

RELIEF VALVE DISCHARGE CALCULATION

D-400 REACTOR

6:15 P. M. - JANUARY 19, 1980

FROM: Farris Relief Valve Catalog No. FE336, Page 3.3

$$A = \frac{V_L}{24.3 \sqrt{1.25 (P_1 - P_2)}} K_p K_g K_u$$

Where:

A = Orifice Area (In.²), Q Orifice = 11.05 In.²

V_L = Liquid capacity in U.S. gallons per minute.

P₁ = Set pressure at inlet, psig = 185

P₂ = Back pressure at outlet, psig = 0

K_p = Overpressure sizing factor, 1% overpressure (From: Farris Book Page 3.7) = 0.07.

K_g = Sizing factor for specific gravity

$$K_g = \frac{1}{\sqrt{G}}$$

G = Specific Gravity

K_u = Viscosity correction factor from curve on Page 3.8 = 1.0

Temperature of reactor at time of release = 109°F.

Reactor contained 34% Vinyl Chloride by volume.

Specific Gravity of water @ 109°F = 0.99.

Specific Gravity of Vinyl Chloride @ 109°F = 0.87.

Specific Gravity of Mixture = (0.34)(0.87) + (0.66)(0.99)
= 0.94

DTH 000084415

$$Kg = \frac{1}{\sqrt{0.94}} = 1.03$$

Then:

$$V_L = (11.05)(24.3) \sqrt{1.25(185-0)} (0.07)(1.03)(1.0)$$

$$= 294 \text{ gallons per minute total discharge.}$$

@ 34% Vinyl Chloride

Discharge of Vinyl Chloride = $(0.34)(294) = 100$ gallons per minute.

or 725 #'s VCM/Minute

Vinyl discharged in two seconds:

$$= 725 \frac{\text{'s VCM}}{\text{Min.}} \times \frac{1 \text{ Minute}}{60 \text{ Seconds}} \times 2 \text{ Seconds} = 24 \text{ #'s VCM}$$
