(TYPE OF REPORT)

REPORT NO MRC-DA-771
JOB/PROJECT NO 103.1020
DATE 18 April 1978
PERIOD COVERED 1 March 1978 - 31 March 1978
TITLE A REVIEW OF THE CARCINOGEN LITERATURE
OF 125 CHEMICALS
AUTHORS Carl R. McMillan

RECEIVED

APR 21 1978

ABSTRACT The first task of EPA Contract 68-02-2773 is to identify 20 significant atmospheric carcinogens. Sampling and analytical methodology based on porous polymer sorbants and gas chromatography/mass spectrometry will then be developed for 15 of these chemicals.

In order to identify significant carcinogens, the literature has been reviewed for about 125 chemicals to determine whether they should be considered carcinogens for this project.

Different criteria must be used to define what tests results indicate carcinogenicity depending on the use to which the resulting list is intended. For this program, some chemicals have been included on the possible carcinogen list based on a limited amount of short-term mutagenicity data. If these lists should be used for other purposes, it would be expedient to review the literature cited and draw the appropriate conclusions based on other guidelines.

Introduction

The first task of EPA Contract 68-02-2773 is to identify 20 significant atmospheric carcinogens. Sampling and analytical methodology based on porous polymer sorbants and gas chromatography/mass spectrometry will then be developed for 15 of these chemicals.

In order to identify significant carcinogens, the literature has been reviewed for about 125 chemicals to determine whether they should be considered carcinogens for this project.

Different criteria must be used to define what test results indicate carcinogenicity depending on the use to which the resulting list is intended. For this program, some chemicals have been included on the possible carcinogen list based on a limited amount of short-term mutagenicity data. If these lists should be used for other purposes, it would be expedient to review the literature cited and draw the appropriate conclusions based on other guidelines.

For this project, a probable carcinogen generally has at least some positive animal data coupled with positive mutagenicity data from at least one well established mutagenicity test or several mutagenicity tests which have not been as extensively validated. The mutagenicity tests which were considered fairly well established include the Ames Salmonella typhimurium test and the enhancement of viral transformation tests (e.g. B. C. Casto), with the E. coli (pol A) differential toxicity and the Drosophila tests also considered important.

Animal carcinogenicity tests were considered less significant if they were conducted more than 5 - 10 years ago, tested by the subcutaneous route of administration demonstrating only local tumors, utilized only a few animals, or reported no concurrent control animals.

Dr. B. C. Casto, BioLabs, Inc. - Northbrook, Illinois, has been a consultant for Monsanto Research Corporation on this EPA contract.

Acetaldehyde

Acetaldehyde is possibly a carcinogen promoter¹, but no references to it as a carcinogen or mutagen were found in Toxline or Cancerline. Two references by Nakahara and Mori in 1939 and 1940² demonstrated no tumors in rats fed acetaldehyde in their food for more than 300 days. It is probably not a carcinogen.

¹Davies, J. C., "Co-Carcinogenesis with Respect to the Contents of Cigarette Tobacco", R. Soc. Health J., 93(6), 296-301, 1973

²Smith, W. J., L. L., "Survey of Compounds Which Have been Tested for Carcinogenic Activity, Second Edition", National Technical Information Service Number PB 216,478, 1951.

Acetone

Acetone (2-propanone, dimethyl ketone, CAS No. 67-64-1) has been extensively tested for carcinogenic activity both by itself and as a negative solvent control for other chemicals¹. No significant positive results could be found on Cancerline or Toxline for acetone. It is also negative on most *in vitro* tests and is used as a negative solvent control for many chemicals in these tests.

¹ Survey of Compounds Which Have Been Tested for Carcinogenic Activity, National Cancer Institute, PHS-149, Volumes 1 & 2, 3, 4, 5, 6 and 7.

Acetonitrile

The only data suggesting that acetonitrile is a carcinogen is a reference citing equivocal results from a 2-year rat study¹. It is considered a non-carcinogen for this project.

¹Fuller, B., et al., "Preliminary Scoring of Organic Air Pollutants", National Technical Information Service Number RB 264 442, 1976.

Acrolein

Acrolein appears to be toxic and reduces ciliary action of the bronchial epithelium^{1,2}, but is not mutagenic in *S. cerevisiae*³ or dominant lethal mice tests⁴. Acrolein has been found to be a mutagen to the TA1538 and TA98 strains of *S. typhimurium*⁵. It will be considered to be a possible carcinogen for this project.

Production and Persistence

It is estimated that 6.5×10^6 Kg is emitted per year, primarily associated with acrylic acid manufacture⁶. Other estimates are 4.2×10^5 Kg/yr released from 2.8×10^7 produced⁷ and a production of 2.8×10^7 produced in 1974 with a 6.7% growth forecasted through 1979⁸. It has an atmospheric half life estimated at 2.6 hours⁹. Its boiling point is -88°C and it has a vapor pressure of 220 mm at 20°C ¹⁰.

Acrylonitrile

Positive Ames tests¹, E. coli mutation tests² and viral transformation enhancement tests³ have been reported along with negative recessive lethal Drosophila melanogaster and negative Vicia faba chromosome aberration tests⁴. Human epidemiological evidence points toward acrylonitrile being a carcinogen⁵. Additionally, one-year interim report from the Manufacturing Chemists' Association of on-going ingestion and inhalation studies of acrylonitrile in laboratory rats report the rats developing a variety of tumors including carcinomas⁶. Based on these findings, acrylonitrile is being placed on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 3.7×10^5 Kg is emitted per year⁷. (Another estimate is 9.6×10^5 Kg per year⁸). Acrylonitrile has a boiling point of 77°C and a vapor pressure of 100 mm at 23°C⁹.

Aldrin

Aldrin has been found to cause neoplasia in two strains of mice¹ and tumors in weanling rats². Aldrin is converted into dieldrin in the environment³ and dieldrin is a carcinogen at 0.1 ppm in dietary exposure to mice⁴. Thus the sale and production of aldrin was suspended⁵. Many other animal studies have been conducted with questionable results⁶, and some *in vitro* tests have been negative⁷. Since there is enough data to suspend production of aldrin, it will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 4.5×10^6 Kg aldrin were produced in 1971⁶. Another production estimate is 1.1×10^7 Kg/year (1976)⁸.

Allyl Chloride

Allyl chloride (3-chloropropene, CAS No. 107-05-1) is on the NIOSH Safety Alert List. No references have been found on the Toxline, Cancerline or the Stanford Research Institute study on hazard priority ranking¹, to indicate that allyl chloride is a carcinogen or mutagen. A recent reference, however, reports that allyl chloride is a mutagen in *S. typhimurium*, *S. cerevisiae*, and *E. coli* test systems². It is therefore classified as a possible carcinogen for this project.

Production and Persistence

It is estimated that 4.2×10^5 Kg is emitted per year from stationary sources³. Another estimate is 2×10^6 Kg released from a production of 1.3×10^8 Kg per year⁴, and a production estimate of 1.3×10^8 Kg in 1972⁵. It is reported to take 27 minutes for 50% of the allyl chloride in a 1 ppm solution to evaporate at 25°C⁶. It has a half-life with HO radical of 21 hours, with O₃ radicals of 9 hours, and hydrolyzes with a half-life of 7 days⁴. It has a boiling point of 45°C, a vapor pressure of 340 mm at 20°C, and a solubility of 3.3 gm/l⁶.

⁶Verschueren, K. J., Handbook of Environmental Data on Organic Chemicals, John Wiley and Sons, Reinhold Co., New York, 1977.

Aniline

The IARC monograph on aniline¹ reports that aniline is probably not a carcinogen and that what early researches believed was cancer from aniline was most likely due to impurities such as benzidine. It has tested negative on a differential growth E. coli test (pol A)² and on S. typhimurium strains TA1535, 1537, 100 and 98 with and without microsomes³. It has also been reported negative in reversion to prototrophy in Aspergillus nidulans (meth₃) and several other tests³. It was classified negative/inadequate in one of the latest reviews³ and will be considered a probable non-carcinogen for this project.

³Report, P. J. et al., "Study of Industrial Data on Candidate Chemicals for Testing", National Technical Information Service Number PB 274 257, 1977.

Anthracene

Anthracene is on the NIOSH Suspected Carcinogen List because of two 1955 references. In the first reference cited (1), anthracene was found to be non-carcinogenic orally and interperitoneally. But when injected in 550 doses over a two-three year period (6 times/week - total dose 4.5 g/rat) 5 out of 9 rats developed local fibrosarcomas. It is now known that multiple injections can sometimes cause fibrosarcomas. Recent studies (2) have shown anthracene to be a non-carcinogen and it is presently being used as a non-carcinogenic standard on studies to develop short-term assays for carcinogens (3-6).

Benz(a)Anthracene

Benz(a)anthracene (1,2-benzanthracene, CAS No. 56-55-3) is well known as a carcinogen. It is carcinogenic orally, subcutaneously and topically for mice¹. It is one of the standard carcinogens used to evaluate the validity of short-term tests and will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that less than 100 kg/year is emitted from carbon black furnaces, the only stationary source cited for this chemical². It is emitted in the exhaust from gasoline engines (61.7 mg/kg exhaust tar) and diesel engines (2.3-15 g/m³ exhaust). It has been detected in the air, soil, food, and cigarette smoke condensate¹. It has a boiling point of 400°C.¹

¹"Benz(a)Anthracene" in IARC Monographs on the Evaluation of Carcinogenic Risk of the Chemical to Man, Volume 3, 45-68, 1973.

²IARC Source Assessment Data (Basel, July 1977).

Benzene

Benzene (CAS No. 71-43-2) is one of the industrial substances suspected of carcinogenic potential to man as listed by the American Conference of Governmental Industrial Hygienists¹ and will soon be controlled as a carcinogen. The International Agency for Research on Cancer² reports animal data which "do not permit the conclusion that carcinogenic activity has been demonstrated". In human data they support a relationship between exposure to benzene or benzene mixtures and the development of leukemia. Along with some positive studies³, many references occur in the literature where benzene is a negative solvent control in animal studies⁴. In spite of these references, it is believed that benzene induces chromosomal damage in animals and man⁵ and is a known carcinogen. An assessment of the air pollution aspects of benzene has been conducted⁶. Since benzene is being controlled as a carcinogen, it will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 1×10^5 kg benzene is emitted per year with solvent evaporation from degreasing operations contributing over 70% of the total⁷. Another estimate is 4×10^7 kg per year released from commercial uses of benzene⁸. It reacts rapidly with HO ($t_{1/2}$ = 3 days) but slowly with RO₂ and O₃ and has a 2.15 log partition coefficient⁹. Its boiling point is 80.1°C and it has a vapor pressure of 76 mm at 20°C¹⁰.

Benzene
References - Continued

"MRC Source Assessment Data Base," July 1977.

"Verschuieren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co. N. Y., 1977.

Benzidine

Benzidine is reported to be carcinogenic in the mouse, rat, hamster, and possibly in the dog¹. Given orally, it has produced bladder carcinoma in the dog after a long latent period and liver tumors in the rat and hamster. Benzidine was a carcinogen to mice when given p.o. either by stomach intubation or in food². These references, along with many others in Toxline and Cancerline show that benzidine should be considered a probable carcinogen.

Production and Persistence

It is estimated that 4.7×10^6 Kg is produced per year³. A release factor of 0.015 is assumed which would give 7×10^4 Kg released per year. This is probably too high since benzidine is well known as a carcinogen. Perhaps 7×10^3 Kg would be closer to reality. It reacts with OH and O₃ with a t 1/2 of one day⁴. It has a boiling point of 402°C⁵ and can be sublimed¹.

⁵Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Benzo(a)Pyrene

Benzo(a)pyrene (3,4-benzpyrene, CAS No. 50-32-8) is a well established carcinogen following many different administrations including oral, skin, subcutaneous and intratracheal routes¹. Positive results have been reported with mice, rats, guinea pigs, monkeys, newts, hamsters, and ducks¹. It will be considered a probable carcinogen for this project.

Production and Persistence

Although not manufactured in quantity, it is a by-product of combustion. It is estimated that 8.3×10^5 kg per year is released from stationary sources with 96% of this coming from: 1) coal refuse piles, outcrops and abandoned mines, 2) residential external combustion of bituminous coal, 3) coke manufacture, and 4) residential external combustion of anthracite coal². It has a boiling point of 311°C at 10 mm and 475°C at 760 mm¹.

¹"Benzo(a)Pyrene" in IARC Monographs on the Evaluation of Carcinogenic Risk of the Chemicals to Man, Volume 3, 91-136, 1973.

²MRC Source Assessment Data Base, July 1977.

Benzoquinone (Quinone)

1940 and 1941 Japanese references¹ state that 3/87 mice painted with benzoquinone (in benzene) developed skin cancer with 9/87 papillomas after 200 days compared to 0/46 skin cancers and 1/46 papillomas for the benzene control. Skin painting with a benzene solution in 1953 was said to cause 16/80 ear duct carcinomas². In 1954 and 1956, inhalation experiments with a total of 50 treated mice were conducted with negative results³. By subcutaneous injection, 24 rats were tested with negative results in 1957³.

More recent references show that benzoquinone does not decrease hatchability of the *Drosophila melanogaster*⁴, is not mutagenic toward *Drosophila* or cultured human leukocytes⁴, produces no increase in recessive sex-linked lethal mutations in *Drosophila* and did not significantly alter the rate of chromosomal translocations or breaks in leukocytes⁵. No other significant data were found in Toxline, Cancerline, or the "Survey of Compounds Which Have Been Tested for Carcinogenic Activity". Benzoquinone is therefore, to be considered a probable non-carcinogen for this project.

Benzoyl Peroxide

Benzoyl peroxide (CAS No. 94-36-0) was extensively tested in mice and rats between 1962 and 1967 by six authors on more than eleven hundred animals¹. Benzoyl peroxide is on the NIOSH Suspected Carcinogen list because in one of these studies, 1/30 mice developed a squamous papiloma after application of benzoyl peroxide in benzene to the skin. No recent mutagen or carcinogen references could be found on Toxline or Cancerline. It has been found negative in a dominant lethal mouse test, on an E. Coli (pol A) mutagen test, and a Micrococcus pyogenes test². There is very little doubt that benzoyl peroxide should be considered a non-carcinogen

MONSANTO RESEARCH CORPORATION

MONS 021930

Benzyl Chloride

Benzyl Chloride (α -chlorotoluene, CAS No. 100-44-7) has been found positive on a differential growth *E. coli* (pol A) mutagen test¹. It is also positive on a subcutaneous rat test at 2.1 g/kg (51 weeks) in 3/14 rats and at 3.9 g/kg in 6/8 rats². It is weakly mutagenic in *S. typhimurium* tests at 2 mg/plate³, and is considered carcinogenic in rats by the IARC². It is considered a probable carcinogen for this project.

Production and Persistence

In 1972 it was estimated that 3.6×10^7 kg was produced with 65-70% of this going towards the manufacture of butyl phthalate and 30-35% towards other organic products⁴. Production has been estimated at 4.5, 3.2 and 4.1×10^7 kg in 1974, 1975 and 1976 and is predicted to grow at 5-7% per year through 1980⁵. It has a boiling point of 179°C and vapor pressure of 1 mm at 22°C⁵.

⁵Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N.Y., 1977.

Biphenyl

There is one reference which shows subcutaneous biphenyl (diphenyl, CAS No. 92-52-4) to induce an excess of tumors in mice¹. No other references could be found in Cancerline or Toxline which would support that data. Biphenyl is therefore placed on the possible carcinogen list for this project.

Production and Persistence

It is estimated that 9.2×10^4 Kg biphenyl is emitted per year from the manufacture of polychlorinated biphenyls². Since the production of polychlorinated biphenyls has been stopped, this source of biphenyl emissions has probably ceased to exist. It has a boiling point of 254°C³.

²MRC Source Assessment Data Base, July 1977.

³Verschuere, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand, Reinhold Co., N.Y., 1977.

Bis (Chloromethyl) Ether

Bis(chloromethyl) ether (BCME, dichloromethylether, CAS No. 542-88-1) is carcinogenic to mice following inhalation, skin application and subcutaneous administration¹. It is also carcinogenic to rats by inhalation and subcutaneous administration¹. Epidemiological data suggests it is also a human carcinogen¹. It is being regulated as a carcinogen and will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that less than 100 Kg BCME is emitted per year². A primary source of emissions is in the production of polymethylene polyphenyl isocyanate². Its production in 1974 was estimated to be less than 450 Kg³. In water the half life of BCME is 38 seconds and in the air (50% relative humidity) its half life is 25 minutes¹. It has a boiling point of 104°C³.

²MRC Source Assessment Data Base, July 1977.

³Radding, S. B., et al., "Review of the Environmental Fate of Selected Chemicals", National Technical Information Service Number

Butadiene

1,3-Butadiene (CAS No. 106-99-0) has not been extensively tested for mutagenicity or carcinogenicity. No references could be found on Toxline, Cancerline, or in the seven collected volumes of Survey of Compounds Which Have Been Tested for Carcinogenic Activity on tests conducted although there is interest in a possible relationship between styrene-butadiene rubber plants and neoplasms of the lymphatic and hematopoietic tissue¹. Butadiene will be considered a probable non-carcinogen for this project.

¹Smith, A. H. and Ellis, L., "Styrene Butadiene Rubber Synthetic Plants and Leukemia" (Letter to Editor), U. Occup. Med. 19 (7); 441, 1977

Captan

Captan has been found to be a potent mutagen, in both prokaryote and eukaryote test systems too numerous to list. It has also been found to produce hepatomas in mice¹. Because of the many positive mutagenicity tests along with a marginally positive mouse carcinogenicity test, Captan has been placed on the probable carcinogen list.

Production and Persistence

It is estimated that less than 100 Kg per year of captan is emitted². (Another estimate is production of 8.1×10^5 Kg per year with 0.01 released or 8×10^4 Kg per year emitted³.)

¹"Evaluation of Carcinogenic, Teratogenic, and Mutagenic Activities of Selected Pesticides and Industrial Chemicals", National Technical Information Service Number PB 223 159, 1968.

²MRC Source Assessment Data Base, July 1977.

³Fuller, B., et al., "Preliminary Scoring of Organic Air Pollutants", National Technical Information Service Number PB 264 442, 1976.

Carbon Disulfide

There is nothing in Toxline or Cancerline to indicate that carbon disulfide is a carcinogen or a mutagen. One industrial epidemiological study showed carbon disulfide to have no correlation with incidence of cancer¹.

¹DiVito, G. and Sommi, G. L., "The Incidence of Infectious Diseases, Hemopathies, and Neoplasms in Workers Exposed to Carbon Disulfide", *Folia Med. (Nagoli)*; 46 (11); 972-979, 1963.

Carbon Tetrachloride

Carbon tetrachloride (tetrachloromethane, CAS No. 56-23-5) has been reported to produce liver tumors in the mouse, hamster, and rat following administration by inhalation and oral ingestion¹. It was not a mutagen as tested by several microbial systems². Carbon tetrachloride is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 1.2×10^7 kg of carbon tetrachloride is emitted per year³. Another estimate is a production of 4.5×10^8 kg with 2.7×10^7 kg released⁴. A document is available on the air pollution assessment of carbon tetrachloride⁵. Estimates of carbon tetrachloride production include 4.5×10^8 kg (1970)¹, 4.8×10^8 kg⁶, 7.3×10^8 kg (1974)⁷ and 5.3, 4.1, and 3.8×10^9 kg for 1974, 1975, and 1976². It is forecasted that the 1975-1976 decline will continue. The half life of carbon tetrachloride in the water is about 70,000 years⁴, and in the troposphere it is about 10 years⁵. It is estimated to have a half life of 10-33 weeks toward atmospheric photodegradation⁵. The boiling point of carbon tetrachloride is 76.7°C and it has a vapor pressure of 90 mm at 20°C⁸. For a review of its production, uses and biological activity, see the Fishbein article⁹.

Chloroacetic Acid

Chloroacetic Acid (monochloroacetic acid, CAS No. 79-11-8) has been reported as being carcinogenic in mice when injected subcutaneously at 100 mg/kg¹. The primary reference, however, does not report a statistical difference in tumors and reports data with the test chemical not much different than the control mice². In other tests, chloroacetic acid was negative when given to 6 rats as 0.005-0.1% of their diet for 208 days³ and negative when given at 46.4 mg/kg in the water of 72 mice for days 7-28 followed by 149 ppm in their diet for another 17 months⁴. It has also been found non-mutagenic by B. subtilis⁵ and S. typhimurium⁵⁻⁸ tests *in vitro*. All of these demonstrate that chloroacetic acid is not a mutagen and is not a carcinogen.

Chlordane

Chlordane has been found to be a carcinogen to mice in a study conducted by the National Cancer Institute¹. It is also a mutagen in tests like the enhancement of viral transformation². It is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 1.1×10^7 Kg per year of chlordane is produced³.

¹"Bioassay of Chlordane for Possible Carcinogenicity. (CAS No. 57-74-9)", National Technical Information Service Number PB 271 977/ISL.

Cresols:

Cresols (primarily o-cresol) have been shown to be promoters of carcinogenicity when given with initiators such as 3,4-benzopyrene (Kasper), 1-methylbenzanthracene, or in complex mixtures^{1,2}. On the other hand, normal adults excrete about 30 mg of volatile phenols per day of which 90% is p-cresol³. Thus, cresols are probably not carcinogens but could be promoters.

Chlorobenzilate

Chlorobenzilate (CAS No. 510-15-6) has been found to produce hepatomas in mice when administered orally^{1,3}, and is listed by the U. S. Commission on Pesticides and Their Relationship to Environmental Health as a group B chemical (positive results in one or more animal species at 0.01 significance level)¹. Several short term tests have been negative for Chlorobenzilate¹. For this project, it is considered a probable carcinogen.

Production and Persistence

A 1976 reference⁴ cites a production of 9×10^4 Kg per year and it is said⁵ that the 1971 production was 1×10^4 Kg.

Chloroform

Some of the current literature¹⁻⁴ indicates that chloroform is a carcinogen. Even though more data is required before a final determination is made, the positive data on mice and rats suggest that chloroform be placed on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 1×10^5 Kg chloroform is emitted per year¹. Another estimate is 1.7×10^7 Kg per year² emitted. Production estimates are 1.3×10^8 Kg per year³, 1.1×10^5 Kg per year², and 1.1×10^8 Kg per year¹. About 96% of production is converted to chlorodifluoromethane. In the troposphere chloroform degrades slowly with a 10 year half life⁷. It reacts with HO radical with a $t_{1/2}$ of 13 hours⁷ and hydrolyses with a $t_{1/2}$ of 3000 years^{6,7}. The log partition coefficient is 1.97 for chloroform⁶. It has a vapor pressure of 160 mm at 20°C and a boiling point of 62°C². It takes only 18-25 minutes to evaporate 50% of the chloroform from a 1 ppm solution at 25°C².

Chloroprene,

Chloroprene (2-chloro-1,3-butadiene, CAS No. 106-99-6) although known to be toxic was not considered to be a suspected carcinogen until three Russian papers linked occupational exposure of chloroprene to skin and lung cancers¹⁻³. Since that time, a short-term viral enhancement test at 125 mg/ml and S. typhimurium (Ames) tests have been positive, while long-term rat and mouse studies have been negative^{4,5}. A review of health records and death certificates for DuPont Corporation employees exposed to chloroprene convinced investigators that no excess of any disease similar to that seen for vinyl chloride had been observed⁶. However, some increase in lung cancer has been seen in this population⁷. It has also been found to accelerate the growth of transplanted Crocker murine sarcoma in the rat⁸. Thus, chloroprene lies on the border between a possible and a probable carcinogen. It will be classified as a possible carcinogen for this project.

Production and Persistence

It is estimated that 7.5×10^4 Kg chloroprene is emitted per year⁹. Another estimate is 2.7×10^4 Kg/year released¹⁰. Some estimates of production are about 1.8×10^5 Kg/year^{11,12}, 1.6×10^8 Kg/year¹³, and 1.3×10^4 Kg and 1.6×10^4 Kg in 1974 and 1975 with 44 annual growth predicted through 1981¹⁴. Because of its low solubility and high volatility, it will soon migrate to the atmosphere¹⁵. In the atmosphere it is said to have an atmospheric half life of less than 10 hours because of OH radical reaction¹⁶. Its boiling point is 59.4°C and it has a vapor pressure of 200 mm at 20°C¹⁷.

Chloropropane

No reference to carcinogenic or mutagenic action of chloropropane could be found in Toxline, Cancerline, or any of the other references consulted. It is probably a non-carcinogen and will be considered as such for this project.

Chrysene

Chrysene (benz (a) phenanthrene, CAS No. 218-01-9) is fairly well established as a weak carcinogen. It has produced skin tumors in mice following repeated painting and 2-20 mg injected subcutaneously in mice produced tumors after a long induction period¹. It is also a mutagen causing 167 revertants per microgram². It is considered a probable carcinogen for this project.

Production and Persistence

Although chrysene is not a manufactured chemical, it is a product of combustion and found widely dispersed in the environment. In one test of automobile exhaust, 12 micrograms were found after one minute of operation³. In the atmosphere, 150-490 µg chrysene has been found per gram organic particulate matter³. It has a boiling point of 498°C³.

¹"Chrysene" in IARC Monographs on the Evaluation of Carcinogenic Risk of the Chemical to Man, Volume 3, 159-177, 1973.

²McCann, J., et al., "Detection of Carcinogens as Mutagens in the Salmonella/Microsome Test: Assay of 300 Chemicals", Proc. Nat. Acad. Sci., USA, 72 (12), 5135-5139, 1975.

³Verschuere, L., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Cumene Hydroperoxide

Cumene hydroperoxide (dimethylbenzyl hydroperoxide) is cited as being a carcinogen but at 14 and 90 mg/kg did not induce statistically significant dominant lethal effects in mice^{1,2}. Cumene hydroperoxide is said to cause neoplasms in mice both by inhalation at 104 mg/kg³ and subcutaneously at 10 g/kg⁴. On the basis of the two animal studies, it is considered a possible carcinogen for this project.

Production and Persistence

It is estimated that the 1974 production was 1.4×10^7 Kg. Another estimate of production is 9.1×10^6 Kg per year with a production loss factor of 0.015 or 1.3×10^6 Kg/year. It has a vapor pressure of 1 mm at 70°C⁵. Because of its low volatility and moderate solubility in water, it is not likely to remain in the atmosphere⁶. Photochemical and HO radical reactions are likely pathways for transformation of peroxides in the atmosphere with a half-life of less than a few hours⁷.

⁶Fuller, B. et al., "Preliminary Scoring of Organic Air Pollutants", National Technical Information Service Number PB 264 442, 1976.

DDT

DDT (1,1,1-trichloro-2,2-di-(4-chlorophenyl)-ethane, CAS No. 50-29-3) has both positive and negative in vivo and in vitro data. It was negative in feeding studies of dogs and monkeys¹ and in a differential growth *E. coli* (pol A) mutagen test². Given orally, it produced liver cell tumors in several strains of mice and some of its metabolites produced lung tumors in mice³. It is positive in a recessive lethal *Drosophila* test⁴. All things considered, it is probably a carcinogen and will be classified as one for this project.

Production and Persistence

In 1971, 2×10^7 Kg was the estimated production⁵. In 1971 it was found in the air in concentrations of 0.1 ng/m³ to 1.56 µg/m³. The soil half life is estimated to be 15 years¹. It has a vapor pressure⁶ of 1.9×10^{-7} mm at 20°C and a melting point of 74°C.

³Vogel, E., "The Relation Between Mutational Pattern and Concentration by Chemical Mutagens in *Drosophila*", IARC Sci. Pub. No. 12, 117-137, 1976.

Di-tert-Butyl Peroxide

Di-tert-butyl peroxide (bis(1,1-dimethylethyl) peroxide, CAS No. 110-05-4) has been found to induce malignant lymphomas in 7/35 mice which inhaled 100 mM of this chemical¹. Skin applications on mice did not prove to be carcinogenic². (Tert-butyl hydroperoxide has also been found negative by skin application tests on mice^{3,4}.) Di-tert-butyl peroxide is on a list of "suspected carcinogens" studied for environmental fate⁵. Since the positive mice test results were by the inhalation route which has fewer false positives than injection, di-tert-butyl peroxide will be considered a possible carcinogen for this project. Considering the type and date (1963) of the positive tests, however, negative short term *in vitro* mutagenicity data would probably change its classification to a probable non-carcinogen by the criteria used for this project.

Production and Persistence

Production is estimated to be 3 million pounds per year⁶. It is only slightly volatile but moderately soluble in water. Thus most of the di-tert-butyl peroxide will remain in the water system. In the water the presence of >1 ppm Fe²⁺ and Mn²⁺ leads to decomposition to acids and alcohols with t_{1/2} <10 hours⁷. In the atmosphere photochemical and HO radical decomposition lead to a t_{1/2} of 79 hours⁸.

Di(2-Ethylhexyl)Phthalate

Di(2-ethylhexyl)phthalate (DEHP, dioctyl phthalate, DOP, CAS No. 117-81-7) is a high volume plasticizer which had in the past been considered virtually non-toxic as judged by various acute and chronic tests¹. Although early animal tests (dog, guinea pig, rat) were negative², at least one source³ now cites neoplastic effects in rats orally given 43.2 g/kg (96 weeks) di(2-ethylhexyl)phthalate. Although this dose is rather high, there are also several references which show this chemical to be both mutagenic and teratogenic^{4,5}. It is therefore classed as a possible carcinogen for this project at least until the present carcinogen bioassay being conducted is concluded⁶.

Production and Persistence

It is estimated that 2.6×10^5 Kg DEHP is emitted per year from stationary sources⁷. Other estimates are 2.0×10^5 Kg produced and released⁸ and 1.8×10^5 Kg produced in 1974⁹. It is said to biodegrade rapidly in water and sludge¹⁰.

In the air it reacts with the HO radical with a half-life of one day¹¹. It has a boiling point of 385°C and a vapor pressure of 1.2 mm at 200°C¹².

2,3-Diaminoanisole

2,4-Diaminoanisole (4-methoxy-m-phenylenediamine) was non-mutagenic in the L5178Y mouse lymphoma cell test and negative on rat skin (in combination with other chemicals) and mouse skin (the sulfate form) carcinogen tests. It did not produce dominant lethal mutations in rats.

It has been shown to be mutagenic in *S. typhimurium*¹⁷, usually with S-9 activation. It also induced sex-linked recessive lethal mutations in *Drosophila melanogaster*¹⁸ (sulfate form) with peak activity in the active germ cells (spermatids and spermatocytes). Preliminary results from an NCI study indicates that rats and mice fed this chemical (0.12 - 0.24%) had an excess of site specific (thyroid and skin) malignant tumors^{19,20}. Also two epidemiologic studies suggest excess cancer among cosmetologists²¹. Diaminoanisole is on the NIOSH Safety Alert list for its carcinogenic potential²² and will be considered a probable carcinogen for this project.

Production and Persistence

NIOSH is unaware of any current domestic production but cites that it is imported on the order of 25,000 pounds per year²³.

Diazinon

Diazinon has been reported to be slightly teratogenic in rats when given on the eleventh day of gestation¹. An increase in chromatid breaks has been noted in the lymphocytes of humans after ingestion of phosphate insecticides including Diazinon² and in cultivated human lymphocytes³.

On the otherhand, Diazinon has been found to be non-mutagenic in *Salmonella typhimurium* mutation tests⁴.

Diazinon also does not cause mutations in the 5-MT *E. coli* test⁵, the WP2 TRY - *trp* *E. coli* test⁶, two other *E. coli* tests⁷ or a *S. cerevisiae* mitotic gene conversion test⁸.

The majority of the information indicates that Diazinon is probably not a carcinogen.

o-Dichlorobenzene

A negative animal study of o-dichlorobenzene (CAS No. 95-50-1) has been conducted¹, but it was a short term (~6 months) study which would not be expected to show carcinogenicity. A few positive case studies have been reported, but with insufficient supporting evidence to show cause and effect. A few *in vitro* tests have been conducted². In *Aspergillus nidulans*, 200 mg/ml for 60 minutes causes an increase in reversion to methionine prototrophy from 3×10^{-7} to 5×10^{-7} reversions. It was negative in a *S. typhimurium* spot test at 1-5 μ l in eight strains. Because of the limited positive test data on systems which have not been extensively evaluated, o-dichlorobenzene will be considered a probable non-carcinogen (with some significant positive data) for this project.

p-dichlorobenzene

Many negative animal studies of p-dichlorobenzene (CAS No. 106-46-7) have been conducted¹, but all of them have been short term (<9 months) studies which would not be expected to show carcinogenicity. A few positive case studies have been reported but with insufficient supporting evidence to show cause and effect. A few *in vitro* tests have been conducted^{2,3}. It is reported that p-dichlorobenzene is a mutagen to higher plants and causes chromosomal breaks⁴. In *Aspergillus nidulans*, 200 mg/ml for 60 minutes causes an increase in reversion to methionine prototrophy from 3×10^{-6} to 11×10^{-6} reversions⁵. Because of the limited positive test data on systems which have not been extensively evaluated, p-dichlorobenzene will be considered a probable non-carcinogen (with some significant positive data) for this project.

Dichlorobenzidine

3,3'-Dichlorobenzidine (CAS No. 91-94-1) has been found to be carcinogenic in the rat following oral and subcutaneous administration and in the hamster after oral administration. Many other positive responses are noted in Toxline and Cancerline and it is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 2.1×10^6 Kg is produced per year with 4.5×10^3 Kg per year released¹. Other estimates of production are 1.6×10^6 Kg in 1971² and 2.1×10^6 Kg per year³. Dichlorobenzene is somewhat reactive towards RO_2 ($t_{1/2} = 40$ days) and very reactive towards HO and O_3 ($t_{1/2} = 1$ day)⁴. Its melting point is $133^\circ C$.

Dichlorobutenes

1,4-Dichlorobutene-2 is a mutagen of *Salmonella typhimurium* with microsome enhancing the effect¹. 3,4-Dichlorobutene-1 is also a mutagen in that system with or without NADP, giving 490 reverts/ μ mol with NADP and 345 reverts/ μ mol without NADP¹. Trans-1,4-dichlorobutene-2 has been found to be a weak carcinogen to ICR/HA Swiss mice when given by subcutaneous injection or by interparental injection but not by skin application. It was found not to be a tumor initiator in a two-stage test. Because of the carcinogenic and mutagenic data, it has been placed on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 8.7×10^5 Kg is emitted per year in the manufacture of polychloroprene², and has a boiling point of 158°C³.

⁴Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dichlorodifluoromethane

Dichlorodifluoromethane (Freon-12) has been shown to be non-mutagenic in *S. typhimurium* tests¹ but may cause some (mutagenic?) changes in conidia formation in *Neurospora crassa*². More information is needed on the mutagenic and carcinogenic potential of Freons. No other information could be found on Cancerline or Toxline. At the present time, it appears as if Freons are non-carcinogens.

1,1-Dichloroethane

The primary reference cited for 1,1-dichloroethane (CAS No. 75-34-3) in the NIOSH Suspected Carcinogen list¹ shows very minor teratogenic effects even at the highest concentration used (6000 ppm). Although there are many references to 1,2-dichloroethane, Toxline and Cancerline provided no significant references on the mutagenicity or carcinogenicity of 1,1-dichloroethane. A recent report from the National Cancer Institute² disclosed findings indicative of a possible carcinogenic potential for this compound but could supply no conclusive evidence. They found dose related marginal increases in mammary adenocarcinomas and in hemangiosarcomas among female rats and a statistically significant increase in the incidence of endometrial stromal polyps among dosed female mice. For this project it will be classified as a possible carcinogen.

Production and Persistence

It is estimated that 2.6×10^7 Kg of dichloroethane is emitted per year from stationary sources³. 50% of the 1,1-dichloroethane will evaporate from a 1 ppm water solution at 25°C in 22 minutes⁴. It has a boiling point of 57.3°C and a vapor pressure of 180 mm at 20°C.

¹Schwetz, B. A., et al., "Embryo- and Fetotoxicity of Inhaled Carbon Tetrachloride, 1,1-Dichloroethane and Methyl Ethyl Ketone in Rats", Toxicol. Appl. Pharmacol., 28, 452-464, 1974.

³MRC Source Assessment Data Base, July 1977.

⁴Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dichloronapthoquinone

Dichloronapthoquinone (Dichlone) did not cause point mutation in a microbial test system¹. It has, however, been found to cause reticulum cell sarcomas (Type A) in 9/64 mice when injected subcutaneously in B6C3F1 or B6AKF1 strains of mice compared to 14/613 reticulum cell sarcomas for the subcutaneous controls². This was significant at a .01 confidence level. Because of the limited number of mice involved, and the lack of other references on Cancerline and Toxline, dichloronapthoquinone will be considered a possible carcinogen for this project.

Production and Persistence

It is estimated that 900 Kg/year are emitted from stationary sources³. Dichloronapthoquinone has a melting point of 193°C and a 7.84 vapor density⁴.

³MRC Source Assessment Data Base, July 1977.

⁴Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dichlorophenol

Nothing was found in Cancerline to indicate that dichlorophenol is a carcinogen or a mutagen. A 1959 reference (1) cited in the NIOSH Suspected Carcinogens list shows 2,4-dichlorophenol may be a promoter or co-carcinogen when applied to the skin of mice in combination with benzene and dimethylbenzanthracene. Other than the above reference, dichlorophenol is not listed in the "Survey of Compounds which have been Tested for Carcinogenic Activity". Because of the lack of data, dichlorophenol has been placed on the probable non-carcinogen list as a possible promoter.

¹Boutwell, R. K. and Borch, D. K., "The Tumor-Promoting Action of Phenol and Related Compounds for Mouse Skin", Cancer Research 19, 413-427, 1959.

Dichloropropene

1,3-Dichloropropene at 1 ppm for six months has shown to have no adverse effects¹. Both the cis and trans isomers are mutagenic to TA1535 and TA100 *S. typhimurium* strains without activation²⁻⁴. It will be considered a possible carcinogen for this project.

Production and Persistence

It is estimated that 6×10^7 pounds of a dichloropropane/dichloropropene mixture is manufactured a year⁵. Assuming 50% dichloropropene, 3×10^7 pounds is released a year. It is said to react with OH and O₃ with a $t_{1/2} = 3$ days, and in water $t_{1/2} = 7$ days⁶. It has a boiling point of 104°C and 50% of a 1 ppm water solution will evaporate in 31 minutes⁶.

⁶Verschueren, W., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dichloropropionic Acid

Dichloropropionic acid (Dalapon) is a herbicide which has been found non-mutagenic in a *S. typhimurium* test¹. No other significant data have been found, so it has been placed on the probable non-carcinogen list.

¹Anderson, K. J., et al., "Evaluation of Herbicides for Possible Mutagenic Properties", *J. Agr. Food Chem.*, 20, 649-656, 1972.

Dichlorovinyl Dimethyl Phosphate (Dichlorvos)

Dichlorovinyl dimethyl phosphate (DDP) has been shown to be mutagenic in many different short-term tests¹, including S.typhimurium tests², but has been shown to be non-carcinogenic by oral and inhalation studies in rats and mice³. Because of the mutagen studies, DDP is to be listed on the possible carcinogen list for this project.

Production and Persistence

It is estimated that 200 Kg/year is emitted from stationary sources⁴. It has a boiling point of 120°C at 14 mm⁵.

⁴MRC Source Assessment Data Base, July 1977.

⁵Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dimethylacetamide

Dimethylacetamide was negative in an mitotic index test for epidermal hyperplasia¹. It is cited in the NIOSH Registry of Toxic Effects of Chemical Substances as being teratogenic to rats after I.P. injection. One reference was found in the Survey of Chemical Substances Which Have Been Tested for Carcinogenic Activity (1968-1969) in which rats were given the chemical intergastrically at 0.1 - 30 mg/d. for 260 doses². The tumors found do not appear to be related to dose. No other references could be found in Cancerline or Toxline which would suggest that dimethylacetamide is a mutagen or a carcinogen, so it will be classified as a probable non-carcinogen for this project.

¹Rieger, M. M., "Cosmetic Science: 1975 Literature Survey", Cosmet. Perfum., 91 (4), 25-36, 1976.

²Hadidian, Z., et al., "J. Nat. Cancer Inst., 41 (4), 985-1036, 1968.

Dimethylamine

Dimethylamine (methanamine, N-methyl) has been reported to combine with nitrates or nitrites both *in vitro* and *in vivo* (by saliva or intestine flora) to form the carcinogen called dimethylnitrosamine or nitrosodimethylamine (more than 20 references in Toxline). Dimethylamine may also combine with ozone and nitrogen tetroxide in the atmosphere¹. In Toxline and Cancerline there are 74 and 16 references respectively which deal with mutagenic or carcinogenic aspects of dimethylamine. These references, along with those in Chemical Abstracts appear to indicate that although dimethylamine is a potent co-carcinogen, it is not by itself carcinogenic. For this project, it will be considered a non-carcinogen but will be considered when cofactors are evaluated.

Dushnetin, E. K. and Sepach, E. O., "The Role of the Reaction of Dimethylamine with Nitrogen Tetroxide and Ozone in Atmospheric Pollution", *(Gig.) Sanit.* 17, 14-18, 1976.

Dimethylhydrazine

1,1-Dimethylhydrazine (CAS No. 57-14-7) has been found to be carcinogenic in mice after oral administration¹. It also causes tumors of the colon in rats (but not swine, dogs, or guinea pigs - perhaps because of toxicity) fed 30 mg/kg dimethylhydrazine². Many other positive references are found in Toxline and Cancerline and it is considered a probable carcinogen for this project.

Production and Persistence

Production is estimated at $<5 \times 10^5$ Kg in 1973^{3,4}, with a 0.01 fraction of dispersion⁴. Since it is polar, non-volatile, and soluble in water, there would not be a significant transfer to the atmosphere⁴. It reacts with oxidizing materials in the atmosphere⁴ and has an expected half life of 2.1 hours by reaction with the HO radical⁴. Dimethylhydrazine has a boiling point of 63.3°C and a vapor pressure of 157 mm at 25°C⁴.

Dinitrotoluene

2,4-Dinitrotoluene has been found by the National Cancer Institute to be non-carcinogenic to mice but carcinogenic to rats¹. It has been placed on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 400 Kg dinitrotoluene is emitted per year from stationary sources². It has a boiling point of 300°C³.

¹ "National Cancer Institute Draft Summaries of Bioassay Reports - 2,4-Dinitrotoluene", Chem. Reg. Rep. 1 (45), 1598, 1978.

² MRC Solids Assessment Data Base, July 1977.

³ Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N. Y., 1977.

Dioxane

1,4-Dioxane (CAS No. 123-91-1) has been shown to be carcinogenic to rats^{1,2} and guinea-pigs³ by oral administration. It produced malignant tumors of the nasal cavity and liver in rats and tumors of the liver and gall bladder in guinea-pigs. It was also active as a promoter in a two-stage skin carcinogenesis study in mice but produced no carcinogenic effect in one inhalation study in rats. For this project, it is considered a probable carcinogen.

Production and Persistence

The 1972 production has been estimated to be 6.3×10^6 Kg^{1,4,5} and the 1973 production of 7.4×10^6 Kg¹, with most of this being released to the environment. In the atmosphere it reacts with the HO radical with a half-life of 9.6 hours^{1,5}. It has a boiling point of 101°C and a vapor pressure of 30 mm at 20°C and 37-39 mm at 25°C^{1,5,6}.

Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., New York, 1977.

Diphenyl Oxide

No positive or negative data could be found for diphenyl oxide (phenyl ether, CAS No. 101-84-8) on Toxline, Cancerline, or in the Survey of Compounds Which Have Been Tested for Carcinogenic Activity (Volumes 1-7). It is, therefore, listed as a probable non-carcinogen for this project.

Disodium Methanearsonate

Disodium methanearsonate has been cited as being carcinogenic, but no further data is given in this reference¹. It has been found to be non-mutagenic when tested with 5 strains of *S. typhimurium*, mitotic recombination of *S. cerevisiae* and relative toxicity assays in *E. coli* and *B. subtilis*². In all tests except the *B. subtilis*, the chemical was tested using the S-9 microsome activation. Methanearsonates have also been tested for mutagenesis by other authors^{3,4}. The lack of confirming data from Toxline or Cancerline and all other indications other than the first reference demonstrate that this chemical is probably a non-carcinogen.

⁴W. Jerson, K. J., et al., "Evaluation of Herbicides for Possible Mutagenic Properties", J. Agr. Food Chem., 20, 649-656, 1972.

Dursban

Dursban has been shown to be more toxic to the repair deficient strains of *B. subtilis* and *E. coli* than in repair proficient strains of these organisms. It was not, however, found to be a mutagen on *S. typhimurium* assays or on the mitotic recombination of *S. cerevisiae*¹. It is considered a non-carcinogen for this project.

¹Simon, V. F., et al., "In Vitro Mutagenic Studies of Twenty Pesticides", *Toxicol. Appl. Pharmacol.* 37 (1), 109, 1976.

Endosulfan

Endosulfan has been found to marginally increase ($P = 0.05$) the total number of tumors and the pulmonary adenomas in mice given the compound orally¹. Endosulfan has been found to be non-mutagenic in three different *E. Coli* mutagen tests². In a National Cancer Institute study³, endosulfan was found to be non-carcinogenic to mice and non-carcinogenic to rats. Because of the limited amount of positive carcinogenic data and the many negative studies, endosulfan has been placed on the probable non-carcinogen list.

Endrin

Endrin (CAS No. 72-20-9) has been reported to cause chromosome breakage in cells¹. Endrin was non-mutagenic by a *S. typhimurium* test using mouse liver micronomes and has tested negative on several *E. coli* tests³. Rat feeding studies (up to 100 ppm) showed no increase in tumor incidence⁴. Endrin will be considered a probable non-carcinogen for this project.

"Endrin" in *IARC Monographs on the Evaluation of Carcinogenic Risk of Chemicals to Man*, Volume 5, 157-171, 1974.

Epichlorohydrin

Epichlorohydrin (chloromethyl oxirane, 1-chloro-2,3-epoxypropane, CAS No. 106-89-8) has been reported to be carcinogenic in mice by subcutaneous injection and active as an initiator in a two-stage skin carcinogenesis study in mice¹. Epichlorohydrin is also a typhimurium causing chromosome aberrations, mutating *S. typhimurium* in a host mediated assay and *E. coli*, and *Neurospora crassa*². It will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 2.2×10^5 Kg is emitted per year³. Production in 1973 was estimated⁴ to be 1.6×10^5 Kg, 1.5×10^5 Kg and 8.2×10^4 Kg on another recent estimate⁵ of 2.2×10^5 Kg. The production is expected to grow 4-5% a year⁶. In the atmosphere epoxides have a half life of 3 to 11 hours⁷. Epichlorohydrin has a boiling point of 117°C and a vapor pressure of 12 mm at 20°C⁸.

Eptam

Eptam (ethyl di-n-propylthiocarbamate, CAS No. 759-94-4) was negative in a bone marrow chromosomal aberration test when fed to rats at 1/5 LD50 (LD50 = 1630 mg/Kg)¹. Eptam may have had an effect on *Vicia faba*². It is cited as belonging to the C4 classification of pesticides³ (negative, but in only one species of animal) but also referenced as being a neoplastic agent⁴. Neither of these primary references could be found on Cancerline, Toxline, Medline, or the entire collection of the "Survey of Compounds Which Have Been Tested for Carcinogenic Activity". For this project it will be classified as a non-carcinogen.

Ethanol

Much has been written about the mutagenicity or carcinogenicity of ethanol (87 references in Toxline) with both positive and negative results. It has been tested extensively in animal systems. In general it is considered a non-carcinogen and non-mutagen and has been removed from the latest NIOSH Suspected Carcinogens list. It will be considered a probable non-carcinogen for this project.

Ethyl Benzene

No data have been found to indicate that ethyl benzene is a mutagen or a carcinogen. A review of its use as a fragrance is noted¹. Ethyl benzene has been found non-carcinogenic to rats, guinea pig, rabbit and monkey by inhalation and to rats orally². It is negative on the viral enhancement of hamster cell transformation³. It is therefore classified as a non-carcinogen for this project.

³Personal communication from B. C. Caston on 9 February 1978.

Ethylene

No data was found to indicate that ethylene is a mutagen or a carcinogen. It is also a normal metabolite of the human body. It is therefore classified as a probable non-carcinogen for this project.

Ethylene Dibromide

Ethylene dibromide (1,2-dibromoethane, ethylene bromide, CAS No. 106-93-4) has been found to produce squamous-cell carcinomas of the forestomach in mice and rats after its oral administration¹. It has also been reported to be mutagenic in *Salmonella typhimurium*, *Escherichia coli*, *Neurospora crassa*, *Saccharomyces cerevisiae*, *Tradescantia*, *Serratia marcescens*, and *Drosophila melanogaster* test systems^{2,3,4}. Ethylene dibromide will be considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 8.9×10^5 Kg of ethylene dibromide is emitted per year from stationary sources⁵. Another reference cites a production of 1.43×10^3 Kg with 1.38×10^8 Kg released⁶. Other references cite production of 1.5×10^8 Kg (1974)⁷, 1.4×10^5 Kg⁸, and 1.5×10^3 Kg, 1.2×10^9 Kg for 1974 and 1975⁹. The use of ethylene dibromide in gasoline is predicted to drop by 10% a year through 1980 while its use as a fumigant may be terminated by EPA action in light of the above animal studies¹⁰. Its air pollution potential has been assessed¹¹. Atmosphere oxidation of alkyl halides is reported to have a half life of less than 20 hours while the half life of HO radical attack is 234 days¹². Its boiling point is 131.6°C and it has a vapor pressure of 11 mm at 25°C¹³.

Ethylene Dichloride

Ethylene dichloride (1,2-dichloroethane, ethylene chloride, CAS No. 107-06-2) has been found in preliminary results to be carcinogenic when fed to male and female rats by the National Cancer Institute¹. Ethylene dichloride fed rats had a significant excess of site-specific malignant and non-malignant tumors. In other studies its has been negative by inhalation in rats, guinea pigs and monkeys but mutagenic to fruit flies². Because of the positive animal studies, it is included on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 6.7×10^7 Kg ethylene dichloride is emitted per year from stationary sources³. Other references cite a production of 3.9×10^9 Kg produced with 2.1×10^3 Kg released⁴, 4.2×10^3 Kg (1973)⁵ produced, and production of 4.2×10^3 Kg, 3.6×10^3 Kg, and 3.6×10^3 Kg in 1974, 1975, and 1976⁶. An air pollution assessment of ethylene dichloride has been made⁷. Ethylene dichloride reacts slowly with provides with a half life of 1000 days and is resistant to photochemical degradation⁷. The HO reaction half life has been estimated to be 234 hours⁷. It has a boiling point of 83.5°C and a vapor pressure of 61 mm at 20°C⁸.

Ethylene Glycol

Although ethylene glycol (1,2-ethanediol) has been reported to give neoplastic effects at 4 gm/kg on mouse skin¹, no other confirming reports of carcinogenicity or mutagenicity have been found. Many reports indicate that ethylene glycol is non-carcinogenic in different species by various routes of administration. These include 18 tests reported in 8 articles before 1950 on rats, mice, and rabbits in food, drinking water, intervencously, subcutaneously, intermuscularly, and via inhalation - all with negative results².

More recently, tests have been negative for ethylene glycol³ including subcutaneous rat tests⁴, subcutaneous newborn mice tests⁵, and inhalation tests using rat, guinea pig, rabbit, dog, and monkey⁶. It is also negative in the Salmonella test for mutagens⁷. All in all, ethylene glycol will be considered a non-carcinogen for this project.

Ethylene Oxide

Ethylene oxide (oxirane, 1,2-epoxyethane, CAS No. 75-21-8) has been found negative on skin painted mice and subcutaneously injected rats¹. Short term inhalation tests (6 months) on dogs, mice, rats, rabbits, guinea pigs, and monkeys were negative¹. An excess of tumors were found in mice exposed to ethylene oxide treated ground-corn cob bedding as an experiment not designed to test for carcinogenicity of ethylene oxide¹. Ethylene oxide is a mutagen in *Salmonella typhimurium*, *Neurospora crassa* and *Drosophila melanogaster* tests^{1,2}. It will be considered a possible carcinogen for this project based on the *in vitro* mutagenicity data.

Production and Persistence

It is estimated that 4.5×10^6 kg ethylene oxide is emitted per year from stationary sources³. Other estimates of production includes 1.8×10^3 kg produced with 4.5×10^7 kg released⁴, 1.8×10^3 kg produced⁵, 1.8×10^3 kg produced in 1974⁵, 1.9×10^3 kg produced in 1975⁵, and 1.8×10^3 and 2.0×10^3 produced in 1974 and 1975⁵. Its primary use as an intermediate is expected to grow at 4.7-5.2% per year until 1980³. Dispersed in the atmosphere, epoxides would be oxidized by HO radicals with a 3-11 hour half life⁶. Its reaction with HO radicals has also been estimated to give half lives of 1.6 days⁴ and 23 hours⁷. It has a boiling point of 11°C and a vapor pressure of 1095 mm at 20°C.

Ethylenimine

Ethylenimine (Aziridine, CAS No. 151-56-4) is well documented as being a potent mutagen, and is used as a mutagen in many plant studies (533 references on Toxline to its use as a mutagen or carcinogen). It has also been found to be carcinogenic in at least two strains of mice following oral administration and producing liver-cell and pulmonary tumors¹. Subcutaneous injection of single doses in suckling mice produced increased incidence of lung tumors in males. Subcutaneous injection in oil produced local tumors in rats¹. It is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 2.7×10^4 Kg is released to the environment per year². Estimates of production are 2.3×10^5 Kg, 1.4×10^6 Kg, 2.2×10^5 Kg (1974), and 2.3×10^6 Kg per year^{3,4}. Ethylenimine is infinitely soluble in water⁵, basic, and polar, and could therefore be expected to be very slow to escape from water to the atmosphere¹. Its reaction with HO in the atmosphere has been found to have a half-life of 1.5 days², 47 hours⁴ and 56 hours¹. It has a boiling point of 56°C and a vapor pressure of 160 mm at 20°C¹.

Fluoranthene

Fluoranthene (CAS No. 206-44-0) was tested for carcinogenicity in 1935 and 1938 on mice by skin (0.3% in benzene for 501 days) and oral (10 mg for 18 months) routes of administration with negative results¹. Arcos and Argus reported in 1974 that in 1963 or 1964 others had found fluoranthene negative by subcutaneous tests in XVII nc/2 strain of mice², and is generally considered non-carcinogenic². Recent tests of mouse skin application, alone or followed by croton oil, were negative after 15 months and 20 weeks respectively³. It has been tested on TA98, 100 and 1537 strains of *S. typhimurium* for mutagenicity⁴. It is considered a probable non-carcinogen for this project.

¹Survey of Compounds Which Have Been Tested for Carcinogenic Activity, NCI, PHS-149, Volume I.

Formaldehyde

Formaldehyde (methanal, formalin, methyl aldehyde, CAS No. 50-00-0) has been tested for carcinogenicity with negative results on many animal species in short term (usually less than a year) tests¹. However, 1300 mg/kg (65 weeks) caused neoplastic effects in rats² and 1 ml of 0.4% formaldehyde solution caused spindle cell sarcomas and fibrosarcomas at the injection site of 4/10 rats evaluated at least 649 days³. Formaldehyde has been shown to be a mutagen in *Drosophila melanogaster*, *E. coli*, barley, *Vicia faba*, yeast, and viral transformation enhancement tests⁴⁻⁶, but negative on the mouse dominant lethal test⁷. For this project formaldehyde will be considered a possible carcinogen.

Production and Persistence

It is estimated that 4.1×10^7 kg formaldehyde is emitted per year from stationary sources with 82% of this being from charcoal manufacture and catalytic cracking in petroleum refining¹. Other estimates of production include 2.6×10^3 kg produced and 2.4×10^3 kg released², 2.6×10^3 kg produced and 6.4×10^3 kg released³, 2.6×10^3 kg produced (1974)⁴, and 2.9×10^3 kg and 2.6×10^3 kg produced in 1973 and 1975⁵. The production of formaldehyde is projected to grow by 4-5% per year in the next five years¹. In solution it is essentially non-volatile, but in the air it will react with HO radical with a half life of 2.6 hours⁶ or 1.2 hours⁷. As a gas it has a boiling point of -21°C and a vapor pressure of 1946 mm at 25°C . Its environmental fate, biological, and environmental effects have been studied^{1,8}.

Guthion

Guthion has been found to be mutagenic in that it induced chromosome breaks in WI-38 cells and in HE₂-2 cells¹. Guthion also increased mitotic recombination in *S. cerevisiae*². However, it did not prove to be a mutagen in *S. typhimurium* assays² or in *E. coli* or *B. subtilis* systems² and did not induce dominant lethal effects in mice³. For this project it is considered a non-carcinogen.

Heptachlor

The IARC monograph on heptachlor (heptachloro-tetrahydro-methanoindene, CAS No. 76-44-8) shows this compound to have both positive and negative data, with more negative than positive¹. It is a mutagen as tested by the enhancement of viral transformation². Recent NCI tests³ with rats and mice demonstrated that heptachlor is a carcinogen for the liver in mice under the conditions of their bioassay. It is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 1.1×10^4 Kg heptachlor is emitted per year from stationary sources⁴. Estimates of production include 2.7×10^6 Kg (1971)¹ and 2.7×10^6 Kg produced⁵. It has a melting point of 95°C and a vapor pressure of 3×10^{-4} mm at 25°C¹.

Hexachlorobenzene

Hexachlorobenzene (benzene hexachloride, CAS No. 118-74-1) induces microsomal enzymes¹, is only slightly teratogenic² and tests positive/negative³ and negative² on the dominant lethal test in rats. When fed to rats it was non-carcinogenic⁴, and by *S. typhimurium* tests (using mouse liver microsomes) it was negative⁵.

Hexachlorobenzene was, however, mutagenic when tested with *Saccharomyces cerevisiae* at 100 ppm⁶ and when fed to 6 week old Syrian golden hamsters at concentrations up to 200 ppm it induced heptomas, hemangiomas and thyroid adenomas in a dose response manner⁷. It is therefore considered a possible carcinogen for this project.

Production and Persistence

It has a $t_{1/2}$ of 2 days in the air reacting with OH to form pentachlorophenol. Its production is estimated to be 1.3×10^6 pounds per year and 0.3×10^6 pounds is used in a dispersive manner as a fungicide for a total of 0.5×10^6 pounds released⁸. It has a boiling point of 322-326°C⁹.

Hexachlorobutadiene

Hexachlorobutadiene injected I.P. in mice apparently caused no lung adenomas¹. A two year study with rats on diets containing hexachlorobutadiene showed no effects at 0.2 mg/kg/day or less, but renal tubular adenomas and adenocarcinomas at 2 and 20 mg/kg/day^{2,3}. A reproduction study also showed no effects at 0.2 but effects at 20 mg/kg/day. At the high doses some toxicity was also evident. A 90 day feeding study (0.3-30 ppm) on Japanese quail showed little effect of this chemical. NIOSH has a safety alert out on the basis of the above tests and it is considered a possible carcinogen for this study.

Production and Persistence

It is estimated that 8×10^6 pounds is produced in the USA with 7.3×10^6 pounds being released per year. It reacts with OH and O₃ with a t_{1/2} of less than one day and has a low water-solubility. The boiling point of hexachlorobutadiene is 210 C with a vapor pressure of 22 mm at 100°C.

Hexamethylenetetramine

Hexamethylenetetramine (CAS No. 100-97-0) has been extensively tested in both rats and mice¹. Almost all of these tests show that this chemical is non-carcinogenic when given either orally (up to 5% of drinking water) or subcutaneously (25 gm/Kg)². It has been tested on E. coli differential growth (pol A) test with positive results which was considered a false positive³. It has also been reported to be non-mutagenic to Drosophila, positive in oral mouse dominant lethal test, negative in an interperitoneal mouse dominant lethal test, and positive on a chromosomal aberration test in cultured lymphocytes⁴. Hexamethylenetetramine will be considered a non-carcinogen (with some positive data) for this project because of the extensive negative animal data.

¹"Survey of Compounds Which Have Been Tested for Carcinogenic Activity", PHS-149, Volume 1 - Number 1230, Volume 3 - Number 847, Volume 4-Number 1234, Volume 5 - Number 704, Volume 6 - Number 534.

Hydrazine

Hydrazine (diamine, CAS No. 302-01-2) has been shown to be carcinogenic in mice after oral and interperitoneal administration and in rats following oral administration¹. It was negative in hamsters after oral administration¹. Hydrazine is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 3.5×10^3 kg hydrazine is emitted per year². In 1966, production of hydrazine was 7×10^6 kg per year with more than 70% of this going toward rocket fuels¹. In 1971 it was estimated that production was 1.4×10^6 kg and 1.7×10^7 kg in 1974^{3,4}. The demand for hydrazine is expected to increase 15-17% a year until 1985⁴. Hydrazine is polar, non-volatile and water soluble suggesting that it will not transfer to the atmosphere at significant rates¹. Oxidation by HO radicals in the gas phase is reported to be rapid with a half life of less than one hour³. It has a boiling point of 113°C and a vapor pressure of 16 mm at 20°C⁵.

⁵Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., N.Y., 1977.

Hydroquinone

Hydroquinone is listed on the NIOSH Suspected Carcinogen list, but it is apparently there by mistake. The 1955 reference cited¹ shows 20 mg of hydroquinone applied to the skin of mice (in benzene) developed only one tumor out of 22 surviving mice as compared with one tumor out of 22 surviving mice for the croton oil control. A more recent reference cites hydroquinone as a bladder carcinogen when implanted in cholesterol pellets producing 32% tumors vs. 12% for the cholesterol control². Hydroquinone is said to be an inhibitor of 3,4-benzpyrene carcinogenesis³, inactive as a promoter⁴, and slightly active as a promoter⁵ of carcinogenesis.

Hydroquinone has been reported as more toxic to repair deficient *E. coli* (pol A⁻) indicating that it may induce DNA damage⁶, but negative in inducing antibiotic resistance in *Micrococcus pyrogenus*⁶. Chromosome aberrations have been noted in several plant systems after treatment with hydroquinone⁷. These mutagenic references almost place hydroquinone on the possible carcinogen list, but they involve test systems which have not been extensively evaluated. Hydroquinone will be considered a probable non-carcinogen (with some significant positive data) for this project.

Kelthane

Kelthane has been found non-mutagenic to E. coli bacteria in the WP2 TYR to prototrophy test¹. It is considered a probable non-carcinogen for this project.

¹Ashwood-Smith, M. C.; "Mutagenicity of Dichlorvos", Nature, 240, 418-419, 1972.

Malathion

Malathion has been demonstrated not to be a teratogen¹ and Ames et.al consider it not to be a mutagen². It has been found to be a non-mutagenic in four test systems³, and a study by the National Cancer Institute found it to be non-carcinogenic to rats and non-carcinogenic to mice⁴. Malathion was found non-mutagenic by a dominant lethal test in mice⁵ but was a slight promoter in rats when given with dimethylbenz (a) anthracene⁶. For this project Malathion is classed as a probable non-carcinogen.

Maleic Anhydride

Only one 1963 reference cites maleic anhydride as a carcinogen¹. In this paper three rats of an unspecified species were injected 550 times with maleic anhydride. Two of the three rats developed fibrosarcomas at the injection site. No other indications could be found in the literature which suggests that maleic anhydride may be a mutagen or a carcinogen in any test systems. In the atmosphere maleic anhydride could be expected to be converted rather rapidly to maleic acid for which no evidence has been found to suggest it has any carcinogenic or mutagenic potential. Since maleic anhydride has some degree of toxicity and is a lacramator, animal studies will probably show it to be a non-carcinogen.

¹Dickens, F. and Jones, H. E. H., "Further Studies on the Carcinogenic and Growth-Inhibitory Activity of Lactones and Related Substances", British Journal of Cancer, 17, 100-108, 1963.

Mercaptobenzothiazole

Mercaptobenzothiazole (2-benzothiazolethiol, Captax, CAS No. 149-30-4) was one of the 80 chemicals evaluated as having the greatest potential for environmental effects¹. The study they cite is a negative mice feeding study² in which two groups of 36 mice of slightly different strains were given 464 mg/kg mercaptobenzothiazole in gelatin orally on days 7-28 and then 1492 ppm in their diet for 17 months with no increase in tumors found. Seventeen months is a little on the short side for carcinogen evaluation by present standards.

In another study³ it was given orally and subcutaneously at 100 and 215 mg/kg respectively to two mouse strains (36 mice per strain). It was found to cause a statistically significant (0.01 level) increase in type A reticulum cell sarcomas when given subcutaneously. It may have been tested for mutagenicity and teratogenic activity but the results are unclear⁴. Because of the limited tests thus far conducted, more data might change its classification, but it will be considered a possible carcinogen for this project.

Production and Persistence

The production of mercaptobenzothiazole is estimated at 6×10^7 pounds per year with the release of 6×10^7 pounds per year⁵. It is reactive towards RO ($t_4=8$ days), HO ($t_4=1$ day) and O_3 ($t_4=9.6$ hrs.)⁶.

Methyl Bromide

Methyl bromide has been tested on barley and is said to be a methylating compound¹. No other references were found on the mutagenic or carcinogenic potential of methyl bromide so it has been placed on the probable non-carcinogen list.

¹Ehrenberg, L., et al., "On the Reaction Kinetics and Mutagenic Activity of Methylating and Beta-Halogenoethylating Gasoline Additives", Radiat. Bot. 14 (3), 185-194, 1974.

Methyl Chloride

No data have been found indicating that methyl chloride (chloromethane, CAS No. 74-87-3) is a carcinogen (e.g. Toxline, Cancerline Survey of Compounds). However, it does appear to be a mutagen to *Salmonella typhimurium*¹. Because of the close correlation between mutagens and carcinogens, methyl chloride has been placed on the possible carcinogen list.

Production and Persistence

It is estimated that 2.3×10^7 Kg methyl chloride is emitted per year from stationary sources². Another estimate³ is 7.6×10^6 Kg/year released from a production of 2.1×10^8 Kg. Other production estimates are 2.1×10^6 Kg, and 2.2×10^6 Kg, 1.6×10^6 and 1.7×10^6 Kg produced in 1974, 1975, and 1976, with a projected growth of 6% per year⁴. Reaction in the atmosphere with the HO radical is slow with a half-life of about one year⁵. It takes 27 minutes for 50% of a 1 ppm water solution to evaporate at 25°C. Methyl chloride has a boiling point of -24°C and a vapor pressure of 3800 mm (5 atm) at 20°C and 2150 mm (2.83 atm) at 25°C⁶.

⁶Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., New York, 1977.

Methyl Ethyl Ketone

Methyl ethyl ketone (MEK, 2-butanone) is included on the NIOSH Suspected Carcinogen list because of a teratogenic reference and as a priority pollutant. MEK does appear to be embryotoxic, fetotoxic, and perhaps teratogenic when tested at high concentrations (1000-3000 ppm)^{1,2}. Rat feeding studies conducted in 1939 and 1940 were negative^{3,4}. Mouse skin application tests in 1965 of mixtures containing MEK were generally negative in the absence of benzo(a)pyrene⁵. MEK has also been tested on TA 1535, 1536, 1537, and 1538 strains of *S. typhimurium* bacteria (Ames Test) and on *E. coli* WP2 - try mutagen tests with both being negative⁵. No other references could be found on Toxline or Cancerline which indicate that MEK is a mutagen or a carcinogen. It is considered a probable non-carcinogen for this project.

⁶Shirasu, K., et al., "Mutagenicity Screening of Pesticides in

Methyl Methacrylate

Methyl methacrylate is on the NIOSH Suspected Carcinogen list because of a paper which shows that 0.25 mg/kg of the compound (1/5 LD₅₀) caused 8% of the rat fetuses to have gross abnormalities (hemangiomas) but no skeletal malformations. A search of the literature could find no other references indicating methyl methacrylate to be a mutagen or a carcinogen. It is therefore listed as a probable non-carcinogen for this project.

Singh, A. R. et al., "Embryonic-Fetal Toxicity and Teratogenic Effects of a Group of Methacrylate Esters in Rats", J. Dental Research, 51, 1632-1638, 1972.

4,4'-Methylene Bis(2-Chloroaniline)

4,4'-Methylene bis(2-chloroaniline) or MOCA (CAS No. 101-14-4) has been found to be a carcinogen in mice and rats after oral administration and produces distant tumors in the rat after subcutaneous administration¹. It is an OSHA regulated carcinogen². Many other positive references are found in Toxline and Cancerline and it is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 4.5×10^4 Kg is emitted per year from a 3×10^6 Kg production³. Other estimates of production are $1.5-2.5 \times 10^6$ Kg in 1970¹ and 1.5×10^6 Kg in 1972^{4,5}. The reaction with the HO radical in the atmosphere is estimated to yield a half-life of 12 hours⁴ or one day³ while the O₃ half-life is one day³ and the RO₂ half-life is 39 days³. It is said to have a melting point of 110°C¹ and a negligible vapor pressure⁵.

"4,4'-Methylene Bis(2-Chloroaniline)" in IARC Monographs on the Evaluation of Carcinogenic Risk of Chemicals to Man, Volume 4, 65-71, 1974.

OSHA Compliance Guide, 29 CFR Part 1910, 1973.

⁵Dorigan, J., et al., "Preliminary Scoring of Selected Organic Air Pollutants", National Technical Information Service Number PB 264 445, 1976.

Methylene Chloride

There are no positive data on methylene chloride (dichloromethane) in Toxline or Cancerline. Interim results of carcinogenic tests in a two-year inhalation study involving nearly 2,000 animals exposed to concentrations of methylene chloride as high as 3500 ppm were negative¹. One recent report cites methylene chloride as being a positive in the Ames test². Methylene chloride is still considered a non-carcinogen for this project until further testing is completed because of the negative NCI animal data.

"Methylene Chloride Passes Early Tests", Chem. Eng. News., 55 (19), 6, 1977.

²Mutation Research, Volume 53, January 1978.

Methylenedianiline

The IARC monograph¹ on methylenedianiline (4,4'-diaminodiphenyl methane, bis(p-aminophenyl) methane, CAS No. 101-77-9) indicates both positive and negative data have been obtained from animal testing of the compound. Given orally to rats, it was found to be non-carcinogenic. Apparently methylenedianiline is on the NIOSH safety alert list (this list has been requested from NIOSH) and because of significant positive results^{2,3} it can at least be considered a possible carcinogen.

Production and Persistence

It is estimated that 2.6×10^4 Kg is emitted per year from stationary sources⁴. The production has been estimated to be 5×10^4 Kg, 7×10^4 Kg, and 1×10^5 Kg in 1965, 1966, and 1972⁵. It has a melting point of 93°C and a boiling point of 231°C at 12 mm.

Methylstyrene

One reference cited in the NIOSH Suspected Carcinogen list shows methylstyrene to be a teratogen¹. Permissible exposure limits have been determined for methylstyrene². Application of methylstyrene to rabbit³ inhalation or rat skin^{3,4} demonstrated only a reversible⁴ irritating response to the chemical. Other toxic responses have been noted in rats, rabbits⁵, and housefly larvae⁶, but no indication of carcinogenic or mutagenic responses were found on Foxline or Cancerline.

Morpholine

Morpholine (diethyleneimide oxide, tetrahydro-1, 4-isoxazine, CAS No. 110-91-8) is cited in one reference as causing neoplastic effects in the mouse after oral administration of 6.33 gm/kg over 28 weeks¹. This refers to a study (with no control animals) in which 40 swiss mice (20M, 20F) were given neutralized morpholine in their food². After 40 weeks, 5 malignant lymphomas and 5 lung adenomas were found in the surviving 38 animals. (When given in combination with sodium nitrite, many more tumors were found.)

In another study, 100 g/kg morpholine as 0.5% of the diet for rats produced no tumors, but 0.5% sodium nitrite added gave 7 tumors³. Many other studies have been conducted with sodium nitrite add to produce nitrosomorpholine in air and in water. In Russian studies, morpholine in the air in 0.008-0.07 mg/l concentrations for four months caused mutagenic chromosomal aberrations in bone marrow cells in rats⁴ and guinea pigs⁵. The future classification of morpholine requires more data, but for this project it will be considered a possible carcinogen.

Production and Persistence

It is estimated that 1×10^7 lbs is produced and 5.5×10^6 lbs is emitted per year⁶.

Naptha

Naptha (coal tar naptha) was found in the report "Preliminary Scoring of Organic Air Pollutants" (PB 264 446) cited as a recognized carcinogen. Actually naphas vary in composition depending on their source with coal tar naptha being mainly benzene and its homologs¹. From other sources naphtha could be principally paraffins, methanol and acetone, or gasoline¹. Even as a mixture, naptha is not found in the Survey of Compounds Which Have Been Tested for Carcinogenic Activity. Of the primary ingredients of naptha, only benzene is a recognized carcinogen and since it is covered separately, naptha will be dropped from consideration.

your dictionary.

1-Naphthylamine

1-Naphthylamine (alpha-naphthylamine, CAS No. 134-32-7) had no carcinogenic effect when given orally to hamsters and both oral and subcutaneous tests with mice give inconclusive results¹. In dogs, it was demonstrated that 1-naphthylamine, if carcinogenic at all, was less so than the 2-isomer¹. Other tests on dogs², hamsters, mice rats, and rabbits³ show that 1-naphthylamine may be carcinogenic and also it is generally contaminated with the 2-isomer which is a potent carcinogen^{1,4}. It is an OSHA regulated carcinogen (Code of Federal Regulations 29 CFR 1910.1004) whether or not it is truly a carcinogen⁵. It is also a positive on the S. typhimurium test⁵, and an enhancement of viral transformation test⁵. For these reasons, it is considered a possible carcinogen for this project.

Production and Persistence

Production has been estimated to be 5×10^4 Kg in 1963⁶ and 3.2×10^5 Kg in 1974⁶. It reacts with oxidizing materials in the atmosphere⁷ and reacts with the HO radical in air with a 12 hour half-life⁸. It has a boiling point of 300.3°C and a vapor pressure of 1 mm at 104.3°C⁹.

Napthalene

Napthalene (CAS No. 91-20-3) has generally been negative when given to rats and mice by various routes of administration (including 10 g total oral dose over 33 months) with only a few tumors reported by other authors in experiments without control animals¹. It is generally considered to be a non-carcinogen by various authors². It has been tested in G46 S. typhimurium and K-12 E. coli strains³. Another reference reports negative results for S. typhimurium strains TA 98, 100, 1535 and 1537⁴. Napthalene is considered a probable non-carcinogen for this project.

Napthoquinone

Napthoquinone is on the NIOSH Suspected Carcinogen list because of a 1940 Japanese reference¹. In this paper α -napthoquinone (in benzene) painted on daily on the back of mice caused 3/77 skin cancers and 11/77 papillomas compared to 0/46 skin cancers and 1/46 papillomas for benzene alone on mice surviving 200 days. β -Napthoquinone produced no cancers or papillomas out of 25 mice surviving 200 days.

A survey of recent literature from Toxline, Cancerline, and the Volumes 1 - 7 of the "Survey of Compounds which Have Been Tested for Carcinogenic Activity" found no pertinent references. Since the only positive reference is outdated and used benzene as the solvent, napthoquinone is being placed on the probable non-carcinogen list for this project.

¹Takizawa, N. "On the Carcinogenic Action of Certain Quinones", Proc. Imperial Acad. (Tokyo) 16, 309-312, 1940.

1-Naphthyl Methylcarbamate

The primary reference to this compound carcinogenic potential from a Russian journal has not been obtained. Another Russian reference from the same year¹ declares that 2-naphthyl methylcarbamate is carcinogenic while 1-naphthyl methylcarbamate is non-carcinogenic. 1-Naphthyl methylcarbamate tested on male and female mice of two strains was found to be non-carcinogenic². No other references were found in Cancerline to indicate that this chemical is a carcinogen. There are negative mice feeding studies (18 months) and rat intergastic studies reported³. It is probably a non-carcinogen based on the available literature.

Nitrobenzene

Although on structural basis nitrobenzene (CAS No. 98-95-3) has been predicted to be a carcinogen, there was no positive indication from actual tests of the chemical cited in "Air Pollution Assessment of Nitrobenzene"¹ or on Cancerline or Toxline. It has been reported to induce sex-linked recessive lethal mutations in *Drosophila melanogaster* when administered as a vapor for 8-10 days². With only one *in vitro* positive test reported, nitrobenzene will be considered a non-carcinogen (with some positive data) for this project.

²Allport, J., et al., "A Study of Industrial Data on Candidate Chemicals for Testing", National Technical Information Service Number PB 274 264, 1977.

Nitrophenol

No data on the carcinogenicity of nitrophenols could be found on Cancerline or Toxline but p-nitrophenol has been found to be mutagenic by one test system and non-mutagenic by five other test systems¹. When comparing S. typhimurium test results with other systems, Ames classified nitrophenol as a non-mutagen². For this project, nitrophenols will be classed as probable non-carcinogens.

²McCann, J. et al., "Detection of Carcinogens as Mutagens in the Salmonella/Microsome Test: Assay of 300 Chemicals", Proc. Nat. Acad. Sci. (USA) 72, 5135-5139, 1975.

Nitrosodimethylamine

There are much data showing nitrosodimethylamine (dimethylnitrosamine) to be a potent carcinogen¹. It has, therefore, been placed on the probable carcinogen list for this project. In the final selection of carcinogens, however, it may not be advantageous to select this compound. This is because nitrosodimethylamine rapidly decomposes in sunlight², under normal conditions is of no significance as an air pollutant², and is generally only found in the air near certain manufacturing plants which had (now repaired) leaks in their system³.

Production and Persistence

Nitrosodimethylamine is emitted in less than 100 Kg/year quantities from the dimethylhydrazine stationary sources⁴. One estimate of production is less than 450 Kg/year⁵. Photolysis of nitrosodimethylamine is reported to be rapid with a half life of less than one hour⁵. It has a boiling point of 152 C⁶.

Nitrochlorobenzene

Nitrochlorobenzene (chloronitrobenzene) has been found to mutate *Salmonella typhimurium*¹ and is indicated as a carcinogen causing neoplasms in another reference summary sheets while listed as not tested in the same appendix². For this project it will be considered a possible carcinogen.

Production and Persistence

It is estimated that 3×10^7 Kg nitrochlorobenzene is emitted per year from stationary sources¹. An estimate of production is 6.4×10^7 Kg, produced of each of the isomers in 1967². Nitrochlorobenzene reacts with oxidizing materials in the atmosphere². In the soil, microflora decomposes this chemical in 64 days¹. The m,p, and o-isomers have boiling points of 236, 242, and 245°C with a vapor pressure of 10 mm at 25°C².

Tardiff, R. G., et al., "Halogenated Organics in Tap Water: A Toxicological Evaluation" in The Environmental Impact of Water Chlorination, National Technical Information Service Number CONF 751096, p. 213-228, 1976.

Parathion

Nothing was found in Cancerline to indicate that parathion is a mutagen or carcinogen. The NIOSH Suspected Carcinogen list reference cites parathion as being a slight teratogen only when given in sufficient quantity as to cause toxic poisoning to be apparent in the dams¹. It has been found to be non-mutagenic by several different ~~in vitro~~ tests², but does cause an antimitotic action in cells.³ It is therefore classified as a probable non-carcinogen for this project.

Grant, W. F., "Cytological Effects of Environmental Mutagens - Pesticides", Mutat. Res. 21 (4) 221-242, 1973.

Pentane

Although n-pentane is cited as a carcinogen in one reference¹, no primary references could be found to substantiate this allegation from Toxline, Cancerline, or the Survey of Compounds Which have been Tested for Carcinogenic Activity. It is said that aliphatic hydrocarbons may be co-carcinogens². For this project pentane will be considered a non-carcinogen.

Pentachlorophenol

Pentachlorophenol (CAS No. 87-86-5) has been found negative in some relatively short studies on rabbit skin and orally in rats, and cats¹. More recently it has been found negative in two strains of mice both orally and subcutaneously⁴. Pentachlorophenol is also negative in *Drosophila* tests⁵, in a host-mediated assay in mice⁶, and other microbial systems⁷.

Some authors consider pentachlorophenol a known mutagen⁶, and there are other positive as well as negative short term tests reported⁸. It is also positive at the 100 µg level in the hamster embryo adenovirus enhancement assay⁹. For these reasons, pentachlorophenol will be considered a possible carcinogen for this project for the first round of evaluations.

Production and Persistence

One estimate of production is 2.1×10^7 Kg (1969 capacity) and a consumption of 2.3×10^7 Kg in 1975¹⁰. In the soil it degrades completely in >72 days¹⁰. It has a boiling point of 310°C and a vapor pressure of 1.1×10^{-4} mm at 20°C¹¹.

Phenol

Phenol (hydroxybenzene, CAS No. 108-95-2) has been reported to give rise to papillomas after administration on mouse skin^{1,2}. Phenol has also been reported negative by injection and negative on the skin of mice³. It has recently been given in combination with other chemicals³. In mutagenicity tests, phenol has been found to be mutagenic to *Drosophila*, revert *E. coli* to streptomycin independence, and induce chromosome breakage in the root tip of *Allium cepa* while being inactive in reverting *Neurospora crassa* to adenine prototrophy⁴. Phenol is also said to cause second chromosome breaks in *Drosophila*, cause chromosome breaks in *Vicia* and *Allium sativum* and it is teratogenic in chickens⁵. One must also remember, however, that normal adults excrete approximately 30 mg of volatile phenols per day in their urine (mainly p-cresol and phenol) produced by gut bacterial metabolism of tyrosine⁶. Phenol has tested negative in a micronucleus test⁷. The only positive animal tests were conducted in the 50's with later negative results. The positive *in vitro* tests are with systems which have not been extensively evaluated. Although it is a borderline chemical, phenol will be considered a probable non-carcinogen (with some positive data) for this project.

Polychlorinated Biphenyls

Polychlorinated biphenyls (PCB, chlorinated diphenyls, Aroclors, Kanechlors) have been cited extensively in the literature as carcinogens^{1,2}. On close inspection, many of the carcinogenicity studies on PCB's have been questionable^{3,4} or negative⁵ and the increase in cancer among PCB workers has been questioned⁶. The latest NCI study of PCB's was negative but they concluded that from the open literature PCB's are probably promoters of carcinogenesis. The PCB's fall on the border between possible and probable carcinogens using the criteria for this project. Because of the positive animal studies¹⁻⁷, it will be classed as a probable carcinogen for this project.

Production and Persistence

It is estimated that 1.8×10^4 kg is emitted per year⁸. Other estimates of production are 1.4×10^7 kg, 2.5×10^7 kg, and 1.8×10^7 kg (1974)⁹⁻¹¹. Production of PCB's has been phased out within the last year so emissions should have dropped to zero. PCB's are essentially non-volatile, but evaporation to the atmosphere is thought to be important¹². Reaction with HO radical predicts a half life of 26 days¹³. They have a boiling point of 365-390°C and a vapor pressure less than 1 mm at 25°C¹⁴.

Propanol

In 1939 and 1940, propanol (propyl alcohol, CAS No. 71-23-8) was found non-carcinogenic in rat feeding studies^{1,2}. The only current references which could be found were by Gibel et al. who refer to tumor formation after oral (50g/Kg) and subcutaneous (6gm/Kg) administration of propanol to rats³ and an E. coli test⁴. The studies which have been conducted on isopropanol have been negative⁵. Propanol will be considered a probable non-carcinogen (with some significant positive data) for this project.

Propylene Oxide

Propylene oxide (methyloxirane, 1,2-epoxypropane, CAS No. 75-56-9) has been reported to cause local sarcomas in a limited number of rats after subcutaneous injection¹. It was negative in relatively short-term (~200 days) studies in rats, guinea pigs, rabbits and monkeys given propylene oxide by inhalation^{1,2}. By *in vitro* tests, transformation of hamster cells³ occurred at 250 mg/ml⁴. It is also reported to cause reversion to adenine, prototrophy in *Neurospora crassa* and cause recessive lethal mutation in *Drosophila melanogaster*⁵. For this project it will be considered a possible carcinogen.

Production and Persistence

It is estimated that 4.4×10^6 kg propylene oxide is emitted per year⁶. Other production estimates include 7.5×10^8 kg per year⁷, 8.0×10^6 kg (1974)⁸, 8.0×10^8 kg (1975)¹, and 7.0×10^9 kg (1975) with U. S. consumption predicted to grow by 9-10.5% a year from 1975 to 1980⁹. If dispersed in the atmosphere, epoxides would be oxidized by HO radicals with a half life of 3-11 hours¹⁰. The rate constant and half life for HO radical reaction predict a 23 hour half life for aliphatic epoxides¹⁰. Propylene oxide has a boiling point of 33.9°C and a vapor pressure of 596 mm at 25°C¹¹.

Pyrene

Pyrene (CAS No. 129-00-0) has generally been tested on mouse skin with negative results¹. It has also been reported negative on mouse skin followed by croton oil or preceded by benzo(a)pyrene¹. It is usually considered to be non-carcinogenic^{2,3} and has been reported as non-mutagenic to *S. Typhimurium* strains TA 98, 100, 1535 and 1537³. It is considered a non-carcinogen for this project.

Survey of Compounds Which Have Been Tested for Carcinogenic Activity, NCI, PHS-149, Volumes 1, 3, 4, 6, and 7.

Sorbic Acid

Sorbic Acid (2,4-hexadienoic acid, CAS No. 110-44-1) is a widely used food preservative. In 1966 and 1968, Dickens et al. reported several rat studies with sorbic acid. In these tests (using 6-12 rats) sorbic acid injected subcutaneously at 2 mg/injection in oil or water sometimes caused local fibrosarcomas at the injection site¹⁻³. Given in the drinking water at 0.1 gm/l, no effects were seen³. It is now known that the pH of the injected solution may cause local fibrosarcomas in some strains of rats. In more recent dose response studies, rats⁴ and mice⁵ (groups of 400 animals) were given 0, 1.5, or 10% of their diet as sorbic acid with no carcinogenic response. Also sorbic acid with 1000 ppm parasorbic acid gave no carcinogenic response⁶. Several *in vitro* tests (eg B. subtilis) have been negative for sorbic acid but positive for reaction products of sorbic acid and sodium nitrite⁷. Better subcutaneous tests should be conducted on sorbic acid, but the negative results on the recent large scale feeding tests and negative *in vitro* results suggest that sorbic acid should be considered a non-carcinogen at the present time.

Styrene

Styrene (vinyl benzene, CAS No. 100-42-5) has been found to be both positive^{1,2} and negative³ on the Salmonella typhimurium mutagen test after activation with S-9 microsomes. Without S-9 activation it has been found negative by this test^{1,3}. In other systems, styrene was found positive on a host-mediated forward mutation, gene-conversion yeast system but negative in this system with microsomes only (not host-mediated). It was negative on a Chinese hamster cell test⁴, in Drosophila melanogaster and S.pombe mutation test⁵, and in enhancement of viral transformation tests⁶. It would thus appear that a metabolic product of styrene is a weak mutagen and styrene should probably be considered a possible carcinogen.

Production and Persistence

It is estimated that 5.6×10^6 Kg styrene is emitted per year from stationary sources⁷. Another source estimate 2.0×10^9 Kg (1975) produced⁸. It has a 1.28 relative chemical reactivity in the atmosphere (where methane is zero, butane is 1.27, 2-pentane is 1.58 and 2-butene is 15.5)^{9,10}. Styrene has a 145.2°C boiling point and a vapor pressure of 5 mm at 20°C⁹.

Sulfolane

Sulfolane (tetrahydrothiophene, -1-dioxide, CAS No. 126-33-0) was one of the eighty chemicals selected as having the greatest potential environmental effects¹. Carcinogenicity and mutagenicity were not cited as reasons for its selection. No data could be found in any of the references searched pertaining to mutagenicity or carcinogenicity of this chemical. It is considered a probable non-carcinogen for this project.

¹Brown, S. L. et al. "Research Program on Hazard Priority Ranking of Manufactured Chemicals," National Technical Information Service Number PB 263 161, 1975.

Tetrabromoethane

Tetrabromoethane (CAS No. 79-27-6) was one of eighty chemicals having potential for environmental effects¹. It has tested negative in some short term (92 day), limited exposure (15 min./day) tests on rats, mice, rabbits and guinea pigs². It has tested positive in a *E. coli* (pol A+, pol A-) differential growth mutagen test but negative in *S. typhimurium* strains TA1530 and TA 1535^{3,4}. With only one *in vitro* positive test (which has not been extensively validated) tetrabromoethane will be considered a probable non-carcinogen for this project.

⁴Rosenkranz, H. S., "Mutagenicity and DNA-Modifying Activity: A Comparison of Two Microbial Assays," Mutat. Res. 41 (1), 61-70 1976.

Tetrachloroethane

1,1,2,2-Tetrachloroethane (CAS No. 79-34-5) has been found to be mutagenic in the Salmonella typhimurium system for TA 1530 and TA 1535 strains¹. It has been cited as a carcinogen based on a National Cancer Institute bioassay² where it was found to be a carcinogen for mice but not for rats³. It is therefore considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 0.4×10^3 Kg is emitted per year from stationary sources (in making trichloroethylene from ethylene)⁴. Evaporation of 50% from a 1 ppm solution of water at 25°C will occur in 56 minutes⁵. It has a boiling point of 146.4°C and a vapor pressure of 5 mm at 20°C⁵. Water solubility is 2.9 gm/l at 20°C⁵.

⁵ Verschueren, K., Handbook of Environmental Data on Organic Chemicals, Van Nostrand Reinhold Co., New York, 1978.

Tetrachloroethylene

The NTIS document "Air Pollution Assessment of Tetrachloroethylene"¹ cites extensive toxicological data but reports no evidence of carcinogenicity, mutagenicity or teratogenicity for tetrachloroethylene (perchloroethylene, CAS No. 127-18-4) in humans. Also no difference in the incidence of tumors were observed between control and experimental rats exposed to 300 or 600 ppm of tetrachloroethylene. A recent report by NCI however, has shown tetrachloroethylene to be a liver carcinogen in B6C3F1 of both sexes. Tetrachloroethylene has, therefore, been assigned to the PROBABLE carcinogen list.

Production and Persistence

It is estimated that 7.8×10^7 Kg tetrachloroethylene is emitted per year from stationary sources with solvent evaporation from degreasing operations accounting for better than 99% of that quantity². Other estimates of production are 3.0×10^7 Kg (1975)², 3.3×10^7 Kg produced and 2.6×10^7 Kg released², and production of 3.3×10^7 Kg, 3.1×10^7 Kg, and 3.0×10^7 Kg in 1974, 1975, and 1976². A 1976 forecast projected a yearly growth of 3-4% but in light of the NCI carcinogen study, lower standards for occupational exposure from NIOSH, and a decrease in fluorocarbon use, the production of tetrachloroethylene is expected to decrease². It is not photoactive and has an expected HO radical reaction half-life of 8 days². Another reference cites photodegradation with a half-life of 2 days². Evaporation of 50% from a 1 ppm water solution at 27°C will take only 24-28 minutes². It has a boiling point of 121.2°C and a vapor pressure of 14 mm at 20°C².

Tetraethyl Lead

Tetraethyl lead (tetraethyl plumbane, CAS No. 78-00-2) has been found to induce lymphomas when injected subcutaneously into neonatal mice¹ although the significance of this test has been questioned². Oral doses were not found to be teratogenic³ and an epidemiological study found no health hazard from occupational exposure⁴.

Tetraethyl lead has been found to cause DNA fragmentation and to enhance viral transformation in hamster embryo at the 12.5 µg level⁵. Tetraethyl lead is considered a possible carcinogen for this project.

Production and Persistence

One estimate of release to the environment is 1.3×10^5 Kg per year⁶ from a production of 1.4×10^5 Kg. The release figure notes that most of this is through use in gasoline where it is converted to lead halides and some lead phosphates⁷. Another set of figures cites a release of 6.6×10^5 Kg from a production of 1.6×10^6 Kg in 1973⁸. The 1971 production has been estimated to be 2.4×10^6 Kg⁹. The production of tetraethyl lead is expected to decrease rapidly from these figures because of regulations requiring less lead in gasoline¹⁰. In the air it has a half-life of 2-3 days from reactions with HO and O₃ radicals¹¹. It has a boiling point of 200°C (decomposes) and a vapor pressure of 0.15 mm at 20°C¹².

Toluene

An extensive search of Cancerline and Toxline along with the NTIS document "Air Pollution Assessment of Toluene"¹ and the Stanford Research Institute hazard priority ranking² failed to find data which would indicate that toluene is a carcinogen. It tested negative³ in a differential growth mutagen test using E. coli (pol. A) and will be considered a non-carcinogen for this project.

¹Walker, P., "Air Pollution Assessment of Toluene", National Technical Information Service Number PB 256 735, 1976.

Toluene Diisocyanate

There is no data on Toxline or Cancerline to indicate that toluene diisocyanate is a mutagen or a carcinogen.

Toluenediamine

Toluenediamine (toluene-2,4-diamine, CAS No. 95-80-7), generally used as a hair dye, has been found by several studies to be non-carcinogenic when applied to the skin of mice^{1,2} and rats³ although the same data can be interpreted to show increased lung tumors and total tumors in the test groups⁴. Toluenediamine has been reported to produce hepatomas in rats when fed at 9.1 percent of diet for 35 weeks⁵ or 11 gm/kg for 36 weeks⁶. In rats, 280 mg/kg (35 weeks) subcutaneously is reported to cause neoplasms⁷. It has also been found to cause morphological transformation in primary Syrian hamster embryo cells. It also mutates *Salmonella typhimurium* strains TA 1538 and TA 98 at 0.5 µg/ml when activated with the S9 microsomes^{8,9}. With positive *in vivo* and *in vitro* tests, toluene-diamine will be considered a probable carcinogen for this project.

Production and Persistence

One estimate of production is 2.9×10^7 Kg per year with 0.015 as a fraction of production loss⁷. It has a boiling point of 292°C and a vapor pressure of 1 mm at 106.5°C⁷.

Toxaphene

No significant data were found to indicate that toxaphene is a mutagen or a carcinogen. It tests negative on the dominant lethal test for mice¹. It has been placed on the probable non-carcinogen list for this project.

¹Epstein, S. S. et al., "Detection of Chemical Mutagens by the Dominant Lethal Assay in the Mouse", Toxicol. Appl. Pharmacol.

Trichlorfon

Trichlorfon has been found to be carcinogenic to mice, rats, and cats given orally, subcutaneously, cutaneously, or intermuscularly. It has also been found to be mutagenic by at least five different test systems. It is, therefore, to be considered a probable carcinogen.

Production and Persistence

It is estimated that 100 kg/year of trichlorfon is emitted from stationary sources¹.

¹MRC Source Assessment Data Base, July 1977.

Trichloroethane

A National Cancer Institute bioassay of 1,1,1-trichloroethane found no correlation between this chemical and any cancers which developed in the control versus the test rats and mice¹. It was negative on an enhancement of viral transformation test². It has been placed on the non-carcinogen list for this project.

"Bioassay of 1,1,1-Trichloroethane for Possible Carcinogenicity",
Carcinog. Tech. Rep. Ser. - Nat'l. Cancer Inst. (U.S.); ISS
NCI-CG-TR-3, 70 pp., 1975.

Personal communication with Dr. C. B. Basto on 9 February 1978.

Trichloroethylene

Trichloroethylene (trichloroethene, TCE, CAS No. 79-01-6) has been found to induce a high incidence of hepatocellular carcinoma in B6C3F1 mice of both sexes by NCI¹. It has also been found to be weekly mutagenic in *E. coli* and to TA100 strain of *S. typhimurium* (0.8-2.0% vapor dose response when exposed one hour) in the presence of activated microsomes². A review of the production, uses and environmental effects has been compiled by Fishbein³. TCE is considered a probable carcinogen for this project.

Production and Persistence

It is estimated that 1.6×10^6 kg of TCE is emitted per year with 95% of that coming from solvent evaporation in degreasing operations⁴. Another estimate is a production of 1.93×10^6 kg with 1.95×10^6 kg released⁵. Other production estimates include 1.8×10^6 kg (1974) and 1.3×10^6 kg/year, with about 60% of the production released to the environment⁶. Production has also been reported to be 1.8×10^6 kg (1974), 1.3×10^6 (1975) and 1.4×10^6 kg (1976) with a 1% decline predicted for future years⁷. Since that prediction, OSHA has lowered the standard for occupational exposure and NCI found that TCE causes tumors in mice which will mean a much greater decline in the expected production⁸. TCE has a high atmospheric photodegradation rate with a half life of 0.3 days at sea level⁹. Other sources predict atmospheric reaction with the HO radical with a half life of 36 hours or less than 50 hours¹⁰. With its high volatility and low water solubility it is expected to fairly rapidly migrate into the atmosphere. In fact 50% of a 1 ppm solution will evaporate from water at 25°C in 19-24 minutes¹¹. Its boiling point is 86.7°C and it has a vapor pressure of 60 mm at 20°C¹².

Trichlorofluoromethane

In mice, trichlorofluoromethane (Freon-11, F-11) in combination with the insecticidal synergist piperonyl butoxide increased the incidence of malignant hepatomas while Freon-11 by itself was found to be non-carcinogenic¹. No other carcinogenic data was on Freon-11 and it has been found to be non-mutagenic in Salmonella typhimurium tests with and without microsomal activation². Preliminary results from an NCI bioassay shows no difference between control and treated male or female rats³. It is probably not a carcinogen.

³NCI preliminary data on trichlorofluoromethane, Nov. 27, 1976.

Trichlorophenol

Trichlorophenol (2,4,6-trichlorophenol, "Dowicide 2S, CAS No. 88-06-2) has been found to be a carcinogen in mice when given orally but not subcutaneously^{1,2}. 7/72 heptomas, 6/72 pulmonary adenomas, and 7/72 reticulum cell sarcomas were found. (2,4,5-trichlorophenol was only evaluated by subcutaneous route¹ and was found negative by this route of administration, as was 2,4,6-trichlorophenol). Trichlorophenol may cause abnormal pollen in broad bean plants¹. No other pertinent literature reference were found on Toxline or Cancerline to substantiate or refute the carcinogenic potential of trichlorophenol. It has been placed on the possible carcinogen list for this project.

Production and Persistence

It is estimated that 5×10^7 Kg trichlorophenol is emitted from stationary sources per year⁴. Since this is used as a pesticide, non-stationary sources (or total production) should be considered. It completely disappears in soil suspensions in 5 days⁵. Trichlorophenol (2,4,6) has a boiling point of 244.5°C and a solubility of 800 mg/l at 25°C⁵.

Urethane*

Urethane (ethyl carbamate, CAS No. 51-79-6) has been shown to be carcinogenic in mice, rats and hamsters following administration by the oral, inhalation, subcutaneous or intraperitoneal routes¹. It generally causes lung tumors, lymphomas, hepatomas, melanomas, and vascular tumors. With all of this positive data, urethane is considered a probable carcinogen for this project.

Production and Persistence

The only production data which could be found cited production from one US company with data not given and production below 454 Kg from a second company¹. It has a boiling point of 183°C and sublimates at 102°C at 54 mm Hg, and is volatile at room temperature¹.

*The name urethane is sometimes applied to high molecular weight polyurethanes used as forms, elastomers and coatings. Such products are not made from the chemical urethane and do not generate it on decomposition.

¹"Urethane" in IARC Monographs on the Evaluation of Carcinogenic Risk of Chemicals to Man, Volume 7, 111-140, 1974.

Vinyl Acetate

Vinyl acetate (CAS No. 108-05-4) has been found to be non-carcinogenic in rats at 2,500 ppm for 4 hrs./day for 12 months by C. Maltoni¹. It has also been found negative on mouse skin², mouse sebaceous glands³, and S. typhimurium tests⁴⁻⁶. Both commercial vinyl acetate and repeated tests of purified vinyl acetate have been found to be mutagenic at a level of 150 ug/ml in viral transformation, vinyl acetate will be considered a possible carcinogen for this project for the first round of evaluations.

Production and Persistence

It is estimated that 6.8×10^6 Kg is emitted per year from stationary sources⁷. Another estimate is a release of 7.8×10^6 Kg from a production of 5.5×10^7 Kg⁸. It reacts with oxidizing materials in the atmosphere⁹, and has a boiling point of 73°C and a vapor pressure of 83 mm at 20°C¹⁰.

Vinyl Bromide

Vinyl bromide (bromoethylene, CAS No. 593-60-2) has not been tested very much. It was not found on the Survey of Compounds Which Have Been Tested for Carcinogenic Activity and from Cancerline and Toxline only one author has conducted *in vitro* tests on it. In this test, *Salmonella typhimurium* strain TA100 was found to give a dose-response mutation frequency of 26 and 9 revertants per micromole per hour with and without the S9 liver microsome fraction¹. It was also found that liver fractions from human biopsies converted vinyl bromide to more mutagenic compounds. Another study by the same authors demonstrated that vinyl bromide is activated by the liver homogenates in the same manner as vinyl chloride. Although there is not much data with which to base any decision, vinyl bromide will be considered a possible carcinogen for the first phase of this project.

Production and Persistence

It is estimated that 4×10^3 kg/year of vinyl bromide is emitted from stationary sources.²

¹ Bartsch, H. et al., "Alkylating and Mutagenic Metabolites of Halogenated Olefins Produced by Human and Animal Tissues," *Proc. Am. Assoc. Cancer Res.* 17, 17, 1976.

³ MRC Source Assessment Data Base, July 1977.

Vinyl Chloride

Vinyl chloride (CAS No. 75-01-4) has been found to cause lung tumors, mammary carcinomas and angiosarcomas in mice following exposure by inhalation¹. Similiar exposure for rats produces angiosarcomas of the liver and other organs, zymbal gland carcinomas and nephroblastomas¹. In view of the extreme rarity of angiosarcoma of the liver in the general population, 16 cases in vinyl chloride workers is evidence of a causal relationship. It has also been found to be a mutagen of *S. typhimurium* (Ames test)² and in enhancement of viral transformation³.

Production and Persistence

It is estimated that 1.4×10^7 kg is emitted per year⁴. The 1973 production of vinyl chloride was 2.4×10^7 kg in the United States of which 97% was used for production of polyvinyl chloride¹. A 1974 EPA estimate was 9×10^7 kg released to the atmosphere¹. Other estimates of production are 2.5×10^7 kg (1974)⁵ and 2.5×10^7 kg, 1.9×10^7 kg and 2.6×10^7 kg in 1974, 1975, and 1976⁶. The demand for PVC is expected to increase at an annual rate of 8-10% through 1981⁷. In the atmosphere it reacts with the HO radical with a 12 hour half life¹. It has a boiling point of -14°C and a vapor pressure of 2660 mm at 25°C¹.

Vinylidene Chloride

Vinylidene chloride (1,1-dichloroethylene, CAS No. 75-35-4) has been found to be mutagenic in the Salmonella typhimurium test¹⁻³ and in a metabolizing *in vitro* system with E. coli K12⁴. It has also been reported to be carcinogenic in rats and rabbits⁵ and in preliminary studies 200 ppm were carcinogenic to rats and mice by inhalation⁶. One reference concludes that airborne emissions of vinylidene chloride are not likely to pose a significant risk to the general population⁷. Vinylidene chloride has been placed on the probable carcinogen list for this project.

Production and Persistence

It is estimated that 2.1×10^5 Kg are emitted a year from stationary services, with 70% of this coming from the oxychlorination of ethylene dichloride⁸. Other estimates of production and release are production of 2.7×10^7 Kg with 4.1×10^5 Kg released⁹, production of 1.2×10^8 Kg with $1.4 - 1.8 \times 10^6$ emitted and a 5 - 10% growth rate predicted⁷, 1.2×10^4 Kg produced with 1.1×10^5 Kg released¹⁰, 7.7×10^7 Kg produced from 1973 - 1975 with a 7% growth predicted¹¹, and 2.7×10^7 Kg produced in 1972¹². The O_3 and HO reactions are estimated to give less than a one-day half life¹³ while another reference cites HO half life of 26 hours¹⁴. Evaporation of 50% from a 1 ppm solution at 25°C will occur in 22 minutes¹⁵. It has a vapor pressure of 617 mm at 25°C and a boiling point of 37°C¹⁶.

Xylene

Some literature suggests that xylenes are non-carcinogenic irritants^{1,2}. Other literature indicates that all of the xylenes cause neoplasms on mice after dermal application³. This may refer to the same study where an increased number of unspecified tumors were observed in the mouse upon dermal application of mixed xylene after the use of croton oil or methane⁴. The results of this study are considered equivocal⁴ and would at most suggest that xylenes are promoters. The old xylene carcinogen literature is negative after skin painting mice⁵ and xylene is considered a non-carcinogen for this project.

INTRODUCTION

Samples of water taken from four sites in the area of the Kearny Plant of Monsanto Industrial Chemicals Company were analyzed for PCB content.

RESULTS

The PCB concentrations found are presented below.

<u>Sample Identification</u>	<u>PCB Concentration, ppb</u>
Ground well	0.06
River above plant	0.11
River at plant	2.7
River below plant	0.48

EXPERIMENTAL METHOD

The samples were worked up following the procedure of ASTM D-1304, Analysis of Environmental Materials: Polychlorinated Biphenyls. Analysis of the extracts obtained following workup were done by electron capture gas chromatography under the following conditions:

GC Model:	Varian Model 3700
Column:	6' x 1/4" glass packed with 4% XE-60
Column Temperature:	200°C
Injection Temperature:	220°C
Detector Temperature:	350°C
Carrier Gas:	N ₂ at 45 ml/min
PCB's Screened For:	Aroclor 1254 and Aroclor 1242

PCB's were identified by comparing the sample chromatograms to standard chromatograms for Aroclor 1242 and 1254, two PCB's that have been used widely. The PCB concentration was then determined from the calibration curve for the appropriate standard.
