either the See-Hees or Army Construction Battalions.

Aside from our own construction equipment which was brought into the shop area for study, servicing, and in some cases dismantling, the only aids we had were films which had been developed for the various services.

Four sessions were held during 1946. The reports on the progress of the men after their return to their field assignments were so encouraging that we have continued this type of training every year. Needless to say, safety training was a very important part of the first conference and continues to be an important part of every meeting we hold.

Naturally, we have modified and improved our technique for conducting meetings. Most of the changes came about through suggestions made by the men attending. Such things as better ventilation of the auditorium, longer breaks to provide more time for exchange of ideas, no-glare lighting, more comfortable seating were obviously required to ease the transition from field work to classroom.

The major criticism of the early meetings was along this line: "I am sure we would get more out of the pictures if they were taken on actual construction projects."

During the 1946 construction season and since, we have been taking pictures of all types of work and where possible, showing both right and wrong methods. These pictures find their way to the screens of our meetings as either 35mm. color slides to illustrate talks, or as frames for sound color strip films.

Over the years we have made many strip films, safety being the most frequent subject, but also on equipment maintenance, supervision, human relations, management problems, and many other subjects.

Here are some of the 35 mm. color slides and the way we use them in our training meetings:

Carelessly built steps and stairs to field tool houses and shops lead to falls and serious accidents.

Ladders should be built of sound material according to approved plans and with uniform rung spacing.

Blocking of equipment must be solid and firmly cribbed.

Most equipment damage accidents are caused by lack of maturity in operators. When selecting operators, be wary of signs of lack of maturity.

Flashing warning lights are required on all equipment that works on nearly finished roads.

Riders should never be permitted on any construction equipment except bona fide instructors or supervisors checking performance.

Proper latches and safety chains are required for all towed equipment.

Provide windshield washing equipment at all service stations to keep truck and pickup windshields clean.

ReflectORIZED belts are required on all men whose work requires them to be aloft at night around construction equipment.

Seat belts are required on all motor scrapers.

There is no such thing as safe ground. All trenches must be braced.

"DO NOT START" tags are clamped to starting controls to avoid a person starting a unit being worked on by another.

Flagmen should be pleasant and informative when dealing with the public. People like to know the reason for, and the expected length of, the delay.

Dump truck safety struts are provided for all dump trucks to avoid danger of falling beds.

All air hoses over one inch in size should be provided with a safety chain to prevent the hose from whipping and injuring men in case of a coupling coming off.

Cable clamps must be installed correctly. Cable must be lubricated.

Operators must visually inspect their equipment before starting a shift, looking for the more obvious faults as well as the less obvious such as crooked frames.

Our safety motto, which we proclaim by billboard as well as small emblems on hard hats is: "THINK! SAFETY PAYS YOU."

THE SLIDING TRENCH SHIELD AS A SAFETY DEVICE

By J. V. OTTER

Engineer—Special Services, Morrison-Knudsen Company, Inc., Boise, Idaho

It is proper and timely for the National Safety Council to include in its program for this Congress consideration of devices and innovations which contribute to accident reduction in the field of trench excavation, because this type of work goes on continuously throughout the entire country and carries with it more than ordinary hazards.

Various types of sliding trench shields will be shown by photographs projected upon the screen. These include examples of fixed-position reusable shoring and boxes from which concept of a moving shield evolved. Following the slides there will be presented a short moving picture showing trench excavation, pipelaying in a moving shield and backfilling of the trench as a continuous coordinated operation.

In my home town paper there appeared a few weeks ago, a photograph with a caption reading:

"Disheveled but not seriously hurt, John Duncan, center, 30-year old workman is given attention by firemen and ambulance attendants after being rescued from a sewer cave-in on North Pendleton Drive on the Boise Bench Tuesday morning. Duncan was buried to his chest and rescuers worked for approximately 90 minutes to free him."

I hasten to say that this did not take place on a Morrison-Knudsen Company project. The example, however, reveals to us in a vivid manner the responsibilities resting upon the shoulders of each subscriber to the National Safety Council, Construction Section.

The man on the job has responded to the safety challenge by operating with more evident interest in his own welfare as well as that of others. New devices and methods

contributing to removal of hazardous working conditions are constantly being developed and put into use. Often the safer methods and devices more efficiently accomplish the work. Where that occurs we have the happy combination of savings in the cost of construction and, reduction in severity and frequency of accidents. Such is the case of the sliding trench shield.

The concept of a protective shield or box slid forward by the trench excavating machine, as pipe laying advances, is probably an outgrowth of efforts to save time and money by replacing conventional, built-in-place shoring with reusable devices.

Ten foot wide panels retain the sides of a 20-foot deep trench where 36-inch sewer pipe is being laid. The panels are handled by overhead crane, but the struts are necessarily installed by workmen operating in the ditch. During the process of installation of the struts there is some element of exposure to accident due to caving ground occurring immediately before the struts are put in place, or immediately after their removal. This is a practical difficulty inherent in all conventional type shoring—in other words—what protects the workman who goes down into the ditch to install or remove the protective devices?

The basic idea of removable and reusable shoring can be shown in a relatively shallow ditch where the danger involved is that of caving of the soil structure at or near the top of the ditch, due to undercutting of the gravel strata existing beneath it. Horizontal stringers are not required by ground conditions in such a case. Vertical members and upper strut were placed by men working above ground. After pipe was laid the

shoring was taken out in the same way and moved forward for re-use as the trenching progressed.

In an improved version of the same idea the vertical members were hung from a pipe extending across the ditch. A trench jack, attached to the vertical members completed the assembly. This assembly was handled as a unit—the only adjustment to accomplish installation being to tighten the trench jack after placement in the ditch and to release it again prior to removal and reuse of the unit. All this was accomplished by men working above ground.

Ingenious removable and reusable protective devices, on a more ambitious scale, speeded installation of 14.2 miles of huge water pipe through the town and country on the southern edge of Los Angeles, California in 1959. The big pipeline—eight feet in diameter—was built by Morrison-Knudsen Company, Inc. and Macco Corporation under a \$12,000,000 contract awarded by Metropolitan Water District of Southern California.

The pipe itself was of heavy steel, coated inside and out with a protective armour coating spun onto the pipe shell. Each section was 30 feet long and weighed a hefty 20 tons, yet it had to be perfectly aligned before being welded within a gaping ditch that ran as deep as 35 feet.

Contributing greatly to progress of construction were many new pipelaying developments devised on the job.

One such development was the adaptation of a single combination dragline and crane to dig the deep trench and place the pipe in cramped urban areas. This rig, a 100-ton Manitowoc, swinging a mighty 5½ cubic yard bucket, laid open a trench with vertical walls made necessary by the narrow right-of-way.

Two other innovations were both in the realm of safety. One was a special steel housing lowered by the big crane into the roughly excavated trench as a safeguard for workmen during fine grading operations which were performed by hand to align the pipe. After the housing was in the open trench, workmen moved inside it and thus had positive protection from any cave-in; rather than relying on temporary shoring to brace the walls of the ditch. The shield, 35

feet long and seven feet wide, had ports along each side for disposal of the hand excavated material.

The other safety innovation involved the use of special made, semi-circular steel cages which enclosed the pipe inside the ditch to provide similar cave-in protection for welders.

The cages were slipped into bell holes—in other words, widened and deepened transverse sections of the ditch—which were dug around the ends of each section of pipe to give welders access. Umbrellas protected workmen from the renowned California sunshine.

Moving to the cooler climate of the Pacific Northwest, we find the origin of the sliding shield in Seattle, Wash. and, a recent example of its practical application on extensive sewer construction recently carried out at Boise, Idaho.

One Ronald Smith, an employee of Valley Construction Company, leading utility contractor of Seattle, is credited with originating the idea of the sliding trench shield, when in 1938 he put two ¼-inch thick steel plates, approximately 6' x 16' in size on edge and welded steel arches between to hold the plates erect and at the proper distance apart and, so positioned as to allow the pipe to be laid beneath the arches. This arrangement proved useful in holding mud away from pipelaying operations at the bottom of a V-cut ditch. He found that the unit could be slid forward in the trench by the excavating machine as the excavator progressed with the ditch digging.

This had the elements of the continuous process trench excavation, pipelaying and backfilling made possible by the use of sliding trench shields employed by Morrison-Knudsen Company, Inc. and their associate, Valley Construction Company, in carrying out a vast program of sewer construction throughout a major residential and commercial area in the suburbs of Boise, Idaho in 1960 and 1961.

Running the southeasterly edge of Boise is a plateau-like sector of former pastures and irrigated farm lands that blossomed, in recent years, into a heavily settled area without accompanying benefit of public sewer facilities. Instead, property owners had to maintain their own septic tanks and cesspools.

Few indeed of those who voted the sewer district into existence had any conception of the magnitude of the project or the impact upon the community that would result from putting over 127 miles of sewer lines through, across, and criss-crossing a 9-square mile area populated by 22,000 people in the relatively short time of 18 months—or about 390 working days computed on a 3-day week basis.

This project, costing well over \$4 million, is, we are told, the largest sewer job let in a single contract, west of the Mississippi River.

In Seattle, Wash., where a large and continuing sewer construction program is underway, the usual size of a job is in the nature of \$500,000. Rarely do they exceed \$1,000,000 and never in the \$4 million range.

The project involved a staggering quantity of work. Disregarding street restoration items and appurtenances, and thinking only of items involving excavation, there was constructed:

1. 459,292 lineal feet of main line sewer (87.0 miles)—with pipe sizes ranging from 8" to 36" in diameter.
2. 1521 manholes averaging 12 feet in height, and
3. 7475 service connections extending from the main line sewer in the street to the property line of each individual user. The aggregate total length of these services was 212,748 lineal feet (40.3 miles).

This meant that streets had to be cut length-wise for an aggregate total distance of 87 miles and cut cross-wise in over 7,400 places.

Compare this undertaking, if you will, with the sewer construction program of the older portions of Boise City where 74½ miles of sewers had been built up to that time. This means that substantially more sewers were constructed in the new District in the short span of 18 months than had been built in the older and larger portions of Boise City in the 94 years since it was chartered as a city by the Territorial Legislature on January 11, 1866.

Since there were few alleys in the layout of the new area, virtually all the sewers had to be installed in the streets, with a resulting upheaval that was a challenge to even the

City's staunchest exponents of western hospitality.

Construction was complicated by traffic. Vista Avenue was cut length-wise to install the mainline sewer and cross-cut at intervals of about 65 feet for installation of service connection stubs to the various properties along the way.

Sewer laying encountered overhead power lines and an underground network of domestic water supply and gas pipelines and telephone cable. On the surface, there was a system of irrigation canals, ditches and laterals conveying water to the urban area and agricultural lands beyond the city.

In the interest of public safety and convenience, no more than 200 lineal feet of sewer trench could be left open behind each excavating unit at the end of the shift. Manholes had to be completed and backfilled in five days.

Trenches varied from six feet to 24 feet in depth and averaged 12 feet deep for the 459,000 lineal feet of 8" to 36" sewer pipelines installed.

There was super-imposed upon the usual concern for safety of employees engaged in doing the work, the burden of the safety and convenience of 22,000 residents and the maintenance of access for fire and police protection, for ambulances, for the delivery of mail, for fuel deliveries during the severe winter weather and for the normal flow of surface traffic, including common carriers and school buses.

Work had to be arranged in such a way that a fire truck could be brought within 400 feet of every structure at any and all times.

Under the high speed construction schedule, production was required of:

1. 10,000 lineal feet of mainline trench excavation and pipelaying and backfilling per week.
2. Thirty to thirty-five manholes per week, and
3. 180 service connection stubs from the mainline sewer in the street to the property line at each residence and business establishment per week.

Nine major spreads of excavating and backfilling equipment were required, including three ladder-type trenching machines and six crawler-type backhoes. In addition ten

smaller tractor-mounted backhoes were used to install service connections. Thus, nineteen excavation operations were in progress simultaneously—each with its attendant exposure of workmen to the hazards of caving ground. This exposure continued for every working day for one and one half years. Danger to children, attracted to the excavations was an ever present concern. The heedless motorist was a problem 24 hours per day—7 days per week.

The characteristic ground condition encountered was that of gravel overlain as much as eight or ten feet of consolidated clay known as hardpan. The trench shield is the design generally used in conjunction with crawler-type backhoes which made fairly wide cut ditches. The lower portion is one-inch steel plate 6 feet high and 16 to 20 feet long with a structural arch at the rear and closed end at the front. Side panels of various heights were used as required.

There was a tendency for gravel to cave-in beneath the hardpan and for the unsupported layer above to fall in. Interchangeable bolted plates at front and rear of the shield were used to adjust its width to that necessary for the diameter of pipe. A hook welded into the back of the backhoe bucket made possible use of the machine as a crane as well as an excavating tool.

Fine grading, pipelaying and bedding of the pipe was accomplished inside the protective box after completion of which it was pulled forward by the backhoe bucket operating in its normal manner of accomplishing a pull toward itself. As a rule the operator simply hooked the bucket over the forward closed end of the box and accomplished the pulling movement. In the event the backhoe bucket could not reach the shield from its standing position, the bucket was hooked to an anchor chain attached to the forward end of the box.

Caving of the trench wall occurred with little or no warning and with terrific impact. Failure of the soil structure was by vertical fracture. The open type shield with structurally reinforced sheet steel side panels withstood the force of the cave-in.

Another type shield has withstood the force of a large cave-in. Cover on the shield protected the workmen inside.

Use of this type shield necessitated the advance cutting of water and gas lines. Serv-

ice was immediately re-established by quick coupling hose connections. As the trench excavating machine arrived, hose connections were detached long enough to let the equipment and shield pass by, and then re-connected. Property owners were, as a rule, not cut off from water and gas service for more than one hour.

The sewer main, in one instance, was located some 10 feet below the gas line but less than 3 feet from it horizontally. In cramped conditions such as this the trench shield has distinct advantages over wider cut V-ditch operations. Because shields permit a narrow ditch to be dug, they also contribute to successful passing of power poles where located close to sewer center line.

Men engaged in laying pipe inside the trench shield were protected by horizontal steel ribbing running lengthwise and by removable cross struts. The removable feature of the struts allowed them to be re-positioned as needed to clear the way for lowering sections of pipe into the shield.

By removal of side panels or substituting side panels of the proper height, shields of the side panel type could pass under some utility pipelines more readily than closed box-type shields for which utilities, as a rule, had to be cut. For major pipeline arteries or telephone duct where such severing was not feasible, the shield was removed from the trench and replaced after tunneling under the service.

Long handled pneumatic tamper permitted required compaction of backfill around the pipe to be accomplished by an operator working above ground. Backfill material, for bedding the pipe, was placed by a workman inside the shield.

Lower rear section of a box-type shield could be cut away, providing "back porch" arrangement for protection of workmen engaged in pipe bedding operations, which followed immediately after pipelaying in the forward end of the box. At the extreme right and at forward end "ears" were provided at various levels. These were for attaching chains used to pull the box behind trench excavating machines.

The sliding shield is pulled behind a ladder-type trenching machine by means of chains. Water sprayed on the trench side

walls reduced raveling and caving, and facilitated sliding of the shield.

An enterprising contractor at Aberdeen, Wash., working in a clay formation which had a tendency to stick to the shield and prevent its movement, is reported to have installed ports along the side walls of the shield into which compressed air at 100 lbs. pressure was introduced to get it on the move again.

Equipment is provided at the left for conveying excavated material to the rear and returning it to the ditch as backfill behind the shield. Fines were separated out by a screening device at the upper end of the conveyor and fed in immediately behind the shield. The fine material was used for bedding pipe being laid inside the shield. Only about 50 feet of trench was open at any one time between excavation and backfilling.

An auxiliary diesel-electric power plant, installed on the front of the trenching machine, provided the required energy to operate the backfilling conveyor and screening plant. Motive power of the trenching machine was sufficient to pull the shield, as well as to perform its ditch excavating function.

Photographs used today were not taken especially for this presentation. Most of them are on-the-job photos, taken during construction by our field engineers in the discharge of their routine duties of recording situations representative of good application of tools and equipment, trouble spots, or other job conditions—good or bad—for proper attention of management.

Sliding trench shields of various design have been developed and used for the past several years by contractors in the Pacific Northwest to effect economies in the cost of sewer construction and to provide better protection for workmen employed below ground surface. Conventional shoring is not entirely displaced by sliding shields but its use can be greatly reduced thereby.

On no two sewer construction projects are identical conditions encountered. Accordingly, adaptations of the basic moving shield concept have been developed to meet some of the varied conditions which include soil structure, trench depth, underground utility installations and the type of trench excavating equipment employed.

Because use of the sliding shield permits pipe laying and backfilling to follow closely behind trench excavation, streets can be made available for surface traffic more promptly than normally possible using conventional methods. Where sewers are constructed in populated areas, this especially is not only a matter of convenience to the public but also better serves the interests of public safety.

Use of the devices and innovations discussed in this presentation have produced enviable safety records.

A total of 326,000 man hours were worked on the 14.2 mile water line project in Los Angeles, described earlier, with no lost time accidents due to caving ground.

Contrary to the expectations of many who contemplated the risks involved on the Boise, Idaho sewer project, with its 127 miles of sewer lines laid in trenches averaging 12 feet in depth and reaching down as deep as 24 feet, the project safety record was good. In fact during the entire 18 months of big production operations, involving over 500,000 man hours, there was only one lost time accident below ground surface. As this was a mechanical type accident, not due to ground conditions, it stands on the record that there were no lost time accidents due to caving ground on that project.

In order to survive in the sternly competitive business of modern construction, constant improvement of methods, tools and equipment is necessary. This evolution affords an opportunity to bring forth parallel advancements in safety practices because the most efficient construction method is usually the safest method.

Existing safety codes of Industrial Accident Boards and other regulatory bodies should be upgraded and modernized as improved construction methods and devices are perfected. New codes should be written on a sufficiently liberal basis to permit accident prevention to keep abreast of advancements in the art and science of construction.

If this is not done, the very codes originally written to safeguard workmen become a deterrent by preventing or delaying adoption and use of new and better and safer ways of doing things.

In this connection, recognition is due the Associated General Contractors of America

for steps recently taken to improve its Manual of Accident Prevention.

No discussion of safety devices would be complete without reference to the most remarkable of all—the workman—whose wisdom as to the nature of the ground came, as did his leathery countenance, from years of exposure to the hazards that lurk in the

sidewalls of an open trench. More often than not, reliance can be placed upon his appraisal as to the extent of the dangers involved.

This man, teamed with management, willing to fix what's wrong, keep what's right and, move ahead with new and better methods and devices is, in the final analysis, what it takes to get results.

HANDLING OF PRESTRESSED CONCRETE MEMBERS

By KEN PHILO

Engineer, Massman Construction Co., Kansas City, Mo.

The title of this paper encompasses an important phase of a young but already large and fast growing industry. It has only been since 1947 that the problem of handling prestressed concrete members in the United States has existed. The methods now established have been evolved from the solution of specific problems on specific jobs with no precedent established. Also the methods of coping with such problems are constantly changing as the designers are ever widening the horizons of prestressed concrete. The net result is increasingly larger and larger members to handle.

A prestressed concrete member is composed of essentially two integral parts—A—pretensioned or post tensioned wire or cable and concrete. In handling such a member, two inherent characteristics of these materials are, in fact, handling limitations. These characteristics are 1—concrete will not resist tension, and 2—wire or cable will not resist compression. Therefore, the essential problem is to load, transport, unload, and erect these members while keeping the stress limitations from being exceeded. Also to be kept in mind is that the prestressed concrete members are but a portion of any major project, and therefore their handling is further complicated by site conditions, and the scheduling of other portions of the work.

To illustrate the specific problem and specific job approach to handling prestressed

concrete members, the recent completion of the Platte River bridge near Achland, Nebr., is investigated.

The Platte river crossings, as designed by the Nebraska Department of Roads, consisted of: a substructure of 26 pile bearing piers and four pile bearing abutments and a 28-span superstructure composed of 168 prestressed concrete girders and a 6½ inch reinforced concrete deck. The quantity of prestressed 14 inch piling was in excess of 30,000 lineal feet and was furnished in 95, 75, and 65 foot lengths. The contract for the subject work specified a completion date of December 31st, 1960, or completion of 165 working days, whichever was the earliest. Anticipated weather and river conditions further narrowed the time allotment to the period from June 15th to December 15th or 185 calendar days.

In planning a job of this nature, the schedule or time table becomes all important. To satisfy schedule requirements, the following plan was evolved. Start construction on the south or Lincoln side of the river because of rail and road access. Divert the river to the north side as far as possible and construct the substructure by use of sand dikes and a well point dewatering system. Build a rail spur from the main C.B. & Q. line parallel to the bridge and extend it across the river on the upstream dike as pier construction proceeded, this spur to be used primarily for prestressed

beam and piling shipments from Lincoln, Neb., some 35 miles away. When the substructure had been pushed as far north as possible, divert the river thru a trestle and under the south spans of the completed bridge, and thus continue construction of the bridge to the north abutment. At Lincoln, in the Nebraska Prestress Corp. yard, new production beds, storage, and loading facilities had to be constructed to manufacture, cure, and load the 110-foot, 56-ton girders and necessary piling for job site delivery on demand.

The overall plan was made possible by the close cooperation of the Massman Construction Co. with the Nebraska Prestress Corp.; The C.B. & Q. railroad; John W. Stang Corp., and the Omaha Ready Mix Corp.

Execution of the plan was initiated May 19th when the first of four crawler cranes was unloaded at the bridge site. Work was immediately begun on the rail spur and dike and storage yard on the south bank just upstream of the right of way. The 30 day period following was used to organize, supply, and equip the job for an anticipated starting date of June 15th. During this period 39-foot track sections were built and stored, pier forms and reinforcing prefabricated and well point material assembled at the job site. Thirty-five miles to the south, girder production beds were being constructed, piling cast and cured, and shipping units readied. Crawler crane job assignments were as follows: well pointing, a Northwest Model 6-D; form setting and pouring a Northwest Model 80-D; dike building and excavation a Northwest Model 95, and pile driving a Model 3900 Manitowoc.

Work had just begun on abutment Number one and the first stage well pointing, when on June 20th the Platte river overflowed its banks and flooded the job site. By June 25th the water had receded to a point where work could begin on a dike to divert the river. This 24 ft. wide dike was started 1000 feet upstream and angled downstream to intersect the bridge at midstream, enclosing the first 12 piers. This dike was pushed on a round the clock basis while connecting cells enclosing twin piers were constructed during the regular work hours which were 6 nine-hour shifts a week. Each cell was formed by constructing

an upstream dike and a downstream dike parallel to and 100 feet from the center line of the twin bridges. A cross dike between each set of piers 10 feet apart completed each cell. As the upstream dike was extended, the rail spur was advanced and as the downstream dike extended, its surface was rocked for a haul road.

Pumping on a 24-hour a day basis was begun July 8 on the first ring of a well point system that was to hold the water down some 20 feet below the dikes for a period of 4 months. This system was composed of five connected rings of which four rings were pumped by 8, 12, and 16-inch pumps, while the fifth ring was being leap-frogged ahead. Each ring was 110 feet by 164 feet and when the whole system was in place, was capable of handling 30,000 gallons a minute.

Pile driving initiated pier construction was begun July 14th. Since only four cells could be dewatered at one time, operations were grouped as follows: Cell one, excavation and pile driving; Cell two, pile cut off and pour footings; Cell three, place reinforcing and form piers; Cell four, pour and strip piers. For efficient progress then each operation including leap-frogging one ring must be geared to the same speed. A four-day cycle was achieved, which resulted in a complete pier every two days. By September 21st, at which time it became necessary to divert the river to the south bank, 18 piers and two abutments had been completed.

The first of the 168 prestressed girders was erected August 20th by a job built gantry crane. This Massman designed and built overhead crane picked the 110-foot 56-ton beams directly from the shipping units on the rail spur parallel to the bridge and traveled on the pier supported rail system to the beams final position. The placement there culminated an erection scheme featuring a minimum of handling. The gantry was moved ahead to each span on the first shipping unit carrying the first beams to be erected in that span. Rail supports for the gantry were moved by crawler crane, a procedure that could be completed in one working day.

Immediately after beam erection, diaphragms were formed by using expandable wooden forms to allow for minor width

differences between the beams. Deck forms and reinforcing closely followed diaphragm stripping, and September 26th the first of the 28 deck slabs was poured. These deck slabs were formed, poured, and stripped at a rate of slightly less than three working days each. The last one being poured December 17th, two days over the schedule.

Now the problems of handling the prestressed concrete members for this job can be analyzed with the proper perspective. Some 300 car loads of material had to be manufactured, stored, and loaded at Lincoln, transported 35 miles to the job site, and there put in place. You may now recall the type of member we are dealing with and its limitations, a member that weighs 150 pounds per cubic foot with dimensions over 100 feet, a member that is imbedded with cables stressed to 330,000 pounds each, a member that has been designed primarily to resist static forces from certain directions only. On this project, such members take three rail cars to carry and 14 inch octagonal members that, when lifted from the horizontal to the vertical, tower as high as a 9 story building. Do not forget that "in place" means in the middle of a river well known for its treachery.

To reduce these problems to a safe economical solution requires a sound plan, proper equipment, coordination, and always an awareness of the handling limitations of prestressed concrete members. To handle the subject prestressed members in the yard, two travelift rigs were used. These rigs were first designed for use in drydocking boats and were then found to be adaptable to prestressed yards. Each rig has two 15-ton hoists, and by the use of a spreader beam between the hoists one end of the girder could be picked up. These travelifts roll on four large rubber tires. The rig spans 32 feet and is 25 feet long. Highly mobile, the two rigs safely and satisfactorily handled all the yard handling, storage, and loading requirements.

For shipping the girders a rail spur was brought into the yard alongside the storage area. To ship two girders, a unit of three flat cars was used. The girders were brought over the rail cars by use of the travelifts and set side by side, bearing on the end 40-ft. cars. The center 50-foot car was utilized as a spacer only. As the unit

went around a curve the cars would take the curve of the track, but the girders remained straight. Therefore, bearing units had to be so designed that both would pivot and one would slide. This was done by using steel bolsters with steel shoes sliding on greased plates. The two girders were also properly placed and tied together while blocked from the ground so they acted as one unit.

At the site the gantry crane served erection conditions admirably well. The gantry crane hoisted the girders by the use of a torque converter double drum single shaft engine with a 20,000 pound lead line pull. Reeved with six part lines, hoisting was a smooth and efficient operation. The gantry was propelled by rubber-banding two lines attached at the opposite end of the track. Two tower bents supported the gantry over the cars and intermediate trusses spanned between the pier supported rails. During moves ahead the tower bents were supported on the cars by eight swinging jacks and the whole unit pulled ahead by a TD 15 dozer.

Pillings were shipped to the job site in 60-foot gondola cars and unloaded on the cross dikes by crawler crane. The 3900 Manitowoc was especially selected and rigged for the requirements of handling a 95-foot, 7-ton prestressed concrete pile. It was initially rigged with 127-foot leads fixed on a swivel at the boom point, and a telescoping moonbeam attachment at the base. One hoist line was used for the hammer, and two hoist lines were used as pile lines. The two pile lines with snatch blocks at the ends picked the long pile with spreaders at four pick up points. Special 2x4 and celotex cushions were used on the pile cap to prevent spalling.

This prestressed structure (the largest west of the Mississippi) was completed in 142 working days. The proper handling of the prestressed concrete members playing no small part in the establishment of this record—without a lost-time accident.

To summarize, then, it is suggested that specific handling methods should be utilized to solve specific job requirements and let the specifications for handling prestressed concrete members be of the end result nature, the only limits of which are the inherent limits of the materials themselves.

PUBLIC EMPLOYEE SECTION

HOW DO WE KNOW PUBLIC EMPLOYEE WORK IS SAFE?

By WILLIAM E. BESUDEN

Staff Member, International City Managers' Assn., Chicago

The observations I wish to make are based on contact with those in the field of safety and with some experience with safety problems. When I first began working for municipal government I was employed by the department of personnel of the city of Cincinnati, Ohio. The department there was just getting underway with a safety program and at times I assisted in safety training. Later as an assistant to a manager I was again impressed with the importance of safety when I attended workman's compensation hearings that resulted in costs to the city of 53,000 dollars because of accidents to employees.

Finally as a member of the International City Managers' Association staff I prepared a brief survey report on "Public Employee Safety Programs." In preparing this report I spent considerable time with the people of the National Safety Council. We also contacted a number of cities and we read the literature of the field.

The observations are based not only on what I have learned about safety from the above experiences but from what I did not learn. The observations I wish to make are four:

- (1) Safety is important.
- (2) You do not know the extent of the safety problem and what is being done.
- (3) You have not decided how to attack the problem.
- (4) The Public Employee Section of the National Safety Council is not known by cities.

The first observation is "Safety is Important," but is it? Your immediate reaction probably is, "Did I come all the way to Chicago to hear some fellow tell me that my profession is important?" Granted everybody thinks that safety is important. It's like being for motherhood. But what is lacking,

it seems to me, is a positive for safety attitude.

Safety is important to state and local governmental agencies because the work done can be dangerous and such agencies represent a large amount of employment. Work such as police, garbage collection, and construction are recognized by most people as dangerous employments. The last census figures (Oct. 1960) show that 3.5 million people, not including educational employees, work for state and local governments. In 1951 the figure was two million—a large increase.

Municipal employment alone increased 20 per cent from 1953 to 1960. It is therefore obvious that governmental employment is on the rise. Contrast this with some industries where employment is on the decline. Automation appears to be bringing an increase in employment in the service industries such as government and a decrease in some production industries.

Safety is important because it concerns people and this is a point I think we often forget. We get wrapped up in the economics of safety and fail to remember that the prime objective of safety programs should be the prevention of human suffering. People are important and I think in this day and age that an appeal to governmental officials based on this fact will carry great weight.

Safety is important because it does save money. Time after time you, I know, have discussed this particular aspect of safety programs. You have been told of many examples and each one of you can tell of still more where a safety program has saved money for a governmental agency.

Some examples that I uncovered in preparing the survey report referred to one in Royal Oak, Michigan, that reduced motor

vehicle losses by \$4,323 in a year's time; Iowa City, Iowa, reduced a workman compensation experience ratio, effecting premium costs from a debit rating of 123.2 to a plus of 31.8; and Glendale reduced the cost of accidents per employee by 21 per cent.

We are all aware of why safety is important. There is no one here that would disagree with any of the things that I have just said. But the question is have you convinced governmental officials of the importance of safety? Have you developed a *for attitude*? I think not. There are several reasons why it is difficult to convince public officials of the importance of safety. Perhaps if we looked at these reasons we would be better able to develop the necessary *for attitude* that is so vitally important to effective safety programs.

First of all, those who have the final say on governmental programs are the elected councilmen, county commissioners, state legislators. These officials come and go and they have not seen the importance of internal safety. It is indeed strange that they pass laws that affect the safety of many not only at work but on our highways. Yet the same officials do not seem to stress safety programs for their own employees. I do not believe that elected officials do this intentionally but I believe the story has not been brought home to them of the importance of safety for the governmental employee. Do not forget that the elected official has many interests attempting to get his ear.

Secondly, the diversification of governmental activities creates a most difficult problem for the safety engineer in governmental employment. Instead of having one integrated production facility he has a diversification of activities. This diversification of governmental activities conducted by one governmental body affects the collection of statistics and other aspects of good programs that we will briefly mention later.

The third problem is demands for money. Each activity has its pressure groups in our society and this places demands on a limited amount of financial resources. True safety programs save money, but elected officials must be made to see this. Otherwise they will consider safety simply as another program costing so many dollars which the

municipal, county, or state government does not have.

The fourth reason that more attention has not been placed on safety programs in governmental agencies is probably that there seem to be more pressing problems. The city official faces many, many problems and some of these are more paramount and of an emergency nature than the problem of safety. For instance the city council is going to be more concerned by the problems of the merchant who is demanding central business district improvement than he is with the safety program. The problem of central business district is not only more pressing but it is more glamorous to the general public.

The second observation I wish to make is: You do not know the extent of the safety problem and what is being done to correct the problem on a national basis. True, *Accident Facts* gives a three year average frequency rate of 17.64 for cities, but this figure represents an average of only 22 cities and approximately 60,000 employees. The total number of cities over 10,000 population is 1,762 and total municipal employment is approximately 1.5 million people.

You do not need to be a statistician to know that this is a poor sample. The figure is all the less valid when you realize that the 22 cities are some of those with the best safety programs. *Accident Facts* also gives a frequency figure for state highway departments. This figure is made up of only 12 states although it probably represents a higher portion of employees working for state highway departments than is represented by the municipal figure for municipal employment.

You do not really know what is going on in the field because there is no full study of safety activities of state and local governments. Yes, you know what some cities are doing. A survey report like ICMA published discusses some of these programs. But how many cities, counties, and states have fully organized safety programs? Few I suspect. For one thing I am told that there are 130 agency members of the Public Employee Section. This represents about 90 cities and 43 counties and states.

Maybe your immediate reaction is "that so many governmental units are small." I

submit that there is a need for safety in all governmental units. Interestingly enough, not all of the cities that belong to the PES are large. There are a number between 25 and 100 thousand and at least one is as small as 9,000.

Do not make the mistake of ending up talking to yourselves. Get out and talk to those that do not belong to your section. Talk safety and get other people interested. Let their reaction to your program.

The International City Managers' Association because of its interest in safety and the National Safety Council plan to make a survey to determine just how many cities have organized safety programs, a few facts about these programs, and how many cities keep accident records according to the American standard method of recording and measuring work injury experience. We are doing this because we believe we will be able to get a good sample of all cities over 10,000.

The International City Managers' Association for over 25 years has published the *Municipal Year Book*. Each year we survey cities for information on what has transpired in a number of fields affecting cities during the past year. In certain areas we get at least an 80 per cent return. We hope to give questionnaires that will represent at least 60 to 70 per cent of those cities with over 10,000 population. These questionnaires provide a good knowledge of which cities have programs and of which cities keep records and how.

The third observation is: You have not decided on how to conduct a safety program. Oh yes, you agree on certain things, or at least that's my impression. You agree for the need of top management support. You agree on the employee participation and you agree on the need for keeping accurate records. However, there is a need to agree that government (municipal employment, county employment, and state employment) is an industry. We find many agencies of the same government conducting their own safety program with little concern of what the

other agency of the same governmental unit is doing.

To acquire top management support the program must have central direction. Management's major task is to plan, control and direct all activities of the organization as determined by elected legislators and to keep a balanced program. It will naturally take interest in and support those activities which receive central direction. Further, if records are accurately to reflect safety experience of municipalities, it is necessary to provide for the central collection of statistics about accidents.

The fourth observation is that governmental agencies do not know of the Public Employee Section of the National Safety Council. On the other hand, there are few governmental officials that do not know of the National Safety Council's work in the area of pedestrian safety and highway safety.

Again it is indeed strange that many governmental officials do not realize that the National Safety Council's largest group of employees is concerned with industrial safety and that you people of municipal, county, and state governments have your own section with your own staff representative ready to serve other governmental agencies and help them in establishing a safety program. It seems to me that you can get out and sell your program more than you have. It was encouraging to hear your chairman briefly speak of some of the things that you have done during the last year in this regard.

I hope I have said a few things that may help you. If I encourage you to get out and be an apostle of safety, I have accomplished one purpose. If I perhaps suggested new ideas for your group to consider as projects, I have accomplished another purpose. Remember, I said that I was going to only make observations. I may be wrong but if I reflect the observations of others who are connected with government employment but not directly connected with safety, they should have some value for you.

LET'S TALK ABOUT OUR COMMON PROBLEMS

Presiding: WARREN D. WILT, Safety Engineer, City of Detroit.

Participants: JAMES F. GLEASON, Safety Officer, City of San Diego;

H. P. GOODIN, Safety Director, City of Minneapolis;

JOSEPH F. WICKLESS, Supervisor of Safety, City of Baltimore.

Mr. Wilt demonstrated the effective uses to which a set of flash cards showing caricatures of typical personalities encountered in safety meetings could be put. The character typology ranged from "quick, helpful" to "highly argumentative." Distribution of the flash cards at a meeting can jar the participants into an awareness of their own attitudes.

Mr. Wilt outlined a number of "safety vitamins" which might be administered to pep up any safety program. He listed the G.A.T.—Gummi-ck Aids for Training; the S.S.P.—Safety is Standard Practice; the B.P.W.—Basic Printing and Writing; the M.V.A.—Making Visual Aids; the I.S.C.—Improved Safety Command; and a D and C vitamin complex for Demonstration and Communication.

John M. Collins of New York City Department of Hospitals, entered the discussion at several points to confirm the fact that communication problems in the dissemination of safety information to New York City hospital employees are quite similar to those encountered across the nation.

Mr. Gleason gave expression to the underlying reason for the existence of problems found in common among safety-men in the public employee section: the rapidly increasing numbers of public employees in the U. S. have created communication problems at all levels of public employment.

Mr. Gleason set forth a three point pro-

gram for achieving safety goals in the public employee field: (1) determine needs in terms of frequency rates in individual departments by way of statistical review and analysis of hazards (2) create interest in safety in a given department by the best available educational and training techniques (3) obtain actual involvement of the employees in the safety program and provide opportunities to maintain their involvement.

Mr. Goodin commented on the role of unions in implementing public employee safety programs. In his experience, the unions had great influence on dissemination of safety information, having a system ready to hand for communicating with the rank and file. In times of labor-management conflict, occasional problems in free transmission of safety messages were noted.

Mr. Wickless posed a number of problems concerning the elucidation of driver psychology. An analysis of accidents involving drivers for the City of Baltimore showed that driver attitude was often a direct cause. Mr. Wickless appealed to the possibility of suitable psychological tests to arrive at a reasonable evaluation of driver temperament.

Mr. Wickless also explored problems of the budgeting of safety programs. The approach to the budget requires, in his view, tactical as well as strategic steps toward the presentation of accident cost analyses in the city council. Timing is of great importance for placing the accident picture in proper perspective.

SAFE BUILDING MAINTENANCE IS COST IMPROVEMENT

By RAYMOND DENOMME
Building Service Supervisor
Detroit-Wayne Joint Building Authority
Detroit, Michigan

The sanitary maintenance of buildings, schools, hospitals, hotels, and industries is a \$6 billion industry that employs over one million people.

These million people, to a greater or lesser degree, are responsible for the health, comfort, and safety of many millions of people each and every day.

As a sanitation program manager, I am interested in the manner in which this money is spent for materials or salaries and in the manner in which these million people do their work.

Until such a time as all or the greater part of this \$6 billion expenditure is wisely expended, and until such a time as these million or more people work in an efficient and economical manner, the sanitation program managers and their staffs will lack the prestige they deserve.

I, therefore, welcome the opportunity to speak to you today because you, not too many years ago, were in a similar position.

You had an important message for labor and industry. You were able to put across your message by pointing out to management that there was a dollars and cents approach to safety as well as a humanitarian approach.

The size of your convention currently being held reflects the success you have attained.

We in the field of sanitation are having difficulty selling sanitation to top management. We lack, at the present time, sufficient supervisory personnel with higher education backgrounds. Consequently, it is difficult for us to adequately present our case to top management.

It is my opinion that a powerful ally, such as you safety people who have been able to attract to your programs men and women of dedication and higher educational backgrounds, can materially help us reach our goal.

My mission here today is to convince you that you have a stake in our future and to ask for your help.

I would like to present my case to you and begin by asking questions.

1. Has it ever occurred to you that every individual working in the field of environmental sanitation is responsible to a degree for the health, comfort, and safety of at least 25 other persons?

Now that I am talking about the safety of 25 or more millions of people, do I have your attention?

2. Just how deep has been your interest in the activities of these one million people whose work performances and use of materials and machines affect the safety of another 25 million people?

In the places that you work and over which you may have direct or indirect supervision, there are floors, walls, furniture, and washroom facilities.

People slip and fall on the floors. Have you done more than just run tests on the product put on the floors? Do you know how these floors are maintained by sweeping, mopping, and refinishing processes? You should because in the majority of cases it is not the product that is at fault but the daily maintenance procedures.

Isn't it true that dirty furniture and walls affect people mentally, emotionally, and physically to a degree that the ground work for an accident is often laid by the poor performance of the cleaning staff?

Their work is usually done when no one is around and they are rarely thought of when you attempt to determine the cause of an accident.

How about washroom sanitation? Are you sure that many accidents occurring in washrooms and directly attributable to poor sanitation practices—which are not reported due to embarrassment—could not be

eliminated if you as safety people worked with the sanitation supervisor more closely?

There are six factors in the attaining and maintaining of a modern sanitation program. I will name these and will point out to you how you are or should be involved in each and every one of them.

1. Management Support of Our Efforts to do a More Efficient and Economical Job

Top management will heed our request for new equipment and for preventive maintenance programs if you in safety can point out to top management that worn out, defective equipment should be replaced or repaired on a regular schedule.

Further, the washrooms, locker room, and eating facilities of the custodial staff are usually of the poorest. This often results in lowering of the employee morale and very often loss of time due to poor dietary habits.

2. A Plan of Attack

A well organized sanitation program is one where work instructions are clearly written or typed and posted in the proper places. Part of this program includes one or more bulletin boards large enough to include safety posters and information on the availability of safety equipment both on and off the job.

3. Supervisory Effectiveness

In the promotion of individuals from the ranks to supervisory positions a review of each worker's safety record should be part of the examination.

A man who will not practice safety as a worker will not teach and preach safety to others when he becomes a supervisor.

There should be an adequate ratio of supervisors to employees. These supervisors should be trained to make periodic checks of each worker's area and to report in writing all safety hazards.

Most important, from the standpoint of safety, the supervisor must be one who recognizes that a "stitch in time saves nine." He should, if possible, take a first aid course and at all times should have access to first aid equipment and the means of reporting and transporting serious cases to a doctor or a hospital.

4. Employee Training

Employees must be trained to do the work

in the most efficient and safe manner possible.

Every injury, however slight, must be reported.

All bulletin board notices should include written memorandums to the employees on this subject.

Equally as important as the safety of the individual doing the work is the safety of those who use the premises. Here again, every employee must know this and be trained to report to supervision all instances of lights out, existing hazards, and potential hazards.

When a trained employee reports a chipped ash tray or broken desk glass and a competent supervisor makes a report to top management and top management removes the hazard, then the employee is impressed with management's concern for his safety and he in turn will be concerned with the safety of others who work in his place of employment.

5. An Adequate Amount of Good Materials and Machines

Cleaning work is a monotonous, repetitious, and generally speaking, unrewarding task. If it can be made easier and more interesting and more rewarding by the use of good materials and the needed machines, then, in all likelihood, employees will do a better job, will make fewer mistakes, have fewer accidents themselves and eliminate factors that contribute to accidents among those who work in our hospitals, hotels, schools, and industrial buildings.

6. Research and Development

Very few supervisors in the field of sanitation are equipped at this time to evaluate properly materials and machines from the standpoint of safety.

It is this area that the safety people can be of great assistance because within the ranks of safety people there are those with chemical and engineering backgrounds.

I sincerely hope that at this point you will see the sanitation worker and the sanitation program manager and his staff in a new light. While it is true I am asking for your help, it is equally true that the building maintenance people of many installations, hotels, schools, office buildings, or industrial facilities have never been out-

done in generosity. Traditionally, we have always returned more than we have received and I can assure you any help that you can give us will be returned to you three fold.

If you doubt that there is need for your participation in our program, then I ask you to spend a little time reviewing the work and procedures of the night cleaning force in your activity.

Check the work habits of the employees. Do they leave the equipment around in a careless manner creating hazards for themselves and their fellow employees? Do they take the proper precautions in using ladders and mobile vehicles in their night's work? Are they cleaning the washrooms properly? Are they reporting hazards or have they stopped because nothing was done in the past?

From my experience in visiting many buildings throughout the country and asking these questions I have asked you above,

I have found a great need for the help and counsel of you in the field of safety.

I have heard it said that people have more accidents at home than at work. I am sure the majority of home accidents are due to poor cleaning procedures, improper use of maintenance equipment, and carelessness in handling products.

These same people who are so careless in this area at home invariably bring these poor habits into our buildings where our children go to school, our friends and relatives are hospitalized, and where most of us work.

It becomes apparent that you in safety can kill two birds with one stone by helping us in sanitation have safer working conditions, safer equipment, and by helping us teach our employees to work safely with the results of having these good safe practices carried back into the employees home and into a worker's off-the-job safety program.

PROGRAMMING SAFETY IN FORESTRY WORK

By HAROLD W. MASTERS

Safety Dir., Asplundh Tree Expert Co., Jenkintown, Pa.

I have been engaged in safety work personally for over a quarter of a century and I don't believe basically there is any difference in organizing and programming a safety program for any industry.

Since the inception of accident prevention so much has been written and spoken about its various phases that it is becoming a difficult job to speak about it from a new angle. I am sure that all of you feel that, although safety is definitely important in tree work as in all other phases of industry, nobody can say very much about it that is really new. There is very little that is new or exciting about the basic philosophies and practices of the problem.

But we at Asplundh believe that we have discovered a new way to get our men more interested in safety. I would like to tell you about this new way because we are genuinely proud of the results. Our accident experience records are the best today they have been since the beginning of our

Company. Safety education and its results depends upon communication: what is involved in speaking, listening, reading and writing. Might we not get somewhere if we look at safety education in the terms of this business of how people communicate and why communication sometimes is unsuccessful?

We started with recognition of the fact that visual education is one of the most effective ways to put across any message. We recognized the impossibility of bringing to our office in Jenkintown our men from the 42 states in which we now operate so we knew that we'd have to take the program to them as a sort of "Road Show." We organized for months, with a number of trial meetings, before we found most of the answers—and then we started rolling in high gear.

Time here doesn't permit description of the entire program, which started with a good dinner at the best local hotel, and

then went on into a carefully planned and scheduled two hour show, with a short intermission between the major parts, but I would like to show you at this time one of the elements which we consider most important and I believe is a most essential factor in the organization and setting up of a safety program.

For the most effective results, will you for the next few minutes, imagine yourselves as employees of the Asplundh Tree Expert Co. so that you will understand more fully the message that I am going to bring you. This should not be a difficult impersonation for most of you. Our tree men, like you, love trees and are outdoor men in better-than-average physical condition. So, from now on, I am talking to you as members of our organization . . .

Do you realize that billions of dollars are wasted each year on accidents, and millions of non-productive hours are caused by accidents. It is unbelievable that intelligent people such as ourselves are forced to tolerate such a deplorable condition. If you stop to realize the homes that could be built, the automobiles that could be manufactured, and the tremendous amount of material things that could be made with the money that accidents cost the people in the United States alone each year, it is something that everyone would like to do something about.

I am going to attempt to help you visualize the tremendous importance, both financially and psychologically, that accidents and injuries have in our business.

As you know, we spend quite a bit of time harping on the subject of Safety. It's an old subject, but important. Sometimes this harping becomes quite monotonous, but nevertheless, it has had favorable effects—and until we have attained a Utopia in accidents, which you and I know can never be, the safety department will still play this harp.

To begin with, we know that tree trimming, whether it is a private job or whether it is a line clearing job, is more hazardous work than the usual office job and many other classes of employment. Tree trimming and line clearing involve falls, hazardous equipment, falling objects such as tools, branches or trees, high voltage wires, and a variety of other hazards connected with

outdoor work, such as poison ivy, brush fires, traffic accidents and weather.

We are inclined to think of an accident involving only the man injured—who suffers pain, lost time, lost income, crippling, and psychological effects. There are many other effects on which I will dwell slightly further on in this talk.

Aside from the direct effects on the injured man, an accident involves many others—the worker's family and friends, the members of the crew, the customer whom the injured man's company is working for, the general public, and the company the injured man works for. You can see from this that an accident is not singular in its effects, but very much plural.

The injured man's family and friends may be seriously affected. Aside from distress and worry, they suffer loss of income—not just at the time, but possibly future earnings will be seriously reduced as a result of physical or psychological effects of the accident. The injured man's children may be denied opportunities that will affect their future—opportunities that were planned without thought of how an accident could affect them. Have you ever been called upon to notify an employee's family of an accident or a fatality? If you have, you know exactly what I am talking about.

Members of the crew, too, are affected. The distress is only part of it. The accident involves adjustments for them, such as trying to operate without the man, or the effort involved in training a new man to become part of a good working team. There are also temporary psychological effects on a working crew when one of its members is injured through an accident. Sometimes it takes a long period of time for the crew to get over this psychological effect, and during that time production and efficiency of that crew is naturally reduced.

Effects on our customers are serious, too. Although we free the customers from any responsibility or worry, they still suffer from our accidents. An accident reflects on them in the eyes of the public. And, of course, interrupting the work means a loss to the customer of income or service as well as the confidence of the public.

The effects on the public may vary greatly. Psychological effects are involved. The public may be directly involved in the accident

—either through personal or property damage. In addition, there is the overall economic effect that is involved whenever an important job is interrupted—and the lost income because of a worker's reduced income resulting from an accident.

The effects on our company are many and serious. We are proud to be experts in our line of endeavor but, when an accident occurs, we cannot maintain our "expert" standing.

When we sell our Asplundh package of line clearance today, we sell much more than just clearing a line. This package has to contain, among other things, a good safety experience and a good accident prevention program.

To operate a business and to present an attractive package, there is a price tag—and this price must include all costs and still allow a profit and a margin for expansion. This price tag includes labor and equipment to do the job. It also includes the cost of insurance to cover compensation, public liability, property damage, and other factors—and many direct costs, such as administration and taxes.

Accidents are expensive—sometimes very expensive—and the price of the accident will go into our price tag or we will go out of business. Someone has to make up the billions of dollars spent each year on accidents—you and I are the "someones." Prices would be quite different if we did not have to include the money it cost to pay for accidents that we didn't want in the first place.

Obviously, accidents involve direct costs, such as money to the doctors, hospitals, and lawyers. Whether the accident is to one of our men or whether it also involves the public, these costs can be very great. These direct costs are borne both by the injured person and the company for which that injured person works. These are only a few of the direct costs.

Obviously, another very costly effect of an accident is the cost of equipment and property. It is no exaggeration to say that a single thoughtless or careless moment may involve thousands of dollars loss in property, equipment and other things.

The direct costs—to damaged equipment and property, and the medical and legal costs of liability—are, of course, largely covered

by insurance. But insurance costs money—premiums—and the cost of premiums must appear in our price tag.

It is our policy to carry insurance which completely relieves our customer of any responsibility or worry involved or any costs of accidents. This makes our package attractive to our customer who is anxious to get rid of these headaches—but it costs money.

The cost of insurance is based largely on our accident experience record. This means that an accident tends to increase the cost of insurance. Only by maintaining a good accident experience can we continue to get low rates on our insurance. The costs of insurance premiums have many times spelled the difference between success or failure of a company.

Now let's consider some less obvious costs involved in an accident that we overlook many times.

An accident interrupts work. There is nothing wrong with members of the crew helping their injured co-worker, but this does represent a loss—a hidden cost—while the crew stops work in production.

An accident often means that work must be rescheduled. The crew loses efficiency, and often this involves hiring and training a man to replace an experienced one who is lost to the crew.

Another hidden cost is that involved in investigating and checking on accidents—including constant efforts to study each accident, in order to prevent one like it in the future. Sometimes this means developing new safety equipment or new methods—which may be quite expensive.

An accident involves a great deal of office work—paper work that goes with keeping records, filing and handling reports, etc. If there were no accidents, our paper work and clerical work could be greatly reduced. The cost of this, then, is involved in accidents and constitutes another hidden cost.

Another effect of an accident is that it makes our work less attractive. The problems of hiring and keeping men are made worse when accidents give the impression that this is an undesirable type of work. This, too, can prove very costly.

When needless accidents occur this price tag gets too large, and we lose a customer

which will effect every worker. This is why we consider safety not a separate subject but an integral part of operations.

We have shown why the Asplundh package must include safety—both from the point of view of the customer who buys the package, and from our point of view as affecting the price of our package. We promise to deliver safety—now let's see how we can accomplish it.

We have seen that an accident is expensive—involving injury, damaged equipment, interrupted service and the overall effect of unexpert work.

To effect an improvement of our accident experience, we must have the cooperation of management, supervisory personnel and the crew. Here the supervisors and foremen become the important link. They are the ones who must make our accident prevention program a reality.

There is a definite sequence and certain factors involved in every accident. First, the social environment and ancestry. Second, personal faults, temperament and habits. Third, an unsafe act or hazard. This leads to an accident which in turn could lead to an injury.

Thus, when environment is wrong, and personal habits or characteristics are inclined to an accident, any unsafe act or hazardous condition may cause an accident which may result in an injury.

It is by preventing the unsafe act or hazardous condition that the foreman or supervisor can prevent an accident and thus prevent an injury. By recognizing the unsafe act or hazardous condition, this domino can be removed, and if there are no accidents, there will be no injuries.

The foreman's part in a safety program includes several things: intelligent hiring and selection of men, careful training, setting a good example, planning for every job and every condition, constant supervision and enforcement of rules and regulations.

This is the only statistic in our entire program. Study shows that there is a definite ratio of non-injury accidents to injury accidents. For every 300 non-injury accidents there will be 29 injuries and one serious injury or fatality. This shows why we cannot consider a safety record good, even if there are no injuries; because if

we have a high number of non-injury accidents, each is a *potential* killer.

We must not get the idea that accident prevention consists only of stepping in at the last minute when an accident is obvious. Too often, the idea of accident prevention is too late.

Accident prevention must start away back—recognizing potential accident hazards. There are many symptoms of a potential accident. Poor housekeeping always invites an accident, as well as giving a bad appearance and creating an atmosphere of sloppy work. Any tendency to disobey rules or disregard instructions invites an accident. Equipment in poor condition constitutes potential danger. Improper handling of vehicles, particularly, invites accidents. Foolish or thoughtless conduct is a sure sign of a coming accident.

The conscientious foreman or supervisor realizes that he has a responsibility to his crew. He might think he is being a "good guy" if he relaxes discipline or looks the other way at times—but he is actually hurting his crew.

For example, a foreman or supervisor is not being nosy or butting in if he points out to his men that their personal lives will affect their welfare and their safety.

The foreman should urge his men to be properly dressed for the job. Aside from appearance, there are real reasons for this. A hat must allow visibility and not be likely to fall off or catch. A loose shirt will snag on branches and affords poor protection against branches or weather. Pants must allow freedom of movement. Shoes must be the right kind.

Safety begins *before* the first man climbs the first tree. The crew must arrive safely at the job-site. The truck must be properly parked, and warning signs must be set up.

Before the job gets underway, tailboard conferences are extremely important. It is here that planning the job, clear instructions, assignment of work and special warning can contribute to safety.

The rules for climbing are important in accident prevention. There is a proper way to climb—and many improper ones involving dead branches, weak branches, trailing ropes, full hands, obstructed vision and loose tools.

Ropes are the treeman's lifeline, but they can also become his deathline. Ropes must be in good condition, properly used and respected at all times.

Properly used, ladders add to safety. But they are a menace if they are in poor condition, broken or slippery. They should be firmly set and climbed properly.

A healthy respect for power lines and all lines is of critical importance. Any wire may become energized!

During the job, many kinds of stupid acts can result in an accident—daydreaming, horseplay or sloppy work, or failure to warn others of a falling limb or tree, for instance.

Power equipment must be respected. In spite of the safety devices built into power equipment, stupidity will result in accidents—usually serious ones.

Poor housekeeping on trucks invites accidents. Disrespect of rules and regulations invites accidents. There is a right way to load a truck, and a proper place for every tool. Good housekeeping can help maintain a good safety record.

Obeying traffic laws and sensible driving are absolute musts for all of our men. On the job or off, this is most important. In addition, trucks must be kept in safe operating condition.

A great many other minor hazards exist in this work. Although they may not seem serious, they may lead to serious accidents. Minor injuries can become serious ones. Common sense added to safety rules will cut down the hazards of poison ivy, scratches, bad weather and cuts.

Our company provides all possible information for achieving a good safety record. Study and experience have led to the development of good safety regulations, and instructions covering every phase of our work give every man what he needs to keep a good safety record.

You may never know it—and may never get credit for it, but every day you have an opportunity to take an action that may save a man's life. The training, supervision, discipline and planning that you do today may make the difference between tragedy and this wholesome ideal—a good worker, healthy and happy, his family secure, his sense of a good job, and society well-served because a job was done the right way.

The end in view is *safety*, and the means of accomplishing this is complete, continuous appreciation of what is involved in an accident. First of all, what an accident involves. Second, prevention of the accident. Third, prompt and proper action when an accident happens. This end justifies this means!

**OFFICERS OF THE
CONSTRUCTION SECTION
NATIONAL SAFETY COUNCIL 1961-62**

General Chairman—*†ROBERT A. WENDELL, Chief, Safety Branch, U. S. Army Engineer Div., South Atlantic, Atlanta, Ga.

Vice-General Chairman—*†FREDERICK H. DEED, Mgr., Accident & Fire Prevention Dept., National Association of Mutual Casualty Companies, Chicago, Ill.

Public Relations Committee Chairman—*HUNTER P. WHARTON, Gen. Secy.-Treas., International Union of Operating Engineers, Washington, D. C.

Training Committee Chairman—*ROBERT O. NIMMO, Safety Coordinator, Peter Kiewit Sons' Company, Omaha, Nebr.

Visual Aid Committee Chairman—*FRED M. LIVINGSTON, Safety Dir., Turner Construction Co., New York, N. Y.

Standards Committee Chairman—*FRANK M. BOODRO, Safety Dir., Perini Corporation, Framingham, Mass.

Special Projects Committee Chairman—*JOHN V. O'BRIEN, Safety Dir., Bechtel Corp., San Francisco, Calif.

Off-The-Job Committee Chairman—*EUGENE C. GUNN, Chief, Safety Branch, U. S. Army Engineer Division, Missouri River, Omaha, Nebr.

Nominating Committee—*ROBERT L. MOORE (Chairman), ROBERT L. JENKINS, Chief, Safety Division, Office, Chief of Engineers, Department of the Army, Washington, D. C.; WILLIAM G. HAWKINS, Safety Dir., A. Teichert & Sons, Inc., Sacramento, Calif.; GERALD O. GRIFFIN, Safety Dir., Dravo Corp., Pittsburgh, Pa.; OTTO S. HOLMSKOG, Consultant, Wausau, Wis.; GEORGE P. O'ROURKE, Sr., President, O'Rourke Construction Co., Dallas, Texas

Honorary Life Members—H. B. ALEXANDER, President, H. B. Alexander & Son, Inc., Harrisburg, Penn.; SAMUEL R. BISHOP, c/o The Hearshstone, Northfield, Mass.; JOSEPH J. HIGGINS, Bethlehem, Pa.

Staff Representative—*CLEMENT J. LUEPKE, National Safety Council, Chicago, Ill.

Past General Chairmen—1918-'21, LEO D. WOODRKE; 1921-'23, F. A. DAVIDSON; 1923-'24, W. F. AMES; 1924-'26, W. F. AUSTIN; 1926-'28, E. C. HARDING; 1928-'29, W. R. RICHARDS; 1929-'31, GEORGE WIDUA; 1931-'34, JOHN RUSSEL, JR.; 1934-'35, EDGAR N. GELINTINE; 1935-'39, W. A. SNOW; 1939-'41, R. J. REIGELUTH; 1941-'43, W. A. HAZARD; 1943-'45, G. O. GRIFFIN; 1945-'47, LLOYD A. BLANCHARD; 1947-'48, FRANK J. CRANWELL; 1948-'49, OTTO S. HOLMSKOG; 1949-'50, J. A. DE LUCA; 1950-'51, HARRY J. KIRK; 1951-'52, H. W. RICHARDSON; 1952-'54, H. B. ALEXANDER; 1954-'55, G. P. O'ROURKE; 1955-'57, R. L. JENKINS; 1957-'59, W. G. HAWKINS; 1959-'61, R. L. MOORE

*Administrative Committee

†Steering Committee

OFFICERS OF THE

PUBLIC EMPLOYEE SECTION

NATIONAL SAFETY COUNCIL 1961-62

General Chairman—†Mrs. LOUISE RATNER, Safety & Claims Examiner, Ohio Dept. of Highways, Bureau of Accident Control & Claims, Columbus, Ohio

First Vice-Chairman—†JAMES F. GLEASON, Safety Officer, City of San Diego, San Diego, Calif.

Second Vice-Chairman—†GEORGE F. KUHN, Safety Supv., Illinois Division of Highways, Springfield, Ill.

Third Vice-Chairman—†JOHN M. COLLINS, Dir. of Safety, New York Dept. of Hospitals, New York, N. Y.

Fourth Vice-Chairman—†DAVID E. KOCH, Safety Dir., City of San Antonio, San Antonio, Texas

Fifth Vice-Chairman—†JOHN H. PHILLIPS, Dist. Engr., Virginia Dept. of Highways, Lynchburg, Va.

Sixth Vice-Chairman—†ARTHUR DIVINCENT, Safety Supv., Metropolitan Dade County, Miami, Fla.

Secretary—†RALPH L. ALTHOUSE, Personal Injuries Supv., Illinois Division of Highways, Springfield, Ill.

Program Committee—†TARVIA H. D. JONES (Chairman), Reg. Engr., Highway-Safety & Bituminous-Paving-Consultant, Graham, N. C.

Legislative Committee—†THOMAS H. JAY (Chairman), Safety Coordinator, County of San Bernardino, San Bernardino, Calif.; FRANCIS L. OTTO, Safety Engr., U. S. Department of Labor, Washington, D. C.; RALPH W. PROPLES, Industrial Safety Engr., Safety Division, Dept. of Labor & Industries, Olympia, Wash.; FLOYD J. UPHAM, Exec. Mgr., North Dakota Safety Council, Inc., Bismarck, N. Dak.

Engineering Committee—J. A. MOORE (Chairman-States), Safety Dir., Nevada Highway Dept., Carson City, Nev.; EDWARD A. BRANDPASS, Safety Supv., Ohio Department of Highways, Columbus, Ohio; BAYNARD A. SWITZER, Chief Safety Engr., California Division of Highways, Sacramento, Calif.; JOSEPH F. WICKLESS (Chairman-Municipalities), Supv. of Safety, City of Baltimore, Baltimore, Md.; J. E. JONES, Safety Dir., Department of Public Works, Baton Rouge, La.; T. D. WILSON, Safety Program Administrator, Industrial Safety Division, Honolulu, Hawaii

Advisory Committee—†TARVIA H. D. JONES (Chairman); *WARREN D. WILT, Safety Engr., City of Detroit, Detroit, Mich.; *DR. B. L. CORRETT, Managing Dir., Milwaukee Safety Commission, Milwaukee, Wisc.; *MILTON M. BOWMAN, Safety Coordinator, City of Cleveland, Cleveland, Ohio; *A. R. LATEINER, Consultant, Safety & Training, Mamaroneck, N. Y.; *JOHN E. PAGNARD, Safety Coordinator, City of Columbus, Columbus, Ohio; *JOSEPH E. HAMM, Safety Dir., County of Los Angeles, Los Angeles, Calif.; *CLARK J. FISCHER, Safety Engr., Milwaukee Safety Commission, Milwaukee, Wisc.; *DANIEL F. MILCHMAN, Safety Engr., (Retired); *M. VAN MECHELEN, Safety Engr., Washington State Department of Highways, Olympia, Wash.; *H. P. GOODIN, Safety Dir., City of Minneapolis, Minneapolis, Minn.

Statistics Committee—WARREN D. WILT (Chairman)

Newsletter Committee—JOHN H. PHILLIPS (Editor); JOHN F. HUEVAR II, Chief Safety Engr., Pennsylvania Dept. of Highways, Harrisburg, Penn.; STEVE STAR, Safety Engr., Dept. of Public Works, Los Angeles, Calif.

Off-The-Job Committee—M. VAN MECHELEN (Chairman); H. P. GOODIN; JOSEPH M. GOVEY, Safety Consultant, New York State Department of Mental Hygiene, Albany, N. Y.; VOIS D. BEZME, Safety Mgr., City of Columbus, Div. of Water, Columbus, Ohio

Membership Committee—JAMES F. GLEASON (Chairman); GEORGE F. KUHN; E. I. UERLHOEF, Safety Dir., City of Fort Wayne, Fort Wayne, Ind.; All Regional Representatives

Regional Representatives—New England, GEORGE C. MURPHY, Safety Supv., State Highway Commission, Augusta, Maine; JOHN L. GUDMARTIN, Safety Engr., Connecticut State Highway Department, Hartford, Conn.

Pennsylvania & Northern New York—HOWARD D. TRIEMER, JR., Safety Dir., Pennsylvania State University, University Park, Pa.; GEORGE C. HOWARD, Safety Dir., City of Rochester, Rochester, N. Y.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

**Celebrating the 50th Anniversary
of the NATIONAL SAFETY COUNCIL**

WHEN: October 29 through November 2, 1962

WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

SAFETY IN THE MANUFACTURE AND OPERATION OF ELECTRONIC TEST EQUIPMENT

By CECIL LIGHTFOOT

Supervising Eng., Mesa-Planar Manufacturing Engineering Dept.
Transistor Products Div., Texas Instruments Inc., Dallas, Texas

With the increased use of automatic and semi-automatic test equipment, safety becomes more important in the design, operation, maintenance, and repair of these devices.

In the transistor industry, breakdown voltage has increased to the point of offering a hazard unless properly controlled. Tests have shown that 12 volts AC, 25 to 60 cycle alternating current is the limitation of some individuals when in good contact with the circuit.

Other tests have shown that when dry electrodes were held in both hands, AC voltages ranging from 20 to 40 were all that were required to produce the maximum current that individuals could withstand for a short time, and still have voluntary control of their muscles.

Tests with direct current indicated that a human being could withstand slightly higher currents for a short time. The currents in these tests ranged from six to ten milliamperes.

The comparative immunity to injury in handling circuits up to 120 volts with the bare hands is due to the high resistance of the dry uninjured human skin. However, this resistance is greatly lowered by:

- Any thorough wetting of the skin.
- Perspiration.
- Many chemicals.
- Cuts and blisters.

Under the above conditions, 110 to 120 volts, alternating current, can produce sufficient current flow to cause a change in heart action, which may prove fatal. It requires only a few seconds contact with a 50-volt standard frequency AC circuit to produce blisters at a point of contact, thus destroying the dry skin high resistance protection.

The current tolerance of the human body is a factor of the frequency of the voltages creating the current.

Alternating currents of high frequency produce little sensation, compared with alternating currents of low frequency and equal magnitude.

Tests have been made to determine the "tolerance current" of typical individuals at several frequencies. The tolerance current was arbitrarily assumed as the magnitude of current that the subject could take through his arms and body, without marked distress or discomfort. Some results of these tests were as follows:

- 30 ma at 11,000 cps.
- 14 amp at 100,000 cps.
- Although the tolerance current was found to increase very rapidly above 11,000 cps, the increase between 60 and 11,000 cycles was much less rapid, ranging from about 5 ma at 60 cycles to 30 ma at 11,000 cycles.

The action of the electric current through the body is an electric shock and can affect the body in two ways.

- The current may pass through the breathing center at the base of the brain and cause this center to stop sending out nerve impulses which act upon the muscles responsible for breathing, as a result breathing stops abruptly.
- In other cases the current may affect the heart muscles, either stopping it or causing an uncoordinated action known as "ventricular fibrillation."

It is absolutely necessary that all possible safety precautions be taken in the design, construction, installation, maintenance and repair of all equipment used throughout the plant.

To fulfill this requirement, all equipment must present no external shock hazard to the operator or unnecessary hazard to the technician responsible for the adjustment or repair of this equipment.

This can be accomplished by the following:

1. Line cords should be three conductor cables with the third wire connecting the cabinet and chassis or framework to an earth ground. This will insure that no potential difference can exist between adjacent test sets. The line cords or power cables should be of the rubber covered type and of the proper size for current carrying capacity. Wire tables listing safe current carrying capacity according to the Underwriters Laboratories should be used as a guide. A good rule is to allow 1000 circular mils cross sectional area for each ampere of current.

2. Interlocks should be incorporated in all cabinets with high voltage exposed or accessible to repair or maintenance personnel.

3. Safety shields should be provided over exposed high voltage points since maintenance personnel do not always have equipment drawings at hand when making repairs; warning signs of high voltage should be placed in a conspicuous place. Remember warnings written into specifications will be of no help under these circumstances.

4. Power transformers or isolation transformers should be used in all test equipment. This isolates the operator or technician from the plant power source. Power transformers with any winding grounded to the frame or shield should never be used. Also any transformer with leakage between windings and core or frame should never be used. Auto transformers should not be used unless preceded by an isolation transformer.

5. All high voltage supplies should be designed with a series limiting resistor. This will prevent current flow from exceeding a safe value should anyone accidentally come in contact with the output terminals or other high voltage points.

6. Bleeder resistors should be designed across high voltage filter capacitors. A charged capacitor can be as lethal as if the equipment in which it operates were still turned on. All metal-can type electrolytic capacitors that have a potential applied on the can should be insulated from the chassis and equipped with safe insulating covers securely fastened.

7. All equipment operated from the AC power system must be equipped with fuses

or appropriate circuit breakers. Normally fuse size is determined by measuring current drain under normal conditions and a fuse of one and one half times this value installed. Fuse sizes for equipment that will draw intermittent heavy surges are usually determined by current measurements during operation. Fuses of the slow blow variety are sometimes selected, especially when used in high voltage equipment.

8. Input power switches should open both sides of the power line. The current rating of the switch should be capable of conducting current in excess of the equipment it is controlling.

9. Plug-in connecting cables must be designed that when disconnected no electrical power can accidentally come in contact with persons working near the machine.

In addition to electrical shock hazard, other safety factors must be considered in the design and operation of manufacturing equipment; they are:

1. In the design of equipment, weight of modules or completed units should be given careful consideration. Weights for women will vary from 25 pounds at table height to one pound when lifted over their head. For men the weight should never exceed 40 pounds.

In the design of tall rack mounted equipment, the heavier units should be nearer the floor if possible. It is a well-known fact that back injuries and other disorders such as strained ligaments and muscles are quite common among workers who have to handle large bulky or heavy items without the assistance of mechanical lifts or other similar devices.

2. Equipment should be designed to be stable during operation. It should not be such that it will slide during operation or be in danger of toppling over.

3. Equipment should be designed without sharp edges and protrusions. These can cause injury to the operator or persons passing the machine in the normal course of their work.

4. All belts and gears should be guarded to protect personnel working on or near the machine.

5. If equipment or any of its components offer a temperature burn hazard to the

operators, protective shields or insulation should be provided.

5. Equipment should be designed to insure a comfortable arm position and if used, correct microscope height. Cramped arms and neck strain are more apt to make an operator work in an unsafe manner.

It is the responsibility of the design engineer to observe every safety precaution in each design but the safety engineer

should inspect and pass on each new design before it is placed into production areas.

The safety engineer should assist purchasing personnel in the selection of all equipment that might affect the safety of operating personnel.

A good safety program well followed will result in more production, higher quality units manufactured, fewer accidents, and higher morale among personnel.

SAFETY IN PRINTED CIRCUIT MANUFACTURING

By HOBART A. WEAVER

Department Chief, Printed Circuit Manufacturing and Project Engineering
Western Electric Company, Inc., Greensboro, N. C.

Printed wiring, the basis for printed circuit assemblies, is a technique for making electrical connections between components by means of metallic foil strips bonded in a prescribed pattern to the surface of an insulating material.

Within the past 5 years, considerable emphasis has been placed on the use of printed circuits by all of the commercial manufacturers of wired electrical products. National advertising campaigns have been directed to their inclusion in television and radio sets as if they, within themselves, were the answer to all of the problems that have risen in the past affecting the reliability and enjoyment of these products. While assuredly much of this is true, other advantages are present which are more tangible to the manufacturer.

The use of printed wiring in large quantities was initiated in the last stages of World War II in the manufacture of the electron tube proximity fuse for combat use, and while the same techniques were not employed that are present in today's manufacture, the ground work was laid for the advantages that could be gained from their usage. Subsequently, much of the development work in printed circuits has been made in the manufacture of electronic equipment for the Armed Services, culminating in 1953 with the Tinkertoy Project as an illustration of automation applied to mass production. Use of this media is becoming

more widespread in all of today's electronic hardware for the Armed Services.

Manufacturing methods for printed wiring are many and varied. Original manufacture perhaps dates back to the advent of ceramic disc capacitors in the 1920's in which a conducting surface was painted on a ceramic base with silver paint and fused into the base material with heat. Subsequent methods incorporated various and sundry procedures but can be reduced to two fundamental processes. The first, of which the disc capacitors listed above are an example, consists of applying the conductor paths to an insulating base. The second process consists of selectively removing unwanted conductive material from an insulating base. This is known as the etched foil process and is used at the Western Electric shops in Greensboro, North Carolina.

Several years ago we began a manufacturing operation for printed circuits to fulfill the needs of several military projects. To our manufacturing engineers this was a new field, and much exploratory work was necessary to start this operation. Essentially, the operation was broken down into the various steps. Each operation had to be investigated not only from a manufacturing aspect, but also from the standpoint of safety.

In Western Electric, the product, process, or project engineer is responsible for

the safe operation of those processes for which he has engineering control. In this way, when a new project such as printed wiring is inaugurated, the project engineer has the responsibility to incorporate all necessary safety features for the protection of employees. He specifies the design and quality of all types of personal protective equipment and prescribes standards for their use. Whenever special situations arise because of unusual operating conditions, the introduction of new processes, raw materials or machinery, the project engineer requests the hazards engineer (in cooperation with the safety organization) to approve his investigation, evaluation of exposure, and specifications for precautionary measures.

In the succeeding paragraphs I would like to review some of our planning for the manufacture of printed circuits with the aim of incorporating safety from the beginning.

The manufacturing process begins with an insulating material clad with copper foil on one or two sides. This insulating material can range from .006" to .250" thick but is generally a 1/16" sheet. The copper ranges from .001" to .010" thick. Several types of insulating materials are used, depending upon the circuit application. For most commercial products the paper base phenolics are generally used as an insulating base material. Whenever the electrical characteristics of the circuit demand superior dielectric strength, insulation resistance and moisture absorption properties, an epoxy glass or "Teflon" glass material is used.

In using the epoxy glass and "Teflon" glass material, problems have been encountered pertaining to safety. Several of our employees have been found to be allergic to the epoxy resins and have received treatment for a dermatitis condition. We have corrected this situation by minimizing exposure not only in the handling of the raw material sheets, but also in subsequent operations where epoxy dust has been created from a machining operation. We have provided our employees with protective skin creams made for epoxy resins. Housekeeping standards are kept very high and our safety and medical organizations are following this situation very closely.

Another problem encountered when using "Teflon" glass material was in the disposal of scrap. We have provided special marked cans throughout our shop to collect "Teflon" scrap to prevent mixing of "Teflon" with other waste material. Since the toxicity properties of "Teflon" are not fully known, we have taken precautions in disposing of scrap. Collected scrap is burned in our incinerator.

However, the practice of burning "Teflon" was introduced only after a thorough investigation was made of the draft system in this incinerator equipment. The height of the smoke stack on the incinerator is 135 feet, which is sufficient to carry the fumes away from other areas of the property. The operator of the incinerator has been informed never to burn "Teflon" scrap without first burning some other waste to ascertain that the draft is functioning properly.

Still another problem with "Teflon" was encountered in the machining operations. Machine operators have been cautioned not to carry cigarettes in an open pack or an open pocket while on the job. There is a hazard of small "Teflon" chips getting into the cigarettes, and thus the person could get "Teflon" fumes directly into the lungs by smoking the cigarettes.

Another problem encountered with the raw material was in handling. Most laminators make sheets of raw material in 36" x 48", or 36" x 72" sizes. Material this large was difficult to handle, especially since the copper surfaces had to be protected from scratches at all times. Also, the sharp edges of the thin copper foil on this laminated material created still another handling problem. To overcome this problem, we now have our material precut to specific working size and packed in polyethylene bags. Ragged precut panels are delivered to us in small containers not exceeding 60 lbs.

After the art work (circuit configuration) has been accurately laid out, photographed, and reduced, one of two methods of printing can be used. The photo process and the screening process are the most commonly used throughout the industry at the present time.

In the photo process, the copper clad raw material is uniformly coated with a light-sensitive enamel. A film negative is used

to photographically print the circuit on the raw material using carbon arc lights as an ultraviolet source. It is necessary to provide better than normal ventilation to exhaust the ozone fumes created by the high voltage on the carbon electrodes.

The other chemicals which are used for developing the panels and for subsequent cleaning solutions are well ventilated and kept away from the arc lights. In this area, also, the air pressure used as a solution blow-off is regulated to a maximum of 20 psi to minimize the hazards of blowing solvents onto the operators.

For the other printing method, screen printing, provisions have been made to draw the fumes from the molten printing wax resist directly off the top of the machine. The solvents used in this operation for cleaning the panel after printing are also directly ventilated.

Metallic finishes are usually required on the copper circuit paths to facilitate subsequent soldering of components to the assembly, whether mass soldering or hand soldering is anticipated.

The two most popular finishes are solder and gold. For most commercial applications, solder is electro-deposited to the circuit paths prior to the etching of the unwanted copper.

The plating operation first begins with a cleaning cycle in ammonium persulfate; next, a water rinse, followed by plating in a 60-40 lead-tin alloy solution. The safety aspect of these operations is that normal precautions are taken to protect the operator while using and handling these chemicals; also, proper instructions have to be passed on as to how these chemicals are to be mixed and what reactions occur when the chemicals are put into solutions.

To us at Western, the plating of a solder alloy was a new operation, and an extensive evaluation of all necessary chemicals was carried on before putting this segment of the manufacturing cycle into use.

The etching of printed circuits is somewhat similar to the plating of the circuits in that it is a chemical operation and the same safety precautions are necessary. The two most commonly used etchants are ferric chloride and ammonium persulfate. The ferric chloride is a more difficult solution to handle than the persulfate. The ferric

can cause irritation of the skin or the eyes. In both our plating and etching operations, the operators are provided with chemical resistant clothing and wear face shields. The operators are required to take a shower at the end of each shift. In addition periodic physical examinations are given to both the etching and plating operators. Also, exhaust systems are installed to each tank, (plating and etching) to insure that the fumes are removed from the work area. The highly corrosive ferric chloride fumes have necessitated the use of specially coated metals or plastics to minimize this corroding condition on our facilities.

Printed circuit boards are generally processed thru the printing, plating and etching operations in panel form; i.e., several images of the same circuit are put on a large piece of material. After these operations, it is necessary to fabricate the individual boards to size and shape. This is done by routing, punching and drilling. In all these operations, safety glasses are required to be used.

In the punching operation, precautions are taken to insure that both the operator's hands will be needed to actuate the controls for press operation. Also, our punch presses are protected against completing a started cycle when they are restarted after a shutdown.

Another method of fabricating small lots to size and shape is routing, an operation of cutting a contour from a template or guide. In this operation, a guard is used on the machine to prevent the operator's hand or fingers from coming in contact with the cutting tool. Also, for this operation, we have provided an exhaust on the bed of the machine to take away the major portion of the epoxy dust and chips. For routing small boards, we have made use of a double-ended routing fixture to afford a larger work piece for the operator to grasp.

On some boards it is necessary to drill small holes for component leads, and this operation for small lot sizes is done manually. For large production runs, multi-spindle drilling is used. For the manual operation, each drill position is equipped with an exhaust system to remove epoxy dust; and to reduce operator fatigue from drilling these small holes, each drill press is

equipped with a 4X magnifying glass adjacent to the drill spindle. Also, the spindles on these presses are readily adjustable; thus the operator raises or lowers the spindles as needed to insure that the drill point is never above the work piece more than $\frac{1}{4}$ ". This does not allow sufficient clearance for getting the operator's fingers under a drill point.

It is necessary in some instances to install terminals or standoffs to some particular circuits on the boards for making external connections. This operation is done with small pneumatic arbor presses. These arbor presses have presented some problems in regard to safety of the operator's fingers. Although the ram on these machines is set at a clearance of $\frac{1}{4}$ " maximum, we have had several minor injuries of pinched fingers. To eliminate these injuries, we have made use of a photoelectric cell to prevent the ram from being actuated if any part of the hands or fingers is in a 2" danger zone from the center of the ram.

In some cases, the photo-cell method would not suffice for large size boards. For the large boards, we have recently installed an electrostatic press. This is a solenoid operated press that contains a mechanical linkage from the foot pedal to a sleeve which surrounds the top tool. The foot pedal is depressed and the sleeve moves to the board. In this position a linkage to the sleeve trips a microswitch which energizes the machine and the top tool is forced downward. If a finger or any other object interferes with the bottoming of the sleeve, the microswitch will not be tripped and the machine will not operate.

In addition to the rigorous mechanical inspection to which each lot of boards is subjected, samples of our material and processes are evaluated periodically by Under-

writer's Laboratories (UL) to provide protection to the consumer and to insure that the material properties, such as insulation resistance and surface resistivity, have not been changed during our processing.

From the preceding paragraphs, it can be concluded that a manufacturing engineer is confronted with numerous problems in planning for the production of a new product. To summarize, we observed what we considered the basic principles of safety in establishing our printed circuit operation. We attempt to apply the following rules in all situations.

1. Recognition of hazards that may arise from the introduction of new materials and processes such as epoxy and teflon glass, plating, cleaning and fabricating.

2. Safety training of operators to do their new jobs.

3. Strict adherence to known safety practices.

4. Close coordination with the safety and medical staff to eliminate hazards.

5. Close coordination with other manufacturers operating in this field and the quick application of additional research and development when needed.

For items 3 and 5 such organizations as yours and meetings of this type are beneficial to us in the manufacturing industry.

I am proud to represent the Greensboro Shops of the Western Electric Company. Our shop now holds the world's safety record for the electrical equipment industry. We have recently passed twenty-seven million man-hours without a disabling injury. That is quite a record, and I feel that, to a great degree, our success is attributable to the fine and useful information that has been disseminated by your group.

SAFETY IN THE USE AND MAINTENANCE OF ELECTRICAL STORAGE BATTERIES

By ROBERT W. HOPEWELL

Mgr., Field Engineers, Gould-National Batteries, St. Paul, Minn.

To start with, I would like to show some slides of typical battery applications about which my discussion will be concerned. These batteries are all industrial types varying from groups of cells assembled into steel trays to individual cells in their own plastic containers.

1. *Ram Truck—Steel Mill* This piece of equipment handles steel rolls weighing many thousands of pounds and propulsion is provided by electric motors driven by the batteries mounted on the rear of the truck.

2. *Hand Truck* A smaller version of an electric materials handling truck is hand operated. The battery is composed of six cells assembled in a steel tray.

3. *Telephone Battery* A different type of application is a telephone central office battery. Its prime purpose is that of a standby power source, in the event the commercial power source fails.

Similar cells are also used in power-generating stations and sub-stations to operate valves, switchgear, and to supply power for emergency lighting equipment.

There are many other applications for industrial type batteries, such as starting batteries for railroad diesel engines, as well as batteries for air conditioning and lighting of railroad cars. These include baggage, coaches, diners and sleeping cars.

I am primarily going to concentrate on the industrial truck type batteries, as these are usually subject to more handling in their everyday usage.

There are three types of hazards involved in the handling of the industrial truck battery.

1. There would be the mechanical hazard involved in the changing and lifting of batteries when it is necessary to supply fresh power to a truck used on a multishift operation.

2. There is the electrical hazard due to possible shorting of the battery terminal when changing batteries, or carelessness when changing or repairing batteries.

3. The last and not the least important is the chemical hazard of personnel injury from splashed electrolyte when watering or repairing batteries.

Hydrogen gas is a by-product of charging and is explosive, therefore, caution should be exercised in handling batteries. This holds true for any battery which contains electrolyte, and to which a charging current is applied.

4. *Overhead Hoist*. As I stated before, whenever a materials-handling truck works more than one shift, it is usually necessary to install a fully charged battery for each shift.

This requires the use of an overhead hoist and what is called a spreader bar. The spreader bar and hoist must be strong enough to handle the largest batteries used. As an example, some of the larger batteries weigh over 5,000 pounds.

5. *Spreader Bar—Gould Design*. Here is a spreader bar, designed by Gould, which provides an insulating hard wood body. This prevents shorting of the battery terminals in the event the hooks come into contact with the intercell connectors.

In some instances where a chain or wire rope sling was used, severe shorting and explosion of the battery cells resulted due to ignition of the hydrogen gases.

6. *Spreader Bar—Four Position Lift*. Here is another type of lifting device designed for one particular size of battery, which uses four lifting hooks. Each hook is individually insulated from the spreader itself.

Here an additional precaution is taken through the use of a rubber mat to cover the top of the battery. This prevents the chains from the hoist shorting across the intercell connectors.

7. *Protective Clothing*. This points out that personnel handling batteries in the charging room, should wear protective aprons, gloves, boots and goggles whenever filling, charging or repairing batteries.

8. *Checking Cells for Water*. Whenever personnel check individual cells for solution level, only flashlights or adequate permanent lighting should be used. Never use matches or cigarette lighters.

9. *Authorized Personnel Only*. Always restrict the battery room to qualified personnel only. This will insure protection of the untrained worker and the equipment from each other.

A most important item is that immediate treatment be given personnel accidentally splashed with electrolyte. The area of the body affected should be flushed with generous amounts of plain water. This includes electrolyte splashed into the eyes.

Following the water bath, the injury should receive supplementary treatment at the plant dispensary.

Any electrolyte accidentally spilled on the floor should be neutralized with washing soda and the floor cleaned.

10. *Battery Repair*. Some of the larger users of batteries have their own repair facilities for the replacement of broken jars and internal cell repairs.

Here we show the proper way to remove a cell from the battery using a hoist together with the proper lifting device. Notice the rope sling. This affords protection to the cell and the worker as the stresses are gradually applied.

Pulling of cells by the worker himself is hard work and could result in serious back strain. Therefore, the method shown here should always be used.

11. *Resealing—Repaired Batteries*. This shows the battery after repairs have been made and the cell reinstalled. Here the battery is being resealed with hot battery compound. Care should be exercised in the heating process, the unheated compound at the top of the pan, should never be punctured with a sharp tool, as hot compound will shoot out causing a severe burn to the worker.

12. *Reburning Cell Connectors*. After cell repairs and resealing have been completed the final operation is to reburn the intercell connectors to the cell posts. This is usually done with an oxygen-acetylene burning outfit using a small burning tip. If this is not available, a carbon burning outfit is used.

This employs power from the cells themselves to heat the carbon tip. Before proceeding all vent caps should be removed and all hydrogen gas purged from the cells by use of a very low pressure air hose. Following this, damp cloths should be placed over the vent openings to prevent ignition of remaining gas.

Welding goggles should be worn to prevent damage to the eyes from the light of the carbon tip which is very intense. Only personnel trained in lead burning should be permitted to make such repairs to storage batteries.

13. *Telephone Batteries*. Let's refer back to the telephone installation. In this installation, we use what is called an anti-explosion vent. (White dome shaped item on top of cell.) This vent is designed to vent the gases produced on charge and in the event of an external explosion it prevents flashback and ignition of the gases inside the cell. It will not prevent an external explosion, but it will minimize the effects.

A similar design has been tried on industrial truck batteries, but because of the frequency of charging and truck motion, operating problems were encountered which did not make its adaptation successful.

This picture illustrates two things that battery personnel should not do.

1. This man is checking the electrolyte levels without wearing protective goggles.

2. He has one hand resting on top of the cell and apparently touching the cell posts. His other hand is resting on the rack, which in most cases is grounded. This is not too serious on a 48 volt system, but on a 120 or 240 volt battery a good shock would result.

Such installations as this should have sufficient ventilation to provide circulation of air so that the hydrogen concentration approaches no more than three per cent.

The amount of circulation or change of air will depend on room volume—number of cells in the battery and also at what charging rate the cells are maintained.

This precaution is only a problem when the battery room is closed off and small.

This is very rarely a problem in industrial truck charging rooms, as they are usually open and have adequate air change.

THE PROPER METHOD OF SELECTION AND USE OF HAND TOOLS

By EUGENE WOLOSZYN

Specification and Steel Application Metallurgist, Youngstown District Works
U. S. Steel Corp., Youngstown, Ohio

Hand tools used throughout the Corporation number in the thousands and are provided to the employees to enable them to do a job safely and efficiently.

In order to get some basic background on the manufacture and treatment of hand tools we have taken a twelve pound carbon double-faced sledge hammer as an example.

In general, this tool starts out as a two and one-half-inch round cornered square and can either be a carbon or alloy grade of steel. To become a finished product the tool must go through the following phases:

Shearing: The bar is sheared into seven-inch multiples.

Forging: The multiple is heated to the forging temperature and forged on the press to the shape of the sledge.

Machining: The rough forging is placed into the lathe and both striking surfaces are machined to the desired contour.

Heat Treatment: The machined sledge is selectively heat treated; by that we mean the two striking faces are heated above the austenitizing temperature for the specified time needed for transformation of the micro-structure. After being held at this temperature both faces are quenched in a suitable medium—usually water or oil is used depending on the grade.

The as-quenched structure is martensite, a hard brittle structure. In order to toughen this structure and lower the hardness to the desired range, the sledge is again heated, but at a much lower temperature, to produce tempered martensite. This is known as the draw or temper.

Inspection: After heat treatment, all alloy sledges are taken to the magnaglo tester and spot checks are taken on carbon sledges. This is a process using magnetic powder to detect fine surface cracks. These magnetic particles are coated with fluorescent material which glows under infrared light. If cracks are present in the sledge, the leakage flux causes a local concentration

of magnetic particles in the vicinity of the discontinuity. Some of the defects noted by this type of inspection are cracks, seams, forging laps, etc., which if present are usually reason for rejection and possible salvage.

Grinding: The last step in the processing is a light grinding of the striking surfaces on a fine abrasive belt to dress up the final product.

Published data and conversation with tool suppliers stress the fact that a good quality hammer can be struck thousands of blows against surfaces without spalling, providing the striking surface of the hammer meets the surface being struck squarely or at a low angle under 20 degrees. If struck against a sufficiently resistant surface with a blow close to the periphery of the hammer's striking surface, the highest quality hammers can be made to spall.

Most of our accidents involving hand tools are caused by spalls flying off the striking surface or surface being struck during usage. Spalling can be defined as a formation of a fragment by chipping. Many times the employee is unaware at the time of the accident that the spall has entered his body due to its speed and size. Data by one of our leading research laboratories report that a spall was propelled from a hammer during tests at approximately 300 feet per second. This was determined by the use of high speed films.

X-ray films taken out of the Youngstown District's medical files indicate the penetrating power of a spall.

A spall remaining in a rigger's body today resulted from a track maul being misused as a back-out hammer. The rigger was approximately four feet away from the struck blow when the spall penetrated his chest and collapsed his lung.

A spall lodged in a roll turner's lower abdomen resulted from using a blacksmith hammer to cold stamp a three-quarter-inch

stamp into a roll. Test results showed the hammer was much too hard.

A spall being carried around in a machinist's left hand flew off of a ball peen hammer when he struck a hand cold chisel trying to shear off a bolt head.

The penetration of a spall into the left arm, near the elbow, of a track laborer resulted from his using a track hammer to strike a spike claw bar.

Spalls penetrating a worker's body are generally not disturbed unless complications are encountered. Damage by surgery probing for the spall could possibly cause more harm than the actual wound. It is not difficult to visualize what could happen if a spall penetrated one of the vital organs such as the heart.

There are many reasons for spalling of hand tools, and the next part of this presentation will show actual laboratory investigations on spalled hand tools taken out of the maintenance metallurgist's files on hand tools.

The first group of these investigations will deal primarily with hand tools as received from the suppliers. The second group will reveal how tools become safety hazards after employees inadvertently abused the tools.

The first example is a back-out hammer which spalled after one day's service at our primary mills.

This tool was given a thorough laboratory examination, which included cutting a sample adjacent to the spalled area for microscopic examination. After mounting, polishing and etching the sample we found the micro-structure was not the desired tempered martensite, but bands of hard martensite, ferrite, bainite, carbides and tempered martensite. This indicates the striking surface of the B & O was ineffectively heat-treated by the supplier.

Our open hearth maintenance group encountered excessive spalling on two hand cold chisels during service. The striking and cutting ends of the two chisels were spalled.

Hardness values recorded on the one chisel showed that the striking surface had Rockwell "C" values of 26-28 and the cutting surface 45-49 "C". The other chisel had 35-37 and 41-46 "C" hardnesses in the same locations.

The hardness specifications for hand cold chisels in the proposed "Forged Hand Tool Specifications" are 45-49 "C" for striking surface and 56-60 "C" for the cutting surface.

It was our opinion that the failure of the two hand cold chisels can be attributed to the low hardness values obtained by the supplier during heat treatment.

Excessive spalling on the striking surface of a 24 oz. ball peen hammer was encountered by a pipe shop employee. The hammer was new and being used for the first time.

Rockwell "C" hardness results recorded on the striking surface showed 56-61; the range specified in the proposed "Forged Hand Tool Specification" is 50-54 Rockwell "C".

Micro examination indicated the tool was effectively heat treated but to higher hardness values, which in all probability resulted in the spalling of the hammer in such a short period of service time.

During a routine tool inspection a three-eighth-inch taper setting punch with a crack was picked up and submitted to the maintenance metallurgist. This punch is used to drive lead screw anchors into concrete.

The striking surface of the punch was a three-quarter-inch hexagon and had a crack extending the length of the punch.

Micro examination showed a seam .045-inch deep extending into a crack .312-inch deep. This surface defect opened up into a crack when struck during the actual setting operation. Check analysis of the punch revealed the steel used was an open hearth resulfurized and rephosphorized grade, which is not recommended in an application where the tool is being struck during service.

A machine shop apprentice using a sledge hammer on a back-out hammer to drive out body bound bolts was struck in the cheek by a spall from the driving end of the tool.

The driving end of a B & O and a surface decarburization on the spalled end measuring .030-inch deep leaves this area softer and susceptible to spalling.

A tool not properly dressed and used incorrectly was the cause of a spall entering an employee's body at the McDonald Roll Shop.

The roll shop hammer had insufficient chamfer and was used to drive a large identi-

heating stamp into a roll. This hammer was too small for this job and, since it was not properly dressed, the shock in striking the stamp caused the spalling action.

A double end box wrench made of alloy steel, which had been flame cut in two to make it usable in an inaccessible position, was involved in an accident. When the burned end of the handle was hammered a spall flew off and entered the worker's body. A longitudinal cross-section of the burned wrench handle was ground and etched. It revealed the flame cutting had resulted in a heat affected zone of martensite.

At Youngstown the mason department supplies the apprentice bricklayers their initial hammers, with subsequent hammers provided by the employees. These hammers were being reconditioned by the Blacksmith Shop.

Complaints of getting cracked hammers after reconditioning initiated the investigation of such a hammer.

Micro examination of a sample through the cracked surface revealed decarburization present at the cracks, which indicated the hammer was cracked prior to reconditioning at the Blacksmith Shop. The original crack apparently progressed during heating and quenching until the entire striking surface was cracked.

Visual examination of a hammer will not always detect cracks, but the use of magnifying glass or dye-check will "highlight" these cracks and the tool can be immediately scrapped.

Many times we have found that damaged tools were the direct result of employee abuse.

Two hammers were in use only one day, dented and spalled striking surfaces resulting to both.

Micro examination and hardness results indicated the tools were effectively heat treated to hardness values specified in the "Hand Tool Specification." It was determined later that the hammers were used to strike materials harder than the ballpeen hammers.

During the microscopic examination of a longitudinal section through the spalled area of the striking surface of a back-out hammer, we observed the presence of a "white layer" which originated in the spalled area and extended to the surface.

We submitted this sample to the Fundamental Research Laboratory at Monroeville, where micro-examination and micro hardness determinations indicated the "white layer" was untempered martensite.

An article, "Spalling of Hand Hammers," published by Battelle Memorial Institute, reported the presence of the "white layer" on spalled areas of hammers investigated by the Laboratory. The authors identified the "layer" as untempered martensite formed at the time the damaging blow was struck. The fresh martensite results from localization of the shear energy along a plane and generates sufficient high temperature to form austenite. On cooling, the austenite transforms to martensite.

A hazardous condition existing at our manganese crusher at the open hearth stockhouse brought about a specific case of development by the safety director, maintenance metallurgist and tool manufacturer.

At the manganese crusher, open hearth labor used a ten pound sledge hammer to break large pieces of manganese so that they could be placed in the crusher. Hammers in use at that time spalled so badly in an eight-hour turn that they had to be scrapped.

Our first step was to get two alloy and two carbon sledges to evaluate material specifications. One of the alloy sledges was given a radius contour instead of the normal chamfer to determine the effect contour may have on this application.

We placed these four sledges into service, and records on their use were maintained by the open hearth labor foreman.

The spalled condition was noted on the striking surfaces of all four sledges. The alloy sledge with the radius contour gave 576 hours of service as compared to 48, 72 and 168 hours experienced by the others. We eventually had this sledge reconditioned twice by the manufacturer, and the service ability of the radius-alloy sledge in service hours was in excess of a 20 to 1 ratio over the original carbon sledges used.

After this favorable experience with a radius contour, we searched for technical or theoretical data to explain or substantiate our change from the normal chamfer contour used on most tools. We found this most difficult, even though some of the tool manufacturers such as Warren, Tamco, Bedco

and Cunningham were actually selling tools of this design.

Questioning representatives of these firms revealed that this contour change had occurred through the years, with no definite reasoning behind it other than it resulted in better tools.

The Corporation's maintenance metallurgists' committee has a subcommittee on forged hand tools. This subcommittee is now preparing a hand tool specification, which should help materially in controlling the quality of hand tools being purchased by the Corporation.

This subcommittee has also presented a proposed research project on hand tools. This program would evaluate the effect contours may have on spalling and the amount of radius that would be optimum in this respect. Other phases to be investigated would be photo-stress examination of striking surfaces during actual service for stress concentration patterns and evaluation of various shapes such as round, hexagon, square and octagon.

Accidents attributed to the use of defective hand tools and the excessive number of defective tools picked up during the safety inspections conducted by operating and safety personnel pointed out the need for a better method of reconditioning our hand tools.

The following procedure was recommended to be followed in the redressing of machine shop ballpeen hammers, double faced sledges and hand chisels:

Inspect: Thoroughly inspect using magnetic particle and/or dye penetrant method prior to any major redressing. Tools having any deep-seated defects that cannot be removed by normal amount of grinding should be scrapped.

Any questionable tools should be tested for hardness by the maintenance metallurgist for agreement with specified hardness levels. This would also determine if the tool is still within the allowable limits of established wear tolerances.

Redressing: These tools should be redressed by grinding to established radii. A template which has been distributed to personnel doing redressing helps them achieve the desired contour.

It is very important that the actual grinding be done in such a manner that the surface does not become overheated. Color changes to deep brown or bluish-purple indicate over-heating has occurred and must be removed prior to being placed back into service.

Re-inspection: All redressed tools should again be inspected by the magnetic particle and/or dye penetrant methods prior to their release into service.

At this point we should like to stress the importance of training the employees to submit their defective hand tools soon enough so that reconditioning does not become a major job. Submitting spalled tools in particular is most important considering the possible presence of the "white layer" discussed earlier in this presentation.

It is also important that the redressing responsibility be given to one individual in each unit. Experience gained by this man will enable him to provide a consistent and uniform redressing without the inherent danger of overheating.

Responsible personnel should always be on the lookout for newly designed or treated tools that are being played on today's market. These tools should be thoroughly investigated before approval is given for their purchase and use by our employees.

As an example, our storeroom received a shipment of seven-eighth-inch hexagon cold hand chisels with a newly designed striking surface. Our secondary mill maintenance group questioned the use of this tool and submitted one to the safety director, who in turn brought it to the laboratory for a check.

The striking face of this chisel had a flared contour. We cut the striking surface of the chisel longitudinally, ground and etched it to show the contour. It showed that the striking surface would be more conducive to mushrooming and spalling due to the abrupt change of section and the inherent weakness of the upset forging flow lines.

Some time ago a pamphlet was published in which a safe-ending procedure was described. It consisted of preparing the end of the tool, depositing a collar of bronze-welding rod and grinding it to the finished shape. They also advocated preparing used tools for safe-ending by cutting the damaged ends by using a cutting torch. If the length of the chisel was too short it was to

be built up by using a steel welding rod. The actual bronze-welding technique required the base-metal temperature to be from 1600-1700 degrees Fahrenheit. The paper concluded that there should be neither a marked increase or decrease in the hardness of the struck end of tools safe-ended.

It was the consensus that this procedure using such high temperatures would create and not prevent safety hazards. Quality tools require a specific heat treatment which is governed by the grade of steel used and must be given under controlled conditions to be effective.

In an effort to publicize the mistreatment and incorrect use of tools causing accidents

in the Youngstown District, a pamphlet was printed listing case histories with appropriate photographs. We gave it the title "Weapon or Tool" and it was distributed to each supervisor in the district.

It is my sincere hope that this presentation has given you a new viewpoint on the common hand tool. Properly specified, used correctly and reconditioned to recommended procedures, it enables our employees to do a job quickly, safely and efficiently. On the other hand, the common hand tool can become a dangerous weapon causing serious accidents if the tools are of poor quality, mistreated, used incorrectly or not properly reconditioned.

SAFE PRACTICES IN MANUFACTURING PROCESSES IN THE SEMICONDUCTOR INDUSTRY

By R. E. BURTON, JR.,
Supt. of Industrial Relations
Western Electric Co., Allentown, Pa.

I am pleased to say that the manufacture of semiconductors at Western Electric's Allentown Works is not a hazardous occupation. I will add, however, that it could be quite hazardous were it not for the emphasis on safety given by our engineers in designing and specifying the facilities to be used, unceasing training in safe habits carried on by our supervisors, and constant practice of common sense safety habits by all employees involved.

This material will cover some of the general elements of semiconductor manufacture as well as some specific operations, will point out the potential hazards involved, and show the steps taken to remove or minimize the hazard.

First, semiconductor manufacture requires the use of a considerable amount of hydrogen, primarily as an atmosphere in furnaces. As most of you are aware I'm sure, the hydrogen flowing out of these furnaces is harmlessly burned to prevent concentrations of an explosive nature from accumulating. To maintain these fires, a gas pilot flame

is used. In our plant piping system the "pilot" gas supply is a separate loop completely independent of the main supply system so it will not be disrupted should it become necessary to shut off the main supply because of emergency.

Supervisors, machine setters and other key personnel involved in operations using hydrogen are required to take a special training course in "Handling Gases Under Pressure." This course is designed to teach proper sequence of operations in starting up and shutting down gas operations with particular emphasis on theoretical emergency situations.

In the hydrogen supply piping system (which by the way is color coded a bright red to prevent mistakes that might otherwise be made by pipefitters working on adjacent pipes) all connections are brazed to prevent leaks. Just in case there is a leak, however, hydrogen alarms located throughout the plant continuously monitor the air and are actuated by traces of hydrogen well below the danger point.

In addition to signalling, the alarms automatically turn on "purge" fans to quickly exhaust the contaminated atmosphere and bring in fresh air. Routine tests using small gas cylinders having a known percentage of hydrogen are used to insure proper operation of the alarm system.

Acids, caustic chemicals and many flammable solvents are also used throughout the plant. Special color coded containers and storage cabinets are provided to maintain an optimum degree of safety in the storage of chemicals. Maximum quantities of each chemical that may be stored by the using person in the operating area are established by the responsible engineer and audited by the plant protection organization. Antidote cabinets are located in strategic areas and plainly marked as are showers. These will not prevent accidents but they may well spell the difference between a minor and a major one. To the best of my knowledge not one of these showers has been required in all the years we have been in operation, but it is still comforting to know they are there.

Where handling of acid is required, normal protective clothing is used. We have adopted special clothing for our plating room personnel which for us is a significant innovation. The clothes are cuff-less and are designed to prevent operators from unknowingly carrying harmful chemicals, such as cyanide normally used in gold plating operations, out of the plating room.

Proper and safe disposal of chemical wastes is another item for consideration. Acids are no particular problem as we have a plant-wide acid drain system of PVC pipe which feeds into a neutralizing basin and thence into the sewer. Waste solvents are something else, because of the potential fire hazard they can create. Waste is collected in containers ranging from 5 gallon cans to 55 gallon drums located in the using areas. These are in turn dumped into an underground storage tank which is pumped out as required by a commercial scavenger. In no case is a container of waste solvent permitted to stand overnight. At the end of the shift all must be dumped into the storage tank.

So much for some of the general features. Let's take a germanium transistor

through its significant chronological stages and see some of the safety problems encountered.

Germanium dioxide is reduced to metallic germanium in a hydrogen furnace. Heavy asbestos gloves provide protection for the furnace tender. The germanium is purified by a process known as "zone leveling" and grown into a rod of single crystal structure having the desired impurities to give it a specific semiconductor characteristic. Orientation of the crystal structure is checked by means of x-ray diffraction. Exposure of the operator of this equipment is monitored by means of a dosimeter with a maximum allowable level of 100 milli-roentgens per week. The operating area for this equipment is enclosed by lead-lined walls to shield against possible stray radiation.

Next, the germanium rod is cut into slices and the slices in turn cut into wafers. Although the material is unique, cutting machines are similar to those used in many machine shops and normal safety measures prevail.

Wafers then go to the assembly area where one of the toughest operations from a safety standpoint, is that of etching. The etchant is generally a solution of hydrofluoric and nitric acid. An uncluttered work area, safety glasses, aprons and rubber gloves, plus proper safety indoctrination of the operator, minimize the hazards. Minor acid burns of the hands, which were at one time a problem, have been virtually eliminated through adoption of a glove testing procedure much like that used by service stations for locating leaks in inner tubes.

With all the safety engineered into facilities, the human element is still present. Safe working habits must be constantly stressed among all personnel. As a degree of insurance to see that this is done, part of the job responsibility of each first line supervisor is the requirement that he hold a safety meeting with his employees each month.

There is a saying in the semiconductor shop that devices are never clean enough or dry enough. We adopt a similar philosophy that operations are never safe enough. It, in effect, challenges all of us to be continually alert in seeking methods to make a safe job even safer.

OFFICERS OF THE ELECTRICAL EQUIPMENT SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—G. Mac DONALD, Vice Pres. and Gen. Mgr., Self Insurers Service Inc., Chicago, Ill.

Vice Chairman—G. R. SMITH, Safety Dir., Champion Lamp Works, Lynn, Mass.

Secretary—S. J. CURTIS, Supv. of Safety and Security, Burroughs Corp., Detroit, Mich.

Staff Representative—H. C. JOHNSON, Industrial Dept., National Safety Council, Chicago, Ill.

Membership Committee—R. E. WHITESIDE (Chairman), Branch Accident Prevention Mgr., Employers Mutuals of Wausau, River Forest, Ill.; J. W. LOOPER (Vice Chairman), Safety Dir., The National Cash Register Co., Dayton, Ohio; F. G. CORRY, Safety Dir., T. E. Circuit Breaker Co., Philadelphia, Pa.; H. H. BROCKHAGEN, Supv. of Safety & Security, A. C. F. Electronics Div., Paramus, N. Y.; W. F. Mc CHESNEY, Counselor, Safety Engineer, International Business Machines Corp., Oswego, N. Y.

Program Committee—M. J. QUINCANNON (Chairman), Supv. of Safety, Western Electric Co. Inc., Winston-Salem, N. C.; M. I. GJERDE (Vice Chairman), Senior Safety Engr., American Mutual Liability Insurance Co., Hackensack, N. J.; W. A. COLEMAN, Chief of Safety and Medical Records Section, Western Electric Co., Allentown, Pa.; J. A. WALDRON, Safety Supv., Packard Electric Div., General Motors Corp., Warren, Ohio; J. M. TRANSUE, Counselor, Security Dir., Philco Corp., Philadelphia, Pa.

Newsletter Committee—F. C. PEREROY (Chairman), Supv. of Safety, Air-Arm Div., Westinghouse Electric Corp., Friendship International Airport, Baltimore, Md.; B. B. FOOD & BEVERAGE INDUSTRIES A NEW CONCEPT IN REHABILITATION

By ROBERT W. WILL
Dir., Minneapolis Rehabilitation Center, Minneapolis, Minn.

The Minneapolis Rehabilitation Center began work with its first client in September, 1960. It is the only institution of its kind in the upper Midwest, geared to serve the needs of persons in the Twin Cities, the State of Minnesota and surrounding areas, on a non-profit basis.

Sole purpose of the Center is to rehabilitate persons who are incapacitated because of combined problems of medical, vocational, social and emotional nature. Its function is to apply coordinated skills of physical-psycho-social therapy to regenerate the self-sufficiency and productivity of stricken clients.

The Center was designed to support and extend the work of other agencies in cases which require concurrent treatment of a combination of physical, emotional and social problems. The Center is equipped, for example, to deal with the all-too-familiar post-accident case where satisfactory return to productive living is prevented by lack of emotional adjustment. If a case does not involve two or more of these problems it is better served by other, single-purpose organizations, such as family service agencies, mental health clinics or vocational rehabilitation services.

Referral of clients to the Minneapolis Rehabilitation Center, therefore, is exclusively from other agencies and services. Moreover, while the Center undertakes immediate management of cases referred to it, general control of the case is retained by the referring agency. Upon discharge of a Center client, case management returns to the referring agency, but the Center maintains a supportive role if necessary; for example, by providing services needed to help the client master new vocational and social situations he faces.

Land for construction of the Center was provided equally by the Center's two continuing sponsors, The Minnesota Society for Crippled Children and Adults and the Sister Elizabeth Kenny Foundation, at a total cost

of \$141,000. Construction costs were covered by grants of \$725,000 from the United Hospital Fund and \$339,000 from the federal Hill-Burton fund.

Upon completion of building, support from the federal fund and from UHF ceased. The two sponsors, however, have agreed to provide \$35,000 each to cover annual deficits from operation.

Deficits occur because fees charged to referring agencies for the Center's services are based only on the actual cost of operation. Individuals requiring service but lacking a sponsor will be charged for services according to ability to pay.

Primarily, the Center's largest initial "customer" for services is the Minnesota Division of Rehabilitation. Additionally, other institutions including insurance companies and workman's compensation groups are expected to employ the Center's services.

It is difficult to state precisely an optimum number of clients to be handled by the Center. It depends entirely on the degree of complexity of each case. It should be fairly accurate to say that the full staff can handle from 100 to 130 clients per day. The average stay of a client is approximately six weeks. None are "in-patients," but arrive at the Center and depart daily according to a schedule arranged by the staff.

Full staff of the Center will average about 60 persons, including part-time services of a Medical Director and a Psychiatrist. Staff members include directors of vocational, social and psychological services, vocational counselors, work evaluation supervisors, placement consultants, case workers, group workers and office personnel.

Operation of the Center, under its Board of Directors, is headed by the Executive Director, assisted by the Rehabilitation Coordinator.

The Minneapolis Rehabilitation Center is an independent, non-profit corporation.

Basically, need for the Center stems from the fact that individual existing agencies—large or small, metropolitan or rural—while providing intensive medical treatment, ordinarily do not have a volume of vocational and psycho-social case requirements sufficient to justify extensive staffing in those areas. The Center provides comprehensive services to enlarge the abilities of all those agencies.

The Center's initial contact with a client is through the referring agency and the Center's rehabilitation coordinator. The latter obtains complete case history data, duplicates it, and circulates it to an intake committee consisting of the coordinator as chairman, director of vocational services, director of social services, director of psychological services and medical director. A client is usually interviewed by the directors of vocational and social services, and by other specialists if the case warrants it.

Upon study, if the intake committee observes that the case requires extensive services of a particular nature before the client can fully take advantage of the Center's combined services, it will be recommended back to the referring agency for specific treatment.

If it appears that the client can begin treatment immediately, his case is accepted for one week of intensive evaluation designed by the Intake Committee to determine the full scope of the problems involved. This evaluation includes psychological testing, plus social and vocational study, resulting in a definitive outline for a corrective program. Upon acceptance, a case worker and a vocational counselor are assigned to work permanently with the client, constituting his case management committee.

After the week's evaluation, a staff review committee, made up of the intake committee, case management committee and referring agency representative, thoroughly evaluates all data gathered. Upon the committee's de-

cision that the Center can contribute substantially to the client, a corrective program in the psycho-social and vocational areas is structured in detail.

If concurrent medical service is required, it will be arranged through the Kenny Institute, the Curative Workshop or other appropriate resources. If a major social or emotional problem will prevent the client from taking immediate advantage of the Center's program, a social service or mental health agency will first be recommended to the client and the referring agency. When accepted by the Center, a client begins a corrective program developed to help him achieve a realistic vocational objective within a period of time consistent with the client's potential. It is not the Center's purpose to remove serious emotional or social problems, but to modify them so they will not seriously handicap the client's vocational opportunities.

The corrective program, devised by the staff review committee, is implemented by the case management group under the direction of the rehabilitation coordinator and with continuous consultation of the medical, vocational and social services, psychiatrist and psychologist. The case management committee meets once daily to coordinate knowledge of the case, to suggest minor program modifications and to reinforce treatment through close coordination of various staff members' efforts.

During his last week at the Center, a client's case management committee presents to the staff review committee a progress report and recommendations for the client's future activities. The senior committee develops this material so that when the referral agency reassumes case management it will understand fully the problems involved and what is required for proper follow-up. The Center may assist the referral agency to find a suitable vocational opportunity for the client and stands ready to assist him as long as is desirable.

A GROUP DYNAMICS APPROACH TO SAFETY PROBLEMS

By A. F. ROMIG

Manager, Training and Safety, Allegheny Ludlum Steel Corp., Pittsburgh, Pa.

Mr. Romig explained the group conference method or "66" technique developed by Don Phillips, President of Hillsdale College, Hillsdale, Michigan. He explained the discussion steps to the group and stressed the importance of determining action, through group dynamics, on a single question at a time. Sample questions which illustrate this point are offered.

Mr. Romig then conducted a group conference along the Phillips "66" technique. The chairman of the tables reported on the "best answer" as follows:

Question 1. What experience at this National Safety Congress will have the greatest impact on your safety program next year?

Answers:

1. The renewal of enthusiasm through the exchange of ideas.
2. The scope and immensity of the Congress gives a better indication of the importance of the movement and the many services and help available from so many sources.
3. The Congress suggested a need for more safety training "in depth."
4. The individual context and experience of others was most helpful.

Question 2. What experience or idea has done the most to alter your personal attitude toward safety?

Answers:

1. The realization that different approaches are needed to sell top managers, particularly of smaller firms, and to help professional safety men.
2. The importance of doing more about off-the-job safety.
3. The need to introduce more creative safety thinking from the company president on down.
4. Recognizing the need to stimulate and promote more interest in safety.

5. Recognizing the importance of accident prevention to production.

Steps in "Discussion '66'" after forming groups of six:—

1. "Will your committee of six first get acquainted; then select a chairman whose job will be to encourage each group member to speak; and a secretary-spokesman who is to record and later report the ideas of the committee."

2. "Will the secretary-spokesmen raise their hands? Please keep your hand raised until you get one of the (five by eight) index cards now being distributed—and on which we are asking that you keep a record of the discussion." On the back of this card can be printed:—

"To work as a committee

A. You will need

1. To get acquainted—know the others in your group.
2. A chairman—who encourages everyone to speak.
3. A secretary-spokesman—who records and reports your group's ideas.

B. After the question is stated by the

leader, it is advisable

1. To make certain that each member understands the question.
2. To take a minute of silence for each person to screen out his best idea.
3. To have each person state his best idea before there is any discussion.
4. To make certain that the spokesman has recorded each idea.

and finally—

5. To discuss the ideas as interest dictates."

3. Now, give the exact question to be used for discussion. Allow time for it to be written.

4. "This question requires an answer from each of you, individually. Will the secretary-spokesman record each response on the back of their cards. Later we shall want to collect all of the cards."

5. "After each member of your group has responded, the chairman can encourage discussion on the basis of these recorded statements. This means, Mr. Chairman, that each should give his answer before any discussion takes place. No names are to be recorded."

6. "You will have about six minutes in which to record and discuss your answers."

7. "Mr. Chairman, would you borrow the card from your secretary-spokesman and read the remaining rules of the game to your committee members. Then go ahead."

8. After four or five minutes, start to determine the approximate length of time needed to finish the assignment. Then, give one minute warning, and ask the chairman to make certain that all have shared. At the end of that minute stop the discussion.

9. Now, ask each committee to take not more than two minutes to screen out its best idea. "Will the secretary-spokesmen please check the one selected?"

10. You are ready for reports, according to the plan which best suits your meeting. And finally, at the close of the discussion, collect all the spokesmen's cards and tell the use to which they will be put.

Sample questions for use in
"Discussion 66"

1. To get acquainted:

A. "What one experience of your life might be most interesting to this group?"

2. To raise questions or ideas before or after a scheduled presentation by speaker of panel:

A. Before: "Mr. _____ is to be our speaker next week. His subject will be _____. His qualifications and experience are _____. To help him prepare for his presentation, what particular phase of this subject would interest you most?"

After: "What one question would you most like to ask in order to round out your information on this

particular subject?" "What additional suggestion would you offer which might contribute to the group's knowledge of this topic?"

3. To canvass attitudes and to evaluate:

A. "In what one way do you feel that this particular policy (program, demonstration, etc.) might be improved?"

B. "In what one way do you feel that our morale might be improved?"

C. "What in your opinion is the most important goal toward which we should be working?"

4. To build agenda or make a program:

A. "What one suggestion do you have for inclusion in our next agenda which would insure your attendance and, in your opinion, the attendance of others?"

B. "What one subject if included in future programs would be so meaningful to you that you would give up almost anything else in order to be present?"

C. "If but one item of business could be handled tonight, what would be your first choice?"

D. "What one problem concerning your work with the organization would you most like to have discussed?"

5. To get action:

A. "In view of the discussion, what specific action should we now take that would be so meaningful to you that you would be willing to give a part of your time to it?"

B. "If our group could sponsor but one activity for community betterment (art, etc., etc.) what would your suggestion be?"

6. To exchange experiences:

A. "What one experience along the line of this topic would you offer which you feel would be most helpful to the group?"

B. "What additional fact of greatest significance would you add to help us round out our information about this particular subject?"

C. "What is the best program idea (activity, undertaking) that you have

shared in or heard about?" (Which might contribute most to the group?)

7. To nominate officers:

A. "What one person in our organization would you be most proud to call 'Our President' (Our Secretary, Treasurer, etc.)?"

8. To initiate thinking on (class) presentation or assignment:

A. "What, in your opinion, is the greatest implication of today's presentation (assignment) in terms of your daily life (or, the material thus far covered; etc.)?"

9. To improve relationships:

A. "In your opinion, what should be our first step to make this a better working unit (team) (staff)?"

11. "What is your best suggestion for improving our relationships within our own organization?"

C. "What is your best suggestion for improving public attitude toward our group?"

10. To evaluate—and also canvass attitudes:

A. "What, in your opinion, was the outstanding accomplishment of the year?"

B. "What is your best suggestion for making these meetings (another program, or activity) more purposeful (productive)?"

C. "In what one way might we best improve our program (meetings) (or, our approach to problems)?"

D. "In what one way do you believe that the national (or, state) office could serve you better?"

MEAT PACKING, TANNING & LEATHER INDUSTRIES GET ALL OF THE FACTS

By NORMAN J. KIRK

Welfare Mgr., Canada Packers, Ltd., Toronto, Ont., Canada

This title, "Get All of the Facts," suggests that an accident occurs, the facts are examined, and corrective measures taken.

I would like to project this business of "get all of the facts" ahead to that period of time before the accident occurred to see how we can prevent the accident from happening in the first place.

Continuing with this thought, I suggest we leave out those areas where it is difficult to set down exact methods to prevent accidents. These intangible areas might include:

—communicating safety to people,
—making people aware of accident situations,

—getting supervision to take the interest that they should in accident prevention, and I am sure you can add many more.

There is, however, one specific section of

accident prevention where you as a safety man can exercise a great deal of control.

I am referring to that area of accident prevention where the premises are examined carefully for hazards and employers' actions are studied for unsafe work habits.

In discussing safety inspections, I do not wish to conjure up in your mind the vision of a government inspector making a routine inspection of the premises—rather other means of effective inspection within your control.

Perhaps I can throw in an idea or two that might be of use to you in uncovering unsafe situations.

To illustrate the value of inspections, I would like to describe an unfortunate incident that occurred at one of our creameries, demonstrating how a thorough safety check might have prevented an accident.

One Friday night in a small Ontario town, one of our creameries remained open to accommodate farmers coming to town. As the accountant had work to catch up, he remained after hours to look after customers and work on the records.

About 6:30 p.m., the accountant's wife came by and asked her husband to keep an eye on their two-year-old son for a few minutes.

As the accountant carried on with his work, he heard a yell from the back of the office. Rushing to the spot where the shout originated, he discovered the child had taken a drink from a pop bottle. Unfortunately, the bottle contained sulphuric acid used for test purposes in the creamery. Despite a valiant effort by the medical profession, the child could not be saved.

Now, what was wrong here and what would a thorough plant inspection have turned up?

1. A pop bottle should never have been used to house a dangerous acid.

2. Even if a pop bottle was used, it should have been stored in a locked cupboard, out of the reach of casual visitors and, in particular, children.

In addition, the accountant should not have been assigned a baby-sitting roll at the office where he could not watch the child constantly and, of course, children should not be allowed to wander through either the plant or office.

It is easy to look back and say what could have been done to have prevented this accident.

It is a fact that if this unit had followed instructions in regard to self inspections, the accident would never have occurred. Each of our plants and units is required to make a thorough self inspection every three months and confirm to head office that the inspection has been made. If this unit had followed the safety inspection "check list" used as a guide, and had complied with that section dealing with the care of acids and other corrosives, the improper handling and storing of sulphuric acid would have been evident.

From the central safety control point at head office, it is essential that the self safety check be carried out. We believe this is one tangible safety measure that can be carried out religiously by each unit.

At small units, the manager and the superintendent do the job.

At larger operations, the forman inspects his own department or the inspection may be carried out by the plant safety committee. The inspection check list we use is directed towards packing plants and fertilizer and feed units.

There is a second safety check we employ and this is done once per year.

The safety director from the main plant visits units which come under the jurisdiction of the plant.

The value of these checks lies in the fact that a person familiar with safety practice visits a plant which is strange to him. This independent inspector is able to spot safety hazards that are taken for granted by those who work with the conditions day by day.

As an example, some years ago while on a tour of units, and while visiting a creamery, I noticed that the employees used as a regular route between the plant and the office an opening between the wall and a butter churn. If you are not familiar with a butter churn, it contains a large protruding loading door. When the churn was in operation the pathway became a very dangerous area as the loading door came around and closed the opening. It was apparent that if the churn was started up and an employee decided to go through the opening at the same time, a serious accident could result. This condition had been taken for granted by the unit for years and when the situation was explained to them they were amazed that they had not spotted it themselves.

Not only at this creamery but at all creameries, the area around the churn was blocked off.

This is a case of accepting a situation through long association with it and never realizing the potential danger.

I would like to discuss a third inspection method and this one I am sure is quite novel.

In the southern part of the province of Ontario, the safety representatives from most of the packing plants meet regularly each month throughout the fall, winter and spring. Meetings are held at a different member plant each month.

The day's program includes an inspection of the plant by the group, and lunch and an afternoon discussion of common accident

problems. A highlight of the discussion is a description of lost-time injuries occurring at the various plants during the preceding month and suggested corrective measures.

I would like to deal specifically with the plant inspection.

First of all, it would be impossible for a group of twelve or more individuals to be all looking for every hazard. To overcome this difficulty and make the inspection more useful, a series of inspection forms were devised, each form covering a specific safety item.

The areas covered include mechanical hazards, protective equipment, miscellaneous, electricity, unsafe practices.

Each member of the group is handed a different report form and looks for the specific safety hazards on his sheet. For example, the man with the form covering electrical hazards would concern himself with this subject only.

To follow this further, let's consider the member who is watching for mechanical hazards. His form indicates he should be on the alert for such things as operating condition of pressure vessels, kettles, tanks, grinding wheels, stuffers and rotors, mechanical machinery; proper guarding of fans, belts, pulleys, gears, motor couplings, pinch points, etc.

As the members go through the plant, each one indicates on the form supplied to him the location of the department and the particular hazard noted.

These reports are handed to the safety man of the home plant and he in turn takes corrective action.

I believe this has been a valuable form of plant inspection, particularly in respect to new operations and operations which had been underway for a long time but had no specific safety program.

Firstly, the inspection is done by people who are familiar with packinghouse operations and safety problems.

Secondly, the group has sufficient status so that management of the plant visited is willing to go along with practical suggestions made.

Generally, at the next succeeding meeting, the representative from the plant visited the preceding month reports on corrective action taken to make his plant a safer place in which to work.

Meat Packing, Tanning and Leather Products

We are always looking for tangible accident prevention methods.

What better approach is there than the various plant inspection methods discussed.

I have not tried to tell you how to make an inspection of your plant and what to look for—each of you knows how to do this job.

I have endeavored to throw in one or two different concepts of inspection and results obtained from their use.

At the beginning of this paper, it was suggested that "get all of the facts" can be applied before the accident happens. Perhaps some of the methods suggested will help you achieve this end.

SAFETY INSPECTION CHECK LIST

Four times a year, a safety inspection should be made at your plant. The inspection should be made at the following times:

- Between January 1st - March 31st
- Between April 1st - June 30th
- Between July 1st - September 30th
- Between October 1st - December 31st.

We are not asking for a written report to be mailed to this office but will check you periodically to see how you are coming along with this important part of our safety work.

When making your inspection, the following check points should be kept in mind:

- Floors and Other Walking Areas
 - (a) Floors kept clean and free of grease.
 - (b) Free of items that should not be there.
 - (c) In good repair.
 - (d) Stairways clean, free of obstructions and well lighted.
 - (e) Are stands in good repair—surfaces slip resistant?
 - (f) Handrails in place and in good repair.
 - (g) Ramps, runways, loading plates, kept in good condition and stored safely.
 - (h) Ladders in good condition.
 - (i) Tank and bin ladders, out-walks -- in good order and with proper protection.
 - (j) Tanks, bins, manholes and chutes covered when not in use.
- Falling Objects
 - (a) Piles solidly made and not built too high.
 - (b) Safety shoes worn by people handling heavy objects.
 - (c) Tools and other objects kept in a safe place.
- Trucks and Truck Handling
 - (a) Trucks, in use in plant, in safe and good mechanical condition.
 - (b) Do employees use trucks in safe way?
 - (c) Truck handles guarded.
 - (d) Are trucks loaded properly—load balanced and truck not overloaded?
 - (e) Proper care when approaching blind corners or areas.
- Moving Machinery
 - (a) Is machinery stopped before oiling, repairs or adjustments made?

- (b) All moving parts, chains, pulleys safe-guarded.
- (c) Do operators receive full safety instruction (particularly on skinning machines)?

Handling Material

- (a) Workers handle packages safely.
- (b) Shipping areas free of congestion.
- (c) Doors and "automatic opening" doors kept in good repair.
- (d) Sharp edges of doors, machinery removed.

First Aid

- (a) Sufficient first aid equipment and qualified first aid attendants.
- (b) Do employees obtain immediate first aid?
- (c) Proper lifting techniques used to prevent strains.

Burns, Scalds, Electricity

- (a) Hot pipes insulated.
- (b) Hot water and steam hose maintained in good condition.
- (c) Acids, alkalis, cleaning materials used with utmost care and stored in a safe place.
- (d) Electric wiring and cables in first-class condition.
- (e) Are all electric tools, motors, machinery grounded?

Knives and Knife Handling

- (a) Knives guarded and kept in clean, sharp condition. Steels guarded.
- (b) Sheathards or sheathes used.
- (c) Safety gloves, arm guards, aprons used where needed.
- (d) Men spaced out to avoid one cutting the other.

Falling Objects

- (a) Overhead rails maintained in good order.
- (b) Switches in good working condition.
- (c) Safety dogs used where needed.
- (d) Rollers, hooks, shackles, chains and block and tackle equipment in good condition.
- (e) Trees and racks in first-class condition.
- (f) Hard hats used in areas where there is a danger of falling objects.
- (g) Are elevators, pent house, pit and electrical devices on elevators in excellent condition?

Eye Protection

- (a) Do workers wear goggles on jobs requiring their use—welding, grinding, chipping, bone sawing, white washing.

Miscellaneous

- (a) Safety belts used when employees doing overhead work.
- (b) Masks and breathing aids used where needed.

SMALL BUSINESS & ASSOCIATIONS

THE WHY AND HOW IN INITIATING AND DEVELOPING AN ASSOCIATION ACCIDENT PREVENTION PROGRAM

By IVAN F. LeGORE

Safety Dir., Portland Cement Assn., Chicago

Part of the business of anyone in business is to improve everybody's chances of working without getting hurt. That is as true of smaller businesses as it is of bigger businesses. The trouble is that the managers of smaller organizations don't think much about it or do much about it, while the managers of bigger businesses do.

One of our nation's biggest problems is to reach several million smaller firms, smaller organizations, which do little to prevent injuries at work. The owners and operators of those enterprises are busy people—hunting up business, scheduling production, making delivery deadlines and meeting payroll. The boss is chief cook and bottle washer; among other responsi-

bilities he has to be personnel manager, purchasing agent, sales manager, dividend collector and loss absorber.

He wouldn't know very well what you were talking about if you told him a safety engineer could do him a lot of good. He'd tell you he couldn't use one and couldn't afford one and, besides, he can't recall any serious preventable accidents they'd been having in his place. Safety work is one of those frills the bigger companies have along with a lot of other things. There aren't enough hours in the day, and days in the week, for the boss to do all the things he should as it is.

The majority of smaller businessmen don't know they have safety problems, don't

know that safety work pays dividends, and don't know how to improve their chances for business success by preventing the wasteful mistakes called accidents. They don't know how to save big fat dollars on a totally unnecessary item of overhead.

It is also a fact that the individual small businessman isn't likely to find out about these things on his own initiative. He may have debit insurance rates and be burdened with costs that add up to inefficient operations, a poor industrial and public relations and delayed deliveries which he can ill afford. Most small companies don't directly pay their medical and compensation bills; their insurance carrier takes care of that for them. Therefore, they seldom know what these direct losses from accidents are, much less understand the indirect losses from accidents that may be, and usually are, more serious.

In the aggregate, the accident problem of smaller firms is a big one. Firms that do little to control work accidents usually have more accidents than firms having safety programs, and that means that smaller firms generally have higher accident rates and higher insurance costs. Reliable surveys bear out that fact. In general, companies paying \$300 a year premiums—and there are hundreds of thousands in that category—are experience-rated and to some degree receive a debit for poor accident experience or credit for good experience. So all but the smallest can reduce their workmen's compensation insurance through the reduction of injuries.

There are cases on record where favorable accident experience has so affected insurance rates and other costs of doing business that a "safe" competitor beats out an "unsafe" competitor. Moreover, even the smallest company's experience contributes to the accumulated experience in its industry and in its state, so its own experience affects it by influencing the overall insurance rate for its group.

The small employer doesn't realize that such things as occasional eye injuries or cuts and bruises should be regarded as warnings that the next mishap might be the big one. He needs to be reminded that mismanagement which results in general inefficiency also causes accidents which in turn cause injuries and hindrances or inter-

ruptions to the work. He should be reminded that his experience with so-called minor injuries is a tip-off that something is wrong; and that something can lead to serious trouble and expense. Most accidents stem from failure to see and correct simple, commonplace causes.

So safety work should be encouraged, not as a frill or something added as a fringe benefit, but safety work should be encouraged as a part of the job, as inseparable from production, an integral part of everything done. It doesn't cost much in time or money, anyone can do it with the right kind of coaching, and it pays big dividends. For safety work not only prevents undesirable things from happening, it reflects sound planning and performance according to plan, it adds to productivity—and who in the world wouldn't welcome that kind of a benefit? A neat, well planned, orderly, well-run, safe job tends to encourage efficient work habits, boosts employee morale and public good will, and it helps the business keep running smoothly.

These are things Mr. Average Employer ought to know for his own best interests. You know them and I know them, but he isn't likely to find out about them by himself. How can we get him to know these things and do something with them?

The Department of Commerce tells us that there are some 16,000 voluntary associations in the United States. More than 4,000 of these represent Chambers of Commerce; some 12,000 represent trade, professional and technical associations. Each one embraces a segment of our daily life. Members of these 12,000 business leagues employ upwards of 68 million people. The 3 million employers that these voluntary associations represent sign the payroll checks that pay the grocery bill, the doctor, the dentist, the landlord and the merchant. They attend some 75,000 organization meetings on the national, regional, state and local levels involving their associations. Hundreds of thousands of business leaders attend those meetings, conferences and seminars.

Glenn Sanberg, who is executive vice president of the American Society of Association Executives, says:

"If we were to harness one-hundredth of the potential in this vast group on the American scene, we could, I believe, reduce

the terrible cost of accidents, both in money and manpower, by one-half overnight. Suppose at every meeting of an association one simple idea could be driven home to those attending—What a difference it would make. One idea—accidents are avoidable. What would happen, for instance, if 1,000 associations would make it their business to spend one-tenth of their conference program in creative planning for accident prevention?

He knows what would happen, and so do we. The records are full of startling examples showing hundreds of thousands of lives and millions of dollars saved through association-sponsored safety work.

Association executives are in a uniquely favorable position to show their members how to save money enough through accident prevention to pay their dues to the association. They know the leaders of their member companies. They have their confidence. They know their problems. They can get them together to share experience and provide mutual aid.

The members of a business association do their business through experience-sharing for mutual aid. And that is exactly the way successful safety work is done—through experience-sharing and mutual aid. The members look to their association for answers to problems, for new ideas, for direction, guidance and inspiration. If the association doesn't assume leadership in their safety work, who will?

Association executives who have assumed such leadership as one of the services of benefit to their members have found that accident prevention is a low-budget activity that is effective in small organizations as in larger ones, and that it becomes an increasingly important activity in terms of the human values involved. An increasing number of associations are finding that the smaller employer can control his hazards if he wants to, and that he can be led to want to control them.

Who else but his association can give the manager of a small plant or organization the same kind of perspective on his section of industry as the manager of a big organization gets from his own safety department? Who else can as effectively convince him, in his own interest, to make use of the knowledge and the techniques and the materials that are at hand for him to use on controlling the hazards of his business? Who else but the people he knows best, the people whom he trusts, the people

and organizations with whom he is on a footing of experienced and successful collaboration? The association is his outfit; his associates in it are his folks; it is his axe that the association is always grinding.

The association can get its member to see his problem and, having seen it, to make a reasonable effort to solve it himself. For safety is a job an employer has to do for himself. There are not enough safety engineers, inspectors or supervisors on earth to do the job of controlling unsafe conditions and unsafe work practices in all our small organizations, even if their managers were willing to contract for their services and had the money to foot the bill. But divide the cost of an association's information center on safety work—helping members to recognize and understand their own problems and to apply the lessons of industry-wide experience in solving them—by the number of member company organizations, and you have a service costing each of them pennies per day.

The small employer has the initiative to do his own safety job, or he would not be an employer. He will do his own safety job only when he wishes to do it. He will want to do it only when he believes he has adequate reasons for doing it. There are plenty of reasons—the success of his association in the field must lie in making them acceptable to him.

Perhaps that covers a great deal of the why of an association accident prevention program. As for the how in initiating and developing such a program, I can best tell you about the program I know best—that of my own organization, the Portland Cement Assn. Our safety work started almost a half-century ago and has steadily expanded to what National Safety Council representatives have said to be, "A position of the highest national importance." The staff of the Council has cited our work as an example to others initiating safety programs, and we have been helpful in every way that we could in their getting started in this field. If some of what I say sounds like bragging, I'll take refuge in what that eminent baseball philosopher, Dizzy Dean, used to say: "Bragging ain't bragging if you can prove it." I can prove it.

The Association and its member portland cement manufacturing companies are pio-

neers as well as eminent leaders in the important field of occupational accident prevention work. Since the inception of the Association, in its present form in 1916 safety work has been sponsored by the accident prevention committee, one of three standing committees appointed by the chairman of the board of directors and responsible to the board. Our constitution and by-laws provide that the president shall direct the promotion of the accident prevention activities of the Association, which indicates the importance accorded this phase of the Association's activities. The safety director reports directly to the president. The various company officials and executives who make up the accident prevention committee roster represent an excellent cross section of the safety thinking within the membership.

This is said in support of the point, which has been proved repeatedly, that there is best assurance of success in a safety program if top executives take an active part in it. Safety work brings all levels and all elements of an organization together in the common cause of making the business successful. The pioneer accident prevention committee told the executive committee of the board they believed that disabling injuries and fatalities were unnecessary to the manufacture of portland cement.

They obtained unanimous approval of a course of action to help the members reduce the number of accidents and aroused the entire membership to attack the problem of helping employees protect themselves on the job. Through experience-sharing for mutual aid, our members conserve manpower and equipment resources and improve productivity by anticipating hazards and hindrances to the work and providing against them, contributing to orderly operations.

Let me say at this point that for 45 years our Association has been a member of the National Safety Council. In taking part in the activities of the Council, we share our experience in solving safety problems and we benefit from the experiences of the other members. We strongly recommend Council membership to our members and most of them belong.

Our program had its origin chiefly in humanitarian motives and with the idea that accident prevention is good business. Safety

work makes good business sense, good social sense and good moral sense.

The returns are many. In the past decade alone, the injury frequency rate dropped one-third and the injury severity rate plunged 60 per cent, producing many benefits besides reductions in the manual rates for insurance which follow improved safety records. Methods improvement is a part of safety improvement. Morale is high up and down the line, workers and executives alike taking great pride in achievements that have made cement the safest heavy industry in the country, according to National Safety Council records.

In the Council's complete list of 40 heavy and light industries, cement ranks sixth. Our lowered frequency and severity rates, the reduction of which in heavy industries like cement, steel and glass is always a major problem, are now comparable to the average rates for all industries. Cement workers used to be rated up for life insurance, but not any more. Our workers get ordinary life at standard rates. Blasters and explosives handlers get life insurance at the second substandard rate as against third and fourth substandard rates for those occupations in other industries.

If time permitted, I could cite many startling examples of what has happened when other associations have caught the spark of safety service. They are on record at the Associations Division of the National Safety Council and are yours for the asking.

Now for more about the "how" in initiating and developing an association safety program, let me distill into about three major factors the things any association can do with a fine chance that they will be effective. Perhaps this is an oversimplification, but if so, so be it. So far, we have made the points that accidents can be stopped; it is profitable to stop them, financially and from the standpoint of morale; accident prevention does not cost much, paying for itself many times over; safety know-how is time-tested and can be used by anyone. Like any other kind of work, safety work requires consistent direction so that it will be done efficiently and persistently—otherwise, individuals must by trial and error become expert in recognizing and solving their safety problems. While

management may tolerate supervisors' trials at accident prevention, rarely can it afford their errors.

There's an old saw to the effect that there are three kinds of people: people who know where they've been, people who know where they're going, and people who have no idea where they are! Leadership that knows where it's been and where it is and where it needs to go is indispensable.

Surveys, questionnaires and accident reports among the association membership develop the need for accident prevention work in much the same manner as other needs of the members are discovered. Evaluation of the membership's experience in the light of the data shows what is most urgently needed in order to improve their accident experience. Needs are revealed in studies of accidents reported, in correspondence and visits with operating executives, in meetings of the association's accident prevention committee and in such regional conferences as may be held of plant managers and key supervisors. Procedures and forms for doing this are available from the Council.

Let me give you one example from our Association of the benefits of an accident reporting system to let us know where we are and what our needs are. Each month the disabling injuries reported by our 180 member company plants are summarized, without identification, in our Accident Round Table with commentaries as to how they should have been prevented. That means that each month's Round Table gives each plant team of supervisors and employees the benefit of 15 years' plant accident experience! This means of sharing accident experience was started years ago, and the safety progress made in our industry proves its worth. Of course, shared safety knowledge stops accidents only when people are wise enough to learn the lessons that mishaps have taught other people the hard way.

It should be understood that accidents won't be prevented from the office of your association. The people who make safety programs successful are the employee whose responsibility it is to get daily jobs done right. It is the association office's first responsibility to keep that fact fresh in everybody's mind. It takes ingenuity and

persuasiveness to get people to recognize and understand their own safety problems and to apply the lessons of experience in avoiding accidents. But those qualities of promotion are the stock in trade of any association employee who is effective in his work of furthering the interests of his members.

Promotion ideas are to the safety man what advertising ideas are to the sales manager. The problem is one of motivation, of getting messages across in such ways that the prevention of accidents will be interesting and important. Safety promotion can be dull, stuffy and dreary if we simply scold and view with alarm and point to the horrible things that go on. But the accident prevention concept can be reduced to practical, realistic, liveable, down-to-earth principles translated so that the average fellow on the street, in the plant or in the office will buy them.

Often a bad job of selling safety is done because we don't know people well enough. Safety is actually a vital, dramatic way of furthering the way of life in America of which we are so proud. Safety habits mesh in the whole pattern of activity of capable workers, good parents, responsible citizens. We can never stop improving our knowledge of how to promote it any more than an association executive can stop improving his know-how in promoting effectively the other business of his members and their employee.

What do you promote? In every telling way you can think of, promote these general ideas:

1. *Accidents are mistakes*, therefore wholly undesirable. The person who disables himself trying to get the job done has done something that is not to his credit, for he can't finish the job he started. He was dull or reckless, not smart enough to look ahead, plan ahead and use his head. Recklessness makes no sense, requires no brains and no skill. Risking one's future is stupid.

Collectively, a good plant safety record reflects competent leadership and capable workers. There is no better indicator of the competence of an operating team than their ability to get the job done without the mistakes and errors in judgment that lead to accidents. Employees' families take pride in championship safety performance as their

men do. In the celebrations and affairs marking outstanding safety achievements, we give due recognition to the family stake in and contribution to the record.

Every wife and mother, every son and daughter expects the head of the household to return home from work all connected up, just as he was when he left for work at the start of the shift. In so doing, their men didn't let them down. And living up to others' expectations is an important manifestation of an individual's, and an industrial team's, worth and ability. Happiness does not come from doing easy work but from the after-glow of satisfaction that comes from the achievement of a difficult task that demanded our best.

Desire to avoid personal injuries is strengthened by setting up a goal of accident-free operation and inspiring people to work toward it. The challenge to prove competence by avoiding accidents appeals to the spirit of competition and cooperation—competition for an outstanding record of performance and cooperation with teammates in achieving it. The association is in an excellent position to set up and administer a trophy competition for outstanding safety work.

Care should be taken to avoid the mistaken idea that safety is separate and apart from production. Actually, safety is an integral part of the job, any job, an essential to good workmanship, an inseparable part of any successful undertaking. In driving a car, a person doesn't do a "steering job," a "braking job," or a "signaling job" separate and apart from the one endeavor that must be performed satisfactorily for him to get to his destination safely. At work, a person doesn't do a "quality job," a "production job," or a "safety job" separate and apart from the one job at hand. Whatever the task, all three elements must be combined for it to be done satisfactorily.

2. *Safety is a choice*. That's another general idea to promote in every ingenious way you can find in developing and maintaining sound thinking and good teamwork for accident prevention. Alertness and the right choice of work practices keep plant teams accident-free. Good attitude is the most important factor influencing the performance of competent workers and drivers.

Studies show that accident makers are

aggressive, intolerant of others and discourteous; resent authority; have an exaggerated opinion of their own importance and abilities; seem unable to respect the rights of others; often act impulsively and take chances. "Man is arrogant in proportion to his ignorance," is an old saying. The worst places to be arrogant or excitable are at work and in traffic.

Everyday living involves a very great number of choices and decisions, many of them critical from the accident standpoint. Choices are made between being tolerant and intolerant, firm or permissive with respect to what is right and safe, respectful or disrespectful of others' rights and welfare, thoughtfulness or impulsiveness. For most plants, supervisors and experienced employees know how to eliminate physical hazards and unsafe methods and practices. The big problem is to get them to apply what they know, to avoid the short cutting and chance taking that lead to disabling injuries and damage to equipment. Failure to find and eliminate dangers breeds accidents. Failure of supervisors to instruct in what to do, how to do it, and the reasons for doing it that way creates many of the problems, mistakes and misunderstandings that lead to accidents and loss of production time. Operating men need to be reminded of this regularly.

The prevention of those unwanted occurrences, called "accidents," reflects sound choices in planning and in performing according to plan. Safety work not only saves someone, or prevents something untoward happening, it adds to productivity. Many familiar developments, such as the Westinghouse air brake, were originated principally for safety purposes but have contributed greatly to efficiency. Shear pins, fuses and relief valves are fail-safe examples.

Preventive maintenance is a fail-safe function that anticipates failures and institutes corrective measures before breakdowns can occur. Putting blocks under jacked-up loads makes fail-safe sense; so does staying out from under suspended loads. Another choice is between good and poor housekeeping. Neat plant grounds and orderly building areas, besides being safer, are evidences of self-respect and pride on the part of capable plant teams.

3. *Safety should be personalized*. Here is another idea that should be strongly pro-

model. Recognition of outstanding safety performance goes to the plant team, but the fact is that the team's successful record is made possible by the competent performance of every individual on the team. Successful safety work requires group effort, but it also demands individual responsibility and accomplishment. The slogan — every man his own safety director—is based on a sound and fundamental truth.

Mass safety education utilizes posters and films, messages and get-togethers. Such influences help to maintain general safety awareness. But safety teaching does not become fully effective until each employee knows the hazards of his job and how to avoid them. There is a need for personalized training that teaches the individual where the dangers are that he must avoid and what he must do to avoid them. Such safety training takes into account the worker's own rate of learning, his interests and worries, his competence and his limitations. Interviews with him provide the employee with frequent opportunities to make safety suggestions and to bring up any problems he has on his mind.

In striving to make safety education more effective, more universal and forceful, we become more and more convinced that a basic part of our effort must be to build good citizens. Evidence accumulates that the thoughtless, ineffectual worker and the thoughtless, ineffectual driver and the thoughtless, ineffectual parent are the same person wearing different hats. He probably was a thoughtless, ineffectual youngster, and he needs guidance if he is to keep out of accident trouble.

The great and growing need is for leadership by all intelligent people to make safety an all-day, everyday way of life. It is they who know how to use sound living principles as guides to self-reliant, self-possessed, self-controlled and capable behavior—always and in all ways. It is they who translate safety knowledge into programs; they who make the programs work.

A leader exercises judgment in handling affairs and dealing with responsibilities. He conceives and develops ideas; he also accepts and adapts good suggestions and puts them into operation. His personal qualities include patience, self-control, perseverance, self-reliance and a sense of values. He has

the discipline of character to say "yes" and "no" to men and proposals, not out of blind obstinacy, but with the firmness derived from weighing alternatives. His goals include good citizenship and good workmanship.

Cement industry employees have proved that accident prevention effort on the job works—that education, engineering and enforcement can prevent the waste and tragedy of accidents. They believe that safety should be no less a personal thing away from work. There is no less need for common sense when an employee goes out through the plant gate. He should have no less sense of responsibility for preserving his own life and the lives of others. We encourage men to improve their safety awareness and habits in the time they are on their own, making it more likely that their services will be available to their employer uninterrupted by disabling injuries sustained anywhere. We are convinced that safety habits mesh in the whole pattern of activity of capable workers, good parents, responsible citizens. Safety work contributes to the self-discipline of capable people. It promotes an understanding of and more ready compliance with authority, that leads to the acceptance and fulfillment of personal responsibility. Failure to take personal responsibility is a critical problem in programs dealing with the prevention of accidents of all types.

Answers to problems are found by minds that stand off and look; that consider the relationships of things to each other; that see where things might go wrong and how they should be straightened out before accidents can occur. Answers are found through experience-sharing for mutual aid, whether the discussion of safety problems takes place among a few persons in a single department or plant or among the representatives of a number of plants or companies.

It is to the everlasting credit of our Association that we have always been in the vanguard of those hard at work to reduce accidents. Our reputation as a pioneer and leader in safety work is a satisfaction to us. It is one that we must extend as well as cherish. I hope this analysis and the highlights of the thinking and activities directed toward the solution of the safety problem may be of benefit to other associations.

TRADES & SERVICES

PUBLIC LIABILITY FROM INCIDENT TO FINAL DISPOSITION

This session was moderated by Raymond C. Ellis, Jr., manager, Member Relations, Variety Stores Association, New York, and was attended by representatives of department stores, chain stores, insurance companies, and safety consultants.

There was considerable discussion on minor accidents and nuisance claims, particularly regarding liability when broken glasses or damaged clothing was repaired or replaced or when first aid was given by anyone other than a professional. It was agreed that a detailed report should be given and that an immediate check of the physical conditions involved be made.

Dr. Murry Paul of Carson, Pirie Scott and Company, Chicago, described his company's accident prevention program which included:

An effective accident prevention organization and program which includes a safety committee representing all stores with a committee in each area.

He pointed out the importance of having the company president and vice president frequently attend the monthly safety committee meetings.

Accident hazards are removed immediately and receive prompt attention from executives and managers. Their program combines safety with fire prevention and includes an emergency evacuation plan with frequent drills in which an entire floor is evacuated.

To stimulate interest they have breakfast meetings of the committee on a semi-annual basis.

Public liability cases are carefully handled

with consideration given to future liability and legal action. The nurses prepare a comprehensive report which includes a maintenance report, reports from witnesses both public and employees, and photographs if possible. The company doctor calls and arranges to send the injured person where his or her doctor wishes; hospital, clinic, etc. If necessary, one of the store personnel accompanies the injured person and this tends to create good public relations.

Insurance company representatives agreed that "no case gets cheaper by sitting on it!" Borderline cases are settled promptly and a monthly report on claims is furnished to top management so as to give information on the importance of making improvements to reduce hazards.

The representative of a large chain store stressed the importance of communications between store managers on the costs of accidents which are translated into lost sales and profits to convince top management that more accident prevention is necessary.

On falls in the stores, the company provides immediate first aid with additional treatment at the doctor's discretion and the customer's expense.

The point was raised regarding customers who refused treatment which raises complications if a report is not made on the incident.

Inquiries regarding the claimant's condition frequently led to the question of the company assuming medical costs but it helped determine whether the insurance claim department should be involved.

GLASS and CERAMICS SECTION

MY BROTHER'S KEEPER

By PAUL J. BROUWER, Ph.D.

Partner-in-Charge, Rohrer, Hibler & Replogle, Cleveland, O.

To find something vital and significant to say to you who have spent so many months and years thinking about safety in your companies is indeed a challenge. I am only hopeful that a combination of my background as a psychologist and my gross ignorance of the specifics of safety work may combine to yield an insight or two which you will find interesting.

One purpose we have for our next few moments: let us explore how we strengthen our resolve to be psychologically free from accident through relaxed awareness of accident possibilities. Thus, I would hope we can share together some understandings of the basic psychology of "accidentitis" and try to pin down some of the implications of these understandings, not alone for each of us who is personally responsible for safety programs but also for our supervisory forces who must do what they can to insure safe living on the job.

I have asked myself, as I am sure you have asked yourselves, why is it that we need to be everlastingly hammering at safety? One would think that except for the small fringe of people who are neurotic or psychotic enough to enjoy hurting themselves or others, people would want to live safely and would feed the steady barrage of instruction and warning which is hurled at them. Somehow or other the need for safety needs constant emphasis. It falls in the same category as crime prevention, church-going, giving to community funds, and what have you. Apparently, as human beings we are so put together that the evils within us—the tendency to be careless, the disposition to be thoughtless and selfish—need constantly to be fought.

Thus our problem of developing keen, consistent safety consciousness is made most intense by human nature itself. I have concluded, as no doubt you have long since concluded, that powerful forces operate against safety consciousness, forces inherent

in the individual and hence forces that we cannot hope to eliminate—we can only hope to counteract through equally strong forces pressing us toward safety consciousness.

If this kind of sentiment is reminiscent of the theologian's dramatic picture of evil and good in never-ending conflict, let it be so, for in actuality I think our conception of our efforts to make our companies as safe a place to live as possible must be as basic and as dramatic a conception as the fight between good and evil. This is an eternal conflict, a never-ending war, and it means that the programs we institute and the gimmickry we develop, no matter how effective, will never solve the problem because the problem is *unavoidable*. We can only reduce the accident rate.

Thus, if we are constantly waging war against forces within human nature itself in our efforts to develop the posture or attitude of safety, our problem becomes the psychological one of dealing primarily with attitudes and dispositions inherent in human nature.

Interestingly enough, the good part of our human nature is responsible for your being in your jobs. You are your brother's keeper or you would not be here. You do have some feeling of responsibility for your fellow man.

Safety programs through the years have called on four broad approaches through which to express the feeling of responsibility for the other man. Now let's examine briefly each of these four with the question, how is the approach likely to be effective, knowing what we do know about human nature? Perhaps such a brief examination may highlight for us those emphases in our safety programs which are psychologically most effective.

Historically we have used, first, injunction and exhortation as means of influencing human behavior. Such familiar highway slogans as "drunk drivers go to jail" or

"drive safely—we love our kids" or "drive carefully—the life you save may be your own" exhort and enjoin us. Billboard advertisements and bulletin board posters in continuing series of exhortative reminders are common practices.

Are these effective? Who knows? We have no way of scientifically testing the impact of such devices. We do know, however, that like the old preacher's hellfire and damnation exhortations they tend to gradually fall on deaf ears. You can only threaten somebody about so long before he doesn't hear you. So this kind of exhortation or warning or threat, whatever you want to call it, loses its impact. The evil in human nature, which we are trying to counteract, is too strong to be affected by threats and promises.

Secondly, we have also historically used explanation as an approach to safety consciousness. We explain to the child that a hot stove burns and that a sharp knife cuts. We explain to the employee that safety shoes prevent crushed toes and that safety glasses prevent loss of sight. Wherever we can, we explain the nature of the physical phenomena which we live with daily, on the job or off, in order that people can intelligently cope with it.

Certainly, explanation is necessary. But somehow or other this in itself is not sufficient because people still have accidents—preventable accidents—although they know better. A truck driver in Cleveland knew that the handbrake was insufficient to hold his truck on an incline; he should set the airbrake as well. But this knowledge did not prevent him from failing to set the airbrake, so that the truck slipped back and crushed him against the wall. Knowledge in and of itself is insufficient to promote safety consciousness, although certainly knowledge is necessary.

Third, we historically have tried to take the accidents out of the material things we deal with by providing protection. We put a two-handed grip on a punch press so that a man cannot get a hand in the press as it comes down because both hands are required to release it. Or we provide a safety-belt for the window-washer. In many ways, we have developed devices which protect the human being from himself. Obviously, however, any protective device is doomed to only

partial effectiveness, for the window-washer still has to attach the belt and the welder still must put on his own helmet.

An accident by definition is an unexpected occurrence. The prevention of accidents, therefore, is a matter of anticipating the unexpected.

A fourth approach, historically, has been to help people to anticipate the unexpected and thereby prevent accidents. Here we are working on the good that is in people. We are working on people and with people. We are recognizing the fundamental principle that preventable accidents are most often in the person and not in the thing.

For example, if you place a bottle of poisoned liquid on a low shelf in a medicine cabinet in the presence of a four-year-old, you know that you are risking an accident. A four-year-old enjoys climbing and exploring. You can therefore hardly call his drinking the poison an accident. In the first place, the lethal effect on his young body of the poison is nothing unexpected. The properties of the poison and the properties of the body interacting together produce death. This is known and fixed and factual.

It is equally predictable that a four-year-old is curious, loves to look into places, such as medicine cabinets where he is forbidden to look, and enjoys climbing on the wash bowl. This too is known and fixed and factual. So when the child does these things, he is behaving in a predictable fashion.

The factor in human nature that prevents the four-year-old from getting the poison is the insight of the parent. The parent understands the nature of the poison and the nature of the four-year-old, and he can predict that if these two get together there will be inevitable and dire results. The parent prevents accident by anticipation.

By the same token, if you have seven children sleeping in one room, heated by an oil stove that is old and dripping oil and the windows are closed, you can predict trouble; and trouble they did have in Elyria, Ohio, where the oil had leaked onto the rug, spontaneous combustion occurred and seven children burned to death. This is not accident! It is an expected occurrence, granted these conditions.

So, as we work with people on safety consciousness, do we not try constantly to teach them, stimulate them, inspire them, if

comes injected with feeling and then it becomes a matter of conviction.

Specifically, how can we translate intellectual perception into feeling and conviction? Again, we have to leave to our respective ingenuity the specific ways and means; but let me give a wild-eyed suggestion or two.

I wonder how many of you have ever talked at some length with a number of people in your companies who have been significantly free from accidents? The approval you would feel toward such a person, the feeling of warmth and positiveness that you exhibit, could well make him say to himself, "By George, I feel really good about what he has complimented me on and I'll try to continue to be a pace-setter in a program of safety."

Or again, could you in your capacity as safety director ridicule and shame the man who did something thoughtless and selfish and thereby ran the risk of an accident? (Of course, choosing your man so that he doesn't respond by hating you but by hating himself.)

I think that psychologically we are justified in using any and every means at our disposal—ridicule, approval, scorn, praise, chastisement, award, flattery, rejection—you name it and use it—anything that will help to inject feeling into the intellectual perceptions.

It goes without saying that the feelings must be genuine rather than put on. The very problem that we are attacking at this point is the problem that arises from living with techniques and ceremony and rites. We need to translate ceremony into meaningful,

significant personal experience; we need to undergird our intellectual understandings, for example, of what safety really means with the underpinnings of strong conviction and belief. I do not need to tell you these things because you have the convictions or you wouldn't be here. But our employees and associates need to be continually experiencing through us and like-minded people the stimuli to feeling responses that come only from a personal involvement.

One more word: While it is true that people in a group may have an emotionalized experience on occasion, such as when there is a mob or revival type of evangelistic meeting or something of that sort, by and large the feeling that we are trying to generate arises from man-to-man, person-to-person relation.

Far better that any of your foremen would talk only with five people personally for five minutes about safety than to talk to 50 people simultaneously for 25 minutes. And this means for practical purposes the generation of feeling must come from employer-employee, supervisor-subordinate, man-to-man experience. This is a personalized thing.

In summary, let me reiterate that we are psychologically sound in promoting safety programs through injunction, explanation, and protection, and that these are necessary to provide the framework of our effort. But that the tapping of resources of desire to live safely requires a generation of attitudes. And that these attitudes can arise best from participation on the part of the individual in meaningful, personal-feeling experiences.

ELECTRICAL HAZARDS IN THE GLASS INDUSTRY

By JOHN A. BERSETH
Chief Electrical Engineer
Pittsburgh Plate Glass Co.
Pittsburgh, Pa.

The Glass Division of the Pittsburgh Plate Glass Company is engaged primarily in the manufacture of flat glass and flat glass products. The two basic products pro-

duced are polished plate glass and flat drawn sheet or window glass. These products are used as such in the familiar glazing applications. In addition, the basic prod-

ucts are fabricated for use in automobiles, aircraft, insulating windows, or building specialties.

To adequately explain electrical safety considerations, it would probably be helpful to briefly describe the basic manufacturing processes. The first step in glass manufacturing is preparation of the dry batch. Ingredients such as sand, salt cake, limestone, and soda ash are accurately weighed and thoroughly mixed. This material is conveyed by belt or bucket to the melting furnace and heated to about 2750°F. The application of heat melts down the solid ingredients to form a liquid glass.

Window or flat drawn sheet glass is produced by drawing vertically from the liquid mass to produce a sheet of desired thickness with a natural polish or fire finish. At the top of the drawing machine, the product is completely formed and cut to desired size, ready for commercial use.

The production of polished plate glass is a considerably different operation. The melted batch is drawn from the furnace horizontally by a pair of water cooled rolls. This continuous sheet of glass is not transparent due to the roughness imparted by the roll surfaces. The continuous sheet of glass is then carried on a roller conveyor through an annealing chamber. Following the annealing operation, the glass is mechanically ground with graded sand particles and rotating cast iron discs. This operation is followed by polishing with an abrasive applied to rotating felt discs. The polishing procedure imparts transparency and luster to the glass.

Older plate glass operations grind and polish on a continuous conveying system made up of large tables. This requires each side of the glass to be ground and polished separately. The installations of recent years are provided with "twin grinders" which grind both sides simultaneously. After twin grinding, the glass is moved to the table type conveyor for polishing.

In the following safety discussion, it is necessary to emphasize that these principles apply only to the Pittsburgh Plate Glass Company. I am not able to state these concepts as those of the flat glass industry. No detailed information on manufacturing equipment or processes is exchanged among

corporations as such communication is forbidden by legal decisions.

The application of electrical equipment to serve the glass division operation offers many challenges to provide safety and reliability. The following are the items that must be fully considered in our installations:

1. Protection of life
2. Protection of plant property
3. Protection of uninterrupted productive output

In all electrical applications, we are required to provide an installation that is as free of danger and hazard to personnel as is humanly possible. This requirement must apply to those who install, maintain, or operate the equipment. The nature of glass production and its consequent need for reliable electrical service make stringent requirements for safety and reliability in the equipment itself.

The electrical requirements for producing polished plate glass are different from sheet glass due to the amounts of electrical energy required. The plate glass operation requires much more energy due to the mechanical grinding and polishing operation. Due to the difference in power requirements, the operations will be discussed separately.

A prime requirement for producing polished plate glass is an extremely reliable source of electrical energy. This is vital to the safe operation of the melting furnace and necessary for continuity of operation in a facility representing high capital investment. The melting furnace operates at about 2750°F. The furnace and rolling apparatus must be continuously supplied with cooling water and cooling air. The melting operation is carried out on a 24-hour, 7-day basis. Once brought to full operating temperature, the furnace will probably remain in this condition for periods approaching 3 years.

This process requirement dictates many features of the main substation, receiving power from the electric utility company. The plants are served with purchased energy at primary voltages ranging from 25,000 to 138,000 volts. All are supplied with at least two separate sources. Where possible, these sources are over geographically sepa-

This metal clad air breaker equipment has recently been challenged by the high interrupting capacity, current limiting, low voltage fuse. These appear to have excellent characteristics for the protection of equipment and offer attractive cost savings. We are using some of this equipment, but are moving slowly as our safety experience with the air circuit breaker has been excellent.

Distribution from this low voltage switchgear is by means of cable in steel conduits, or the new interlocked steel or aluminum armor construction. We have lately used 4 conductors on these circuits. Three phase conductors and one full sized neutral are used. The grounded neutral is run to the distribution point and is provided to insure a low resistance ground path for fault current. This insures adequate current to trip the circuit breaker instantaneously in event of a ground fault.

In the plate glass operation, the greatest use of the distributed power is for electric motors. The control of these motors 10 years ago did not prevent any more complication than pushbutton or travel limit switches. For that reason, control circuits were supplied at 600 volts. The advent of the need to supply automatic operations with the installation of many relay and logic functions has led to the adoption of 115 volt control circuits. This provides greater safety to operator and maintenance man and permits the use of much smaller relay and limit switch components.

The extensive use of automatic operation has necessitated the installation of machine tool type control panels. We have a standardized construction that separates the motor switching elements from the relay or logic control. One panel section is devoted to motor disconnect, short circuit protection, and motor contactor. A separate section is used to house all logic relay elements. For trouble shooting, the maintenance man need have no exposure to 480 or 600 volts if the difficulty is in the relay section or at a switch on the production machine.

In producing the rough rolled plate glass, the rolling machine cannot be permitted to stop. Serious and costly damage to rolls, gears, and refractory would be the result of such a failure. For this reason, these

loads are supplied with direct current. The direct current is supplied by mercury arc rectifier or motor generator. For absolute continuity of service, a large standby battery is provided. If the utility power should fail, this battery will supply all the vital furnace auxiliary motor drives for about one hour. With multiple service to the plants, failure of supply for more than this time is of low probability.

In the large plate glass operations, emergency lighting has been provided by the familiar self contained battery and lamp units. These are strategically located throughout the plant. They are for personnel safety only. Failure of utility supply stops production of all items except the melting and rolling operation. Our experience over the years has indicated total power failures are not of a frequency or duration to require additional precaution.

The previous discussion was based on a plate glass operation. Similar situations are found in the sheet glass operation but on a smaller scale. This is due, as previously noted, to the smaller use of electrical energy.

The main substation is provided with multiple circuit supply to provide service continuity. Switchgear is provided with the same safeguards as the plate operation. Since transformers are not larger than 1500 KVA, no differential protection is warranted. Fire protection for transformers is by physical isolation of the units except in instances of unavoidable congestion. Here the fire fog water system is applied to minimize hazard to adjacent equipment and structures.

Loads are served at 480 volts using the grounded neutral system. A direct current installation, with a standby battery is used to serve motors which cannot be permitted to fail. These motors serve the melting furnace and the machine which draws glass from the furnace.

Further protection against failure of utility supply is provided by a standby alternating current generator. This is required, since the sheet glass plant electrical loads are not large enough to justify more than normal utility supply.

In the utilization of energy the same methods are employed as in the plate glass operation regarding switchgear, motor wiring, motor control, and other similar items.

A third activity of the Pittsburgh Plate Glass Company Glass Division operation is concerned with the fabrication of sheet and plate glass. This involves the manufacture of automobile windshield, side lights, and back lights. Also, items such as double glazed units, glass doors, airplane glass, electrically conducting glass, ceramic coated spandrel glass, glass with heat reflecting coatings, and other similar products.

In fabricating these products, the glass generally must be brought to elevated temperatures of about 1200°F. This requires a furnace. Most furnaces are electrically heated and are of our own design. Safety features are the protection of heating element terminals to avoid accidental contact by personnel, use of proper insulating material to prevent failure, providing equipment to prevent overheating, and the provision for rapid shutdown in any emergency. The latter feature is provided by permitting the operator to de-energize the equipment, but not permitting him to re-energize without proper maintenance inspection. This is enforced in that restoration requires entrance to a substation and the manual operation of a breaker.

The preparation of glass for these operations has developed many needs for automatic devices. This requires extensive use of our standard machine tool type control panels and the necessary interlock to insure safe operation of cutters, grinders, and washers.

One operation that makes for an interesting application of electric energy is the welding of glass sheets. This process is used in the fabrication of an all glass double glazed window. Two sheets are welded together with an air space between to form an excellent thermal insulating glass window. The welding is performed with 60-cycle current at potentials in the neighborhood of 18,000 volts. This requires safety interlocks to prevent accidental contact by the operator

with energized welding electrodes. It also requires circuitry to limit current flow to safe values and prevent excess voltage from flashing over the glass surface. This welding is performed with the glass at 1200°F and, therefore, requires the use of refractory materials which are considered insulators even at high temperatures.

To complete this discussion of the electrical safety features in the Glass Division, I will briefly review a few problems common to production of plate glass, sheet glass and fabricated products.

Portable tools always are of concern, since grounding of the case is absolutely necessary. In new installation outlets at 110 volts, 1 phase are provided using the 3-wire plug. This provides a means of grounding. Outlets for welders and other large tools are provided at 480 or 600 volts, 3 phase. These use plugs requiring 4 conductors, the fourth being a ground conductor. Even though these facilities are provided, it is difficult to prevent the making up of adapters so that conventional plugs may be used with tools. The operations must be very attentive to such violation of safe practice.

A reliable fire alarm system must be installed for each plant operation. This system will be provided with adequate numbers of manual pull stations and will also be integrated with sprinkler flow alarms, annunciator drops at a central location and coded audible signals which locate the fire area in order that help can be promptly dispatched.

This discussion has reviewed the major factors in the Glass Division's Engineering approach to electrical safety and is a presentation of our present practice. However, achievement of safe practice requires constant vigilance. Therefore, we are in continuous examination of all principles to produce installations that will protect life, property, and production continuity.

IMPORTANT HUMAN FACTORS IN SAFETY

By HUGH L. RUSCH

Vice President, Opinion Research Corporation, Princeton, N. J.

Safety is a subject about which many millions of words have been written and spoken. Our final authority on word usage, namely, Webster's New International Dictionary—the unabridged edition—has almost three columns, each 10½ inches high by 2½ inches wide, devoted to safety. Starting with the word "safe," and going on with such items as "safety arch," "safety belt," "safety catch," "safety factor," "safety island," "safety lock," "safety match," "safety pin," "safety razor," "safety switch," "safety valve," and ending with "safety zone," there is almost more dictionary space devoted to this subject than any other item in the entire book. Even such a basic item in human needs as the word "food" occupies less than a column in the big dictionary.

The comprehensive nature of this 49th annual National Safety Congress and Exposition, here in Chicago all of this week, with people in attendance from all over the world, during which hundreds of thousands of words will be spoken and written, is further evidence of the importance of the Safety problem.

Someone may even ask the question—"Are we perhaps saving and writing too much about safety?" The answer to that question is self-evident—an emphatic "No!"—particularly when we stop to consider that we continue to kill nearly 40,000 of our citizens each year in traffic accidents alone.

Or when we consider that last year, one of the safest on record, injured workers lost 38 million man-days of work. If you add the time that these workers will be off in subsequent years, as a result of their disability, the lost man-days, according to our Department of Labor in Washington, reaches the staggering total of 160 million. Compared with the man-days lost due to injuries, the man-days lost by strikes in 1960—deplorable as that is—was only 19 million.

Safety surely belongs in the hierarchy of human needs, as illustrated on our first chart.

Chart A
Hierarchy of Human Needs:

1. Physiological needs

- (a) Air
- (b) Water
- (c) Food
- (d) Procreation

2. Safety needs

- 3. Social needs
- 4. Esteem needs

5. Self-realization needs

The protection of life and limb from bodily harm really ranks along with our need for air, water, and food, does it not?

And the human being is still the most important factor on this earth. We have built almost-human robots, but they still are not quite human. Those almost human computers are excellent examples. But, as Professor Baumol of Princeton University recently said to me, referring to those complex computers, "Somebody, somewhere, and in some way, must still tell that machine what to do before it can begin functioning." After all, every machine that has ever been built has come out of someone's mind. And, quoting Charles Lindbergh, "The mind therefore must be bigger than the machine!"

But now returning to the subject of the many millions of words that have been spoken and written about safety, which I mentioned at the outset, I would like to direct our attention to that problem, and to explore that picture with you as the main theme of my message here today.

In conducting this exploration with you, I would like to draw on the research programs of our employee and public opinion index for industry. This is a comprehensive opinion-measuring system, established in 1943, which is serving over 80 leading corporations and associations throughout the country. A number of you are acquainted with our index.

The work consists of finding out what's in people's heads, and how they feel and

act about the problems and issues of the day. Included are international, national, state, city, and county issues, and, of course, the subject is safety.

Practically all of the work is done by the personnel interview method, and with a national staff of over 1,400 field interviewers, a nation-wide survey of 5,000 to 6,000 interviews can be conducted in a couple of days.

Just as the industrial world has established, over a period of years, very fine physical and chemical laboratories to obtain great benefits from the forces of nature, we believe there is need for another laboratory, which we call, for want of a better term, a research department for better human relations. This laboratory deals with such things as having a greater concern for people and their well being, not only around the bargaining table but in every phase of their work in business and industry, including safety. Such a laboratory should take its place beside our big physical and chemical laboratories; we like to look upon our index as just such a laboratory.

Safety has been explored quite extensively in the index research programs, and I would like to report to you some of these findings. They bear directly on the subject I have been assigned, and I think you will be interested in seeing them.

Let's look first at the extent to which companies communicate with their employees about safety. The employee publication is a very important source of news and information for employees, and we have analyzed the content of a sample of 100 representative employee publications, using typical three month periods, over a period of years. A large majority—well over 80 per cent—of these publications run articles on safety, as we note here:

Chart B
Employee Publications Dealing with Safety News

(Based on a sample of 100 representative employee publications over a period of three months in each year.)

1958.....	83 per cent
1959.....	83 per cent
1960.....	84 per cent
1961.....	88 per cent

Glass and Ceramics Section

These articles deal with safety in the home, and at play, as well as at work in the plant. Where the articles have been presented in an interesting manner, with a novel slant, we have found that readership scores very high.

Delving further into the quantity of information on safety included in the employee publication, a content analysis—based on actual measurements of the amount of space devoted to such articles—shows that four per cent of the total goes to safety and health. Some other subjects get more space, as seen in the following Chart C, but even four per cent is indeed a large amount.

Chart C
Content Analysis of 100 Representative Employee Publications

(Published during a typical three month period)

	Per cent of Total Space Given to Each Subject
Personals or social news	21 per cent
Employee promotions and awards	17 per cent
Company products	11 per cent
Recreation and sports	9 per cent
Special department news	7 per cent
Safety and health	4 per cent
Company financial reports	3 per cent
Company expansion	2 per cent
Employee benefits	1 per cent
Other	25 per cent
	100 per cent

Considering that there are approximately 9,000 employee publications in the nation, with an estimated total annual budget of \$300,000,000.00, the four per cent represents a total effort of approximately \$12,000,000.00.

It is also important to note that employees give top management a high vote of confidence on safety. As we note in Chart D, a very large majority of 82 per cent of employees say they are very sure they can depend on top executives in their company to make working conditions as safe as possible.

Chart D

Employees Give Top Management a High Vote of Confidence on Safety

"Very sure I can depend on top executives in my company to..."	Percent of Employees Saying This
Make working conditions as safe as possible	82
Keep the company growing, moving ahead	80
Run the company efficiently	79
Look out for shareholders	79
Protect employees from arbitrary firing	69
Keep promises to employees	67
Provide steady work and avoid layoffs	60
Deal fairly with unions	47
Advance the most deserving employees	45
See that employees get fair share of company income	44

On this point top executives get a rating even higher than on a number of other attributes of good leadership.

Drawing on the index survey, "Progress Sharing—A Powerful Theme to Increase the Following for Management's Leadership," we note further that company management gets a very favorable vote on plant safety. A total of 61 per cent of the employees in a national sample of manufacturing companies say that management has done most to make progress on plant safety, compared with only 31 per cent naming labor unions, and only 8 per cent naming government, as we note on Chart E.

Chart E

Management Scores High on Making Progress on Safety

(Based on 500 personal interviews with a national sample of employees of manufacturing companies in cities with populations over 25,000)

"Which has done most to make progress on..."

	Plant Safety (Per cent of employees saying this)	Wages (Per cent of employees saying this)
Company Management	61	24
Labor Unions	31	63
Government	8	13

Contrasted with the high scores on plant

safety, note that the company management score on wage progress is only 24 per cent, and labor unions get the lion's share of the credit on this, with 63 per cent of the employees so voting.

This subject of the employee's opinions about the company's concern for safety was also explored in our survey entitled "The Index Productivity Quiz." In it we have a challenging correlation of safety and high productivity, which I believe will be of definite interest to you. This productivity quiz, incidentally, has proved to be a good research tool for measuring employee attitudes critical to good operating performance.

Our productivity study was conducted in collaboration with nine participating companies, whose headquarters are located throughout the industrial northeast of the nation, all the way from New England to St. Louis and Minneapolis. One company was selected from each of the following industries:

aircraft and auto parts, building materials, food, metal fabricating, metal products, railroads, rubber products, shoes, steel.

We interviewed a total of 1,597 employees in 18 plants of these nine companies. First of all, we note that the employee gives his company a high vote of confidence on safety, as brought out in Chart F.

Chart F

Employees Give Their Companies a High Vote of Confidence on Safety

(Random sample of 1,597 employees in 18 plants of nine companies)

"My company is working very hard to improve safety and reduce lost-time accidents."

I	I	No
Agree	Disagree	Opinion
Per cent	Per cent	Per cent
83	15	2

"As my company has grown and prospered, employees have gotten their share."

I	I	No
Agree	Disagree	Opinion
Per cent	Per cent	Per cent
47	50	3

A total of 83 per cent of these 1,597 employees say "My company is working very hard to improve safety and reduce lost-time accidents," whereas only 15 per cent dis-

agree. On the other hand, only 47 per cent of them agree with the statement, "As my company has grown and prospered, employees have gotten their share"; 50 per cent disagree with this.

In selecting the 18 plants, each of the nine companies was asked to pick one "high productivity" plant—where they knew that output per man-hour was high—and then one "low productivity" plant. This gave us paired comparisons on a long series of questions, which were asked the employees, including the question on safety, the results of which we just saw in Chart F. Among the employees of the nine high productivity plants, 89 per cent say that "My company is working very hard to improve safety and reduce lost-time accidents," but only 77 per cent in the nine low productivity plants say this, as we note in Chart G.

Chart G

Employees in High Productivity Plants Give Their Companies More Credit on Safety Than Employees of Low Productivity Plants

(Random sample of 1,597 employees in 18 plants of nine companies)

"My company is working very hard to improve safety and reduce lost-time accidents."

Nine High Productivity Plants

I	I	No
Agree	Disagree	Opinion
Per cent	Per cent	Per cent
89	10	1

Nine Low Productivity Plants

I	I	No
Agree	Disagree	Opinion
Per cent	Per cent	Per cent
77	21	2

Each pair of plants makes the same products, and each uses similar machinery. Hence the comparison made in Chart G is valid. While we cannot say that this definitely proves increased safety results directly in increased productivity, we feel, however, that there is indeed a correlation between efficient operation and safe operation, as the employee sees it.

Let's now explore how employees feel concerning the amount of information they receive from their companies about many aspects of their jobs, including safety. This was one of the objectives of a study con-

ducted in five companies, one from each of the following industries: chemical industry, electric power utility, gas utility, manufacturer of earth-moving equipment, oil producing and marketing. A total of 3,786 employees were interviewed.

One of the conclusions of this survey was that top executives are not very knowledgeable about which phases of company operations the employee wants more information, and about which he does not. Many of the topics that communications executives and managers consider only secondary or unimportant targets, we find that the majority of employees select as subjects on which they want more information.

For example, among the five companies, Company A executives seriously underestimate employees' information needs on 10 out of 20 topics. Company B executives misread the market on six out of 15 topics; Company C executives, seven topics out of 16; Company D executives, six out of 17 topics.

But the reverse is also true. We found overemphasis on information employees consider unimportant, or where a saturation level has been reached. Safety information is an example of this. Most managements rank safety a must of employee communications.

But in every collaborating company where employees had the opportunity to state their information needs the majority said, "We get enough information on safety," as we see in Chart H. A total of 67 per cent of the employees in the five companies say this. And the consistency of the data is clear because this figure varies only from 64 per cent of 69 per cent in the five cases. Only about one employee in four wants more information on safety—between 25 per cent and 30 per cent.

Chart H

What Kinds of Information Do Employees Want from Their Company?

(Based on 3,786 interviews with random samples of employees in five companies)

Safety at work—at play—at home	Want More Information	Get Enough Information	Not Interested
	Per cent	Per cent	Per cent
	27	67	6

Company plans for the future—predictions of company's growth.

Want More Information	Get Enough Information	Not Interested
Percent	Percent	Percent
75	21	4

Yet management must keep the safety problem alive in employees' minds. The solution is not to stop communicating on safety, but to bring the information supply more in line with the employee demand by linking safety to other employee needs.

"THE HOUSE THAT BILL BUILT"

We have an excellent example of an outstanding article on safety in an employee publication that received very high readership and made a powerful impact on the employees. It appeared in the monthly employee publication of the Bell Telephone Co. of Pennsylvania, which is called *The Telephone News*—a 9"x12" magazine with around 60 pages.

The article, written by Mr. David H. Dumigan, assistant editor, proves how creative imagination and good execution can lift a more or less accepted subject out of a humdrum pattern and get real reader interest. Bell of Pennsylvania employees get safety information through many channels, and hence might be expected to be bored with more of same. By focusing on safety in the home, the editor gave new currency to the idea of safety consciousness.

The first page of the article showed Mr. William Boyd of Camden, Del., a cable splicer with Bell of Pennsylvania, in the workshop of his home, and displayed prominently the gate he had installed to keep his two small children from getting hurt with sharp tools. In another photograph we saw Bill and his wife Ruth examining the tacking she had placed on a throw-rug to give non-skid qualities to one of her latest crocheted creations.

In still another photo Bill was installing a light switch on a stair rail post to provide adequate lighting for people who use the stairs. Falls on stairs account for more than half of the nation's home accidents.

This article, which ran about 12 pages, with many photographic illustrations, received the highest readership scores of thousands of employee magazine articles that we

have tested in hundreds of such publications. A total of 84 per cent of the employees who received this issue of *The Telephone News* could prove they had read some or all of the article. The average readership score for typical articles in employee publications runs only about 12 per cent.

A total of 65 per cent of the Bell employees could play back from memory, about a week after they received the magazine, some ideas from the article. A total of 19 per cent could play back ideas contained only in the photographs. The playback shows that many employees could recall as many as half a dozen specific safety hints.

Among the supervisory people at Bell of Pennsylvania, the readership scores were even higher—a total of 89 per cent read some or all of this article. The idea playback from the text only was 74 per cent among supervisors.

Hence, we conclude that people do not feel saturated with news advocating safety; provided such information is presented in an interesting manner.

We have come to the same conclusion about communications concerning highway traffic safety, based on a comprehensive survey which we conducted under the sponsorship of the Pure Oil Co. and the American Trucking Association Foundation. The findings strongly suggest that straight safety reminders—exhortations such as "You must drive safely"—are no longer very effective. But safety information linked up with suggestions on how to improve driving skills—how to drive on icy roads, and who has the right-of-way in traffic circles—do register with and motivate drivers.

The title of this study was "Centering Traffic Safety Around Drivers' Motivations." It was aimed at answering two important questions:

1. Do mass communications motivate people to become safer drivers?
2. If so, what approaches are most effective?

The project included a canvass of existing material on traffic safety, broad and extensive interviews and group discussions with traffic safety experts, law enforcement officers including judges and local and state police, and a group of professional drivers

such as chauffeurs, taxi men, and bus and truck drivers. A comprehensive written questionnaire with 76 questions was then used in interviewing a representative sample of adults, and also a representative sample of teenagers.

The study revealed many new facets of the American driver's mind. It shows him to be very sensitive to the problems relating to safe driving in general, and the role of mass communications in particular. He feels that existing communications can very definitely be improved.

It is impossible of course, in the time allotted here, to present any more than the very top highlights of a survey of this magnitude, and I will try to do that. A digest of the study has been published by the Pure Oil Co. and the ATA Foundation, Inc., and I believe copies are still available.

Let's look first at what people say about important highway traffic issues and problems of the day, some of which are being debated in traffic forums, traffic courts, schools and legislatures. In Chart J we have recorded how adults as well as teenagers vote on some of these issues. The questions were worded exactly as they appear on the chart.

As to whether driving is a privilege or a right, we note that a large majority, 34 per cent, of adults, and a still larger majority, 94 per cent, of teenagers, say that it is a privilege and not a right, as we see under the first question in Chart J.

The movement which is under way requiring drivers to take periodic tests in order to retain their license gets high approval from both adults and teenagers: 72 per cent of adults and 86 per cent of teenagers vote.

On the question of whether teenagers are the most reckless drivers, there is sharply divided opinion as might be expected, as we see in the third question in Chart J. However, the vote is not unanimous; about six out of ten adults agree. But it is also of interest to note that about one out of six teenagers condemns his own age group as being the most reckless.

When it comes to increasing the number of police cars in order to make the highways safer, only minorities of both adults and teenagers approve of such a move.

Chart J OPINIONS OF ADULTS AND TEENAGERS ABOUT IMPORTANT HIGHWAY TRAFFIC ISSUES

	Percent Who Agree
1. Driving is a privilege not a right.	
Adults	34
Teenagers	94
2. Every driver should have to take a road test every 5 years.	
Adults	72
Teenagers	86
3. Of all drivers, the most reckless are teenagers.	
Adults	57
Teenagers	18
4. The only way to make highways safer is to increase the number of police cars.	
Adults	38
Teenagers	22
5. They should take the license away from people who get caught driving while drunk.	
Adults	96
Teenagers	78

Going on now to another area of inquiry in the interviews, the driving public itself seems to visualize mass communications as an integral part of solving the traffic safety problem. In Chart K are the replies to three questions that test people's reactions to safety communications. Note that on all three statements the respondent had to take an opposing view to a frequently repeated cliché. These three statements did not actually appear in the order here listed; all statements on a given topic were distributed throughout the entire questionnaire.

As we note in Chart K, approximately two-thirds of each group—adults as well as teenagers—evaluate favorably our safety campaigns.

Chart K
EVALUATION OF SAFETY
CAMPAIGNS BY ADULTS
AND TEENAGERS

	Percent Who Disagree
1. Safety appeals along the highway are a waste of money. Few drivers pay attention to them.	
Adults	64
Teenagers	58
2. Safety promotion material from insurance companies is mostly for the sake of publicity and doesn't do any real good.	
Adults	69
Teenagers	68
3. Once you hear one safety campaign, you've heard them all. They're all alike.	
Adults	63
Teenagers	67

Exploring the question of giving publicity to accidents as a means of reducing them, we note an interesting reaction in the minds of drivers, as brought out in Chart L. On the first question, we see that people think that accident reports in the newspapers are helpful in improving safety; about seven out of ten of both groups so vote. However, as brought out in the second question in Chart L, drivers usually feel "This can't happen to me!" when they see a picture of a traffic accident.

Chart L
HOW ADULTS AND TEENAGERS
FEEL ABOUT THE PUBLICITY
GIVEN TO TRAFFIC ACCIDENTS

	Percent Who Agree
1. Accident "box scores" in newspapers remind people to drive carefully.	
Adults	73
Teenagers	66
2. When the average driver sees a picture of an accident he usually thinks "That can't happen to me."	
Adults	56
Teenagers	60

This point of view also seems to be verified by other testimony that we obtained from the interviews, namely, that every person considers that he (or she) is not an "average" driver, but definitely above average. Nine out of ten adults in the study rated themselves above average in driving skill. They say they're better than average also at obeying traffic laws. Another interesting point is that among those adults with some record of a traffic violation—about 15 per cent of the total—100 per cent rated themselves above average in driving skill.

As all of the evidence, which we have here briefly highlighted, shows, people approve of mass communications as a means of improving safety, but the evidence also indicates that the approach to the communications job, as well as the communications themselves, can be vastly improved in their effectiveness.

On traffic safety, because most everyone feels that he is above average in driving skill, perhaps the first step is to establish—diplomatically, of course—that he does not know all the answers. Show him that some new things have come along since he took his driver's license test, perhaps 15 or 20 years ago. For example, who has the right of way at the traffic circle—the fellow who is in the circle, or the fellow who is about to enter?

The evidence also makes very clear that simple exhortation, or preaching, is not very effective. The message must be presented in an interesting manner with a new and novel slant.

Summarizing the entire presentation now, in a few capsule sentences if possible, the points listed below that follows seem to be evident from our studies bearing on the important subject of safety. These points apply to people's reaction to safety programs, whether they are working in a large industrial plant, puttering around in their homes, taking the car down the street a few blocks to the grocery store, or driving along at 60 miles an hour on one of our super highways.

1. Safety is a basic human need.
2. Industry has been talking about safety in large volume for many years.
3. Employees give management a high rate of confidence on safety.

4. Safety and productivity are linked together.
5. Greater communications skill is required in talking to employees about safety.

6. People approve mass communications for improving highway safety.
7. More effective approaches to the mass communications job must be found.

SAFETY WITH GLASS

By E. C. OSTRANDER
Personnel Director, Kopp Glass, Inc.
Swissvale, Pittsburgh, Pa.

This title can take in a much larger field than we propose to cover here. Glass is not only useful, but absolutely necessary to our present state of civilization. All of the contributions of glass to our well-being and safety would take much too long to tell here.

For instance, a Dutchman named Anton Van Leeuwenhoek ground some glass lenses, made a microscope, and observed microbes. One hundred and fifty years later, more or less, we have Louis Pasteur bending over the same instrument, and who knows how many lives have been prolonged! Modern medicine is dependent on the microscope and many other items of glass.

With very few exceptions, the glass we are going to discuss here functions only as it is seen. The items made of this glass are signals; signals with meaning for safety. We define safety as "freedom from danger or hazard." We strive for safety in two ways:

I. We Eliminate the Hazard.

In general, we do this by making a building fireproof, putting the manhole cover back on, or, in the hospital operating room where a few added degrees of radiant temperature could damage exposed brain tissue, we filter the rays to exclude the infrared or heat ray; and, at the same time, give a high level of illumination. Tl's also keep the operating team more comfortable and efficient.

Again we eliminate the hazard when we use glasses which transmit invisible light, either ultraviolet or infrared. A pilot's cockpit may be illuminated with ultraviolet light which will fluorescent the instrument panel so that the instruments can be read

as you read the dial of your night clock. At the same time, the pilot will not be seen by an enemy observer, but will have visual security.

A more recent method of illuminating the cockpit of a plane is with deep red light which provides security and still leaves the eyes of the crew dark-adapted.

The invisible infrared light is used in a way similar to the ultraviolet. The headlights of an army vehicle will flood the road with infrared light. This light is picked up and thrown on a screen similar to a television picture tube. The driver can maneuver his vehicle by what he sees on the screen, but no light is visible. This eliminates the hazard.

II. We Lengthen the Odds.

The second way we strive for safety is to lengthen the odds. With signal glassware, we do this in six different ways.

1. By warning—Often there are obstructions which are hazards to airplanes—things like water towers, radio masts, or high tension lines. These are marked with obstruction lights in a prescribed way, thus giving warning.

Again, as planes come into a large airport, it is necessary to stack them up, each at a directed level to await his turn to land. On each plane above and below the fuselage is a rotating beacon light.

Deep in a mine, the cars which remove the mineral have lights mounted on them to give warning.

Ships and watercraft of all kinds have port and starboard lights to give warning and show their direction of travel. The hazards of the sea lanes are marked with signal glass.

2. By defining or pointing out areas of safety—Exit lights in hotels or theaters mark safe ways to leave.

Runway or taxiway lights on an airport mark the safe lanes for landing or taxing the plane.

3. By creating order, we lengthen the odds. We have traffic systems based on time at every important intersection of streets or highways. You wait your turn. Or more recently we find automatic counting devices which change the time cycle of the traffic signals to favor a heavy flow from any direction.

On the railroad, the system works according to conditions. The train is stopped if there is a stalled train ahead. The signal along the right-of-way is duplicated in the cab with a smaller facsimile of the signal.

4. By improving visibility with street lights and floodlights, we make our streets safer.

5. By indicating lights, we inform the observer that the toaster is on, the wheels of a plane are down, that the fluid level in a pressure system is correct, or that a fire is burning in the stove.

We have rendezvous lights on planes so that a bomber pilot can find his refueling plane.

6. We have certain other glass items that contribute to safety.

Suppose a man falls overboard from a vessel, his shipmate tosses a life buoy cylinder over after him. This contains a battery, a mercury switch, a light source, and a lens. As the buoy floats upright, the mercury switch closes, and a beam of light streams over the waves. The man swims to the light and is supported by the cylinder. A boat puts off from the ship and finds the man at the light.

Swimming pools are illuminated under the surface by lights which permit the bottom of the pool to be seen. This can't be done with floodlights above the surface because of reflections.

III. Required Properties of These Glasses.

1. Color and Transmission.

The color must be quite precise. We have working limits, of course, to take care of variations in thickness, and variations from melt to melt. But to the average observer, the color looks the same from, say, traffic light to traffic light. Transmission of the

light through the lens must be high to give more punch, and to demand your attention.

2. Refraction.

This property of glass is its light-bending power. It varies mainly according to the composition of the glass. A lead glass is denser and will bend the light more. The design of a lens must take into account the refractive power of the glass.

3. Design.

The proper design may add strength to the glass item, may lower wind resistance by streamline effects, may be a compromise necessary to fabricate the item, or may be a means of cutting down the weight, as items used on an airplane. The most important function of design, however, is light distribution. A traffic lens on a four-lane highway must reach up the road far enough to give warning in time to stop. This means a narrow, powerful beam. A traffic lens in the city may control more pedestrian traffic than vehicular; therefore, the beam must spread so that it can be seen over a wide area. The lens design controls the distribution of light, with the help, sometimes of reflectors.

4. Coefficient of Expansion

This property of glass is the rate of expansion on contraction with change in temperature. If the expansion is small, the glass withstands heat shock and is said to be heat resisting. Consider how some pieces are tested in use. A 200 watt bulb is put under a runway light. When equilibrium conditions are reached, the temperature of the glass will be greater than the boiling point of water. It's a real shock when a sudden shower drenches the glass. But the glass does not break.

5. Tempering.

Most of the qualities of glass are the result of the design or of the composition. However, we temper to make glass stronger by heating to a point where the glass will flow under stress, but will not deform of its own weight. We then chill with streams of air. The surface shrinks as it is cooled by the air. The inside flows to relieve stress. Then the inside of the glass shrinks as it cools, putting the surface in compression and making it stronger against heat shock and impact. Since glass normally breaks only when a surface is in tension,

it follows that the surface compression must be overcome before the glass will shatter.

6. Resistance to Weathering.

The composition of the glass must be such that the surface will not be affected by weather nor the color by sunlight or any other natural agent.

7. Freedom from Flaw or Error.

The signal glass item must be free of any flaw which would compromise the signal or cause failure of the glass in any way. The dimensions shall be within the tolerances specified, and the appearance shall be as near perfect as possible.

IV. Conclusions.

A. We have shown three instances where a hazard was eliminated with special glasses.

1. By elimination of the infrared or heat ray while illuminating with visible light.

2. By elimination of the visible rays while illuminating with infrared light.

3. By elimination of the visible rays while fluorescing the dials on the instrument panel with ultraviolet light.

B. We have shown how the odds are lengthened in six ways.

1. By giving warning of the presence of stationary or moving objects.

2. By defining or pointing out areas of safety with runway and exit lights.

3. By creating order with traffic signals, either railroad or highway.

4. By improving visibility with street lights or floodlights.

5. By indicating a fact or condition with panel lights or sight glasses.

6. By special applications as in the life buoy or swimming pool lights.

C. We have discussed the properties of color, refraction, design, rate of expansion with change of temperature, and the effect of tempering or heat treating. We spoke of the need to withstand the effects of weathering and, of course, there must be freedom from any flaw.

We all have traveled here more safely because of glass signals for safety.

ROUND TABLE DISCUSSION — GROUP NO. 1

Discussion Leaders: H. V. GARDNER, Corporate Safety Dir., Owens-Illinois, Toledo, Ohio

J. H. GATRELL, Personnel Mgr., Blue Ridge Glass Co., Kingsport, Tenn.

Recorders: ROBERT W. MOULTON, Safety & Plant Protection Supvr., Ball Brothers Co., Inc., Muncie, Ind.

E. S. KNEPPER, Supvr., Training & Safety, Hazel Atlas Div., Continental Can Co., Inc., Wheeling, W. Va.

The first question that was thrown out for discussion was: "How do you develop safety rules for your plant?" (From here on questions will be identified by preceding them with a question mark, and suggestions with an "S".)

S—First, ask supervisors, clear them through the safety committee. Clear through union committee members.

?—Did unions go along or resist?

S—In most cases, unions will cooperate most wholeheartedly.

?—After development, what did you do with safety rules?

S—Put in booklet form and distribute. Get all new employees' signatures, indicating that all have seen them and read them. Give copy to all new employees and obtain signatures. Post on bulletin board for present employees. Have basic rules written into labor contracts.

?—What do you do to keep them up to date?

S—Review them periodically at safety meetings and/or also discuss at safety meetings.

?—What happens if a safety rule is violated?

1961 National Safety Congress

S—Penalty for first warning; second, three days off; third, discharge.

The second question thrown out by the chairman:

?—What kind of training is necessary to develop proper safety attitudes on the part of foremen?

S—Build in with incentive plan.

S—Have business agent discuss safety rules with the plant manager.

S—Build into appraisal system.

S—"Holler" loud enough to get results.

The next major question was:

?—How do you keep foremen interested?

S—Each time there is a serious accident the foreman should be called into the plant manager's office with the safety man to discuss the accident.

S—We don't give adequate discipline and, more important, we don't give credit for a job well done.

S—Training by supervisors to employees on the job (tailgate sessions).

S—Make part of production.

S—Plant manager brings general foreman in to review safety reports prepared by insurance men.

S—Best procedure is for the plant manager to say, "This we will do."

S—Have maintenance men sit in on safety review meetings.

S—Most rely on supervision and safety committee to observe unsafe acts.

S—Costs should be published only to supervisors. They are more important than frequency rates and severity rates.

S—Fit into a production bonus plan; if workmen's compensation costs are paid they will affect each supervisor's pay.

?—Should the safety engineer report to line or staff?

S—Under industrial relations we can get closer to having safety as part of production.

S—It can work either way, depending on many things, i.e., size of plant, type of organization, work situations, people, etc.

?—Discuss the safety director's duties.

S—A general discussion followed. Most safety men have various duties. Various

representatives discussed their duties and line of reporting.

?—Does anyone here have authority to hold up production until guards are installed?

S—Very few have authority but this depends on the strength of the individual as a safety engineer.

S—Coordination with engineering — nothing is more permanent than temporary guards.

?—Discuss new theories on reaction from silicone dioxide on the lungs.

S—Dr. Usher, Owen-Illinois Glass Co.'s medical doctor, commented that there is more than silicones to worry about in most states. Chronic bronchitis is compensable.

?—How much exposure time must there be before dust is a contributing factor?

S—Dr. Usher commented that there is a wide range of factors affecting susceptibilities of lungs to disease.

?—How is safety supervisory training done and what materials are used?

S—Make safety a part of all training sessions.

S—NSC home study course.

S—Insurance carries supervisory training course.

S—Personal contact training.

S—Supply canned talks to supervision.

S—Use supervisory safety manual published by NSC. Have foremen share the instructor's responsibilities.

S—R-T discussion as part of production meetings.

?—What do you do about a so-called illegitimate back case?

S—Take all cases to court. After the trial, after the claimant is granted a 50 per cent disability, management can say, "We do not have any jobs for people who are 50 per cent disabled." This is one way of preventing future claims.

S—Management should file suit before the employee does.

S—Make certain that the company establishes a record of honoring all legitimate claims and insist on dismissal for those for whom there is proof positive that the claim is illegitimate.

Glass and Ceramics Section

S—Get doctor's agreement and signature that the man can do the job. Industrial engineer should submit job description to the doctor to assist in his decision.

?—What is the opinion of the courts versus commissioners?

S—Here, there was a lengthy discussion

with the conclusion that, depending on the state or location, one may be preferable to the other.

?—If an employee has an agreement pending and the doctor says he is capable, do you let him return to work?

S—A definite yes.

RUBBER SECTION

OFF-THE-JOB SAFETY AT WORLD BESTOS

By J. R. SPEERS

Plant Manager, World Bestos Div., Firestone Tire & Rubber Co., Newcastle, Ind.

As you know, directly and indirectly, off-the-job accidents cost many concerns millions and millions of dollars each year. It is our feeling that any program that stresses off-the-job safety not only will help our employees and their families, but will certainly improve the efficiency of our working group.

Any accident that disables a skilled worker, wherever it may take place, costs his firm money in the loss of skilled manpower, in the time spent retraining a replacement, and in increased medical costs.

It is our understanding that America's labor force last year suffered work accident fatalities that numbered less than half of those killed in traffic, home and public accidents.

The annual economic loss totals more than 13 billion dollars and about 86 per cent of this damage comes from non-work accidents.

Therefore, you can see that every industrial concern has a big stake in the off-the-job safety program for their employees.

We at World Bestos have been conducting off-the-job safety programs in December and in May of each year. Our program for off-the-job safety for May, 1960, was presented to our Firestone group at our regular meeting during the annual safety conference of all Firestone plants in Chicago last year.

At that time, it was suggested that I present the program that we had worked up to you.

Our plant, the World Bestos Div. of Firestone Tire and Rubber Co., by nature of its products, is a small plant in comparison to the balance of the Firestone subsidiaries. Consequently, being a small plant, having approximately 325 employees, we are somewhat limited as to staff and many of our staff members wear several different hats.

At the time of our off-the-job safety program, we were also running an off-the-job safety program at all Firestone subsidiaries, which is known as the "safety check program".

This program is initiated by the Firestone Tire and Rubber Co. for the purpose of checking employees' automobiles to make sure that they are safe. I am sure that you are familiar with this type of check, as many communities in our country have this program, or a similar one of their own.

In addition to our employees' cars being checked, we also offer to check the cars of employees of other local industries and the high school, and you can see that with our people doing the work of performing the checks on automobiles, it takes part of our staff to complete the safety check program.

When you look around for a committee or a chairman to work on the off-the-job safety program, with the small staff that you have, you sometimes are puzzled as to how to get these jobs accomplished.

I decided, at the time, that probably the best thing we could do to really put life behind the program was to pick a committee of men from the various fields in our plant and put them in charge of the off-the-job safety program.

We, therefore, picked the following to head up this program: a production foreman, a manager of our development department, our plant engineer, our buyer from the purchasing department.

As you can see by the fields from which these men were picked, while they would have knowledge of safety and its processes, they were, nevertheless, not trained experts in the sense that a safety director would be, nor would they have his background.

However, this off-the-job safety committee took over the job and set up a promotional scheme and program that I feel is

one of the best ever put forth for an off-the-job safety campaign.

This program was designed to make every employee well aware of the hazards of off-the-job accidents and to drive home to the members of his family the important part they play in making the home and its surrounding community a safer place in which to live.

This program was timed so that safety off-the-job would be uppermost in their minds before, during, and after the Memorial Day weekend. This was done in order to make every possible effort to keep our employees accident-free during this period.

The following is what was used to make employees more safety conscious:

1) Each employee was given and asked to wear during the contest a mechanics cap upon which was imprinted, "I am pledged to off-the-job safety."

The budget for these caps was nil due to the fact that the manufacturer of the mechanics caps had shipped them to the World Bestos Div. in error, and had not imprinted them for their intended purpose.

He advised that we should scrap them rather than return them and he would furnish new ones to the purchase order he had been given.

Our men, seeing this opportunity to get a promotional item for nothing, asked to have the caps and they stenciled them with the words, "I am pledged to off-the-job safety." The workers used these caps to the very best of benefit.

2) The committee arranged for displays throughout the factory which would accent the most common household and off-the-job accidents. These displays all carried display cards and drawings explaining what steps could be taken by the employee to eliminate these hazards from his home. These displays included:

A) Child in abandoned ice box. (A life-size doll represented the child inside the box and a plastic cover enabled the employees to see inside the ice box.)

This came at a very opportune time, as there was a rash of this type of fatality throughout the nation where children had crawled into abandoned ice boxes in numerous communities.

B) Broken step ladder. (Broken side rails, loose steps, no safety braces or safety feet.)

C) Power mower. (With guards removed and carelessness in operation.)

D) Child suffocated in plastic bag. (A life-size doll used inside a baby crib, wrapped in plastic laundry bag.) You will recall that this was about the time that there were also a considerable number of fatalities occurring from such conditions.

3) Two large signs, twelve feet by four feet, were erected, one at the entrance of the plant for the employees, and the other on the edge of the company property along the busy city street for the general public. These signs read, "May is World Bestos Off-The-Job Safety Month."

4) The committee drew up plans for an off the job safety contest and set up prizes which would tend to promote family participation. These prizes were:

First prize, Westinghouse electric toaster.

Second prize, charcoal grill.

Third prize, electric skillet.

The contest required both the employee and his family to participate as follows:

A) Required to make a complete safety check of their home in order to correct the ten most common hazards as listed by the National Safety Council, as these contributed to more than four million off the job accidents each year.

B) Take home from work each day the daily safety slogan and copy the same on their contest forms. (Ten days in all.)

C) Employee and wife (or husband) must sign a certificate at the end of the contest that the members of their family have remained accident-free during the period of the contest.

5) Mailed to each employee:

A) General information on safety and the causes and effects of over four million home accidents each year.

B) Information sheets and contest rules.

C) Contest entry form which contained:

1) Check list of the ten most common hazards as listed by the National Safety Council.

2) Blanks for the daily slogan contest.

3) Contest rules.

Rubber Section

4) Certificate for signatures of employee and family that they had remained accident-free during the contest period.

6) The committee contacted the New Castle city officials as follows:

- A) Mayor.
- B) Police captain in charge of local first-aid unit and ambulances.
- C) Editor and photographer of local newspaper.

These men were taken on a personal tour of the plant, shown the displays, and the program was explained to them in detail. The committee asked for and received their cooperation in carrying our safety messages to the citizens of New Castle.

7) Arranged local publicity through newspapers and radio, directed at letting the community know what the people at World Bestos were doing for safety in their homes. Here we used extreme care to make sure that our plant workers were brought into this publicity, regardless of what it was.

We were able, through the committee's efforts, to set up di-plays at the plant without any cost to our company whatsoever.

For example, the committee salvaged an old stepladder with broken side rails, etc., out of the junk pile and beside this display they made a 22 inch by 28 inch display card with a drawing showing a man falling from a defective ladder while painting. The safety slogan here was, "Fix Up Before You Paint Up."

Then, the committee found the oldest, most defective power mower they could locate in the community for the next safety display, and here again, a 22 inch by 28 inch card with a drawing of a child's foot pressing the release of the mower. The safety message here was, "Stop The Mower Before Making Adjustments."

On the next display, the committee went to the local junk man and got from him at no cost an old ice box. The committee borrowed a life-size doll and placed this inside the ice box, and then placed a plastic door on the ice box to replace the regular door. This was done to enable everyone to see inside the box, and along with this ice box was a display card showing a drawing of a child trapped inside, and he was crying the safety message, "Please Remove All Doors From Old Ice Boxes."

The last display, again, was one of importance, especially at that time, and was of a child suffocating in a plastic bag. The committee borrowed a child's baby bed and placed therein a life-size doll wrapped in a plastic bag. In large letters over the display was the following: "Don't Let This Happen to Your Child! Destroy All Plastic Bags."

Also, about this time, the committee worked out a deal with the local theatre wherein they got the theatre to supply them, at no charge to the company, sufficient tickets to the theatre to be used as prizes when the committee called an employee's home on each day to find out if they knew the previous day's safety slogan, which had been posted on the safety bulletin board.

This was done to accent and insure the safety slogan's getting home to the employee's family. This was set up to keep the whole family talking safety, and we printed up some small cards and attached these to the employee's pay checks on the day before the contest started. The cards read:

"If we call, will your family know the slogan? Each day during the hours of 11:00 A.M. to 12:00 noon the committee will phone the homes of five employees. If anyone present in the home can repeat, word for word, the safety slogan of the previous day, we will send them two free passes to the theatre. Enter the slogan daily on your contest entry blank and keep it near the phone. You may be a winner."

Each day the committee then would pick at random five names to be called, (three from clock, two from salary). When the phone was answered, the committee would say:

"This is the safety committee of World Bestos calling. If you can give me yesterday's safety slogan we will send you two family passes to the theatre. You have 30 seconds to answer."

If they gave the answer, the committee congratulated them and sent them the tickets. The committee would suggest they be ready in case they were called again.

Each day, then, the committee would post in the safety booth near the prizes the list

of names called and whether or not they could answer with the safety slogan.

This created a great deal of interest and I think almost everyone in New Castle knew our previous day's safety slogan.

During all of this safety program, we received very fine cooperation from the local paper in getting the safety message not only to our employees, but to the citizens of New Castle, and the acceptance of this program was very good.

We also received from the city of New Castle and its mayor a letter thanking us for the off the job safety campaign as conducted by the World Bestos plant, wherein he stated that he was sure that our program was a big factor in keeping the accident rate in our city to a minimum during this period, and that if other industries in New Castle would follow our example, New Castle could be made one of the safest cities in the country.

Just prior to the Memorial Day shut down, all of our employees were handed what is known as a teaser card, which stated:

"Notice!—Layoff."

Then in small print:

"Of accidents during the memorial day weekend. You read this notice because

you thought it meant your job. Read it again—it may mean your life."

This was handed to the employee on his last working shift before the holiday weekend by his foreman, and it is needless to say that this notice received quite a bit of attention from the employees.

The purpose of this teaser card was to shock them into thinking about safety just before they took to the highways for the weekend.

At the end of the contest, forms and certificates were accumulated from the employees and the judging was done by individuals not connected with the safety program. The winners of the contest were then given their prizes. These prizes went as follows:

First prize: Employee of maintenance crew.

Second prize: Production employee, asbestos sheet packing operation.

Third prize: Production employee, heavy duty brake block unit.

Really, everybody was a winner somewhere along the line by participating in our off-the-job safety campaign, but the real big winner was World Bestos, who was able to report to the parent company in Akron that we had no off the job accidents during the campaign period.

PRODUCTION AND ACCIDENT PREVENTION ARE PARALLEL AND PARAMOUNT

By JIM LOW

Staff Speaker, National Association of Manufacturers, New York, N. Y.

The only reason you are here learning new accident prevention techniques is that you feel you haven't reached perfection . . . that you have the belief that nothing is good enough . . . that "good enough" is seldom "good" and never "enough."

You believe we have made progress in creating safer conditions, yet some additional tool or tools must be used to reduce the figure of thousands of on-the-job lost-time injuries.

You believe that a record shouldn't be simply something to stand on—rather to build on. I challenge you to use your most important tool—*Leadership*—to help people reach the goal of a safe, rich life—not just seeking after rich living. In order to help them, you must recognize their basic, human needs—must remember the *four fundamental wants of people*:

1. a sense of belonging;
2. recognition;

3. new experiences;
 4. security. (Not just economic, but emotional, spiritual and psychological.)
- In order to find the greatest satisfaction, we must not forget these eleven fundamentals of leadership:
1. Remember the "three R's" — be Ready; be Reasonable; be Right.
 2. We must know our business.
 3. We must remember the rule to "Be Yourself!"
 4. We must be able to sell.
 5. We must be willing to take responsibility with authority.
 6. We must know our organization's policies and objectives.
 7. We must learn to express ourselves effectively.
 8. We must have a knowledge of our economic system.
 9. We must be able to inspire.
 10. We must have character, integrity and consistency.
 11. We must use the Golden Rule.
- I challenge you also to set an example by the way you live. Always remember the lesson in this verse:
- I'd rather see a sermon than hear one —any day.
- I'd rather one should walk with me than merely show the way.
- The eye's a better pupil and more willing than the ear.
- Fine counsel is confusing, but example's always clear.
- The best of all the preachers are the men who live their creeds.
- For, to see the good in action is what everybody needs.

I can soon learn how to do it if you'll let me see it done;

I can watch your hand in action tho' your tongue too fast may run.

All the lectures you deliver may be very wise and true,

But I'd rather learn my lesson by observing what you do;

For I may misunderstand you and the fine advice you give,

But there's no misunderstanding how you act and how you live.

There is no place in employee-human relations for that disease called complacency. Safety is your business and it's a good business—but never let yourself get so bogged down with "busy-ness" that you forget this important function of your business:

I challenge you to remember that:

The best verse hasn't been rhymed yet;

The best house hasn't been planned;

The highest peaks haven't been climbed yet;

The mightiest rivers haven't been spanned.

So, don't worry and fret, faint-hearted;

The chances have just begun;

The best jobs in safety haven't been started;

The best work hasn't been done.

I challenge you to keep in your mind, your heart and actions the theme of this National Safety Congress, "Safety Everywhere . . . All the Time"; to believe that production and accident prevention are parallel and paramount; that your goal will be closer, depending upon your use of your tool—*Leadership*.

THE INDUSTRIAL NURSE'S ROLE IN THE SAFETY PROGRAM

By REGINA KNAPP, R.N.
Head Nurse, General Tire & Rubber Co., Akron, Ohio

The role of the Industrial Nurse has many aspects and it would take much time to clarify the exact position the nurse should have in planning and executing a safety program in industry, but she definitely should be on the team. The nurse and the safety man touch directly on every person in the plant—they cross every organizational line and have the broadest field of all for communications.

I believe results obtainable from present safety measures have reached a plateau and limited progress can be expected from this avenue of approach.

I do not like the fatalistic concept of accident proneness as a cause of accidents. I believe psychological factors are more often the cause of Industrial Injuries. Future gains depend upon the medical team. There is no one in industry better qualified or in a better position for psychological counseling than the Industrial Nurse.

Today with the increase in productivity per person, there is a shift in the nature of work being done; there is a definite swinging away from manual labor. Automation demands thinking, understanding and directing of machines. There is less wear and tear on the muscles and bones and more demands on the nervous system. The sound body is the product of the sound mind.

Three words keep milling around in my mind when I attempt to formulate the Industrial Nurse's role in this particular phase—men, minds and machinery; impossible to separate yet equally impossible to coordinate perfectly. I believe it is this area of imperfect coordination that results in accidents. We cannot arrive at total success in weeding out the why's in this area but there are some things we can do to narrow the margin of the unknown.

It is not easy for me to decide which comes first: men, minds or machinery but from personal experience, I will start with machinery.

I recall an experience in my early days of industrial nursing. An employee came to the dispensary with a badly bruised toe. Following the pattern of obtaining the history of the injury while repairing the damage, I asked, "How did you do this?" He answered "I dropped a pallet on my toe." My answer to him was ignorant and abrupt because the only pallet I knew anything about was the pallet in a person's mouth. From his reaction to my stupidity, it was apparent to this employee:

1. This nurse knows nothing about the machinery with which we work.

2. This nurse is not interested enough in the employee's to find out about our working environment.

An industrial nurse cannot hope to be a part of any safety program without a working knowledge of the types of potential accidents in her plant. She need not know how to operate the machinery but must know what kind of injuries can be caused by them. Then she will know the areas in the plant where the most accidents are likely to occur. From this understanding, she quickly recognizes too many injuries in a relatively safe department. Properly maintained machines, always operate in a prescribed manner so when an accident occurs, we must turn to the human element for the cause. With this knowledge, the next step is to contact the safety department and report on the undue frequency.

This approach creates a good working relationship between the medical and safety department. It is rarely possible for the safety department to correlate minor injuries with a department or an individual without the help of the nurse.

Minor injuries disrupt the production in any department. A quick check can be made into the situation by the safety department. No report by itself gives the answer but we already know it is more often human than mechanical failure that causes accidents.

PLAN NOW--

TO ATTEND THE 1962 NATIONAL SAFETY CONGRESS

Celebrating the 50th Anniversary of the NATIONAL SAFETY COUNCIL

WHEN: October 29 through November 2, 1962
WHERE: Conrad Hilton Hotel, Chicago

The National Safety Congress brings together safety people from all over the country—10,000 of them! By attending the Congress you become part of the largest and most important safety meeting of the year. You meet safety men with the same safety problems and responsibilities you yourself have. You exchange views and ideas on accident prevention, health, hygiene and fire prevention—on safety in industry, in traffic, at school, at home and on the farm. From a program of more than 400 meetings, discussions and demonstrations you select the activities that interest you most and that most closely relate to your safety work. This week-long educational program—planned and presented by the National Safety Council—can be your most inspiring, most thought-provoking safety experience of 1962.

See the Latest in Safety Equipment At the Greatly Expanded Congress Exhibit Hall

See nearly 300 exhibits! This alone—the largest of all safety equipment exhibitions—will make your trip to the Safety Congress worthwhile. The industry's leading suppliers will display their newest and best safety products for your inspection. See . . . compare . . . ask questions. There is no finer opportunity to reach well-informed buying decisions for your company.

OFFICERS OF THE GLASS AND CERAMICS SECTION NATIONAL SAFETY COUNCIL 1961-62

General Chairman—CLINTON BALLINGER, Owens-Illinois, Gas City, Ind.
First Vice-Chairman—WILLIAM H. PRICE, Owens-Corning Fiberglas Corp., Toledo, Ohio
Second Vice-Chairman—E. S. KNEPPER, Continental Can Co., Hazel-Atlas Div., Wheeling, W. Va.
Secretary—J. E. MORRISON, Pittsburgh Plate Glass Co., Pittsburgh, Pa.
Newsletter Editor—ROBERT W. MOULTON, Ball Brothers Co., Inc., Muncie, Ind.
Program Committee—JOHN RHEINHEIMER (Chairman), Kaiser Aluminum & Chemical Corp., Mexico, Mo.; ROBERT EVANS, Ford Motor Co., Nashville, Tenn.; WILLIAM H. PRICE, Owens-Corning Fiberglas Corp., National Bank Bldg., Toledo, Ohio; DAVID T. QUIGLEY, North American Refractories Co., Cleveland, Ohio
Engineering Committee—JOHN J. FOSTER (Chairman), Foster-Forbes Glass Co., Marion, Ind.; HOWARD J. BAKER, Pittsburgh Corning Corp., Port Allegeny, Pa.; J. W. BLOOM, Owens-Illinois, Fairmont, W. Va.; LEE B. HAWTHORSE, JR., A. P. Green Firebrick Co., Mexico, Mo.
Health Committee—GLENN S. USHER, M. D. (Chairman), Owens-Illinois, Toledo, Ohio; *RUSSELL W. FRANK, Ferro Corp., Cleveland, Ohio; *W. G. HAZARD, Owens-Illinois, Toledo, Ohio; *JOHN V. SKENDALL, Harbison-Walker Refractories Co., Pittsburgh, Pa.
Membership Committee—JOHN S. HALL (Chairman), Kaiser Aluminum & Chemical Corp., Columbiana Refractories Plant, Columbiana, Ohio; *JOHN B. FULLER, Kopp Glass Inc., Swissvale, Pittsburgh, Pa.; JORGE HERNANDEZ OSUNA, Accion Social Regionomontana, Monterrey N. L., Mexico; E. W. MISKINIS, Pittsburgh Plate Glass Co., Glass Research, Harmer Township, Pa.
Associations Committee—FRANK J. BENTLEY (Chairman), Brockway Glass Co., Inc., Brockway, Pa.; A. H. BURKETT, Owens-Illinois, Toledo, Ohio; FRANK DAVIDSON, Owens-Corning Fiberglas Corp., Newark, Ohio; DOHN SIPE, Pittsburgh Plate Glass Co., Fiber Glass Div., Shelbyville, Ind.
Newsletter Committee—ROBERT W. MOULTON (Chairman), Ball Bros. Co., Inc., Muncie, Ind.; *EDWIN L. WRAY, Ball Bros. Co., Inc., Muncie, Ind.; JOHN RHEINHEIMER, Kaiser Aluminum & Chemical Corp., Mexico, Mo.; JOHN J. FOSTER, Foster-Forbes Glass Co., Marion, Ind.; GLENN S. USHER, M. D., Owens-Illinois, Toledo, Ohio; JOHN S. HALL, Kaiser Aluminum & Chemical Corp., Columbiana Refractories Plant, Columbiana, Ohio; FRANK J. BENTLEY, Brockway Glass Co., Inc., Brockway, Pa.; JOHN J. LONG, Pittsburgh Plate Glass Co., Cumberland, Md.; *H. V. GARDNER, Owens-Illinois Glass Co., Toledo, Ohio; FRANK MANNING, Ford Motor Co., Glass Div., Dearborn, Mich.; DOAN NOCE, Pittsburgh Plate Glass Co., Crystal City, Mo.; J. E. MORRISON, Pittsburgh Plate Glass Co., Pittsburgh, Pa.
Safety Promotion Committee—JOHN J. LONG, (Chairman), Pittsburgh Plate Glass Co., Cumberland, Md.; *J. H. GATRELL, Blue Ridge Glass Co., Kingsport, Tenn.; TERRY CASTLE, Castle-Hanson Corp., Rochester, N. Y.; RALPH W. PETTIT, Sw. Corhart Refractories, Louisville, Ky.
Safety Contest Committee—*H. V. GARDNER (Chairman), Owens-Illinois Glass Co., Toledo, Ohio; *HARRY A. JACKSON, Frigidaire Div., General Motors Corp., Dayton,

Ohio; DALE H. KUEHLMAN, Libby-Owens-Ford Glass Co., Rossford, Ohio; ANDREW ORESICK, Pittsburgh Plate Glass Co., Ford City, Pa.

Off-the-Job Safety Committee—FRANK MANNING (Chairman), Ford Motor Co., Glass Div., Dearborn, Mich.; CHARLES CASEY, Thatcher Glass Mfg. Co., Inc., Lawrenceburg, Ind.; *JAMES L. MORRIS, The Federal Glass Co., Columbus, Ohio; EUGENE S. GARR, Armstrong Cork Co., Dunkirk, Ind.

Training Committee—DOAN NOCE (Chairman), Pittsburgh Plate Glass Co., Crystal City, Mo.; W. W. BOXELL, Foster-Forbes Glass Co., Marion, Ind.; GEORGE MELOS, General Refractories Co., Philadelphia, Pa.; *CLYDE C. RUDDICK, Pittsburgh Plate Glass Co., One Gateway Center, Pittsburgh, Pa.

Nominations Committee—*EDWIN L. WRAY (Chairman), Ball Bros. Co., Inc., Muncie, Ind.; *JOHN V. SKENDBALL, Harbison-Walker Refractories Co., Pittsburgh, Pa.; *CLYDE C. RUDDICK, Pittsburgh Plate Glass Co., Pittsburgh, Pa.

'Blowers and Puggers' Committee—(Past General Chairmen)—FRED G. ANDERSON, Corning, N. Y.; H. V. GARDNER, Owens-Illinois Glass Co., Toledo, Ohio; JOHN P. STEPHENSON, Ball Bros. Co., Inc., Muncie, Ind.; JAMES L. MORRIS, The Federal Glass Co., Columbus, Ohio; J. C. DITTMER, Cranford, N. J.; T. R. DONOGHUE (deceased), Pittsburgh Plate Glass Co.; W. G. HAZARD, Owens-Illinois, Toledo, Ohio; HARRY A. JACKSON, Frigidaire Div., General Motors Corp., Dayton, Ohio; J. H. GATRELL, Blue Ridge Glass Co., Kingsport, Tenn.; JOHN B. FULLER, Kopp Glass, Inc., Pittsburgh, Pa.; RUSSELL W. FRANK, Ferro Corp., Cleveland, Ohio; CLYDE C. RUDDICK, Pittsburgh Plate Glass Co., Pittsburgh, Pa.; JOHN V. SKENDBALL, Harbison-Walker Refractories Co., Pittsburgh, Pa.; EDWIN L. WRAY, Ball Bros. Co., Inc., Muncie, Ind.

Staff Representative—CHARLES S. WOLFF, National Safety Council, Chicago, Ill.

INTEGRATING ACCIDENT PREVENTION WITH PRODUCTION

By THOMAS A. SULLIVAN
A. O. Smith Corporation, Milwaukee, Wis.

We would like to offer the experience of our Granite City plant as a case study in the integration of accident prevention with production.

We have tried to present facts to you and not draw conclusions. If these facts can give you clues as to steps you can take in your own plants to tie accident prevention into your production processes this is the most that we believe can come from such a study. We would be the last to claim we have discovered any panacea for the complex subject of plant safety.

This case study is interesting because it was a new plant in a new area for A. O. Smith Corp. The exposure volume is significant, about 3,000,000 manhours per year.

From the beginning we had a safety director, who is still there. He is a staff man and must get all action through the operating people.

At the start-up of the plant two problems developed which complicated our problem immediately.

Certain automatic assembly equipment was not ready when product deliveries had to be made.

Our competitors were not ready to produce at all so we had to carry the entire requirements of our customer for the first few months of our operation.

As you might suspect, this required the hiring of green workers and green supervisors and made the training problem almost insurmountable at the beginning.

We have tried to put our whole story on this chart. It looks complicated but if you will follow along with me we will take it one step at a time.

The chart is divided into four areas:

The accident frequency data.

Production demands and union relationships.

Management action.

Safety and housekeeping.

Accident and frequency data show the number of lost time accidents per month since the plant began production in Sept. 1954. You will note that we have identified injuries to maintenance men separately from production people as the nature of their exposure is different and may be of some significance. For example, in 1959 and 1960 every other accident was in maintenance, although the hours of exposure of the production people is 10 times that of the maintenance men.

The frequency rate is a 12 month running average.

Production demands and union relationships are grouped together as things over which the management of the plant did not have complete control.

The start-up of new models in the summer of each year should have an adverse effect on safety because new equipment is present and men are back from a layoff of 4 to 6 weeks and presumably "out of practice." An examination of the chart does not disclose such a trend. Rather the accidents seem to bunch up in the later months when the heat is on to produce at peak efficiency. However, the data is not conclusive here either.

The effect of union activity on safety, while at first appearing adverse—after the union certification in 1955—does not show any discernable pattern. The accidents occurring after the major work stoppages in 1956 and 1957 do not seem to be related to the stoppage any more than to the model changes which occurred shortly thereafter.

In fact, it looks as though the formation of the Union-Management Safety Committee in 1959 had a major favorable effect on accident frequency. The frequency rate for the two year period since April 1959 is 0.78 per million manhours of exposure.

Management actions—There were four manufacturing superintendents during the period on the chart—identified as A, B, C and D. The frequency rate for each was: A—3.47; B—1.20; C—3.15 and D—1.53.

Making allowance for the start-up problem which seriously affected A's record, it looks like B had the best record and C the poorest. I would like to venture my opinion here that the attitude of the manufacturing superintendents toward housekeeping and safety had a major effect on the record of this plant.

There were three managers during the period on the chart. The frequency rate for each was: 1—3.08; 2—1.88, and 3—0.00.

The Monthly Management Plan of Action Meetings starting in February 1958 have had important results. The safety director presented safety projects to the manager and his entire staff and got their backing. A time table and plan of action was set up for each project and progress compared from meeting to meeting.

The need and approval for two engineering studies developed as a result of these staff meetings were safety of welding fixtures and a fighting survey—especially on the second shift. The welding fixture study not only corrected some serious safety hazards, but also resulted in a corporate-wide manual on "Engineering and Designing for Safety."

Safety and housekeeping—In 1956 the safety director began issuing safety procedures. These are tabulated in Exhibit I attached. They also are shown as P on the chart. It is to be noted that there was a flurry of them right after the Management Plan of Action Meetings started and again after the Union-Management Safety Committee started.

The two most significant procedures were: Eye protection, issued June, 1957, and Investigation of near injuries, issued April 1958.

The eye protection procedure eliminated policy confusion on border areas such as locker rooms, aisles, yards, etc., and signaled the beginning of a strict eye protection enforcement campaign.

The investigation procedure was an outcropping of the Management Plan of Action Meetings and became an effective communication device on hazardous conditions.

It is the belief of our safety director that good housekeeping is an important factor in developing a safe plant. This belief he demonstrates in a practical way by continually developing programs to improve housekeep-

ing practices. On the chart you will note that they started back in October 1954 and continue on a regular basis up into 1960. It will be interesting to look at Exhibit II which lists these programs. You will note how the operating supervision are tied into the program.

These, then, are the facts that seem to have some relation to the safety record of this plant which has twice earned the National Safety Council's Award of Merit and has twice earned the A. O. Smith Corp. President's Safety Award in competition with twenty other divisions of the company. Perhaps in studying this data you can form your own conclusions and find some application to your own problems.

EXHIBIT I GRANITE CITY PLANT HEALTH AND SAFETY PROCEDURES

Description	Date of Original Issue
Plant and Fire Brigade.....	Feb. 1956
Sickness and on the Job Injuries.....	Jan. 1957
Receiving Plant Visitors.....	Mar. 1957
Cutting and Welding Permits.....	April 1957
Fire Safety and Prevention.....	April 1957
Safety Eye Protection.....	June 1957
Gate and Bundle Passes.....	July 1957
Oxygen and Acetylene Cylinders.....	Nov. 1957
Press Repeat Control.....	Mar. 1958
Flammable Liquids.....	Mar. 1958
Safety Locks and Tags.....	Apr. 1958
Investigation of Near Injuries.....	Apr. 1958
Power Truck Maintenance.....	Apr. 1958
Tornado Alert and Evacuation.....	Sept. 1959
Portable Grinding Wheels.....	Sept. 1959
Compressed Air.....	Oct. 1959
In-Plant Railroad Safety.....	Nov. 1959
L.P.G. Equipped Power Trucks.....	Jan. 1960

OTHER GENERAL BULLETINS
Basic Winter Driving Rules. Released annually
Heat Exhaustion Released annually
Accident Costs Issued as needed
Points of Safe Conduct..... Issued as revised
*Key Programs

EXHIBIT II GRANITE CITY PLANT HOUSEKEEPING

October 1954—
The first step toward orderly housekeeping was the establishment of safety lines to identify aisles in the production area of the plant.

November 1954—
Housekeeping conditions were reported by plant patrolmen on their Patrolman Watch Reports. These items were occasionally organized into a housekeeping action report by the safety supervisor and sent out to all supervisors.

October 1955—
A Housekeeping Committee was formed to make housekeeping inspections, and report their findings to the supervisors involved. This committee consisted of the safety supervisor, plant superintendent, plant engineer, and production control supervisor.

February 1956—

The activities of the housekeeping committee were stepped up. Regular meetings were scheduled and other staff members were assigned to serve on the committee.

January 1957—
Housekeeping responsibilities were clearly defined by the Granite City staff and the safety supervisor.

April 1958—
The Manufacturing Superintendent assigned housekeeping inspection to area foremen.

May 1958—
Our housekeeping program was intensified. Color slides of housekeeping conditions in

the plant were reviewed by the Granite City staff after each inspection and then by all manufacturing and maintenance supervisors.

January 1959—
Management concentrated on improving the switch board area, compressor rooms, the propane farm system, pumphouse, and other isolated areas.

January 1960—
Elimination of all homemade employee's conveniences such as benches, shelter, salt-menders, etc.

July 1960—
Repainting all work areas and machinery, aisle lines and storage areas.

MODERN ROLE OF THE SAFETY SPECIALIST

By CHARLES A. CRAFT

George Fry and Associates, Management Consultants, Chicago

The subject of safety is not foreign to me or to virtually any layman. In fact, it has been pounded into us at every turn from the time we were able to walk and to understand. With all the exposure we have had, we should know all about safety. But, we certainly don't act like it! We're the ones (calling ourselves grown men and women), who are so "unsafety conscious" that we

—find ourselves in the middle of a busy intersection, after the light has turned to green w/ out having looked either way.

—neglect to connect the ground wire on a power tool.

—drive at 70 miles an hour on a toll-road, two lengths behind the car in front of us.

Suddenly it all became clear! I realized what this five-day meeting and the 103-page program was about. It's a dire plot! Half spend their time plugging up the structural and mechanical weaknesses to make us complacent so that the other half can spend their time bombarding us with posters and slogans to overcome our complacency. It may not be modern, but it's a good "racket."

Seriously, I suspect this is one of your biggest problems. The better you do your job, the more complacent we become, and the more we take you for granted.

When we talk about something being "modern," we imply a change has taken

place. I am sure we will all agree that, in general, our lives and our environment have changed—so much, sometimes, that it is almost frightening. To determine his modern role, a safety specialist is primarily concerned with changes that have taken place within his own environment, with respect to the specific company for which he works and the people with whom he deals.

Since as an individual you are, or should be, most familiar with the changes that have taken place within your own specific environment, it may be presumptuous for me to talk to you on this subject. But, in case some of you have not recognized the changes, or have interpreted changes to be more far-reaching than they really are, I will proceed with my analysis.

Each company, of course, is different and because of time limitations, we can consider business and industry only in general.

It has been my experience that major changes have and are taking place in industry. For purposes of my presentation today, I have divided the changes into two categories.

As the first category, in general, business has become more sophisticated, larger in size, more diversified, more market oriented, more cost conscious.

The net results of these changes is that business is becoming more involved and

more complicated. More time and attention are required for areas directly related to the major objective of maintaining a profit for the stockholder. Consequently, there may be a tendency to spend less time in areas not as directly related to the end objective.

I am including safety as one of these areas. I am sure that there are many who are ready to challenge the assumption that safety is not an important factor in the ultimate profit goal and probably rightly so. But, remember, I said not as directly related as other areas. I am not necessarily defending this condition, but am merely stating it as a situation that at least is understandable—a situation to which you have contributed personally by the excellent progress in reducing the accident rate.

There has been a second category of change in business which is just as natural today as it was when the very small business first grew into long pants—when the owner was unable to maintain a close day-to-day contact with the individual worker because of the company's size.

To counteract the tendency to neglect those areas that may appear to be less directly related to the ultimate profit objectives and to better fulfill their objectives, management is doing more planning and organizing, developing or taking on more staff specialists, and establishing more controls.

Yes, we do find major changes have taken place, and are taking place in business in general. It is logical to presume that there have been and will be major changes in the role of the safety specialist—changes to make him more modern and more up-to-date with the modern business world.

I can cite several changes in the technical role of the safety specialist. For example:

1. In a company that has grown to a multiplant operation, the safety specialist may find himself in a different role, because he no longer has close contact with the production floor.

2. In some cases, the apparent large increase in the amount of claims has resulted in more time required of the safety specialist.

3. Also, in some cases, opportunities for reduction in insurance rates have become more apparent and the safety specialist is being used more in this respect.

4. Because of these changes, the location of the safety specialist in the organizational structure may have changed.

I am not going to dwell on changes of this type for several reasons:

First, they are not universally applicable.

Second, I don't know enough about your business to discuss them intelligently.

And, third, they are, to me, in themselves, relatively unimportant.

What I believe is substantially more important is that, regardless of the specific change in his role, the safety specialist must fully understand the ramifications of the change. While remembering his basic purpose, objectives, and goals, he must take intelligent and responsible action. For example, he must understand that because of growth, diversification, and more complication in general, it is not surprising that top management is paying less attention to his area of activity. If this is taking place, he must understand that the good job he and others have done to improve the safety record makes it even less surprising.

He must further understand the part he plays in the second category of overall change: better planning, better organizing, and more and better staff specialists. Top management is doing more of this because it is the logical way to make up for the lessening of specific attention caused by growth, diversification, and increased complications. The safety specialist, in this situation, must realize that as a staff specialist, he is expected to see that his function is properly and completely fulfilled; this is the reason for being a staff specialist.

Furthermore, if he does not feel that his function is receiving the proper relative attention in the over-all plan and organization he is expected to say so. To become effective, as in the case of any important function, the function of safety must have a proper definition in the organizational plan, and the related responsibilities, and authorities must be clearly defined.

If this is not the case, and the situation is to the detriment of results, the safety specialist, as a specialist, is expected to "speak his piece" and not to assume that top management has thoroughly analyzed the situation and that this is their last word. I dwell on this because I have seen some weak organization plans from the viewpoint of safety, and, believe it or not, a surprisingly high percentage with virtually no mention of the subject. I am sure, in most cases, this was not the intent of top management.

One danger connected with a major change in his role is that a safety specialist, like anyone else, may be so impressed with the growth, diversification, and sophistication surrounding him that he tends to forget the basic purpose and objective of his function. Many things have changed, but I am sure that the basic purpose and objective of safety is not one of them. Regardless of the size, diversification, sophistication, or complications in a business, the man and the machine in the shop remain basically the same. Certainly the elements are shinier, faster, and sharper, but I wonder how much human nature has changed?

Some of us, in considering our place in the organization, become more concerned with its effects on our place in the sun, than with its fulfillment of our primary objectives. I cannot generalize about specifically to whom in the organization a safety specialist should report. Whether it be to engineering, to personnel or to the treasurer is, in itself relatively irrelevant. The basic consideration is to be sufficiently close to the employee and to the operations affecting him, whether by contact or by influence, to be effective and to fulfill the basic purpose. However, I would like to talk about your general position in the company organization.

I am reasonably sure that in the case of most of you here today, two conditions are common:

- You, as a safety specialist, are in a staff position rather than a line position.

Those in the line position have been given either in written form, verbally or inferred, "the responsibility for the safety of the employees reporting to them."

To a beginner in business, these two conditions appear to be at cross purposes and, unfortunately, many who have been in business for many years still fail to understand them. If you as an individual are having problems getting your messages across, this may be your trouble: possibly you have not given the subject enough thought or study.

To understand this condition, we must review some of the basic principles of organization. If you remember, I mentioned earlier that one of the changes that companies are making today to counteract the lessening of top management's attention to specific functions is to improve on and increase the number of staff specialists. This is one of the reasons for staff specialists, but there is a more basic reason.

There is, or should be, in your company, a direct line from the top production man down to the employee on the bench: a line of specialists in the field of producing a product. The man at the bench is the real production specialist and as we go up the line, the scope of supervision broadens as does the requirement to co-ordinate the actual production operation with other areas essential to safe, economical performance.

So, basically, we have a production line manned by individuals who are, in varying degrees, specialists in producing and in co-ordinating. These men are dealing directly, day in and day out, with equipment, materials, facilities and people for the fundamental purpose of producing products according to schedule. This is their forte, their specialty. And, in order to do their job effectively, they must have both responsibility and authority. Many would go even further and specify the need for full responsibility and authority.

Although most production line personnel have a working knowledge of supporting areas such as quality control, engineering, personnel, accounting, safety, etc., and some are at least semi-specialists in one or more of these areas, it would be impractical to expect them to be specialists in all of these areas, particularly with respect to the details. Nor could we expect them to have the time to perform the details involved.

The more basic reason for staff special-

ists is to supply specialized experience and time. How must they supply it? As a service to the line supervision? The line supervisors must retain the responsibility and authority, and too often, herein, lies the rub. Here communications and understanding often fail. Notice that I said "service" to the line supervision and not "servitude."

The staff specialist must function as a service to the over-all company as well. He must have an outlet through which he can recommend those changes important to the company as a whole without undermining the line organization—a large order, but a necessary and reasonable one if understanding, judgment, initiative, and ingenuity exist. In my opinion, at least half of the staff specialist's job is the same regardless of the specialty: namely, "working effectively with people in a service capacity."

I have been discussing a fundamental and basic phase of business. I apologize to you who have found it repetitive, who already have a clear definition of line-staff relationships, and who have no major problems in this respect. To those of you who do have major problems concerning your dealings with the line organization, I suggest that you question your understanding of the relationship as it has been established and your related attitudes and actions.

I am not putting the entire onus on the safety specialist. The line supervisor has a definite share in the responsibility for making the relationship work, and the arrangement may be relatively ineffective if top management has not supplied the necessary education, clarification, and cooperation. But, I think it is significant that I have encountered a greater number of sub-standard performances among staff specialists which were caused by a failure to adjust to this relationship than those

sub-standard performances which were a result of lack of education, experience, or ability.

It was suggested that I also discuss "how the safety specialist can be of greatest value to management." I believe I have touched upon this subject throughout my talk so I am going to close with a summary of major points.

To be of the greatest value to management, I believe the safety specialist should:

1. Be a specialist! Study the field, learn the technical aspects, be creative, develop approaches, and trade ideas.
2. Analyze the current place of safety in his organization, determine the existence or lack of clearly defined responsibilities and authorities, and suggest necessary changes to management.
3. Re-define the basic purpose and objectives of his function. Consider his position in the organization only as to how the purpose and objectives of his function can best be fulfilled.
4. Keep management informed of the status of the accident records, of the related cost to the company, of the planned programs for cost reduction, and of the progress being made.
5. Study and thoroughly comprehend line-staff organizational relationship and the reasons for this relationship. Realize that to fulfill the basic purpose and objectives of his function, this relationship must be effective, and that a large portion of his job is to make it effective. To do so he must:
 - be a student of human nature.
 - be understanding of the responsibilities and problems of those with whom he deals.
 - be humble but responsible, and dedicated.
 - sell himself as well as his programs.

THE PSYCHOLOGY OF ACCIDENTS

By JOHN MACIVER, M.D.

Asst. Medical Director, U. S. Steel Corp., Pittsburgh, Pa.

I should like to begin by locating what I have to say within a larger frame of reference. My overall philosophy of accident prevention is that it involves the whole person living within a total community within what has been called his "life-space." I would add the codicil that "no man is an island," that for the most part we do not live as individuals, but as groups, large and small, family groups, industrial groups, and all the rest. This total community—this life-space—may be quite safe, only relatively safe, or quite unsafe. No one would disagree with the assertion that we cannot be satisfied, despite our occasional triumphs, with the overall accident picture in our communities.

I am not concerned in this presentation with accidents in this total context. Rather, I want to "focus down" on one segment, the psychology and psychopathology of accident occurrence. Psychology I would roughly define as the study of behavior which is more or less normal or healthy or which "makes sense," as opposed to psychopathology, or the study of behavior which is more or less abnormal or unhealthy or which does not appear to "make sense."

It is in practice oftentimes difficult to separate behavior of the one sort from the other. In thus restricting myself I am eliminating vast areas of investigation and activity which have played a premier part in reducing the accident toll. This is the part played by engineers, chemists, hygienists, and public health workers in making our environments so much safer than they were in years past.

Let us imagine a community—and there are tens of thousands of them in this country—where great efforts and equally great sums of money have been directed towards the ultimate goal of a safe life for all—for child and adult, and older; for housewife and workman alike. And still the accidents occur. Even though they occur less frequently than before, the toll stands out in clearer and more terrible relief within the framework of our healthier communities

—communities, where for example communicable disease mortality is virtually a thing of the past.

We might conclude that if our results do not quite measure up to our efforts, perhaps we have been neglecting one or more aspects of the problems we face. I do indeed think we have been neglecting the human animal—the fellow who gets into accidents despite all our work, energy, teaching, and admonition. I might add that just about all of the safety specialists I have talked with in recent years seem to agree on this point: we must in the future, and beginning now, endeavor to get a clearer understanding of the psychology and psychopathology of accidents, especially all those accidents that from an engineering and rules and regulation viewpoint have no business happening.

I am not in the position to set down the answers to this great problem. The answers lie first in the recognition of the psychological aspects of accidents and their prevention, and second in the recognition that a great deal of sophisticated and expensive individual and team research will be required. All that I should like to do is to suggest a few leads or possible directions for thought and discussion. A favorite word among researchers these days is "heuristic," which means, that a stated point of view is not given with finality, but in the hopes that it will lead to statements which are more precise and which have higher truth-values. The heuristic approach is, of course, as old as Socrates, and it is this approach which I am taking.

As a student of human behavior who is a psychiatrist, I might say a few words about mental illness and its relationship to accidents. I am not impressed by any overwhelming relationship between mental illness and accidents with the dual exception of alcoholism and mental illness among the elderly. By no means do I wish to deny some correlation between accidents and psychological disease of every type. However, and I want to underline the following as

a most important point, when a task is hazardous in small measure or large, people with psychological handicaps tend to be selected out of these tasks by either formal or informal procedures; and further, it is my impression that such psychologically handicapped individuals show some tendency to select themselves out of hazardous positions. Where superordinate or peer group or self-selection is for one reason or another only weakly operative, then, of course, the correlation between psychological handicap and accident occurrence becomes stronger in proportion to the complexity of the task and the hazards which the task presents.

If this has validity, another important point follows. If in fact there is a complex and in part hidden selection process which works in favor of minimizing the probability of accidents, why do accidents occur in this selected population?

I would suggest that accidents tend to take place when for any number of reasons, an individual who is usually a safe operator temporarily falls into the psychologically handicapped group, but continues at the same task. It behooves us, then, to bring to light temporary states of stress, to recognize them in ourselves and others, and to take appropriate steps to withdraw from the task until the stress is dissipated. This, I suggest, is what I believe more or less permanently psychologically handicapped individuals tend to do on their own.

And now, a few words on "accident-proneness," so called. Many people in the safety field who have investigated this concept—I think that I can include myself in this number—have recommended that the term be dropped, at least for research purposes or where terminological precision is required. There is little objection on the other hand to using the phrase casually in a descriptive sense. I can assure you that "accident-proneness" as a specific psychological entity becomes pretty elusive when one tries to pin down what it really means.

Some have suggested that the term "accident susceptibility" be substituted. "Accident susceptibility" takes into account all the factors, not just the psychological, which tend to predispose an individual to accidents or to protect him from them.

Let me proceed to what I think of as

a special difficulty we face in accident prevention in the light of normal human psychology. Human beings learn many things from repetition. There is a conditioning process; habits are formed; and we are thereby enabled to acquire multitudinous patterns of automatic behavior. This is behavior which we carry through, as we say, "without thinking." These habits are positively conditioned by actual repetition of the unit of behavior. There also exists a negative conditioning process. This is well illustrated in Mark Twain's witty saying that a cat that sits on a hot stove will never sit on a cold one. Let me make it clear that I do not want to minimize unduly the importance of relevance of negative conditioning by pain or minor accidents or admonition from any of a number of sanctioning sources.

Rarely an individual is born without pain receptors—that is, there is a neurologically-based inability to feel pain—and opportunities for negative conditioning from the environment are severely reduced. Such individuals are severely handicapped and accidental injuries become a serious problem.

There are, however, two great difficulties with negative conditioning in accidents. These are 1) Significant accidents—while in the aggregate they occur in great numbers—are quite infrequent in the life of the individual. And since there are so many things *not* to be done and to be avoided, even though the deleterious consequence, the accident, may be months or years away, the human psyche does not stay impressed by the negative sanction. 2) Negative conditioning is not nearly so conducive to psychological automation as is positive conditioning and the resultant active habit formation.

I can illustrate the dilemma by a fictitious colloquy between a harried mother and her probably male child. Mother: "Junior, don't do that." Junior: "Then what shall I do?" And Mother, her patience exhausted, counters with: "I don't care what you do, but don't do that." The mother in this dialogue, with whom we can all sympathize, has not provided a positive program for her young hopeful's self-assertive and exploratory drives.

Positive conditioning—not what *not* to do but what to do—allows for repetition and the development of patterns of healthy auto-

matic behavior, for the realization of inward gratification, and at times for reward and approval from one's fellows. This is a most important point for safety education. As between the precept "Never put a knife into a toaster" and "Always lock out an energy-producing device before you work on it," the second statement is not only far more powerful and susceptible to generalization, it is positive and makes far more sense psychologically.

This leads me to another point on human motivation and mastery. As humans we yearn to mastery, and at times we do not shrink from facing hazard, injury, or even death in challenging an at-times unorgiving foe—our environment, the world we live in. Perhaps this is seen most clearly in our recreational pursuits, but I believe the tendency goes far beyond recreation and sports. Man has had some of his very greatest moments while wilfully facing danger.

By the rule of opposites, safety is often thought of as dull, and safety procedures as unworthy. To invoke the little boy again, mother says, "Junior, be careful, don't do that," and the boy, with a touch of disdain born of healthy self-confidence, says, "I can do it," and does it. This is mastery. So with the mountain climber who challenges the mountain because "it is there," or the

experimental pilot and the spacemen. The drive for mastery, again.

What many lose sight of is that there is no one more safety conscious or conservative than the men who are engaged in what might be considered perilous enterprises. As Shakespeare has Hotspur say, "Out of this nettle, danger, we pluck this flower, safety." The result of the popular confusion between mastery and foolhardiness is the tremendous paradox that it may well be more hazardous to cross Times Square against the lights than to shoot off into space. Our challenge in safety education is to give free rein to the bent for mastery while at the same time to clearly distinguish between being the master and being the fool.

I have touched only superficially on a few points in this complex field of safety psychology. I would not ask you to agree with anything I have said; by the same token I would be immensely gratified if anything I have said perchance leads to further thought and discussion.

Let us give more and deeper thought to safety psychology. Our reward for giving this subject the attention it deserves, and applying what we learn, will be communities truly healthier to live in than any the world has yet seen.

COMMUNICATIONS FOR SAFETY—HOW CAN WE MAKE OUR SAFETY MESSAGES MORE EFFECTIVE?

By LEE W. BAKER

Mgr., Information and Community Services, Allis-Chalmers Mfg. Co. Milwaukee, Wis.

Essentially, it seems to me, the National Safety Council and its auxiliary groups are among the most "communicatingest" organizations that I know of. They constitute a regular communicating machine, you could almost say, on the subject of safety.

On the general subject of communication, I want to mention some information I gleaned recently from the *Social Science Reporter*. An article in that publication dis-

cussed a University of Minnesota study of 100 companies regarding the pattern of "dropoff" in communication from the top down. This pattern was shown: vice presidents understand 67 per cent of what they hear from the board of directors and top management; at the general supervisor level, 56 per cent of the same information survives; by the time it reaches the plant manager, the level is down to 40 per cent;

among foremen, it dips to 30 per cent, and among individual workers, the level of understanding sinks to 20 per cent. In other words, one out of five messages from the top gets through to the men on the line.

What is the reason for this heavy loss in communication? And what can be done about it?

According to the Minnesota people, top management does not have a good understanding of the attitudes, opinions, ideas and suggestions of the people at the bottom of the whole business structure. Downward communication is only going to be raised significantly in its efficiency when top management acquires a better understanding of these factors.

One way to reduce the loss, it is suggested, is to cultivate good listening habits in everyone in the business—top management, general supervisors, plant managers, foremen and individual workers.

The article also pointed out that in verbal communication the mind moves faster than the voice. Most adults think four times as fast as they talk. The average American speaks at a rate of 125 words a minute among his family and friends, 100 words a minute in front of an audience. Yet most of us think at a "cruising speed" of 400 to 500 words a minute.

As a result, most speakers have trouble holding their audiences' attention. Most audiences "think circles" around speakers, and many get lost on tangents. Thus learning from listening operates at an average efficiency of only 25 per cent. Two days after a talk, you've forgotten three-fourths of what you heard. Well, there are some interesting facts for you to think about while you're cruising along at 400 to 500 words per minute ahead of my talking speed.

From those observations on general communication, let us move to the more specific subject—and my real topic—communication for safety.

Briefly, to start off, I'd like to say a word about our objective in this kind of communication. What are we trying to accomplish when we communicate for safety? Primarily I think you'll agree, this is the point of the subtitle: "How can we make our safety messages more effective?" Our real objective is to communicate effectively

with people—to communicate in a way that has an effect—that leads to a desired action or result.

This means that effective safety communication is that which has a result in people thinking more safely, in people acting more safely, in people living more safely. From the standpoint of industrial safety, and that is the concern of most of you, I think, your objective is to communicate so effectively that you see a really obvious and practical result through a reduction in severity and frequency rates.

If we accept this objective, let's think about how we are going to carry on effective safety communication to gain the objective.

There are a lot of ways to communicate. Media—we usually say, when talking of the various means of communication—are the way to get safety messages, and other messages, across to people. These media can be subdivided by the method of communication we use.

The first category I call environmental media. This is an unusual name—perhaps. Here I include such things as:

1. The absence of mechanical guards on machines—the lack of adequate warning signs—when needed.
2. Also—in the employee environment—careless, unsafe, behavior on the part of the supervisor.
3. These, of course, are negative aspects of environment communications. They can be turned around for the positive effect. Thus, the installation of all necessary mechanical safeguards and warning signs indicate the employee is working in an environment managed by people who believe in safety. Thus, also, the supervisor who acts in a careful and safe manner—avoiding for example, the temptation to temporarily forget safety in the interests of expediency when faced with a rush job—communicates the attitude of safety minded management.

The other media are less unusual and more commonplace. There are the visuals—the banners over plant gates or across large shop areas; films, both slide and movie; special exhibits and displays, preferably easily portable, so they may be moved from

one location to another; then there are the items to be worn—buttons, pins and pocket protectors.

The next media category is a very large one—and certainly widely used in communications on safety—it is the written media, the use of printed materials. In this category are employee publications—the magazines and newspapers issued by most companies these days—pamphlets and folders, used as employee handout material—letters to employees and mailed to their homes—special safety reports, such as an annual record of figures, telling the story of the past year's accident trends and accomplishments—letters and reports to supervisory management.

Finally, there are the media of oral communications. These are the most common, occur more frequently than any other. And—if there can be a rating from the standpoint of importance—then I suggest that the oral media are the most important—can be the most effective.

There is more than one way I could substantiate this statement. One good reference source is a leading opinion research organization.

When information is the prime objective in employee communications, according to this report, printed media are best suited for the job. . . . these are the employee publications, letters, bulletins and others referred to a moment ago. These media lend themselves to repetition, they can be easily distributed, contents can be controlled and adjusted to meet a specific situation.

But . . . when motivation is the objective, and certainly this is important in consideration of safety messages, the word of mouth communications better fills the bill. Person-to-person channels are adaptable to the individual employee's interests—and they meet his desire for participation . . . provide a direct feedback channel for the employee to express himself.

In the oral or person-to-person category are safety messages conveyed to employees in group meetings. These may be conducted by the supervisor or by a staff safety representative. The oral communications between the staff safety representative and the supervisor are important in conducting a total safety program. Uppermost in importance, however, is the supervisor—em-

ployee relationship. From the standpoint of safety messages this is the prime oral communication—it follows that the supervisor-employee communication is the No. 1 of any media.

All other communications are really a support program, to reinforce this personal safety communication with the supervisor.

Now two quick observations—one favorable to those of you who are interested in more effective safety communications, the other posing an obstacle.

On the favorable side, most managers rank safety a *must* in employee communications. This has been reported in a national opinion survey. In my own company, we conducted a communications seminar earlier this year. In advance of this, we sent questionnaires to plant managers on subjects pertinent to the seminar. One portion of the questionnaire asked the plant managers to look over a list of 23 topics for communications and rank them as very important, important, not very important. We found the entire group of managers ranked only three topics as very important for employee communications. One of these topics was safety. Management does want to talk safety.

Now—about the obstacle. Survey reports show that when employees are asked to state their information needs, the majority say, in effect, that they are well enough informed on safety. Yet there has to be constant communications with employees on safety—to keep the subject alive in employee minds. A recommended way to overcome this obstacle is to find ways to link safety with other subjects. Instead of straight safety reminders—such as, for example, "Work Safely" or "Drive Safely"—safety information can be linked with useful suggestions on handling materials, operating machine guards, good housekeeping—or with suggestions on how to improve driving skills, such as how to drive on icy roads, or who has the right of way in traffic circles.

In connection with the use of media I can't refrain from mentioning—and giving a high recommendation to—the extremely comprehensive "Everywhere . . . all the time!" program of the National Safety Council. This program—originally developed by Allis-Chalmers people following the

inspiration and urging of Mike Biancardi—demonstrates how to use a variety of media to make safety messages effective.

We would all like more dependable ways to weigh the effectiveness of the media we use. The search for testing effectiveness goes on constantly by people who work in every field of communication. We're somewhat in the position that John Wanamaker of department store fame was in . . . you know, he revolutionized merchandising through advertising, but he frequently said, "I know 50 per cent of my advertising budget is wasted, but I can never be sure which 50 per cent of it is."

Even though we can't be sure . . . we must always keep trying to find out. Comments and reactions of supervisors, employee feedbacks, studies and surveys—all can be helpful in determining the effectiveness of safety messages.

I have for your consideration what I've called—and not very originally, I'll admit—ten tips for effective safety communications.

The first of these ten tips is—

1. Know your safety communications objectives.

Your safety communications ought to be aimed at the main causes of accidents. These causes, I understand—stem from the human elements of the employee and supervisor—and from the working conditions.

Your objective should be to eliminate all lost-time accidents . . . to reach that magic "zero frequency" figure and hold it, through information, education, motivation and inspiration. The humanitarian aspects of this objective are obvious. The economic aspects, while not so obvious, are equally important . . . not only in the reduction in compensation costs, but also in the corollary point that a safe operation is generally a more efficient operation.

2. Establish your safety communications channels all the way from top management down to the individual employee.

Your safety communications must come from the top. This doesn't mean the president or board chairman must sign each piece of literature, but it does require an open endorsement by top management of the objectives espoused in your safety communications. Once you have this executive

endorsement, your superintendents and supervisors have some assurance that they can communicate with authority on safety matters, just as they can on other matters of management concern. Nothing undermines a foreman's safety efforts more than the uneasy feeling that his boss is going to "chew him out" for spending so much time on safety.

3. Encourage your supervisors to be safety supervisors.

A good portion of your safety communications should be directed at the line supervisor, to assure his alignment on the "safety team." In a well-run operation, the supervisor may be running a department which has a lost-time accident as infrequently as once a year or less. He may tend to take his employees' safety for granted in these circumstances. Actually, with this type of safety record, the supervisor knows a good deal about the principles of accident prevention. But he needs constant reminders to keep these principles in application. A good point for him to remember is that safety is a management obligation and he, the supervisor, is the first line of management. The Bell Telephone System uses a slogan which has become a way of life for employees . . . "No job is so important that we can not take the time to do it safely."

4. Remember, good safety communications is a two-way street.

Just as other forms of employee communications require some provision for registering employee reaction and comment, so do your safety communications. Nothing could hurt your accident prevention efforts more than a "w. what?" attitude toward employee suggestions and complaints. The man on the job is often in a better spot to see and analyze hazards, and to recommend action before he or a fellow employee is injured. He must be convinced that his suggestions, his opinions are important safety communications.

5. Keep your safety communications flexible.

Naturally, any good communications program requires advance planning. And safety communications are usually timed to give vacation safety tips in June, winter driving suggestions in the fall, and so forth. But it would be a mistake to format an in-

flexible program which would not be adjustable to fit the existing conditions. If a rash of back injuries occurs, the campaign should shift to lifting and material handling, even though it may have been committed to electrical hazards in your original scheduling. A shift in the use of various communications media may also be called for, when it becomes apparent that certain efforts are less effective than it was hoped they would be.

6. Use sound approaches to tell the same message again and again.

Repetition of sound safety principles is the key to making accident prevention a way of life for your employees. These messages may be carried in different ways, from time to time, for variety's sake or to cover a portion of your audience which does not seem to be "getting the message."

But it is not necessary to "spin your wheels" looking for completely new and different treatment of accepted safety messages. It is not necessary to disguise a safety message as something else to make it palatable. Variety of approach should be used only to broaden the coverage of a message, or to remind the employee of what you have already been telling him.
