SUBJECT: BROCHURE ON
SILVER ANNIVERSARY ROOFS

To Members of the Lead Industries Association, Inc.:

We are pleased to enclose a copy of our just published brochure entitled "Silver Anniversary Roofs." In it are described four sheet lead roofs that have provided their owners with 25 and more years of maintenance-free service.

The brochure will be mailed to our list of over 12,000 architects, building contractors and others in the building field. It will also be used for distribution at our exhibit booths at the American Institute of Architects' meeting, and the National Association of Home Builders Show.

Additional copies are available free of charge in quantities up to 25 and at our cost of 15¢ each for larger quantities.

Sincerely yours,

David M. Borcine

Look Ahead with Lead

ALA 12-A-3

NEW JERSEY STATE PRISON FARM

Back in 1935, the New Jersey State Prison Farm looked like this (left) as the dome was being reroofed with 3-lb hard lead. Note the vintage autos in this picture. Twenty-five years later (right)—the dome has a timeless silvery-gray patina. There is no evidence of discoloration of the stone-

work by rain-water runoff. Total maintenance to the roof was insignificant damage to one sheet, among the hundreds, which worked loose in a hurricane. It was quickly readjusted after the storm. Close-up shows how the loose-lock horizontal

seams mate with vertical butt seams. No solder was used since the joints were filled non-hardening mastic during installation.

As a testing ground embodying the most rugged conditions any roofing material might be called upon to answer, the atmosphere over New Jersey's heavily congested industrial areas is preeminent. Acid forming wastes from a thousand refineries, smelters, and factory chimneys present a constant hazard.

Almost in the midst of this territory stands one of the largest lead covered domes in the world. Finished in three pound hard lead this roof covers the main building at the New Jersey State Prison Farm in Rahway. The Edwin R. Muddy & Sons Co. of Trenton, N. J. were responsible for the craftsmanship on this job which has withstood the searing heat of summer sun as well as winter's stinging cold since 1935 without any expenditure for maintenance. The pictures here show the dome at its twenty-fifth anniversary with the characteristic lead patina in evidence. Equally important is the fact no discoloration from rain-water runoff has marred the stonework below. The close-up of roof construction shows sheets loose locked to battens and to each other with flat seams staggered on either side of battens.

Lead roofed Arcade of the Drink Hall at New York's famous Saratoga Springs.

SARATOGA SPRINGS

A third veteran serenely enjoying its silver anniversary with promise of many more to come is found at Saratoga Springs, New York's world famous watering place. A development of some 1,300 acres, it has recently undergone a multi-million dollar rehabilitation.

As modern and up to date as the newest of the facilities recently created are the original hard lead roofs. Three pound lead roofs on the Main Hall arcades and the Administration Building arcades and pavilion are intact, have been left untouched by the present architect and, according to Senior Maintenance Supervisor, Mr. John J. Walsh, have not had one cent of maintenance charged against them since the day they were installed. Architects originally were Joseph Freedlander, Dwight James Baum and Marcus Reynolds. Presently, work is under the direction of Architect Herbert B. Phillips in collaboration with Arnold Vollmer, Associates, all of New York City.

The view of the lead roofed arcade of the Drink Hall will give an idea of the extent of this installation. The orderliness of the bottom pattern blends beautifully with the rhythm of the marching arches beneath. In addition, the non-staining characteristic of the metal guarantees it will remain a perfect foil for the soft reds of the brickwork and the clean accents of limestone quoins and belt courses.

Photo and detail drawing show how the bottom ends are finished at the eaves. Note the unusual peaked bottom design employed.

FEDERAL COURT HOUSE,

Foley Square, New York City

The last building in our quartet is a distinguished member of a growing group of fine buildings dedicated to the Federal Service: the Federal Court House on Foley Square in New York City. Built in 1935 and designed by Cass Gilbert, nearly the full vocabulary for uses of lead in building is found here. Three pound hard lead was used for roofing and flashing, sheet lead was used under floor slabs and in foundations, for waterproof flooring and for shower pans and lead was used in paint, a total running into hundreds of tons. Typical details will show the various uses, methods of joining and fastening.

As has been found true in all cases where installation was carried out properly, the material here endured every demand made upon it. In this case the New York Regional Office of the General Services Administration for the Federal Government reports that no direct maintenance has been charged against lead installations in the building.

New York City's Federal Court House has lead roofing, flashing, and waterproofing.

Lead covered setback at base of lead lined tower roof. Lead lined gutter is visible at the left.

Detail section showing flashing at base of tower roof and concealed flashing locked to lead on set-back.

O

NOTES AND TECHNIQUES

Roof seams offer interesting pattern possibilities. The steeples in A, B, and C illustrate the variety possible in the same basic structure. A further degree of freedom is offered in the choice of seam employed—B, for example, might be done with standing seams or, if greater relief were desired, with batten seams. Good practice would indicate a standing seam for A, a flat seam for C.

There are many reasons for using lead other than those of longer life and lower maintenance charges. Lead roofs provide savings both in material costs and in installation charges which make them highly competitive with all comparable roofing materials. Costs today, per square foot, for a range of metals in the usual roofing gauges find lead about equal to copper and cheaper than other metal roofs except aluminum, terne and galvanized steel. Moreover, since installation techniques are virtually the same for all metals, lead's workability yields an additional premium in labor costs, a significant item in today's market.

Unlike other metals, lead will retain the shape into which it is easily formed. Every joint is an expansion joint with no welding or soldering required. The use of standing seams or batten seams, as illustrated by their use in these four roofs, is not only an utilitarian device for fastening sheets of lead together, it is a means of accomplishing design freedom by using patterns of one or the other or both. Details of the three types of seams and suggestions for their use can be found in the accompanying drawings. Compatibility, a factor in the selection of any roofing material, is not a problem with lead. Lead weathers to a soft, silver grey patina. The resulting color harmony with any masonry will never be destroyed by staining since the corrosion products of lead become a part of the surface minerals and can not wash off.

A pattern can be established by alternating standing and batten seams.

SPECIFICATIONS

SHORT SPECIFICATION

Unless otherwise particularly specified, all sheet metal work shall be of hard sheet lead and all material and labor in connection therewith shall be executed in strict conformity with the recommended practice and Standard Specifications of the Lead Industries Association, which specifications are hereby declared and made a part of this specification, with the same force and effect as if written herein in full.

STANDARD SPECIFICATION

MATERIALS

Unless noted otherwise, all lead shall be hard lead, containing not less than 6% or more than 7.5% of antimony and the remainder shall be lead.

Sheet lead shall be free from pits, dents, buckles, waves, scratches, grit, foreign matter, porosity, and other intrinsic defects. All lead shall be 3 lb. hard lead except where herein specified otherwise, and except as follows:

1—Where flashings may be 2 1/2 lb. hard lead, tarp flashing, non-sealed lap flashing, closed valley flashing, cup flashing, window and door head and sill flashing, chimney cap flashing, gutter lining where gutters are not over 6" wide, gable and flashing (valley cap and base flashing, base flashing (where no heavy wrought rods are used).

2—Where roofing may be 2 1/2 lb. hard lead, small standing seam roofs, where seams are not greater than 15" o.c. between roofing where buttoms are spaced not over 18" o.c.

No sheet shall exceed 2' 6" x 8' 6". Occasional larger sheets may be permitted; flashing sheets shall be not over 8' 0" long. Sheets with flat surfaces more than 12' wide without longitudinal bands reinforcing them shall be not over 8' 0" in length.

COATING FOR CONTACTS WITH FRESH CEMENT OR CONCRETE

- Black asphaltum brush coating, as made by
- Layer of 15 lb. asphalt impregnated rag felt

ROOFING FELT

- Under all lead roofs by 30 lb. per square building felt, as made by

CLEATS & NAILS

- Cleats shall be—16 oz. copper or 3 lb. hard lead
- Hard copper wire nails

SOLDER

- 50-50 solder for hard lead—Standard Specification of the A.S.T.M. B 22.21

JOINT & SEAM COMPOUND

- Vulcanite #7700 or Equal non-hardening compound

LAYING & WORKMANSHIP

EXAMINATION OF SURFACES

- All defects found in surfaces prepared by other trades to receive lead roofing shall be reported to the Architect in writing. The Architect will cause all defects to be remedied. The commencing of work by the Contractor indicates his acceptance of the surfaces.

TYPES OF ROOFS

- Roofs shall be—standing seam (a) bottom (ribbed)—spaced ... " o.c. (preferably 18")
- Bottom, as set by others, shall be ... " wide at top, tapered to ... " wide at the bottom, and ... " high at center, with the top edges slightly rounded.
- Finished standing seam shall be ... " high when completed (not less than 1 1/2").

LEAD PROTECTION

- This care in handling this material as to prevent scoring, burning, or sharp bends

- Place all lead work which is to come in contact with fresh cement or concrete with one one heavy coat of asphaltum or felt on side which is to make the contact

SEAMS & JOINTS

- Seams shall be joined by loose locks or overlaps made in the direction of flow which shall be filled with non-hardening compound where there is possibility of water seepage or ice standing or driving into the joint. Where bonds in seams cross the seams, the sheets shall not be notched to facilitate working

1—Flat lock seams shall finish at least 1" wide

2—Lap seams shall lap at least 3" on vertical surfaces or built in flashings or elsewhere

3—Sheeting seams shall finish at least 1" high unless otherwise specified. Soldered seams shall only be used for marking great pipes, making special roofs, and for other special conditions, and in no case shall be used to join roofing or flashing sheets to make continuous runs of roofing or flashing greater than 8' 0" and 8' 0", respectively

CLEATS

- Cleats shall be 16 oz. copper except that if any part is exposed, 3 lb. hard lead shall be used. Cleats, except where otherwise specified, shall be at least 2" wide and 4" long, secured by two nails. Continuous cleats shall be in lengths not exceeding 8' 0" and a space of least 12" wide shall be left between sections. They shall be nailed at least every 8". All cleats shall have sufficient metal on the nailed end to turn back over the nail heads to protect the lead lying over the nails

FASTENING

- Cleats shall be used to secure sheet lead to supporting surfaces in such manner as to permit free expansion and contraction of the lead. Nails or screws shall never be driven through sheet lead unless particularly specified, except that pieces of lead not larger than 18" square may be nailed along one edge only if nail heads are covered

BENDS

- All bends shall be made with an easy radius. Where metal turns up on a wall curve, or bottom or other surface, provide a clearance between bend in metal and such surface of at least 1/2" for expansion

VERTICAL SURFACES

- Sheeting for vertical surfaces shall be installed by the standing seam method or flat seam method. At the bottom it shall be loose lashed to base flashing and at the top to through wall flashing or lead coping

1—Standing seams shall run vertically. Sheets shall be not more than 2' 0" wide with this dimension horizontal. They shall not exceed 8' 0" in height and if the wall is higher than this, the sheeting shall be installed in more than one sheet vertically, with loose laths between sheets. Continuous cleats broken only at standing seams shall support the sheeting of these horizontal joints. Cleats 2" wide shall be folded into the standing seams at 12" intervals

2—Flat seam sheeting shall be installed in sheets not exceeding 8' 0" long and 18" high with long dimension horizontal. It shall be supported by continuous cleats, broken only at vertical seams, in all horizontal seams. One 2" wide cleat shall also be folded into the back of the end of each sheet

FLASHING

- Where flashing is built into a wall and emerges more than 3" into the open, it shall be loose lashed where it emerges to a separate piece
- Flashing riveted into a register shall have separate flashing piece loose lashed to the riveted piece
