TEN-DOSE ORAL SUBACUTE TEST IN RATS

Summary: [REDACTED] was administered orally to young adult Crl:CD<sup>1</sup> male rats at repeated dose levels of either 1,000 mg/kg, 100 mg/kg or 10 mg/kg for 10 days over a 2-week period. Clinical signs observed included: weakness, stained perineal area, lethargy, prostration, humped-posture, congestion, chromodacryorrhea and weight loss. Compound-induced macroscopic and microscopic lesions were present in the thymus, spleen, bone marrow and kidneys of high-dose animals. Because of the mortality seen in the high-dose group, reversibility of these lesions could not be adequately evaluated. No treatment-related lesions were observed in the low or intermediate dose groups.

Statistical analysis of clinical laboratory measurements data showed that rats dosed 10 times with [REDACTED] at levels of 100 mg/kg and 1,000 mg/kg had higher than normal erythrocyte counts and hematocrits which appeared to be related to the dose. Rats dosed with 1,000 mg/kg [REDACTED] had higher leukocyte counts, almost twice the normal range established by the controls. These animals also showed a three-fold increase in serum blood urea nitrogen and increased hemoglobin, serum glutamic pyruvic transaminase activity, and creatinine. The 100 mg/kg treated rats showed a slight increase in serum total protein. An increase in

the relative number of neutrophils (1,000 mg/kg group) and a slight to moderate hypochromia (100 mg/kg and 1,000 mg/kg groups) was seen.

In the recovery groups, a slight increase in serum creatinine levels in the 100 mg/kg treated rats was observed. In the absence of this parameter being significantly different prior to the recovery period, the significance of the finding is questionable. No other differences were detected in the clinical pathologic parameter studies in the recovery rats (only 1 rat was examined in the 1,000 mg/kg group).

Analysis of blood for organofluoride revealed a dose-related increase in concentration following the 10th dose (1, 30, 79, and 197 ppm, exposures of 0, 10, 100, and 1,000 mg/kg, respectively). These values dropped to 0.5, 12, 25, and 25 ppm (1 rat), 0 to 1,000 mg/kg, respectively, 14 days after the last treatment, indicating clearance from the blood is relatively slow.

Procedure: The test material, as an aqueous solution at concen rations of either 10%, 1% or 0.1%, was administered by intragastric intubation to 3 groups of young adult Crl:CD<sup>®</sup> male rats, 10 rats per group, 5 times a week for 2 weeks at repeated dose levels of either 1,000 mg/kg, 100 mg/kg or 10 mg/kg; an additional group of 10 rats served as controls and was intubated with distilled water. Two test rats at 1,000 mg/kg died before the 6th dose and 1 before the 9th dose. Five control and 14 test rats were sacrificed approximately 4 hours after the last dose. Two test rats at 1,000 mg/kg died during the recovery period. The remaining 5 controls and 11 test rats were observed over a 14-day recovery period and then sacrificed. All rats were examined grossly, selected tissues were weighed and selected tissue and organs were evaluated histologically. Clinical pathology measurements were taken on all surviving rats 4 hours after the 10th dose and after the 14-day recovery period. Blood was also collected at the same periods for fluorine analysis.

Oral Subacute Study in CD® Rats

April 21, 1982

Summary

Compound-induced macroscopic and microscopic lesions were present in the thymus (Lymphocytic depletion), spleen (Lymphocytic depletion), bone marrow (Hypocellularity), and kidneys (Nephritis) of high-dose animals. Because of excessive mortality in the high-dose group, reversibility of these lesions was not adequately evaluated. Compound-induced lesions were not observed in the low or intermediate-dose groups.

Introduction

Every animal (except #301558) in this study was given a complete post-mortem examination. Microscopic examinations were also performed on selected tissues from each available animal.\* Groups I (0 mg/kg), II (1000 mg/kg), III (100 mg/kg), and IV (10 mg/kg) consisted of ten male rats each. Each group had a 12 day feeding phase and a 14 day recovery phase except the

high-dose group. Due to marked clinical toxicity and early mortality in this group, only one rat survived the 14 day recovery period. Two additional high-dose rats survived for three and seven days in the recovery phase.

Histomorphological lesions were tabulated by individual animal in Table I and were summarized in Table II.

### Results

Macroscopically, compound-induced tissue alterations were restricted to the spleen (splenic atrophy - 3 rats) and thymus (thymic atrophy - 3 rats) in the high-dose group. Both lesions were associated microscopically with mild to severe lymphocytic depletion. Animals from all groups had multifocal areas of reddish-gray mottling in the pulmonary parenchyma. These lesions were associated histomorphologically with multifocal areas of granulomatous interstitial pneumonitis.

Microscopically, compound-induced lesions were present in the spleen (lymphocytic depletion - 7 of 9), bone marrow (hypocellularity - 5 of 7), thymus (lymphocytic depletion - 5 of 8), and kidneys (purulent tubulointerstitial nephritis - 8 of 9), of the high-dose group. Compound-induced lesions were not present in the other test groups.

The renal lesion in this study was rather unique in that there was selective toxicity for the distal and collecting tubules and the medulla was more severely affected than the cortex. The lesion was characterized by degeneration and regeneration of the tubular epithelium with tubular ectasia. This was associated with a marked interstitial infiltration with neutrophils and edema fluid. Occasionally, there were small foci of renal papillary necrosis associated with the neutrophilic exudate. One rat (#301555

- Group II) that survived the 14-day recovery period did not have similar compound-induced lesions.

There were several other microscopic inflammatory and/or degenerative lesions that were considered, because of their common occurrence and/or their low frequency, to be incidental spontaneous lesions in this group of rats.

## APPENDIX B

E. I. DU PONT DE NEMOURS & COMPANY  
(INCORPORATED)

HASKELL LABORATORY FOR TOXICOLOGY  
AND INDUSTRIAL MEDICINE  
ELKTON ROAD, NEWARK, DELAWARE 19711

## CENTRAL RESEARCH AND DEVELOPMENT DEPARTMENT

Subacute Oral Toxicity of [REDACTED]

Medical Research Project No. [REDACTED]

Haskell Laboratory No. 14008

June 29, 1981

Blood samples from three groups of 10 male rats intragastrically dosed 10 times with [REDACTED] at levels of 0 mg/kg (controls), 10 mg/kg and 100 mg/kg and 1 group of 7 male rats dosed with 1000 mg/kg were examined.

After the tenth dose, blood was taken from the tails of these rats for the measurement of erythrocytes (RBC), hemoglobin (Hb), mean corpuscular volume (MCV), platelets, leukocytes (WBC) and relative number of neutrophils (Neut), lymphocytes (Lymph), eosinophils (Eosin), monocytes (Mono) and basophils (Baso). The hematocrit (Ht), mean corpuscular hemoglobin (MCH) and mean corpuscular hemoglobin concentration (MCHC) were calculated from these data. Alkaline phosphatase (AP), glutamic-pyruvic transaminase (GPT), glutamic-oxaloacetic transaminase (GOT), urea nitrogen (BUN), creatinine (CREAT), and total protein (TPROT) were also measured in the serum. Five rats from the 0 mg/kg, 10 mg/kg and 100 mg/kg groups and four rats from the 1000 mg/kg group were then sacrificed for pathology. After a 14-day recovery period, the measurements were repeated on the surviving rats in each group.

The data were analyzed statistically by a one-way analysis of variance. Least significant differences were calculated to compare [REDACTED] treated rats with the controls when the ratio of variances (F) indicated a difference among the groups. Significance was judged at the 0.05 probability level.

The results of the clinical laboratory measurements are summarized in Table I; statistical analysis in Table II. Measurements on individual animals are listed in the computer printout attached to the report.

Statistical analysis of the data showed that rats dosed 10 times with [REDACTED] at levels of 100 mg/kg and 1000 mg/kg had higher than normal erythrocyte counts and hematocrits which appeared to be related to the dose. These two groups also had a slightly lower MCH and MCHC when

compared to the control animals. Rats dosed with 1000 mg/kg [REDACTED] had higher leukocyte counts, almost twice the normal range established by the controls. These animals also showed a three-fold increase in serum BUN and increased hemoglobin, GPT and creatinine. The 100 mg/kg treated rats showed a slight increase in serum total protein. Examination of the differential smears showed an increase in the relative number of neutrophils in the 1000 mg/kg group and a slight to moderate hypochromia in the 100 mg/kg and 1000 mg/kg groups.

Fourteen days later, only one rat remained in the 1000 mg/kg [REDACTED] treated group. Statistical analysis at this time included the control, 10 mg/kg and 100 mg/kg dose levels. Other than a slight increase in serum creatinine levels in the 100 mg/kg-treated rats, no clinically significant difference between the control rats and [REDACTED] treated rats was found for the other measurements made on the blood.

ANALYTICAL REPORT

September 16, 1981

[REDACTED]  
CENTRAL RESEARCH AND DEVELOPMENT  
HASKELL LAB

DETERMINATION OF FLUORINE IN RAT BLOOD  
(Job No. 812-668; PRAL Nos. 81-2101-2119, 81-2419-2434, 81-2611-2612;  
[REDACTED])

As part of studies [REDACTED] (exposure of rats to [REDACTED])  
[REDACTED] the 37 rat blood samples submitted 5/20/81 - 6/11/81 have  
been analyzed for fluorine by the Wickbold Torch procedure. The analyses were  
done by Erik Kissa at Jackson Lab (after preliminary freeze-drying here), and  
results are given in the attached copy of his report.

FLUORINE IN RAT BLOOD CONTAINING [REDACTED]

The fluorine content of dried rat blood was determined by the oxyhydrogen torch method calibrated with p-fluorobenzoic acid (corrected for a blank and adjusted to 100% fluorine recovery). The results (see attached pages) suggest that the [REDACTED] recovery rate is similar to that of [REDACTED]:

| Amount of [REDACTED]<br>mg/kg | Average F ppm<br>Date Sampled |      |
|-------------------------------|-------------------------------|------|
|                               | 5/15                          | 5/29 |
| 1000                          | 197                           | 25*  |
| 100                           | 79                            | 25   |
| 10                            | 30                            | 12   |
| 0                             | 0.9                           | 0.5  |

\*Only one rat survived

Two fluorine values, seemingly out of line, were confirmed by duplicate analyses. The standard deviation of the fluorine content of blood is larger than that of the analytical method, indicating a large variation of fluorine in blood from rat to rat. We need only about 0.8-1 mL blood for analyses. If a rat can donate this amount and recover, it may be better to sample the same rat periodically to follow the decrease of fluorine in blood with time.

(a) Sample Designation for [REDACTED]

Group I - control

Group II = high, 1000 mg/kg

Group III = intermediate, 100 mg/kg

Group IV = low, 10 mg/kg

For samples 81-2101 through -2119, recovery time was 4 hours, after the final dose 5/15/81. For samples 81-2419 through -2434, recovery time was 14 days.

Samples 81-2611 and 81-2612 were "blanks", blood from stock rats not part of the study but dried and analyzed along with the others.

(b) Total fluorine content, not corrected for inorganic fluorine values which are probably insignificant.
